trial which examined whether involving a non-cohabitating caregiver (CarePartner) in a mobile health (mHealth) intervention benefited HF outcomes more than mHealth alone did. The mHealth intervention involved weekly interactive voice response (IVR) phone calls to monitor symptoms. In the mHealth+CarePartner arm, participants' CarePartners received a summary of the participant's IVR responses. Results of the trial indicated that medication adherence improved significantly more in the mHealth+CarePartner condition. For this secondary analysis, we used serial mediation models to evaluate indirect pathways that might explain this effect. Specifically, we tested whether improvements in patient-reported relationship quality and self-efficacy mediated the effect of intervention upon medication adherence. Relationship quality was measured by frequency of talking with the CarePartner, perceived difficulty of talking with the CarePartner, and negative emotions associated with talking to the CarePartner. Indirect effects were estimated using bias-corrected bootstrapping with 95%CI, which showed a negative association between the intervention arm and self-efficacy. Paired t-tests showed that the mHealth arm was associated with improvements in self-efficacy ($t=-4.27$, $p<.01$) while the mHealth+CarePartner arm demonstrated no change ($t=-1.59$, $p=0.12$). Findings suggest that constructs that explain the success of patient-focused self-management strategies, such as self-efficacy, are unlikely to sufficiently explain the success of dyadic interventions in HF.

CARE PREFERENCES IN DEMENTIA: THE IMPACT OF INCONGRUENCE ON PERSONS WITH DEMENTIA AND CARE PARTNERS

E. Shelton^{1,2}, S. Orsulic-Jeras², C.J. Whitlatch², S. Szabo³, 1. *Cleveland State University, Akron, Ohio*, 2. *Benjamin Rose Institute on Aging, Cleveland, Ohio*, 3. *Cleveland Clinic, Cleveland, Ohio*

The psychosocial impact of care preference incongruence on persons with dementia and their family caregiver remains unexplored in the literature. In-depth interviews were conducted with 128 dyads each consisting of a person with dementia and a family caregiver. Baseline data from an intervention study were used to examine incongruence between the preferences of the caregiver and the person with dementia (actual incongruence) as well as the caregiver's own preferences and the caregiver's perception of the person with dementia's preferences (perceived incongruence). Preferences for three care-related domains were recorded: personal activities of daily living (PADLs), instrumental activities of daily living (IADLs), and socioemotional tasks. Outcomes included dyadic relationship strain, quality of life, and mood for both the caregiver and person with dementia. Results indicated that perceived incongruence of care preferences was a better predictor of negative psychosocial outcomes than actual incongruence. Actual incongruence for socioemotional care preferences was a predictor of greater relationship strain and worse mood for the person with dementia, while perceived incongruence for socioemotional care preferences was related to lower quality of life and worse mood for the caregiver. Unexpectedly, perceived incongruence for PADLs predicted higher quality of life and better mood for the caregiver. Findings have implications for communication between care partners, especially regarding

socioemotional care preferences. These socioemotional preferences, which might be overlooked in the creation of a care plan, may influence the person with dementia's well-being.

INSTRUMENTAL AND EMOTIONAL EFFECTS OF CARE RECIPIENTS' COMPANION ANIMALS ON CAREGIVING

J. Bibbo, C. Proulx, *Human Development and Family Science, University of Missouri, Columbia, Missouri*

This study examined the impact of older adults' companion animals on informal caregivers' instrumental and emotional experiences. Older adults report strong emotional bonds with their companion animals (CA) which often become increasingly important as health declines and dependence upon others increases. Individuals requiring assistance meeting their own needs are likely to need assistance in meeting the needs of their CA. The care recipient's companion animal may be an important, though presently overlooked, factor in the caregiving experience.

This study measured the amount of care tasks/activities informal caregivers of older adults devoted to their care recipients' CAs. Role theory was used to model the impact of the CA (i.e., number of tasks/activities performed and caregivers' perceived costs of the CA) on the caregiving experiences of burden, satisfaction, and mastery. Caregivers for an individual ages 50+ who did not consider the care recipient's CA to be his/her own animal completed an online questionnaire. Descriptive statistics and path analyses were conducted in Stata. Preliminary results ($N = 42$) indicated caregivers performed an average of 14.96 pet care tasks/activities ($n = 27$, $SD = 5.38$, range: 5–22), increasing time in the caregiver role by 27.19% hours per week. The number of tasks/activities did not have direct effects on caregiver outcomes. The perceived costs of the CAs were positively associated with caregiver burden ($\beta = 0.31$, $p = .01$) and negatively associated with caregiving mastery ($\beta = -0.39$, $p < .01$). Care recipients' CAs may significantly impact both the instrumental and emotional experiences of caregivers.

HOW PHYSICAL HEALTH CONCERNS AFFECT OLDER ADULTS' ABILITY TO CARE FOR THEIR PET

R.L. Mueller, E.G. Hunter, *Gerontology, University of Kentucky, Lexington, Kentucky*

Research attests to the numerous physical, mental and social health benefits for those individuals who care for a pet. Older adults are a growing population, but care for the smallest percentage of pets cared for in the United States. The primary goal of this study was to identify and explore major variables as related to an older adult's present physical health that currently affects their ability to care for their pet. The study explored whether health constraints were present in the older adult, and if so, if the older adult viewed them as inhibiting their ease or ability to care for their pet.

Participants were aged 60+ and had to currently care for a pet. Nineteen qualitative, in-depth face to face interviews took place lasting approximately 90 minutes and included a physical and social health assessment and demographic information. An interview guide facilitated questions targeting physical and social health.

Approximately 15 of the 19 older adults interviewed, four men and fifteen women, reported some form of physical

health concerns; i.e. arthritis, balance concerns, immobility, muscle atrophy, allergies etc. though not all reported these physical health concerns as affecting their ability to care for their pet. Concerns involved inability to pick up their dog, large or small, difficulties with lifting and carrying 20 pounds of litter, inability to walk their dog, allergies to the pet and struggling to carry a cat or small dog in a carrying crate. Strategies to overcome limitations were developed through behavioral change and/or social support.

CAREGIVERS IN CALIFORNIA: ARE THEY DIFFERENT FROM THE NATIONAL CAREGIVERS?

E. Ume, M. Shaheen, S. Teklehaimanot, *Charles R Drew University, Los Angeles, California*

Purpose: To determine the prevalence of caregiving and characterize the California caregivers (CGs).

Background: National reports on caregiving in the USA revealed that 18% are CGs. Half of CGs provides care to their parents. CGs spent 24 hours/week providing care and most provided medical/ nursing care without training. CGs who provided higher hours of care may report their health as fair/poor and consider caregiving as highly stressful.

Methods: We analyzed data related to demographics, access to care, insurance, self-perceived health status, chronic conditions and provision of care from the 2009 California Health Interview Survey (CHIS).

Results: Of 11,321 CGs, 51% were currently CGs, 45% were ≥ 50 years, 57% were female, 55% were white, 52% were married. Most of CGs were US-born (76%) and live at $\geq 300\%$ federal poverty level (54%). Most of the CGs were insured (81%), 19% reported fair/poor health status, 60% were overweight/obese, 75% used alcohol, and had hypertension (28%), and heart failure (22%). CGs tended not to attend the Medi-Cal training for long term CGs (3%).

Conclusions: The percentage of the California's CGs was higher than the national level of CGs, lower in current CGs, and similar in reporting fair/poor health status. California CGs were high income earners relative to the national level. CGs utilized negative coping behaviors to manage the burdens of caregiving. These results provide evidence of the negative impact of caregiving on CGs' health outcomes in CA. Efforts must be intensified to provide consistent support for CGs to help mitigate long-term fatalistic outcomes for CGs.

SESSION 790 (POSTER)

CHRONIC CONDITIONS AND DISEASES

RACIAL-ETHNIC DIFFERENCES IN MULTIMORBIDITY COMBINATIONS OVER TIME

A.R. Quinones¹, A. Botosaneanu², S. Markwardt¹, H. Allore³, 1. *OHSU-PSU School of Public Health, Oregon Health & Science University, Portland, Oregon*, 2. *University of Michigan-Dearborn, Dearborn, Michigan*, 3. *Yale University, New Haven, Connecticut*

Background: Multimorbidity, defined as having multiple chronic conditions, is common and disabling. Comparatively little research on multimorbidity has focused on how disease combinations progress over time and whether this differs by race/ethnicity.

Methods: We analyzed up to 16 years of follow-up for 7,116 participants who start at age 51–60 in the Health and Retirement Study (HRS). Participants reported having ≥ 2 of the following chronic conditions: hypertension, heart disease, lung disease, diabetes, cancer, arthritis, stroke, cognitive impairment, or high depressive symptom burden (CESD score ≥ 4). We identify the most common disease combinations that characterize white, black, and Latino adults from middle-age forward (i.e., when they become study age-eligible until death or dropout).

Results: The racial/ethnic composition of our sample was 56% (non-Latino) white, 26% (non-Latino) black, and 14% Latino. We find that white, black, and Latino middle-aged adults start with relatively similar prevalent multimorbidity combinations: (1) hypertension + arthritis and (2) hypertension + diabetes are the most prevalent combinations across all three race/ethnic groups. However, after 2–4 years of follow-up, race/ethnic patterns of prevalent multimorbidity combinations emerge. Black and Latino adults are characterized by prevalent combinations that include cognitive impairment earlier in the lifecourse relative to white adults.

Conclusions: These findings have implications for clinicians and researchers who seek to identify how multimorbidity combinations evolve differently for middle-aged and older adults from white and underrepresented race/ethnic backgrounds. It will be important to further disentangle the competing challenges of greater morbidity and increased risk of mortality over time in future studies.

HEALTH DISPARITIES: ARE THEY REGIONAL? A DESCRIPTIVE ANALYSIS OF OLDER ADULTS IN THE UNITED STATES

J. Minahan, E. Valdivieso, D. Johnson, T.A. Baker,
Psychology, University of Kansas, Lawrence, Kansas

Unequal access to social, financial and educational services cause differences in the mental and physical health of older adults. This study investigated health disparities of older adults in the United States using the 2014 Behavioral Risk Factor Surveillance System published by the CDC. Respondents selected were 65 years and older, and analyzed variables included: general health status, BMI, physical and mental health status, exercise, history of depression and cognition. When compared with other regions, the southern U.S. had the highest percentage of individuals endorsing poor perceptions of health (23.5%), a lifetime prevalence of depression (20.2%) and trouble with cognition (13.2%). Of those who reported a lower quality of health in last month, individuals from the South indicated the highest average of days of poor physical and mental health (13.1 and 12.1, respectively). With respect to health behaviors, this same region demonstrated the lowest percentage of individuals participating in physical activities (71.2%). Obesity was found to be highest in the Midwest (31.6%) and South (31.4%). Difference in health indicators between U.S. regions are interpreted using the social determinants perspective and fundamental cause of health inequalities. According to the 2014 U.S. Census, the southern region has the highest percentage of older adults living below the poverty line, as well as the lowest household annual income and education rate. Differences in social capital and unavailable resources shape

older adults' health behaviors by determining their lifestyle choices, and ultimately influence their physical and mental health.

ENTERING OLDER AGE AS LONG-TERM SURVIVORS OF END-STAGE RENAL DISEASE: LESSONS FROM EXPERIENCE

J. Trask¹, E.L. Csikai², 1. *Social Work, Jacksonville State University, Jacksonville, Alabama*, 2. *The University of Alabama, Tuscaloosa, Alabama*

The global prevalence of chronic kidney disease is growing and older adults are over-represented among dialysis recipients. Increasing incidence of End Stage Renal Disease (ESRD) at all ages has corresponded to the rapid growth in the leading causes of diabetes and hypertension. Long-term ESRD with dialysis treatment may accelerate biological aging and result in premature vascular disease, impaired cognitive functioning and frailty (Kooman, van der Sande, & Leunissen, 2016), thus compromising quality of life. In a qualitative phenomenological study, in-depth, face-to-face interviews were conducted with ten individuals (6 male; 4 female; ages 42–68) diagnosed with and managing treatment for ESRD for twenty years or longer (currently receiving in-center hemodialysis). The number of years since ESRD diagnosis ranged from 20–45 years. A semi-structured interview guide was constructed to explore factors that facilitate and challenge long-term survival with ESRD. The primary themes that emerged from the data were Reactions to Initial Diagnosis (discovery/reactions), Treatment Experiences, Quality of Life, and Vision for the Future. Most participants realized, through trial and error, that consequences were severe for not adhering to the prescribed treatment regimens and shared ongoing struggles with treatment adherence. They attributed their current success to desire to 'find' a good quality of life, family, friends, faith in God and hope for the future. The results of this study indicated that holistic interventions are needed to facilitate adherence, self-efficacy and social support in order to live longer and healthier well into old age.

SOCIAL CONTROL, SELF-EFFICACY, AND PSYCHOLOGICAL FUNCTIONING IN OLDER PATIENTS WITH TYPE 2 DIABETES

F. Yang¹, J. Pang², 1. *Shanghai University, Shanghai, China*, 2. *Nanyang Technological University, Singapore, Singapore*

Diabetes mellitus is one of the most prevalent chronic diseases globally. If not managed well, it would cause a variety of severe complications that would adversely affect patients' functioning. Research shows that family's involvement is beneficial to patients' adjustment only when there is a healthy interaction between family members and patients. This cross-sectional study examined the role of persuasion-based and pressure-based social control received from family members in diabetes management and whether patients' self-efficacy moderated the relationship between persuasion/pressure and patients' psychological functioning. Participants were 96 men and 103 women with type 2 diabetes mellitus in Singapore, with a mean age of 63.3 years. Results show that persuasion was positively related to self-care adherence. In addition, significant interaction effects were found. Patients with lower self-efficacy benefited from persuasion, but were

adversely affected by pressure. In contrast, patients with higher self-efficacy were adversely affected by persuasion, but were less negatively affected by pressure. In conclusion, findings highlight the importance of reducing pressure-based social control, considering patients' self-efficacy when family members seek to influence patients' self-care behaviors, and targeting patient-family interaction in future interventions with an ultimate goal of promoting patients' better adjustment to diabetes.

AGING WITH DIABETES AND DIABETIC FOOT: ASSOCIATION BETWEEN ADHERENCE TO TREATMENT AND COGNITION

R. Natovich¹, I. Harman-Boehm^{2,3}, T. Kushnir^{2,4}, 1. *Sheeba Medical Center, Ramat-Gan, Israel*, 2. *Ben-Gurion University of the Negev, Beer-Sheva, Israel*, 3. *Soroka Medical Center, Beer Sheva, Israel*, 4. *Ariel University, Ariel, Israel*

Diabetes and aging are independent risk factors for cognitive decline. Self-care is a cornerstone in diabetes management and prevention of complications, including cognitive decline. The presence of ulcers (diabetic foot, DF), represents an increase in self-care burden and in cognitive demands needed for adherence to self-care recommendations (ASC). We examined the association between ASC and cognitive functions in people with diabetes with (GD) and without DF. This case control study included 99 individuals with DF [58y±6.9, diabetes duration (DD) 15.1±7.8, HbA1c 8.8±2.1, 76% males]; and 95 controls [(61y±7, DD 13.4±8.5, HbA1c 7.4±1.3, 76% males]. Groups were matched for DD and gender. ASC was determined using The Summary of Diabetes Self-Care Activities questionnaire; Cognitive function was assessed by Neurotrax computerized battery, Digit symbol and Verbal fluency tests. Association between adherence (high/low) and group (GD/DF) on cognitive functions was assessed by a series of ANOVA's. Adherence to nutrition was found to be positively associated with memory (101.5±11.2 vs 93.5±14.4**), phonemic fluency (96±21.1 vs 86.3±19.9*), semantic fluency (99.5±19.9 vs 90.7±15.6*), psychomotor abilities (94.7±13.7 vs 85.2±18.9***). A highly significant group effect was found, as DF scored significantly lower than GD in all tested cognitive domains (p<0.0001). No interaction effect was found between group and adherence levels on cognition. Cognition was not associated with adherence to physical activity, blood checks or medication. The results demonstrate the importance of adherence to diet for preserving cognitive functioning in people with diabetes, with and without DF, an issue of special relevance in older age.

NURSING INTERVENTION FOR ELDERLY HIGH-RISK PATIENTS WITH DIABETIC FOOT ULCERATION

L. Imhof, A. Keller-Senn, *Institute of Nursing, Zurich University of Applied Sciences, Winterthur, Switzerland*

Foot ulcerations is one of the most severe complications of older patients with diabetes. The incidence rate is as high as 62% and up to 10 % of those patients have an amputation within three years. Patient education comprising instruction on foot care and self-monitoring has been suggested as pivotal part of treatment.

An RCT evaluating the effectiveness of a nurse-led intervention for patients with existing diabetic foot ulceration

and/or amputation was conducted. In addition to dressing and wound inspection (usual care), the patients in the intervention group received eight individualized, face-to-face counselling sessions at patients' homes over five weeks and two telephone follow-ups.

From 254 identified high risk patients, 118 could be enrolled (age M=64.2/±11.5 years). During the 12 months follow-up, overall hospital or ER admission was significantly lower in the IG compared to the CG (40.0% vs. 62.5%, RR=0.67, p=.029). Hospital/ER admission specific due to foot ulceration was lower (18% vs 31.3%, ns), but not statistically significant, as were new wounds (42.6% vs. 56.1%, n.s.).

Survival time in overall hospital admission was significantly longer in the IG compared to the CG (M=280 days/CI: 240, 321 vs. M=206 days/CI: 164, 249, p=.021).

Although the study did not show significant effects on wounds or hospital admission specific due to foot ulceration, the nurse-led intervention showed preventive effects in this high risk population of older patients with diabetes. Therefore, further full-powered research investigating patient-directed, and more individually tailored interventions should be conducted in this high risk patients.

EFFECTS OF SYNERGISTIC DEPRESSIVE SYMPTOMS AND DIABETES ON MOBILITY IN OLDER MEXICAN AMERICAN ADULTS

M. Mutambudzi, N. Chen, K.S. Markides, *University of Texas Medical Branch, Galveston, Texas*

Current literature suggests that diabetes and depressive symptoms are independently associated with mobility, and that mobility in turn may predict disability and mortality. This study aimed to investigate the synergistic effect of depressive symptoms and diabetes on mobility as measured by performance oriented mobility assessment (POMA) scores over a 9-year period in older Mexican Americans. A secondary objective was to examine whether mobility scores over time were associated with increased risk of functional disability and mortality. We used data from 1,458 participants of the Hispanic Established Population for the Epidemiological Study of the Elderly (H-EPESE) survey, for adults 75 years and older for the years 2004–2013. Generalized linear mixed models were used to examine the effects of synergistic depressive symptoms and diabetes on mobility over the study period, after which we examined the effect of mobility over time on disability and mortality. Our findings suggested that diabetes and depressive symptoms were significantly and independently associated with mobility over time. Synergistic depressive symptoms and diabetes however were not significantly associated with mobility. The change of POMA scores over time when compared to the baseline (2004–2005) scores was strongly associated with functional disability (p<0.01) and mortality (p<0.01). Further, synergistic depressive symptoms and diabetes showed a significant association with functional disability (p<0.01), but not mortality in our models. While our preliminary analysis did not find synergistic depressive symptoms and diabetes to be significantly associated with mobility, further research is warranted given the high prevalence of both functional disability and diabetes in this population.

EFFECTS OF NON-PHARMACOLOGICAL TREATMENTS ON QUALITY OF LIFE IN PARKINSON'S DISEASE

S. Ahn¹, T. Bredow², F. Yu¹, 1. *University of Minnesota, Minneapolis, Minnesota*, 2. *Bethel University, Arden Hills, Minnesota*

Parkinson's disease (PD) is a multifaceted neurodegenerative chronic condition with a declining trajectory over an average 20–30 years. Health-related quality of life (HRQOL) is increasingly recognized as an important aspect of PD treatment given the lack of cure for PD and expected life expectancy upon diagnosis. The purpose of this systematic review of the literature is to analyze the effects of non-pharmacological treatments on HRQOL in persons with PD to suggest the best practices in PD care. Keywords, e.g., PD, QOL were used for literature search in PubMed, CINAHL, and PsycINFO databased up to June 15, 2016. Of the 161 articles generated, 12 met the eligibility criteria. The level and quality of each article were determined by two authors independently using the Effective Public Health Practice Project (EPHPP) Quality Assessment Tool for Quantitative Studies. Our findings show that 58% of the 12 included studies represented 'Level I' (RCT) and 42% 'Level II' (quasi-experimental designs). About 50% of the studies have strong quality, 8% moderate quality and 42% weak quality. The interventions varied tremendously across studies (e.g., music therapy, cognitive training, spa therapy, neuromuscular therapy, reflexology, acupuncture, self-management program, physiotherapy network, and telemedicine) with only 3 studies evaluated a similar intervention (i.e., exercise). About 83% of the studies showed that the interventions improved HRQOL. We conclude there is a pressing need to increase the volume of high quality research in each intervention category to further establish the minimally and optimally effective doses of those interventions.

MULTIMORBIDITY AND LONELINESS AMONG CANADIAN OLDER ADULTS: THE MEDIATING EFFECT OF PAIN PERCEPTION

O. Atoyebi, A. Wister, *Simon Fraser University, Vancouver, British Columbia, Canada*

Multimorbidity negatively affects the activities, lifestyle and quality of life of older persons causing complex interactions between physical and psychological conditions. These may make social interaction difficult, leading to potential feelings of loneliness. However, it is not known how the pathways between multimorbidity and loneliness could be modulated by the perception of pain. This study aimed to determine if an association exists between multimorbidity and loneliness and whether this association is mediated by pain perception.

This cross-sectional study used data drawn from the 2008/2009 Canadian Community Health Survey, targeting persons aged ≥ 80 ($n=6,427$). Loneliness scale was derived by summing up responses to questions measuring loneliness (Hughes et al., 2004), multimorbidity was measured using an additive multimorbidity scale and pain was assessed with the HUPDPAD variable in CCHS. Ordinary least square regression analysis with six hierarchical blocks was used to estimate the relationships among multimorbidity, loneliness and pain variables.

Multimorbidity expresses a statistically significant beta coefficient with the loneliness scale ($\beta=0.092$, $p<0.001$) in block 3, after controlling for age, sex, marital status, education and income. The inclusion of perceived pain in block 4 reduced the effect of multimorbidity on loneliness to $\beta=0.049$ ($p<0.001$). Inclusion of functional status in block 5 further reduced this association to $\beta=0.043$ ($p=0.001$).

In this study, multimorbidity modestly increases the risk of loneliness among older persons as hypothesized, while perceived pain appears to slightly mediate this effect. Further study is needed to help clarify these associations using more refined measures and other sub-populations.

SESSION 795 (POSTER)

CHRONIC DISEASE MANAGEMENT

THE ASSOCIATION BETWEEN MEDICAL, SOCIOECONOMIC, AND SELF-RATED HEALTH STATUS IN KOREAN ADULTS

J. Lee, K. Kwon, Y. Kim, *Department of Rehabilitation Medicine, Uijeongbu St. Mary's Hospital, The Catholic University of Korea, Uijeongbu, Korea (the Republic of)*

Method: This study sample was consisted of 3610 Korean adults aged 50 years and older which were based on data obtained from the 2009 to 2011 Korean National Health and Nutrition Examination Survey (KNHANES) IV and V. Self-rated health status was measured using the visual analogue scale of the EuroQol 5-dimension (EQ-VAS). The complex sample general linear regression model for EQ-VAS was performed to determine the association with medical and socioeconomic status.

Results: The mean EQ-VAS score was 69.17 ± 4.04 (mean \pm standard error). The score of self-rated health status reported by the EQ-VAS was lower in the subjects with knee pain (-5.46 ; $p=0.001$), hip pain (-5.17 ; $p=0.002$), and back pain (-5.87 ; $p<0.001$) in comparison with the subjects without joints pain, male (-3.72 ; $p=0.02$) in comparison with female after adjustment for age, sex, anthropometric factors, socioeconomic factors and medical comorbidities. The lower EQ-VAS score was also associated with lower education level ($p=0.001$), lower physical activity ($p=0.001$) and lower income level ($p<0.001$). Interestingly, medical comorbidities including stroke, heart disease, diabetes mellitus and radiographic osteoarthritis except high blood pressure were not statistically associated with lower score of EQ-VAS ($p>0.05$).

Conclusion: The presence of pain or lower socioeconomic status was associated with lower score of self-rated health status. Adequate pain management may be important considerations in ensuring a better perceived health-related quality of life for aged 50 years and older.

CAN WE IMPROVE MEDICATION USE IN OLDER ADULTS: AN INTERDISCIPLINARY MEDICATION THERAPY INTERVENTION

D. Moga, D. Rigsby, E. Abner, G. Jicha, *Pharmacy Practice and Science, University of Kentucky, Lexington, Kentucky*

Older adults are at higher risk for experiencing medication side effects due to an altered metabolic profile and higher comorbidity rates. Many of the clinical guidelines

for optimizing pharmacotherapy in this population include anticholinergic drugs on the list of potentially inappropriate medications. Although several drugs exhibit anticholinergic effects, prescribers may be unaware of such properties, thus a team effort (pharmacist-physician) might be the key for successfully implementing interventions to reduce inappropriate prescribing in this population.

We conducted an interdisciplinary medication therapy management (MTM) intervention for older patients who were prescribed one or more anticholinergic medications. We recruited 50 subjects ≥ 65 years with normal cognition ($n=33$), mild cognitive impairment ($n=12$), or mild dementia ($n=5$) enrolled in the University of Kentucky Alzheimer's Disease Center cohort. Participants were randomized to either MTM (direct physician-pharmacist review and modification of medications) or control intervention (FDA materials on inappropriate medication use). After 8 weeks, primary outcomes included change from baseline in the number of anticholinergic drugs and Medication Appropriateness Index (MAI). The intervention reduced anticholinergic use in 56% of the participants (intervention arm) vs 8% (control), $p<0.0001$. The intervention also improved medication appropriateness: mean difference in MAI from baseline 4.16 (intervention) vs 1.13 (control), $p=0.03$.

An effective intervention to address medication appropriateness in a complex population is an essential first step to improve pharmacotherapy-related outcomes. Our MTM proved to be effective and acceptable (per patients' verbal feedback during study visits) method for reducing inappropriate medication use and shows promise for larger scale interventions.

REASONS FOR CARE SEEKING IN THE EMERGENCY DEPARTMENT BY OLDER ADULTS WITH CHRONIC ILLNESS

B. Lutz¹, A. Jones¹, D. Carden², A. Hall³, J. Schmucher⁴, J.S. Harman⁵, P. Hendry², 1. *University of North Carolina-Wilmington, Wilmington, North Carolina*, 2. *University of Florida, Gainesville/Jacksonville, Florida*, 3. *University of Alabama at Birmingham, Birmingham, Alabama*, 4. *University of Wisconsin-Madison, Madison, Wisconsin*, 5. *Florida State University, Tallahassee, Florida*

Health care in the US is highly fragmented with little continuity. Poorly executed transitions result in a cycle of crisis care. In this grounded theory study we identified factors that influenced care-seeking by older patients in the emergency department (ED) This study was part of a larger randomized controlled trial (RCT) testing the effectiveness of an ED-to-Home Transitional Care Intervention (TCI). The RCT included 1004 community-living Medicare patients, > 60 years who sought care in 2 EDs; 40 of these were purposively selected for in-depth interviews and were asked about their decisions to seek care in the ED. Narratives were analyzed using comparative and dimensional analysis. Findings suggest that care seeking decisions were well thought-out based on perceived symptom acuity and severity, previous experiences with similar symptoms, and advice from others. Availability and promptness of primary care, and immediacy and comprehensiveness of ED care were also taken into account. These older patients are often "resource-poor" and have complex unmet social and health-related needs. TCIs

addressing concerns about physical and mental health, social environment, health literacy, and availability and accessibility of resources need to be considered. Facilitating ready access to comprehensive primary care and case management services may also be necessary to eliminate the cycle of repeated ED visits in this population. Research is needed to better understand the social and medical complexities of older adults who seek care in the ED, the impact of patient complexity on hospital-based crisis care, and key constructs for tailoring patient-centered ED-to-home TCIs.

SELF-MANAGEMENT OF OLDER INDIVIDUALS WITH CHRONIC HEART FAILURE IN JAPAN

A. Mitsuoka¹, H. Hirata², 1. *Nagoya Medical Center, Nagoya, Aichi, Japan*, 2. *University of Shiga Prefecture, Hikone, Shiga, Japan*

Background: Facing a super-aged society, the prevalence of chronic heart failure (CHF) among older individuals continues to grow in Japan, and this will become a social problem in the future. Although older individuals with CHF often repeat hospitalization, about 70% are capable of maintaining self-management at home, without being re-hospitalized for more than one year. However, few studies exist that focus on this population in Japan. **Purpose:** This study aimed to explore why older individuals with CHF are capable of maintaining self-management at home. **Methods:** This study was a descriptive qualitative design. Eight participants aged 75 years or older with New York Heart Association class I or II heart failure, who have not been re-hospitalized for more than one year, were interviewed regarding the self-management of their health. **Results:** Eight categories were extracted, including "self-management guidance by medical staff," "support from caregivers," "experience dealing with CHF symptoms by themselves," "understanding their own disease," "carrying out daily living in accord with what they think is good," "not worrying about disease," "having methods to maintain good health in his/her own way," and "being aware of the disease in their function with aging." **Implications:** These findings suggest that medical staff need to provide appropriate self-management guidance for each older individual with CHF. In order to effectively provide such guidance, medical staff must understand and respect the important habits and views that older individuals with CHF have acquired over the course of their lives.

THE DIVERT-CARE CATALYST TRIAL: TARGETED CHRONIC-DISEASE MANAGEMENT FOR HOME CARE CLIENTS

A.P. Costa^{1,3}, D. Haughton⁵, G. Heckman², S. Bronskill^{4,3}, S. Sinha^{6,3}, R. McKelvie¹, 1. *Dept. of Clinical Epidemiology & Biostatistics, McMaster University, Hamilton, Ontario, Canada*, 2. *University of Waterloo, Waterloo, Ontario, Canada*, 3. *University of Toronto, Toronto, Ontario, Canada*, 4. *Institute for Clinical Evaluative Sciences, Toronto, Ontario, Canada*, 5. *Hamilton Niagara Haldimand Brant (HNHB) Community Care Access Centre (CCAC), Hamilton, Ontario, Canada*, 6. *Mount Sinai Hospital, Toronto, Ontario, Canada*

Home care patients are a large population of vulnerable older adults living in the community. They are medically complex, access care across settings, have very high rates

emergency department use, and have relatively poor access to effective chronic disease management. We tested a multi-disciplinary intervention deployed with a case-finding tool to determine its 'real-world' effectiveness.

A cardio-respiratory disease management intervention was developed based on existing guidelines and deployed using the validated Detection of Indicators and Vulnerabilities of Emergency Room Trips (DIVERT) Scale. Intervention components were refined and delivered by a multi-disciplinary group of geriatricians, cardiologists, primary care providers, home care coordinators, nurses, and pharmacists. Components included: sustained self-care training, patient self-care resources, medication review, advanced care planning, clinician communication tools, and staff education.

We conducted a non-randomized pragmatic cluster trial. One hundred home care patients from three geographic areas were enrolled for the intervention over 6 months. The control group included patients who met the same eligibility in the six surrounding geographic areas. A city-wide control group was also included ad hoc. Data were analyzed based on intent-to-treat. The absolute risk of an emergency department visit was reduced by 20% over the 7-month follow-up. Nursing costs increased by approximately \$4 per day, or approximately \$500 over the entire follow-up period. Results were similar with the ad hoc control group.

Targeted, multi-component cardio-respiratory disease management interventions are feasible and effective for home care clients. The trial received honours from provincial health care organizations. A large pragmatic cluster-randomized trial is being planned.

SLEEP DISORDERS IN OLDER DEPRESSIVE PEOPLE

G. Prada^{1,2}, R. Nacu^{1,2}, L. Lungu^{1,2}, A. Prada², A. Ilie³, I. Alexa³, A. Herghelegiu¹, 1. *Clinical department, National Institute of Gerontology and Geriatrics "Ana Aslan", Bucharest, Romania*, 2. *University of Medicine and Pharmacy "Carol Davila", Bucharest, Romania*, 3. *"Gr.T. Popa" University of Medicine and Pharmacy, Bucharest, Romania*

Introduction: Disorders of sleep and mood disorders occur often in elderly, have impact on quality of life and morbidity, and influence each other. Objective of the study was to identify sleep disorders in elderly and adults diagnosed with mood disorders.

Material and method : We analyzed 2 randomly selected groups of adults and older patients, total of 440 subjects, 110 men and 110 women in each group. A previously validated questionnaire has been used to assess sleep, with a total of 23 items. Neuropsychologist evaluated mood disorders. 71% adults and 89% elderly resided in urban area. Over 32% adults had higher education and 64% elderly had medium education.

Results: More elderly (21%) as compared to adults (7%) lost their spouse. 1/3 of subjects in both groups felt tired after waking-up; 86% adults and 63% elderly continued to feel tired whole day. Adults had significantly more often ($p<0.001$) altered sleep program. 2/3 of elderly had difficulty with initiating sleep. Most elderly slept 4 hours every-day, statistically significant difference from adults ($p<0.01$). Elderly woke-up during night because of various pains and

renal conditions, while adults because of depression. Women had sleep disorders mainly due to depression in both age-groups. Nightmares were more prevalent in elderly ($p<0.05$). Elderly with mood disorders sleep less ($p<0.01$), wake-up during night. Elderly describe more often poor quality of sleep ($p<0.01$).

Conclusions: Women present more frequently with sleep disorders. Older depressive people sleep less, wake-up more often during night and take longer to sleep again than adults.

PROFILES OF MORBIDITY, DISABILITY, AND RISK FACTORS FOR OLDER ADULTS IN TAIWAN: A GIS-BASED APPROACH

Y. Tsai^{1,3}, L. Chuang^{2,4}, C. Chiu¹, 1. *Institute of Gerontology, National Cheng Kung University, Tainan, Taiwan*, 2. *Department of Sports Medicine, Kaohsiung Medical University, Kaohsiung, Taiwan*, 3. *Sinhua Branch, Tainan Hospital, Ministry of Health and Welfare, Tainan, Taiwan*, 4. *Lee's Clinic, Pingtung, Taiwan*

Association of morbidity and disability in older adults changed over time, and it has great implications informing public health policy concerning care for the older population. This study used Q-GIS to discern the relationship between disease risk factors, including physical conditions, environment, health behavior, social-economic and medical resources, and disability in older Taiwanese over time. The data were based on nationally representative National Health Interview Survey in 2005 and 2009. There were 2,709 and 2,914 nationally representative older adults (65+) in 2005 and 2009, respectively. According to our analysis, behavior such as smoking, significantly associated with asthma ($r=0.55$, $p<0.05$) and tends to increase stroke ($r=0.36$). Hypertension was more prevalent in both urban and resource-lacking areas than in general rural areas. Depressive symptoms has higher self-reported rate in older adults living in mountainous eastern Taiwan than in other areas. Medical resources and family income both negatively associated with hospital admission rate ($r=-0.38$ and -0.30 , respectively). However, prevalence of chronic disease has weak association with disability or hospital admission rate geographically. The gap between urban and rural medical resources grew larger in 2009 than in 2005. Our Q-GIS model shows that lack of medical resources or family economic support, but not chronic disease, increases hospital admission rate. Findings from this study suggest that improving medical resources and family income may be the most critical factors to promote health for the growing older population in Taiwan.

RELATIONSHIP BETWEEN SILENT HYPOGLYCEMIA AND TREATMENTS, OR HBA1C IN ELDERLY PATIENTS WITH DIABETES

M. Koshizaka¹, T. Ishikawa¹, Y. Maezawa¹, M. Takemoto¹, Y. Tokuyama², T. Saito², K. Yokote¹, 1. *Chiba University, Chiba, Chiba, Japan*, 2. *Kashiwado Hospital, Chiba, Japan*

Introduction: There are few researches that studied about the relationship among HbA1c, the diabetic treatments and the blood glucose profile in the elderly patients with diabetes by continuous glucose measurement system (CGM).

Methods: We compared the percentages of time estimated as hypoglycemia (glucose level <70 mg/dL on the CGMS)

and severe hypoglycemia (glucose level <50mg/dL on the CGMS), and other parameters, between the patients treated with insulin, SU, or glinides and the patients treated without them. We performed the same comparison between the group of HbA1c less than 8% and the group of HbA1c 8% or more.

Results: The percentage of hypoglycemia time was significantly higher in the patients treated with these 3 class drugs than the patients treated without them ($2.8 \pm 6.6\%$ vs. $0.7 \pm 1.7\%$, $P=0.0011$). The percentage of hypoglycemia time was significantly higher in the patients with HbA1c less than 8% than the patients with HbA1c 8% or more ($3.2 \pm 7.1\%$ vs. $1.1 \pm 2.9\%$, $P=0.0352$). Compared with the patients without hypoglycemia, the patients with hypoglycemia had significantly lower BMI ($20.9 \pm 4.5\text{kg/cm}^2$ vs. $23.0 \pm 4.3\text{kg/cm}^2$, $P=0.0118$). The average insulin total daily dose in the patients with hypoglycemia was more than that of the patients without hypoglycemia (14.4 ± 15.5 units vs. 9.2 ± 13.0 units, $P=0.0297$).

Conclusion: In the 65 years or more elder patients with diabetes, the patients treated with insulin, SU or glinides had hypoglycemic risk. It is necessary to carry out the optimal blood glucose control comprehensively by HbA1c, CGMS and other predictors, in order not to cause hypoglycemia in the elderly patients with diabetes.

APPLICATION OF PEPTIDES FOR COMPLEX TREATMENT OF AUTOIMMUNE THYROIDITIS

D. Gorgiladze, R. Pinaev, V. Aleksandrov, *Scientific and Production Center of Revitalization and Health, Saint-Petersburg, Russian Federation*

Background: Improvement the existing methods of treatment of autoimmune thyroiditis by using complex application of low molecular weight peptides.

Methods: We have conducted a study of the effectiveness of treatment in 218 patients with autoimmune thyroiditis aged from 39 - 51 years. All peptide preparations used in this study, were developed by the St. Petersburg Institute of Bioregulation and Gerontology, and are essentially complexes of low molecular weight peptides with a molecular weight up to 5000Da, isolated from thyroid and pineal glands of young animals. We measured: indicators of the thyroid hormones levels, indicators of the antibodies levels, indicators of high-fidelity infrared thermography and ultrasonography of thyroid gland.

Results: It was revealed that application of a complex of peptides of thyroid and pineal glands in patients with autoimmune thyroiditis helped to improve general health and laboratory indicators. This complex also caused an antibodies level reduction and the positive changes in thyroid gland, detected by ultrasonography.

Conclusions: It is preferable to apply the complex of peptides of thyroid and pineal glands, as part of complex treatment as well as for prevention of diseases in middle and senior age. The existing conventional treatment regimens of autoimmune thyroiditis require the inclusion of these high-performance schemes, physiological peptide preparations targeted action aimed at increasing the reserve capacity of the organs and tissues involved in the pathological process.

DEVELOPMENT OF CARING MODEL FOR ELDERLY PERSONS WITH CHRONIC ILLNESS BY VOLUNTEERS IN COMMUNITY

N. Suwankruhasn, *Medical Nursing, Chiang Mai University, Chiang Mai, Thailand*

Elderly person with chronic illness need continuity and long term care. Some elderly persons live alone or with family members who cannot care them. Thus, they need help from others. People in a community are a group of care provider for elderly person.

The study aimed to develop the caring model for elderly person with chronic illness by volunteers in the community, Nong Hoi village housing, Muang district, Chiang Mai.

This research and development consisted of 5 processes: 1) surveyed and analyzed the current situation, problem and need. 2) designed the caring model for elderly person with chronic illness (draft version). 3) trial of the model 4) evaluated and improved the model, and 5) distributed. The study population included 24 elderly who lived alone or family members need caring help, 264 elderly with self- help or less dependence, and 17 caregiving volunteers.

The research finding revealed that the caring model for elderly person with chronic illness by caregiving volunteers covered health and social welfare (allowance elderly, disability living allowance, and environment and safety). Elderly were divided into 2 groups: the first group was independence/less dependence; and the second group was lack of self-help/ high dependence. The first group received health assessment and participated in health promotion projects in which caring volunteers were developed to write a proposal for funding from other agencies. The second group received home visit, health assessment, and necessary help by caring volunteers and health care team from the municipal hospital. In a case with health problem would be referred to the municipal hospital, municipal service for older person, or Chiang Mai Provincial Social Development Human Security Office.

DETERMINANTS OF HIGH SELF-CONFIDENCE IN DIABETES MANAGEMENT AMONG OLDER DIABETES PATIENTS

S. Lee², D. Lee¹, S. Choun¹, *1. School of Social & Behavioral Health Sciences, Oregon State University, Corvallis, Oregon, 2. The Roy J. and Lucille A. Carver College of Medicine at University of Iowa, Iowa City, Iowa*

Self-confidence in diabetes management is important in initiating and maintaining diabetes self-care behaviors, such as healthy diet, being physically active, monitoring blood sugar, medication compliance, good problem solving skills, risk-reduction behaviors, and healthy coping skills. Self-confidence represents that patients are capable and effective in achieving desired health outcomes. Patient's level of confidence in diabetes self-care is associated with patient's perception on the degree of problems present in diabetes management, difficulties in self-care, understanding of self-care methods, self-rated health, and social support. We used data from the Health and Retirement Study (HRS) to explore the determinants of self-confidence in diabetes management among older diabetes patients. The sample consist of 1,888 diabetic patients (mean age = 70 years, $SD = 8.8$, age range = 50 - 96, women = 52.4%) who

completed diabetes survey in 2003. We conducted regression analysis, controlling age, gender, education level, marital status, and types of diabetes. Results revealed that patients who reported higher confidence in diabetes management tended to experience less difficulties in self-care, better understanding of self-care methods, and greater social support. Additionally, those who had higher confidence in self-care gave higher ratings for their self-care and perceived higher self-rated health. Importantly, receiving emotional and tangible support from family and friends is significantly associated with increasing patients' confidence in self-care activities. These results indicate that improving confidence in self-care is essential to have successful diabetes management. Our findings can aid healthcare providers in identifying patients who will potentially struggle with self-care practices.

LONG-TERM LIFESTYLE INTERVENTIONS IN MIDDLE-AGED AND ELDERLY MEN WITH NONALCOHOLIC FATTY LIVER DISEASE

Z. Bao, *Department of Geriatrics, Shanghai Institute of Geriatrics and Gerontology, Shanghai, China*

Nonalcoholic fatty liver disease (NAFLD), a metabolic disorder related to insulin resistance and metabolic syndrome, has become a public health concern worldwide. Currently, principal therapeutic modalities targeting NAFLD are lifestyle interventions. However, the efficacy of long-term lifestyle interventions in NAFLD management remains largely unexplored. This study aimed to evaluate the efficacy of long-term lifestyle interventions in middle-aged and elderly men with NAFLD. All the 280 eligible patients were randomized to control or test group. In test group, patients received counseling by two physicians every 3 months via phone visit. A diet tailored to their calorie need and increased physical activities according to individual situations were prescribed. Patients in control group received no intervention. After periodic interventions for 2 years, body weight, abdominal circumference, ALT, TCH, LDL-C and HDL-C decreased in test group. Specially, fatty liver index (FLI) and NAFLD-fibrosis score (NAFLD-FS) in test group reduced markedly. However, in control group, there was only significant decrease in LDL-C, HDL-C level and NAFLD-FS ($P < 0.001$), whereas other parameters remained essentially unchanged. Liver steatosis grade in test group decreased significantly, while the situation aggravated in control group. In NAFLD, long-term lifestyle intervention exerts an anti-obesity effect and attenuated liver dysfunction and steatosis.

NUTRITIONAL PROFILE AND INTEGRATED MODELS OF CARE TO THE AMAZONIAN ELDERLY

M.A. Faber^{1,4}, J. Faber², A.B. Lima³, R.P. Lima³, 1. *Postgraduation, Idaam College, Manaus, Amazonas, Brazil*, 2. *Hospital 28 de agosto, Manaus, Amazonas, Brazil*, 3. *Universidade do Estado do Amazonas, Manaus, Amazonas, Brazil*, 4. *Uninorte, Manaus, Amazonas, Brazil*

The bad nutrition that occurs in the elderly may be due to physiological changes of aging, the socio-economic conditions, diseases and the interaction between nutrients and drugs. The food served to the elderly should be mostly cooked or prepared to facilitate mastication. These types

of food contain less vitamins, minerals and fiber. Examine the association between body mass index, waist-hip ratio, waist circumference and nutritional profile in groups of elderly relating it to their food habits and observer by type of shelter of this population taken care of in one of them Centers in Manaus, aiming at to know the reason of the search of the aged, the medical attendance, types of requested examinations. During 2015, 1076 elderly was accompanied, amongst routine medical consultations; inclusion revisit. Excrement and blood biochemical analysis had been requested, and gauging of the arterial pressure. The highest BMI, WHR, and WC quartiles and predefined BMI categories were analyzed as predictive variables. The alimentary consumption was registered during 3 days and each specific nutrient. We used a statistical analyzed by SPSS. Was found overweight prevalence's (65, 8%), 87% hypertension, 48% intestinal parasitism; 45% high cholesterol, 47% anemic and 32% diabetics. The diet compared to the Dietary Reference Intakes showed inadequate. BMI = $30,3 \pm 10,5$ e $28,3 \pm 4,0$ and WHR = $0,91 \pm 0,05$ e $0,93 \pm 0,08$.

DELIVERING TAILORED REHABILITATION THROUGH AN ELECTRONIC PATIENT RECORD TO PROMOTE PHYSICAL FUNCTION

J.A. Richardson, L. Letts, D. Chan, H. Siu, L. Thabane, S. Sinclair, *McMaster University, Hamilton, Ontario, Canada*

Rehabilitation has potential to exploit technology to address changes in physical functioning associated with chronic diseases and aging. This cohort study was designed to determine feasibility of using an electronic patient health record to prevent the physical functional decline in persons ≥ 44 years with and without chronic diseases/conditions. Participants completed self-report measures including assessments of function and preclinical disability, the Rapid Assessment of Physical Activity (RAPA), at baseline, 6, 12, and 18 months. Participants, 97 persons with chronic diseases/conditions (CD) and 50 persons without (NCD), identified goals using the Patient Specific Functional Scale (PSFS). Using the assessment results, physical and occupational therapists tailored recommendations delivered electronically to address the goals. A library of therapist intervention pages (TIPs) on rehabilitation strategies was created, with topics such as back pain, energy conservation, managing arthritis, balance exercises etc.. Forty-two percent of persons with CD had no difficulty or preclinical changes at baseline compared to 92% without chronic disease; 35% with CD and 8% (NCD) had early changes or difficulty; while 23% (CD) had established difficulty in physical functioning, experiencing significant or longstanding difficulties with physical functioning, mobility, or activities of daily living. Although the range of health-related activities identified with the PSFS varied, functional mobility and exercise/physical activity items were prominent. After 6 months, significant changes in physical activities (RAPA; $p=0.05$) were detected in the CD group. Findings suggest that on-line monitoring and delivery of rehabilitation strategies support improvements in physical activities and thus promote physical functioning for people with chronic conditions.

FUNCTIONAL GAIN OBTAINED BY A CATALAN MODEL OF INTEGRATED GERIATRIC CARE

S.J. Santaegugènia², F.J. Tarazona-Santabalbina¹, M.A. Mas²,
1. *Geriatric Medicine, Hospital Universitario de la Ribera (Alzira, València, Spain)*, Alzira, València, Spain, 2. *Servicio Geriatria y Cuidados Paliativos. Badalona Serveis Assistencials, Badalona, Barcelona, Spain*

Background: Health systems based in the care have obtained better results in clinical care for patients with health and social complex needs. In this context an integrated geriatric model of care could improve results in functional gain, health outcomes and patients' quality of life.

Methods: Quasi-experimental study was designed. During the years 2006 to 2012 1.309 patients were attended in this new catalan integrated geriatric care model (CICM) and 1.068 patients were enrolled in the usual care (Catalonian geriatric care model).

Results: CICM patients were significantly older (81.6 versus 78.3 years old). There were no differences for the main admission reasons in both groups. At admission time, CICM patients had a higher degree of dependence, measured by Barthel Index score (32.8 versus 39.9 points) and total dependence prevalence (38.4% versus 32.2%), higher clinical complexity and more geriatric syndromes. In the ANCOVA analysis, functional gain was significantly higher in CICM group (17.2 (SD 0.8) points in Barthel Index than control group (-5.6 (SD 1.1)), adjusting by age, gender, number of geriatric syndromes and Barthel index score.

Conclusions: Patients enrolled in CICM group obtained a higher functional gain. The results of this study may be an useful start to design future randomized controlled studies.

OUTCOMES OF A MOBILE, NURSE-LED INTERPROFESSIONAL COLLABORATIVE TEAM IN UNDERSERVED RURAL AMERICA

G.A. Jensen, L. Jones, M. Kutzke, L. Lange, C. Larsen, M. Klamm, N. Jelen, *Sanford Health, Sioux Falls, South Dakota*

The evolution of healthcare payment systems in the USA has fostered increased emphasis on health maintenance by patients who actively engage with providers who use evidence-based strategies and tactics. For those with rising risk or pre-existing chronic conditions, improved self-management and touch point surveillance can prevent use of high end health services such as emergency room visits and hospitalizations. While cooperating with patients, primary providers, health coaches and community stakeholders, the Health Co-Op pushes inter-professional care delivery beyond the traditional hospital and clinic settings, out into communities.

This project describes early impact of an innovative trial involving a person-centered, health delivery model to improve access and outcomes for rural, frontier and diverse populations in the Upper Midwest. The model involves the deployment of a dedicated, community-based, nurse-led, mobile Interprofessional Collaborative Practice (IPCP) team into small urban, rural and diverse underserved adult populations, including ~75% older adults, non-English speaking Hispanics and Native Americans. The Team includes experienced health professionals including nurses, a pharmacist, physical therapist, occupational therapist, dietician and social worker. Each discipline contributes to the IPCP collective

identity, including intra-IPCP referrals, weekly Team Skype conferences, and documentation in EPIC for discrete data abstraction. A federal HRSA grant (#UD7HP26906) and 5 community partnerships support the free, non-primary care weekly Co-Ops, in rent free "store front", high traffic, locations. The project is also a part of the emerging NEXUS network of IPCP projects, and the National Center for Interprofessional Practice and Education (Regents of the University of Minnesota, 2013.) Outcomes after 18 months and more than 1600 visits and home visits include improved or sustained measures of population health (e.g., SF 36; PROMIS 10; preventive health practices; HgbA1c; hypertension control), experience of care (CGCAHPS), and reduced cost (number of hospital days), consistent with the IHI Triple Aim.

SESSION 800 (POSTER)

COGNITION II

EFFECTS OF COMBINED PHYSICAL, SOCIAL, AND INTELLECTUAL LEISURE ACTIVITIES ON COGNITIVE STATUS

L. Lai^{1,2,3}, L. Harkouk¹, K.Z. Li^{1,2,3}, 1. *Dept. of Psychology, Concordia University, Montreal, Quebec, Canada*, 2. *Centre for Research in Human Development, Montreal, Quebec, Canada*, 3. *PERFORM Centre, Concordia University, Montreal, Quebec, Canada*

This presentation describes observational work examining the potential benefits of combined social, physical, and intellectual leisure activities on cognition. A sample of 333 recent retirees (46 - 79 yrs.) completed questionnaires to evaluate their engagement in everyday social, physical, and cognitive activities. Cognitive outcomes included tests of global cognition (MoCA), switching (Trails B-A), and processing speed (Digit Symbol Coding). Multiple stepwise regression models revealed that physical and social activities were most predictive of global cognition and switching ability. Importantly, high levels of physical activity protected against low MoCA scores, particularly for individuals who did not engage in high levels of social or intellectual stimulation. These findings suggest that in training intervention designs, physical activity should be prioritized, but that other types of leisure activity confer additional benefits when combined, above and beyond the individual activity types.

THE IMPACT OF COMBINED PHYSICAL AND COGNITIVE TRAINING ON MOBILITY OUTCOMES—DOES FORMAT MATTER?

H. Bruce^{1,2,3}, L. Lai^{1,2,3}, K.Z. Li^{1,2,3}, 1. *Dept. of Psychology, Concordia University, Montreal, Quebec, Canada*, 2. *PERFORM Centre, Concordia University, Montreal, Quebec, Canada*, 3. *Centre for Research in Human Development, Concordia University, Montreal, Quebec, Canada*

Researchers have demonstrated that with age, declining sensorimotor abilities are compensated for by the recruitment of higher level cognitive processes. This view was recently supported by showing that cognitive dual-task training improved mobility and posture among older adults.

Moreover, preliminary evidence suggests that combined physical and cognitive training is more effective than single domain training in improving mobility among older adults. However, to date there has been no investigation contrasting sequential and simultaneous training conditions. To explore this hypothesis, 41 older adults were assigned to either a sequential or simultaneous training group consisting of 12 weeks of computerized divided attention training and aerobic training. All participants completed pre- and post-training assessments consisting of mobility (STS: Sit-to-Stand) and cognitive (*n*-back working memory) tasks performed singly and concurrently. Additionally, the sound intensity of the cognitive stimuli was manipulated in order to increase auditory challenge. Pre-post comparisons on the STS mobility task revealed that both groups improved under dual-task conditions at both levels of auditory challenge. Additionally, participants in the sequential training group demonstrated improved dual-task performance on the cognitive task. These results suggest that while both training protocols were successful in improving mobility under challenging dual-task conditions, sequential training was more effective in improving dual-task cognitive performance. Therefore, focusing on one training intervention at a time appears to be more beneficial than dual-task training where participants are required to divide their attention between two tasks.

METAMEMORY ACCURACY FOR OLFACTORY MEMORY IN AGING

J. Szajer^{1,2}, C. Murphy^{2,3,1}, 1. SDSU/UC San Diego Joint Doctoral Program in Clinical Psychology, San Diego, California, 2. San Diego State University, San Diego, California, 3. University of California, San Diego, San Diego, California

The California Verbal Learning Test (CVLT) is known to have utility in the identification of Alzheimer's disease (AD) and other dementias. Odor memory tasks have also been shown to have particular utility in aiding the early detection of AD, where loss in olfactory function has been shown to become evident prior to significant impairments in memory functioning. However, declines in memory are heterogeneous. Metamemory, or the ability to monitor, judge, and control one's memory, is one factor that has been shown to influence trajectories of age-related declines in memory functioning, even in neurodegenerative disorders like AD.

The current study investigated age differences in metamemory based on retrospective confidence ratings of recognition memory performance on an olfactory analogue of the CVLT, the California Odor Learning Test (COLT). Confidence ratings were self-reported using a bipolar visual analog scale. Participants included 16 older (70-88yrs) and 25 younger (18-26yrs) adults. Age groups were equivalent on demographic variables (e.g. gender, education). Odor threshold was assessed and controlled for.

Across memory measures, younger performed better than older adults ($p < .05$). Analysis of confidence accuracy indicated that overall, older adults demonstrated stronger calibration between recognition memory performance and confidence; however, young adults demonstrated better confidence resolution, rating correct responses with higher confidence ($p > .05$).

More accurate metamemory in aging has been associated with fewer memory errors and higher quality of life, while metamemory impairments can precipitate errors in judgment, and difficulty managing responsibilities (e.g. medication adherence, finances). Thus, further research on aging metamemory remains important.

PREMORBID PERSONALITY AND THE OCCURRENCES OF THE RISK OF MCI AFTER 3 YEARS IN JAPANESE ELDERLY

Y. Masui¹, H. Inagaki¹, Y. Gondo², T. Kurinobu¹, K. Ikebe², K. Kamide², Y. Arai³, T. Ishizaki¹, 1. Tokyo Metropolitan Institute of Gerontology, Itabashi, Tokyo, Japan, 2. Osaka University, Suita, Osaka, Japan, 3. Keio University, Shinjyuku, Tokyo, Japan

Background: Recent studies have reported that the onset of dementia or mild cognitive impairment (MCI) in old age has associations with personalities of individuals before their onsets. However, it had not been confirmed in Japanese elderly people.

Objective: To investigate the associations between personality traits and MCI risks by the prospective study on Japanese elderly people who are cognitively intact.

Methods: Data were obtained in two waves three years apart from 1251 community-dwelling older adults (637 women, mean age=74.6±4.9 years at Wave 1). Cognitive function and 5 big five personality traits were measured at Wave 1 by Japanese version of Montreal Cognitive Assessment (Moca-J) and NEO Five Factor inventory. After 3 years, Moca-J was conducted at Wave 2.

Result: The score of Moca-J less than 26 was judged to have MCI risk. 325 individuals had no MCI risk at Wave 1. Three years later, 147 of 325 individuals were with risk of MCI at Wave 2.

As a result of a binary logistic regression analysis with whether having MCI risk or not at Wave 2 as a objective variable, it was indicated that the occurrences MCI risk in three years significantly associated with high neuroticism (OR=2.11, 95%CL:1.31-3.40, $p < .01$), and with low openness (OR=.50, 95%CL:.31-.86, $p < .01$) at Wave 1. There were no significant associations between other personality traits and MCI risks.

Discussion: These results suggested that, as reported by preceding studies, the associations between personality traits (neuroticism and openness) and MCI risks in three years on Japanese elderly people.

SELF-REGULATED LEARNING OF MOVEMENT SEQUENCES IN ADVANCED AGE

A. Olivay Hausmann, University of Cologne, Faculty of Human Science, Rehabilitative Gerontology, Köln, Germany

Self-regulated learning can be defined as a self-directed process by which learners transform their mental abilities into a new skill. The purpose of this study was to demonstrate a possible impact of self-regulated learning on the acquisition of movement sequences among elderly people. Earlier studies revealed that with increasing age, sequence acquisition is more error-prone. It was hypothesised that this would not be observed in self-regulated sequence learning: While older subjects were expected to choose a slower pace and less ambitious learning goals, no association between error rate and age was expected. N=140 subjects (aged 50-94) were

trained in a sequence of typing movements. At each trial, participants imitated a part of the sequence presented on a wooden plank. Participants determined the learning pace (number of sequence elements per trial) and learning goal (final number of elements). They were asked to acquire as many elements as possible while remaining able to flawlessly demonstrate the acquired sequence part later on. As hypothesised, a higher age was associated with fewer elements per trial and fewer final elements, but not with higher error rates, which were exceptionally low in all subjects. These results prove the potential of self-regulated learning for the compensation of age-related declines in sequence learning. Further investigations should explore how older subjects' sequence learning can be fostered so that they feel safe adopting more ambitious learning goals without risking more errors.

EXPOSURE TO GREEN DOES NOT ALWAYS RESTORE ATTENTION IN OLDER ADULTS

A. Setti^{1,2}, M. Cassarino¹, I. Tuohy¹, 1. *School of Applied Psychology, University College Cork, Cork, Ireland*, 2. *Trinity College Dublin, Dublin, Ireland*

Objectives: Exposure to green scenes has been proven restorative for directed attention (Attention restoration theory, ART) in young adults, but very few studies have beneficial effects of green on older adults' attention. The present study aimed to test ART on older individuals considering the potential influence of current environment of residence.

Methods: A sample of 37 community-dwelling people aged 60+ (mean age: 66.2, standard deviation 7.1; 48.6% female), was divided into two groups. Each group first completed the sustained attention to response task (SART) to fatigue directed attention, after which they viewed images of either restorative (natural) or nonrestorative (urban) scenes, and then completed the SART again.

Results: Participants who were currently rural and were exposed to nonrestorative images showed a significant increase in number of commissions between the two sessions of the SART, $t(10) = -3.01$, $p = .013$, Cohen's $d = -0.912$, and significantly faster reaction times, $t(10) = 3.112$, $p = .019$, Cohen's $d = 0.981$; on the other hand, rural participants exposed to restorative images became slower ($t(8) = -2.614$, $p = .031$, Cohen's $d = -1.253$, but did not show any significant differences in terms of accuracy. No significant pattern was found for urban participants. The findings held after controlling for sex, age, education and MMSE.

Conclusions: The results did not show attention restoration and suggest that the environment of residence of older individuals, which could be considered as a form of long-term exposure, mediates the influence of exposure to nature on attentional skills.

MEDIATORS OF THE EFFECT OF CHILDHOOD SOCIOECONOMIC STATUS ON COGNITIVE PERFORMANCE

C.E. Franz¹, A. Beck², A. Yao¹, W.S. Kremen¹, 1. *University of California San Diego, La Jolla, California*, 2. *San Diego State University, San Diego, California*

Growing up in a low socioeconomic status (SES) background in childhood has been associated with lower general cognitive ability (GCA) in childhood, adulthood, and later life. Less examined is the extent to which childhood SES affects

specific cognitive domains in later life and whether these associations are mediated by other factors. Participants were 1009 Vietnam Era Twin Study of Aging (VETS) male twins with mean age of 56 (range 51–61), and 62 (range 57–67) at the adult assessments. Measures included: childhood SES (parental occupation+education), and three mediators: age 20 GCA measured with the Armed Forces Qualification Test, adult SES, and cognitive engagement at age 56 (e.g., self-improvement, educational and cultural activities). Thirteen neuropsychological tests were utilized to measure seven specific cognitive domains at age 62. Childhood SES, age 20 GCA, cognitive engagement, adult SES, and cognitive domains were all significantly correlated. Multiple mediation analyses were conducted separately for each cognitive outcome. For abstract reasoning, there remained significant direct effects of childhood SES (accounting for 39% of the total effect) as well as a significant indirect effect accounting for 61% of the total effect. Associations between childhood SES and episodic memory, processing speed, verbal fluency, visual-spatial ability, working memory domains as well as age 62 GCA were fully mediated by the paths through age 20 GCA, cognitive activity, and adult SES. Thus, the long term effect of childhood SES on cognitive performance was predominantly indirect; results suggest the importance of early indicators of GCA when making inferences about later life cognition.

SUBJECTIVE MEMORY COMPLAINTS, LEARNING POTENTIAL, AND OBJECTIVE COGNITIVE FUNCTIONING IN OLDER ADULTS

G. Rodriguez, N.M. Mendoza Ruvalcaba, *Gerontology, University of Guadalajara, Guadalajara, Jalisco, Mexico*

Introduction: Subjective memory complaints in older adults should not be considered only as an age-related phenomenon or a symptom of depression. Instead, these complaints deserve to be taken seriously, at least as a possible early sign of dementia.

Methods: Cross-sectional study, $n = 201$ older adults 60-years and older (mean age=71.88, $SD=7.07$ years, 84% women) were interviewed in a senior center. Memory complaints were self-reported, learning potential was assessed by using The Rey Auditory Verbal Learning Test (RAVLT). For objective cognitive functioning a battery was applied, for episodic memory (Subtest-RBNAS), working memory (Digit Span Backward WAIS-IV), processing speed (Symbol Digit WAIS-IV), attention (Trial Making Test-A), executive functioning (Trial Making Test-B). Socio-demographic and health data were also asked. Pearson's correlation test was performed.

Results: 13.4% reported his memory as bad, 64.7% regular, 18.4% good and only 5% excellent. Subjective memory complaints are significantly related ($p < .01$) with worse performance in all cognitive test. Moreover, it was found a statistically significant difference ($p < .05$) in the learning curve, between those who complain and those who have no memory complaints. Age does not correlate with subjective memory complaint. There was a negative correlation between subjective memory complaint and depression.

Conclusion: The results support the consideration of memory complaints of as possible predictors of changes in

cognitive functioning, due to its correlation with objective assessment of cognition in older adults.

COGNITIVE FUNCTIONING IN OLDER MUSICIANS: BENEFITS OF TRAINING WITH A MUSIC ENSEMBLE

J.V. Strong, VA Boston, Pembroke, Massachusetts

Previous research suggests that learning a musical instrument during childhood may have an impact on cognitive functioning later in life. There are many aspects of musical training, including participating in an ensemble (e.g., band, orchestra), or learning to improvise or compose proficiently. Music training history of community dwelling older adult instrumental musicians (N=45) was collected and each participant completed a standard battery of neuropsychological tests. Analyses were run to determine if there were differences in cognitive scores between subgroups of musicians: 1) those who participated in an ensemble and those who did not, 2) musicians who compose and those who do not, 3) musicians who improvise and those who do not, and 4) musicians considered competent on one vs. multiple instruments. Results found that musicians who participated in an ensemble showed higher performance on tests of immediate memory (California Verbal Learning Test, $p<0.05$), verbal fluency (Animal Naming – $p<0.02$ and COWAT-FAS – $p<0.05$), visual memory (Brief Visual Memory Test-Revised – $p<0.01$), and a version of the Stroop Task (DKEFS Color Word Interference Trial 3 – $p<0.01$). There were no differences between groups of musicians who did or did not compose, improvise, or play multiple instruments. These findings suggest that there are aspects about playing in an ensemble that may provide increased mental control and memory performance later in life.

COGNITIVE-PHYSICAL-PSYCHOLOGICAL INTERVENTION IMPROVES COGNITION AND SOCIAL SUPPORT IN OLDER ADULTS

X. Zhu¹, S. Yin^{2,1}, J. Li¹, W. Ren¹, L. Huo¹, Z. Zheng¹, 1. *Institute of Psychology, Chinese Academy of Sciences, Beijing, China*, 2. *Hubei University, Wuhan, China*

Cognitive, physical and social activities are cognitively beneficial for older adults, but intervention has rarely been conducted in combination of these three components. This four-armed controlled non-randomized trial investigated the synergistic effects of a multimodal intervention on cognition, well-being and brain plasticity in a sample of healthy older adults. Four groups older adults respectively received multimodal intervention (cognitive training, Taichi exercise and group counseling), or cognitive plus Taichi training, or cognitive training, or lectures (active control group) during six weeks. Seventeen participants in the multimodal intervention group and 17 controls completed resting-state functional magnetic resonance imaging scanning before and after intervention. Cognitive performance and well-being were assessed at baseline, post-intervention and 3-month follow-up. A total of 156 participants completed intervention and 134 were available at follow-up. Compare to the control group, three intervention groups showed improvements to varying degrees on cognitive function. The cognitive plus Taichi group had largest increase with the multimodal group as the second best at post-intervention, while both group showed parallel maintenance effects on cognition at

follow-up. Enhancement and maintenance in social support were only found in multimodal group. Moreover, multimodal intervention induced strengthened functional connectivity between the medial prefrontal cortex and medial temporal lobe, as well as regional alterations of intrinsic activity in frontal, temporal and cerebellum regions. The results suggest that cognitive-physical-psychological intervention is helpful for preserving brain and cognitive function during old age, and has advantages in comprehensive promotion of both cognitive and emotional well-being.

DAILY LEISURE ACTIVITY AND COGNITIVE FUNCTION IN LATER LIFE: AN 11-YEAR FOLLOW-UP STUDY

Y. Chang¹, I. Wu², C. Hsiung², 1. *Department of Public Health, China Medical University, Taichung City, Taiwan*, 2. *Institute of Population Health Sciences, National Health Research Institutes, Miaoli County, Taiwan*

Previous studies used the composite measure of leisure activities to examine the relationship between leisure activities and cognitive function in later life. The aim of this study was to investigate differential effects of cognitively stimulating leisure activities (CSLAs) on cognitive decline in the elderly population using four waves data (1996, 1999, 2003 and 2007) from the Taiwan Longitudinal Study on Aging (TLSA). 2,532 Taiwanese community-dwelling elders aged 67 and older were included in analysis. In each wave, leisure activities and cognitive performance of participants were assessed using questionnaire-based instruments. Four CSLAs including watching TV, radio listening, reading and gambling were assessed in terms of weekly frequencies. The number of error responses from a 9-item Short Portable Mental Status Questionnaire (SPMSQ) was used to measure cognitive performance. Generalized estimating equation models with negative binomial distribution were employed to examine associations between 4 CSLAs and error numbers of SPMSQ. After adjusting for covariates including age, sex, education, marital status, financial status and physical function, the lowest frequency (< once a week) in all four CSLAs were associated with increased error numbers of SPMSQ comparing to their counterparts who were in the highest frequency (almost everyday) in up to 11-year follow-up. Among 4 CSLAs, the greatest effect on cognitive performance was found in reading activity, followed by watching TV and listening radio. We conclude that daily activities in these 4 CSLAs were protective of cognitive function in later life.

SUBJECTIVE MEMORY AND ITS RELATION TO DEPRESSION AND COGNITIVE FUNCTION IN VIETNAMESE ADULTS

O. Meyer¹, A. Leggett², S. Liu⁴, S. Zarit³, 1. *University of California, Davis School of Medicine, Sacramento, California*, 2. *University of Michigan, Ann Arbor, Michigan*, 3. *Pennsylvania State University, University Park, Pennsylvania*, 4. *University of California, Davis, Davis, California*

The population in Vietnam is aging rapidly. Subjective memory complaints that accompany aging have been associated with a variety of poor mental and cognitive health outcomes for adults in the U.S. The relation of subjective memory complaints to objective measures of cognitive

functioning is tenuous – some studies indicate that subjective memory complaints are associated with subsequent cognitive decline, while others demonstrate that subjective memory complaints are related more to mood. However, little research has been done with aging Vietnamese. In this study, we examined the relation between subjective memory and depressive symptoms (CES-D) as well as cognitive function (MMSE). Whether subjective memory is more strongly related to depression than it is to actual cognitive function has implications for treatment and interventions in Vietnam. The sample consisted of 477 adults 55 years and older living in Da Nang, Vietnam and surrounding rural areas. In separate multivariate regression analyses, memory complaints were significantly associated with depressive symptoms ($\beta = .19$, $p < .001$), controlling for several covariates; memory complaints were also significantly associated with MMSE score ($\beta = -.10$, $p < .05$), although not as strongly. Results suggest that memory complaints are associated with depression, possibly because one notices a decline in memory even when objective memory measures show no evidence of impairment. Consistent with the literature, these findings suggest that depression may precede cognitive decline related to dementia. However, future research should test the pathway between subjective memory complaints, depression, and dementia using a longitudinal sample.

LEISURE ACTIVITIES, EDUCATION, AND COGNITIVE IMPAIRMENT: A POPULATION-BASED LONGITUDINAL STUDY

J. Li¹, X. Zhu¹, C. Qiu², Y. Zeng³, 1. *Center on Aging Psychology, Key Laboratory of Mental Health, Institute of Psychology, Chinese Academy of Sciences, Beijing, China*, 2. *Aging Research Center, Department of Neurobiology, Care Sciences and Society, Karolinska Institutet, Stockholm, Sweden*, 3. *Center for Healthy Aging and Development Studies, National School of Development, Peking University, Beijing, China*

Background: We examine the association between leisure-time activities and the risk of developing cognitive impairment among Chinese older people, and further investigate whether the association varies by educational level.

Methods: This follow-up study included 6586 participants (aged 79.5 ± 9.8 years, range 65 – 105 years, 51.7% female) of the Chinese Longitudinal Healthy Longevity Survey who were aged ≥ 65 years and were free of cognitive impairment in 2002. Incident cognitive impairment was defined at the 2005 or 2008/2009 survey following an education-based cut-off on the adapted Chinese version of Mini-Mental State Examination (MMSE). Participation in cognitive activities (e.g., reading) and nonexercise physical exercise (e.g., housework) was assessed by a self-reported scale. Cox proportional hazard models were employed to examine the association of leisure activities with incident cognitive impairment.

Results: During a 5-year follow-up, 1448 participants developed incident cognitive impairment. Overall, a high level of participation in leisure activities was associated with a 41% decreased risk of cognitive impairment compared to low level engagement in leisure activities after controlling for age, gender, education and other confounders. The beneficial effect was significant in nonexercise physical activities but not cognitive activities. Moreover, there was a significant

interaction between leisure activity and educational level, such that the beneficial effect of leisure activities was larger in educated elderly than their uneducated counterparts, and only educated elderly benefited from cognitive activities.

Conclusions: Late-life leisure activities protect against cognitive impairment among elderly Chinese people, and the protective effects are more profound for educated elderly.

EXECUTIVE FUNCTION IN OLDER ADULTS: A PSYCHOMETRIC EVALUATION OF THE HEAD-TOES-KNEES-SHOULDERS TASK

E.S. Cerino, K.A. Hooker, R.S. Stawski, M. McClelland, *College of Public Health and Human Sciences, Oregon State University, Corvallis, Oregon*

Executive function (EF) abilities are recognized as components of cognition most likely to show age-related declines, and measurement of EF is often computer-based, task-focused and lacking ecological validity. We investigated a new way of measuring EF in older adults by adapting a brief, behavioral measure of EF in children, the Head-Toes-Knees-Shoulders task (HTKS). An easy to administer measure would allow for early detection of declines and intervention among those at risk for mild cognitive impairment. A sample of 150 community-dwelling older adults (Mean age = 68.55, SD = 6.34) completed the HTKS, NIH Toolbox (NIHTB): Cognition Battery and Positive and Negative Affect Schedule. The HTKS showed good internal consistency, $\alpha = 0.84$. Significant associations between HTKS variables and measures of attention, inhibitory control, and processing speed demonstrated convergent validity (HTKS completion time r 's ranged from -0.20 to -0.30; HTKS total score r 's ranged from 0.17 to 0.24). HTKS completion time exhibited the strongest associations to NIHTB measures, suggesting that the time it takes older adults to complete the HTKS may be a better measure of EF than the total score. Non-significant associations between HTKS variables and positive and negative affect demonstrated discriminant validity. These results provide evidence for use of the HTKS as a brief, low-cost, easy to administer measure of EF in older adults. Further research is needed to determine its potential to identify individuals at risk for poor cognitive outcomes. A brief, valid measure may allow for wider screenings aimed toward intervening early when interventions are most effective.

SOCIAL CONTACT AND COGNITIVE FUNCTIONING IN OLDER ADULTS LIVING IN THE COMMUNITY

D. Chon¹, Y. Lee¹, J. Kim¹, J. Kim², K. Lee¹, 1. *Institution to Ajou University, Gyeonggi-do, Korea (the Republic of)*, 2. *Institution to Department of Health Administration, College of Health Science, Dankook University, Cheonan, Korea (the Republic of)*

Korea is one of the countries showing the fastest growth in the population of elders, with a rapid increase in the number of people with dementia. Social contact has been identified as a potential moderator of cognitive decline associated with aging. This study examined the relationship between social contact and cognitive functioning using a national survey of older adults. Data obtained from 3721 participants 65 years and older from the Korean Longitudinal Study of Aging (KLoSA) (2012–2014) were analyzed. Social contact was scored by the frequency of meeting close acquaintances

and cognitive function was measured by a Korean version of the Mini-Mental State Examination (MMSE-K). Multiple linear regression was used to compare social contact in 2012 with the MMSE-K score in 2014, adjusting for covariates. Participants with higher frequency of social contacts were more likely to have higher MMSE-K score in the overall population ($B = .138, p < .0001$). The magnitude of the association was stronger among those at risk of dementia ($B = .307, p < .0001$), compared with those who were cognitively normal ($B = .082, p = .014$). This study demonstrated that frequent social contact was associated with higher levels of cognitive functioning in later life. Further studies are warranted to investigate whether social relationships buffer against cognitive decline.

EFFECTS OF BIOFEEDBACK ON BLOOD PRESSURE AND COGNITIVE FUNCTIONING OF OLDER ADULTS WITH HYPERTENSION

H. Zeng¹, L. Pan², 1. *Xiangya School of Nursing of Central South University, Changsha, Hunan Province, China*, 2. *The Second Xiangya Hospital of Central South University, Changsha, Hunan Province, China*

We explored the effects of biofeedback-assisted relaxation training on blood pressure and cognitive functioning of the community-dwelling older adults with essential hypertension. One hundred and eight older adults with essential hypertension were selected from a community in Changsha and randomly divided into equal-sized control and experimental groups. Participants in the control group were given routine service of the community, while those in the experimental group received biofeedback-assisted relaxation training plus routine service of the community. All participants were assessed by trained assistants blind to study group allocation using mercury sphygmomanometer, Mini Mental State Examination (MMSE) and Montreal Cognitive Assessment (MoCA), before the training and at 3 and 6 months of the training. Spearman correlation analysis indicated SBP and MoCA score, attention, abstract, delayed recall scores were related negatively ($r = -0.308, -0.317, -0.290, -0.342$, respectively) ($P < 0.01$); DBP and MoCA, abstract, delayed recall score were also related negatively ($r = -0.206, P < 0.05$; $r = -0.218, P < 0.05$; $r = -0.245, P < 0.01$). Repeated measures analysis of variance showed that there was significant time effect as well as interaction effect between intervention and time on SBP ($P < 0.01$), and significant intervention effect, time effect as well as interaction effect between intervention and time on DBP, MMSE and MoCA ($P < 0.05$). Therefore, there is a negative correlation between blood pressure and cognitive functioning; biofeedback-assisted relaxation can be used to control hypertension and improve cognitive functioning of community-dwelling older adults with essential hypertension.

EFFECTS OF SERIAL SUBTRACTIONS ON ELDERLY GAIT SPEED IN A VIRTUAL REALITY SETTING

T. Leeder, A. Helseth, S. Myers, M. Schieber, J.A. Blaskewicz Boron, *University of Nebraska at Omaha, Omaha, Nebraska*

Falls are the leading cause of fatal injuries in older adults aged 65+ with one in three adults falling each year. Cognitive processes are involved in gait, and thus, as cognitive changes

are normative with age, this may impact fall risk in the elderly. Sixteen older adults aged 70.8 ± 5.3 years took part in a dual-task (DT) study where they walked on a split-belt self-paced treadmill with and without a virtual reality (VR) setting while simultaneously performing a serial subtraction (SS) task. For SS, individuals were given a random 3-digit starting number and told to subtract by three from that number for one minute; this process occurred three times. Only correct substitutions were counted toward their total score. Previous literature showed that individuals will slow their gait to deal with a cognitive task, and our results supported this trend. Subjects tended to walk slower in both the VR and non-VR settings while dual-tasking compared with the walking-only control trial; walking while SS was significantly slower in the VR session ($p = .008$). Initial analyses found no significant differences in correct scores between conditions, however, when grouping based on age, there was a significant difference ($p < .001$). Subjects below 70 years performed better in the SS task (69 correct) compared to subjects 70 and older (30 correct). Overall subjects tended to score higher and walk faster in the VR condition. This could provide evidence of VR conditions better approximating daily life and thus implementing them as part of a fall intervention program.

SESSION 805 (POSTER)

CRITICAL AND CULTURAL GERONTOLOGY

A CRITICAL ANALYSIS OF AGING IN PLACE AND AGE-FRIENDLY EFFORTS

J.C. Yeh, *University of California, San Francisco, Institute for Health & Aging, San Francisco, California*

Movements to make communities age-friendly are gaining global attention, as population aging and urbanization pressure cities, including San Francisco, to reconsider how built and social environments influence residents' wellbeing throughout the life course. The preventive frameworks of age-friendly efforts emphasize that all sectors of society should adopt and design practices that are age-inclusive, meaning a separate world should not be built for older people alone. Rather, the world must work for all people, regardless of age. This qualitative study interrogates the conceptual frames that inform policies and practices striving to be age-friendly and how those conceptions compare to the lived experiences of community-dwelling older adults. To interpret meaning and processes situated in the experiences of informants, this study employs constructivist grounded theory as its methodological approach. Data collection includes semi-structured in-depth interviews with experts in the field and low-moderate income older San Franciscans, as well as visual representation through informant-produced photographs. Findings include the various meanings and interpretations of 'aging in place' and 'age-friendly' efforts, as well as the paradoxical power of age-friendly discourse that is universalizing and potentially obscuring inequalities across lines of difference, throughout the life course. Applied, this research may improve policies and practices affecting an increasingly longer-living, yet still unequal, society by providing a critical understanding of how aging and place are co-produced.

CHOREOGRAPHIES OF CITIZENSHIP: TOWARDS A RECONCEPTUALIZATION OF DANCE, DEMENTIA, AND EVERYDAY LIFE

P. Kontos^{2,1}, A. Grigorovich^{2,1}, 1. Dalla Lana School of Public Health, University of Toronto, Toronto, Ontario, Canada, 2. Toronto Rehabilitation Institute - University Health Network, Toronto, Ontario, Canada

There is a growing literature that argues for the value of dance as an embodied practice for persons with dementia, as it draws significantly on the body's potentiality for innovation and creative action and significantly supports non-verbal communication and affect. Despite the critical knowledge base on dance from phenomenological analyses and somatic and performance studies, dance scholarship and practice in the dementia field largely represent a movement towards cognitive science with an emphasis on embodied cognition and psychotherapeutic use of dance. This has restricted understanding of dance in dementia and has consequently limited the development of opportunities to more fully support this embodied form of self-expression in long-term care settings. We articulate this argument by analyzing findings of an ethnographic study of selfhood in Alzheimer's disease in a Canadian long-term care facility in the context of a relational model of citizenship. Specifically we focus on findings that feature self-expression through dance in the context of everyday life in long-term residential care, specifically during recreational and religious social programs, and non-structured activities. We argue that these examples can more fully be understood and supported with a relational model of citizenship that recognizes that corporeality is a fundamental source of self-expression, interdependence, and reciprocal engagement. This model brings a new and critical dimension to understanding self-expression through dance by persons with dementia, while also addressing broader issues of inclusivity and the ethical imperative to fully support dance through institutional policies, structures and practices.

AUSTRALIAN ATTITUDES AND POLICIES ON INTERGENERATIONAL EQUITY: IMPACTS OF SOCIAL CHANGE

H.L. Kendig¹, K. O'Loughlin², R. Hussain¹, L. Cannon¹, 1. Research School for Population Health, Australian National University, Canberra, Australian Capital Territory, Australia, 2. The University of Sydney, Sydney, New South Wales, Australia

This paper aims to investigate changing attitudes and policies concerning intergenerational equity in Australia through the aftermath of the Global Credit Crises.

Data are from a representative national sample of adults aged 18 years and older in the Australian Attitudes to Ageing (AAA) study conducted as a component of the national Australian Survey of Social Attitudes (AuSSA) in 2009–10 (n= 1525) replicated in 2015–16 (n= 1211). At baseline a majority of respondents thought that life-long social and economic opportunities were better for baby-boomers than for the preceding cohort now in later life, but views on future prospects were more divided. Results from the latest round found continuing stability of attitudes, although there was an increased perceptions of declining prospects for future

cohorts and younger people. At both times a majority (especially among ageing baby-boomers) opposed policies raising the age of pension eligibility and most believed that older people were getting 'less than their fair share' of government benefits. Across all age groups at both times, only a small proportion perceived strong intergenerational conflict. Significant age, gender, and social class differences were found at both time periods.

The findings confirm modest increases of social tensions between age groups that will be interpreted in terms of cohort succession and responses to contentious government actions on retirement incomes and debt reduction. Deeply-seated beliefs in older people as a homogeneous 'needy' group contrast with increasing evidence of accumulating wealth inequalities and economic challenges ahead especially for younger people.

SOCIAL CAPITAL, HEALTH BEHAVIOURS AND HEALTH: DOES REPORTING HETEROGENEITY PLAY A ROLE?

M.G. O'Doherty¹, D. French², A.P. Steptoe³, F. Kee¹, 1. UKCRC Centre of Excellence for Public Health for Northern Ireland, Queens University Belfast, Belfast, Ireland, United Kingdom, 2. Queen's University Management School, Queens University Belfast, Belfast, Ireland, United Kingdom, 3. Institute of Epidemiology and Health Care, University College London, London, United Kingdom

Social capital has been shown to be associated with self-reported health and health behaviours. Subjective measures such as self-reports are not as robust as objective measures which are too expensive to implement across large cohorts. To overcome the problems of interpersonal incomparability of self-reports, anchoring vignettes have been proposed as a method of identifying reporting heterogeneity and correcting self-reports for such differences, enhancing the comparability of subjective measures.

Using ELSA Wave 3 (2006/07) in participants aged 50 years and older (n=9343) associations between three dimensions of social capital (local area & trust, social support and social networks) and four health behaviours (smoking, alcohol use, physical activity and vegetable consumption) were examined using logistic regression and controlling for socio-demographic variables. Using vignette methodology to study the effects of socio-demographic factors and social capital on self-reported health allowed us to correct for reporting heterogeneity and threshold variation with a series of hierarchical ordered probit models for a sub-sample of 2341 subjects who completed the health vignettes.

Positive associations were observed between healthy behaviours (not smoking and mod/high physical activity) and local area & trust and social networks; positive associations were also evident with excessive drinking. All dimensions of social capital were independently associated with self-rated health, with physical activity appearing to mediate associations between social networks and health. Independent of social status, high levels of social capital were associated with healthier behaviours and self-reported health. However, ignoring reporting heterogeneity appears to underestimate the positive effect of social networks on health.

AGE AND SEX DIFFERENCE IN WORRIES ABOUT AGING IN EAST ASIAN SOCIETY

H. Cheng^{1,2}, H. Weng¹, T. Lu¹, Y. Yang³, 1. *Institute of Gerontology, College of Medicine, National Cheng Kung University, Tainan City, Taiwan*, 2. *Department of Family Medicine, National Cheng Kung University Hospital, Tainan City, Taiwan*, 3. *College of Medicine, National Cheng Kung University, Tainan City, Taiwan*

Aging may intensify worries about the future according to personal experience and social stereotypes. In previous studies, different genders and ages showed different concerns in some countries. However, there was no study to discuss worries about aging in different gender and ages across different countries simultaneously. In this study, we try to explain the variables related to worries about aging and that in different ages and gender in the Eastern world. In our study, 3802 participants in China (mean age 47.61 years old), 2134 participants in Taiwan (mean age 47.63 years old), 2496 participants in Japan (mean age 53.70 years old), and 1533 participants in Korea (mean age 47.79 years old) were included from East Asian Social Survey (EASS) database 2012. In both Taiwan and China, women had higher worries about aging than men. Age, education, urbanization, family members, occupation, and social placements were significant factors that contributed to worries about aging. In China, the 41–64 year-old group showed the highest concern, whereas in Taiwan, it was the 20–40 year-old group that had the most worries. Recognizing the worries about aging is useful in identifying senior needs and will help determine policies on the aging society.

GENERATION TO GENERATION: LESSONS LEARNED FROM AN INTERGENERATIONAL COLLEGE SOCIAL CLUB

L. Wagner, R. Mannas, O. Traina, *Psychology, University of San Francisco, San Francisco, California*

Traditional college-aged students have little opportunity to foster meaningful relationships with older adults. Coursework for gerontology students often focuses on difficulties in aging, including disease and decline. Students can easily miss getting to know older adults as vibrant individuals and may then treat them stereotypically in clinical settings. Generation to Generation, a gerontology elective at University of San Francisco (USF) for older (over age 55) and younger (18–30 year old) adults, promotes positive intergenerational contact. Results from the course suggest intergenerational interactions in a classroom setting increase younger adults' positive attitudes toward older adults (Wagner, Dangerfield, & Rodriguez, 2014). When the course was not offered (instructor on sabbatical), previous students formed the Generation to Generation Club. The club held bi-monthly lunchtime discussions in which students from USF and the Fromm Institute for Lifelong Learning discussed topics ranging from dating to ballot propositions. In addition, a mentorship program matched 19 USF students with 19 Fromm students. Pairs communicated with the goal of getting to know someone outside their peer groups. Evaluation indicated that respondents enjoyed group discussions, the mentorship program, and wished to participate again. Challenges included coordinating times where members of both groups were available and encouraging

continued attendance despite last-minute cancellations by individuals from both groups. The Generation to Generation social club model of discussion-based learning and personalized mentoring succeeded in stimulating intergenerational relationships and decreased stereotyping of each age group. Replication on college campuses with lifelong learning or at senior centers close to educational institutions is encouraged.

OLD VOLK: AGING IN TWO GERMANIES, 1945–1990

J. Chappel, *History, Duke University, Durham, North Carolina*

This paper is a contribution to the historical study of aging. It uses the natural experiment of the divided German nation, where for several decades a region with similar economic, cultural, and demographic characteristics was divided into two radically distinct social and political systems. In West Germany, American-influenced policymakers and sociologists conceived a “problem of aging” organized around the concepts of autonomy, dignity, and pension reform. In East Germany, Soviet-influenced counterparts conceived the problem entirely differently, avoiding gerontology and the language of dignity entirely, seeking instead different and more egalitarian strategies to incorporate the elderly into the body politic.

My finding is that the socialist style of aging ultimately failed due to internal contradictions and economic collapse, but that it nonetheless provides important resources for the present as we seek ways to manage growing populations of the elderly in Germany and around the world. Socialists pioneered models of housing and community integration for the elderly that are currently being dismantled at great cost, both to East Germany's elderly and to scientists from around the world looking for examples of communal forms of eldercare. The methodology of this paper is cultural history. I have examined hundreds of German-language newspaper articles, social-scientific studies, state archival documents, and even television shows in order to explore the imagination of aging in each nation. This is pathbreaking work, as vanishingly little work on aging has been written by trained historians.

SESSION 810 (POSTER)

CROSS-CULTURAL AND CROSS-NATIONAL STUDIES

A META-ANALYTIC STUDY OF CULTURAL DIFFERENCES IN HOLISM AND ANALYTICISM ACROSS AGE GROUPS

Y. Fang², H.H. Fung³, M. Lu³, 2. *CUHK Jockey Club Institute of Ageing, Hong Kong, Hong Kong*, 3. *The Chinese University of Hong Kong, Hong Kong, Hong Kong*

Holism (i.e. a context-dependent processing style more prevalent in East Asian cultures) and analyticism (i.e., a context-independent processing style more prevalent in Western cultures) are well-researched in cultural psychology, and, to a lesser extent, in developmental psychology. In two meta-analyses, we examined the degree to which cultural differences in holism and analyticism between East Asians and Western Europeans were similar among younger and older age groups. We based our meta-analysis on 42 studies (N=2510) that included holism- and/or analyticism-related

outcomes and recruited participants from both East Asian and Western Cultures. Studies that examined age differences recruited participants from younger (18–30 years) and older (60–88 years) age groups. Using random effects analyses, we found that cultural differences in both holism and analyticism-related outcomes were significantly moderated by age group. For holism, younger East Asians were significantly more holistic than younger Western Europeans, Hedge's $g=.55$, $p<.001$, while there were no significant difference in holism among older East Asians and older Western Europeans, Hedge's $g=-.17$, $p=.385$, $Q=10.32$, $p=.001$. For analyticism, younger East Asians were significantly less analytic than younger Western Europeans, Hedge's $g=.69$, $p<.001$, while the same cultural difference was even stronger among the older adults, Hedge's $g=1.72$, $p<.001$, $Q=10.98$, $p=.001$. We discuss the implications of these results for the distinct theoretical perspectives that cultural differences are more strongly expressed in old age (Fung, 2013), and that age is an equalizer for cultural differences (Park, Nisbett, & Hedden, 1999).

PREVALENCE AND CORRELATES OF LATE-ONSET SUICIDAL IDEATION AND ATTEMPTS AMONG KOREAN ELDERS

G. Kim, S.Y. Wang, S. Park, *The University of Alabama, Tuscaloosa, Alabama*

Purpose of the Study: The present study examined prevalence and correlates of late-onset suicidal ideation and attempts among community-dwelling older adults in South Korea.

Methods: Drawn from the 2013 national survey of older adults in South Korea, 10,267 adults aged 65 or older were analyzed. Data were analyzed using chi-square tests, correlation and logistic regression analyses.

Results: Prevalence rates for late onset suicidal ideation and attempts were 10.9% and 12.5%, respectively. One of the main reasons for late onset suicidal ideation was financial strain (40.4%), followed by health issues (24.4%) and feelings of loneliness (13.3%). Several significant correlates of for late onset suicidal ideation and attempts were found. Those experiencing late onset suicidal ideation were more likely to be female and have lower educational attainments and annual income and greater functional limitations. Late onset suicidal attempts were associated with female gender, not married status, unemployment, lower annual income and no functional limitations.

Conclusions: Late-onset suicidal ideation and attempts among Korean elders were found to be high compared to older adults in other countries. Understanding correlates of late-onset suicidal ideation and attempts may help reduce suicidal rates and improve the treatment for Korean older adults experiencing late-onset suicidal ideation and attempts. Clinical implications are also discussed in a cross-cultural context.

HAPPY LIFE EXPECTANCY AND HEALTH: A CROSS-NATIONAL STUDY OF JAPAN AND TAIWAN

A.R. Bardo¹, T. Yamashita², D. Liu³, 1. *Sociology, Duke University, Durham, North Carolina*, 2. *University of Nevada, Las Vegas, Las Vegas, Nevada*, 3. *Des Moines University, Des Moines, Iowa*

Good health is generally recognized as an important condition not only for longevity but also happiness. However, few studies have simultaneously examined the role of health for mortality and happiness. The purpose of this study was to examine the contribution of health to happy life expectancy (i.e., the proportion of remaining life that one can expect to live happy) in Japan and Taiwan that share a similar culture and health profile. Data come from the 2012 wave of the East Asian Social Survey (Japan: $N = 2,273$; Taiwan: $N = 1,925$) and the Human Mortality Database. Prior research often used Sullivan's multistate life table method to estimate life expectancy with cross-sectional survey data, but it is limited in its ability to include covariates (e.g., education, income, and health). In this study, we utilized a Bayesian extension of this method to estimate happy life expectancy. Results show that, on average, adults with good health can expect to have relatively long and happy lives. For example, both Japanese and Taiwanese men who are healthy can expect to live about 21% longer and spend a greater proportion (i.e., approximately 20%) of their life happy compared to their unhealthy counterparts. Findings indicate that poor health shortens life because of an increased risk of mortality, but they also suggest that poor health substantially reduces quality of life in terms of happiness. This study adds to a growing body of evidence that shows that health can have a long-term impact on happiness across the life course.

ARE GERMAN AND KOREAN FAMILIES BETTER OFF AFTER SOCIAL LONG-TERM CARE INSURANCE?

H. Lee, *Health Insurance Policy Institute, National Health Insurance Service, Wonju, Gangwon-do, Korea (the Republic of)*

Germany and Korea introduced social insurance systems to finance long term care (LTC) need in 1995 and 2008 respectively. Both LTCI systems aim to help people with LTC need and their families. Even with the similarities as social insurance, the two systems took a different approach toward family caregivers. German LTCI incentivizes family caregivers such as paying pension premium, while Korean LTCI lacks those kind of direct support for families. This study reviews the different approach toward family caregivers of physically dependent people of both systems and investigates how subjective wellbeing (SWB) of families was affected after the introduction of LTCIs in both countries.

To analyze the effect of German LTCI on SWB of German families, the study used the German Socio-Economic Panel from 1992 to 2002. For the analysis of the effect on Korean families, Korean Longitudinal Study of Aging was used from 2006 to 2012. Each analysis included all the adults, who were interviewed in the baseline year in "pre-policy" period. The other waves in both datasets were regarded as "post-policy" treatment conditions. This study took difference-in-difference approach employing logistic regression to evaluate the LTCI effect on SWB of the families of the LTC needy.

The study found that SWB of German families was improved while no change was observed in Korean families after LTCI introduction. The immediate effect of LTCI on SWB measures of German families was relatively large at the beginning period. Active policy measures could be needed to improve SWB of Korean families.

RELATIONSHIP BETWEEN CULTURAL ORIENTATION AND ATTITUDES TOWARD AGING AND THE ELDERLY: U.S. AND CHINA

G.Q. Zhan, S.M. Pearcey, R. Radomski, D.R. Moodie,
Kennesaw State University, Kennesaw, Georgia

The current study examined Chinese and American young people's cultural orientation (i.e., individualism/collectivism) in relation to their attitudes toward aging and the elderly. Seven hundred seventy-nine college students (434 Chinese, 345 American) filled out a questionnaire that included Triandis and Gelfand's IC scale (Cultural Orientation Scale), Kogan's attitudes toward old people scale, as well as relevant demographic and background information. Cronbach's alphas indicated satisfactory reliability of both scales for the two cultural groups. Results show the two groups differed significantly on the IC scale, but in a surprising way that partially challenges the traditional views on individualism/collectivism paradigm. Specifically the Chinese students scored significantly higher than the American participants on both the vertical individualism and vertical collectivism subscales, indicating that while they are more likely to accept hierarchy and inequality in society, they are nevertheless able to view the self both as part of a collective and as fully autonomous. The American students on the other hand scored significantly higher on both the horizontal individualism and horizontal collectivism subscales, indicating while they are less likely to accept hierarchy and inequality in society, they are also able to view the self both as part of a collective and as fully autonomous. Results also show that the American participants hold more positive attitudes toward aging than their Chinese participants. For both groups, collectivistic orientation is positively correlated to attitudes toward aging and the elderly. We will discuss these findings in the context of globalization and the possible eroding of traditional Chinese values.

CONSTRUCTING TRANSNATIONAL FAMILIES: GENERATIONAL TIES, FILIAL PIETY, AND CAREGIVING ACROSS BORDERS

J. Yoon, *Syracuse University, Syracuse, New York*

Research at the intersection of migration and aging has primarily focused on elderly migrants, and has only recently begun to address the issue of transnational family relationships of older parents left behind by their migrant children. The current study contributes to this nascent area of research by examining the intergenerational relationships of Korean Americans with at least one older parent living in Korea. Korean immigrants represent a theoretically rich population to study because, as labor migrants, they have largely been successful in American society, but retain values of filial piety from their native culture. The empirical design consists of in-depth, open-ended interviews of twenty Korean Americans living in the Northeast of the U.S. Most subjects are first-generation immigrants from Korea. A grounded-theory approach is used to detect consistent thematic content across interviews. Findings suggest that there is uncertainty among these immigrants as to future expectations for their parents' later years and how to plan for their care. They tend to feel ambivalent over the difficulties of maintaining family ties and fulfilling filial obligations over great distance, a challenge further complicated by practical issues of formal elder care

availability in contemporary Korea. There is also some tension, both internally for the immigrants and between family members, over future plans and expectations for care, including the expectations of parents. Such conflicting factors mean that when the time comes to respond, intergenerational care provision will involve complex negotiations among members of these transnational families.

FUTURE TIME PERSPECTIVE OF OLDER GERMANS AND JAPANESE LIVING ALONE

T. Ikeuchi¹, F.R. Lang², H. Osada³, 1. *Research Team for Social Participation and Community Health, Tokyo Metropolitan Institute of Gerontology, Tokyo, Japan*, 2. *Institute of Psychogerontology, Friedrich-Alexander-University of Erlangen-Nürnberg, Nuremberg, Germany*, 3. *Graduate School of Gerontology, J. F. Oberlin University, Tokyo, Japan*

Objectives: Changes in age-related future time perspective (FTP) were found to influence people's social network characteristics (SNC). Earlier studies revealed different patterns of adaptation to their personal network among older adults with or without nuclear family members. Using the framework of socioemotional selectivity theory (SST), this study examined the differential role of living arrangement in SNC between the cultures of Germany and Japan, which share many distinct characteristics, including the types of living arrangements among older adults.

Methods: Our sample consisted of 139 German (71% live alone) and 136 Japanese (49% live alone) adults ranging in age from 60 to 90. The moderating role of living alone in the three way interactions of subjective health (SH), FTP, and SNC was tested.

Results: Among Germans, more extended FTP was associated with an increasing number of very close social partners, when living alone and having rather poor or average health, as well as when living with someone and having rather better health. These findings were consistent with SST. However, no such associations were found among Japanese. Our additional analysis on the interaction between the effects of culture and living alone on FTP revealed a greater cultural effect in the live-alone situation than in the not-live-alone situation.

Conclusions: Our study suggests that culture-specific associations between SH, FTP, and SNC may reflect differences of living arrangements between Germany and Japan. For example, living alone may have a stronger impact on the phenomenon of SST in Germany than in Japan.

ELDERCARE NORMS REGARDING THE PROVISION AND FINANCING OF HOME CARE ACROSS 24 COUNTRIES

A.L. Janus, A.S. Koslowski, *Sociology, University of Edinburgh, Evanston, Illinois*

We use 2012 data from the International Social Survey Program to examine cultural norms surrounding assistance with daily activities at home for older people across 24 economically developed countries. We focus on individuals' expressed support for four different elder care arrangements characterized by differences in who provides and covers the costs of elder care. People's elder care beliefs vary substantially both across and within countries. Support for "private responsibility"—i.e., private sources such as family

members are responsible for both providing and financing elder care—is greatest in the English-speaking countries (44 percent), followed by Eastern and Southern Europe and East Asia (both 35 percent), Western Europe (25 percent), and the Nordic countries (9 percent). By contrast, 74 percent of people in the Nordic countries express support for “public responsibility”—i.e., formal sources such as government agencies are responsible for both provision and financing—and support for this arrangement ranges between 29 and 41 percent in the other country groups. We use multilevel models to examine how people’s support for different elder care arrangements are related to societal opportunity structures, familial opportunity structures, and ideological factors. Our results suggest the importance of both opportunity structures and ideological factors in accounting for people’s elder care beliefs. The most important factor at the country level is the percentage of GDP spent on services, which is associated with greater support for “public responsibility” in elder care and less support for “private responsibility” and “publicly financed informal care.”

LIVING IN MANDATORY PALESTINE: PERSONAL NARRATIVES OF THE GALILEE FROM THE 1940S TO 1967

S.Y. Hantman², R.R. Greene¹, 1. *University of Texas-Austin, Austin, Texas*, 2. *Tel Hai College, Kiryat Shmona, Israel*

This paper presents the results of a research study entitled “Living in Mandatory Palestine: Personal Narratives of the Galilee from the 1940’s to 1967.” Forty narratives were collected: twenty from Jewish settlers and twenty from Arabs who have lived or where born in the Galilee, prior to the establishment of the State of Israel and thereafter. The study uses a narrative approach to gerontology that explores the lives of older study participants from a life course–ecological perspective, encompassing cultural, historical, and political reminiscence.

Resilience was analyzed through people’s narratives of critical events that occurred at the personal, interpersonal, sociocultural, and societal levels. Personal-level narrative themes spoke about internal feelings. Interpersonal-level narrative themes such as continuity, personal responsibility to each other, coping, modesty and acceptance addressed relationships between people. Sociocultural-level themes express the beliefs and mores of family, tradition, religiosity, Zionism, modesty and leadership of the time. Societal level narrative themes such as relating to belonging to persons, places, and ideologies are indicative of the work of societal institutions. Initial results point to a strong idealistic commitment to family and state regardless of ethnic background.

MULTIMORBIDITY, HEALTH, AND AGING IN CANADA AND AUSTRALIA: A TALE OF TWO COUNTRIES

A. Wister¹, H.L. Kendig², B. Mitchell¹, I. Fyffe⁴, V. Loh³, 1. *Simon Fraser University, Vancouver, British Columbia, Canada*, 2. *Australian National University, Acton, Australian Capital Territory, Australia*, 3. *University of Sydney, Sydney, New South Wales, Australia*, 4. *Gerontology Research Centre, Simon Fraser University, Vancouver, British Columbia, Canada*

Multimorbidity has been recognized as a major public health issue that is prevalent among older adults, affecting

objective and subjective health, and health care utilization. For instance, in Canadian and Australian population health surveys, self-reported multimorbidity is estimated between 50% and 65% among persons 65 and over. This exploratory study examines selected health outcomes associated with multimorbidity across older age groups/cohorts and gender, comparing Canada and Australia. Data were drawn from the 2008/09 Canadian Community Health Survey and the 2009 Australian HILDA survey. Seven major chronic illnesses were identical across the two data sets, and were combined into an additive measure of multimorbidity. OLS and logistic regression models were performed within age group (45–54, 55–64, 65–74, 75+) and gender to estimate associations between multimorbidity and several health outcomes, including: loneliness, life satisfaction, perceived health, mobility restriction, and hospital stays, adjusting for marital status, education and foreign born status. Overall, country-level differences were identified for perceptions of loneliness, life satisfaction, and perceived health. Australians tended to experience a greater risk of loneliness and lower self-rated health in the face of multimorbidity than Canadians, especially among older men. Canadians tended to experience lower life satisfaction associated with multimorbidity than Australians. No country-level differences were identified for the effects of multimorbidity on hospital stays or mobility limitations. The effects of multimorbidity on health is variable depending on population, age group/cohort, and gender. The strongest country-level associations are for indicators of health-related quality of life, rather than health care or mobility limitation outcomes.

GENDER GAPS AND SES GRADIENTS IN ALCOHOL CONSUMPTION AMONG OLDER ADULTS IN 19 COUNTRIES

J. Medina², E. Calvo¹, I. Madero-Cabib¹, 1. *Universidad Diego Portales, Santiago, Chile*, 2. *Calvolab, Santiago, Chile*

The prevalence of alcohol consumption and its effects on mortality and morbidity have received substantial attention. Most of the evidence is based on single-country studies or in comparative studies of the general population. In contrast, comparative estimates of the prevalence of alcohol consumption among older adults have received less attention. Using recent data from the Health and Retirement Study (HRS), English Longitudinal Study on Ageing (ELSA), Survey of Health, Ageing and Retirement in Europe (SHARE), China Health and Retirement Longitudinal Study (CHARLS), and Korean Longitudinal Study of Aging (KLoSA), this study harmonizes information on alcohol consumption and categorizes respondents as: lifetime abstainers, current abstainers, occasional drinkers, moderate drinkers, and heavy drinkers. Preliminary results suggest that moderate drinking is more prevalent in European countries, while lifetime abstainers are the norm in Asia. Gender gap and SES gradients are substantial, but they vary considerably across countries.

HOME ASSESSMENT OF PERSON-ENVIRONMENT INTERACTION (HOPE): A CROSS-CULTURAL VALIDATION STUDY

J. Rousseau^{1,2}, C. Chu³, P. Guitard⁴, 1. *École de Réadaptation/School of Rehabilitation, Université de Montréal, Montreal, Quebec, Canada*, 2. *Research Center Institut Universitaire de Gériatrie de Montréal, Montreal,*

Quebec, Canada, 3. CIUSSS de l'Est-de-Montréal, Montreal, Quebec, Canada, 4. École des Sciences de la Réadaptation / School of Rehabilitation Sciences, Université d'Ottawa / University of Ottawa, Ottawa, Ontario, Canada

Aging is frequently associated with impaired mobility. Consequently, the elderly face environmental barriers within their home environment and Aging-in-Place becomes a challenge. Few assessment tools exist to address the issue of home adaptation. HoPE is based on a Person-environment Interaction Model and specifically designed for home adaptation evaluation. Since its original version is in French, this study's aim was to yield an English version. Based on a back-translation methodology for cross-cultural research, the first steps of the Vallerand's method were completed: 1) an English experimental version of HoPE was produced by comparing the original version with the translated and back-translated versions by independent translators, 2) this experimental version was submitted to an expert panel to validate the transcultural equivalence using a consensus approach. Comparative data analyses included: 1) highlighting the similarities/differences across the three versions of HoPE (original, translated, back-translated), and 2) reporting the experts agreement/disagreement. Results show that 70% of the experimental version is transculturally equivalent. For the remaining 30%, the experts reached a consensus except for 6 terms for which decision was based on the majority; then, the English version of HoPE was produced. Considering these results and the psychometric properties of its original version (French), this cross-cultural adaptation of HoPE provides clinicians and researchers with a new and valid tool to understand the Person-Environment Interaction in the home setting.

THE ASSOCIATION OF MULTI-ETHNICITY AND HEALTH AMONG OLDER ADULTS: THE CASE OF COSTA RICA

B. Reyes Fernández², T.A. Baker¹, 1. University of Kansas, Lawrence, Kansas, 2. University of Costa Rica, San Jose, Costa Rica

The Hispanic population is considered one of the most diverse groups of individuals nationally and globally. Assessing the multi-ethnic background of Latin America is very convoluted, and an area that is often ignored, particularly as it deals with health outcomes of older non-White Hispanic adults. This lack of attention has a direct impact on the needs of Black Latinos, in particular and other Latin American minorities in general. This tends to render these groups as practically invisible in terms of health outcomes, behaviors, and other related psychological outcomes. To better understand the global assessment of older minority populations, this project takes the case of Costa Rica as an example of a multi-ethnic country that is aimed at understanding the health needs of its older adult population. An introduction is directed at the historical context of immigration and cultural encounters that have taken place in unjust and inequitable circumstances, particularly among the Black Latino population in Costa Rica, with emphasis on the population coast of Limón, Costa Rica. Although ongoing, preliminary results of a study are provided describing inequities of wealth and segregation, with its deleterious consequences on health. Special attention is guided at how health is defined, how race

has impacted well-being, and understanding the dynamics of this long-standing relationship. These data will direct our understanding of models, facilitators, and barriers that define the life experiences of Black Latinos and other marginalized populations, while highlighting areas that promote medial advancements, equity in access to care, and health promotion and well-being.

SESSION 815 (POSTER)

DEATH, DYING, AND BEREAVEMENT

CIRCUMSTANCES SURROUNDING THE DEATH OF A LOVED ONE AND ADAPTATION TO BEREAVEMENT

S.T. Stahl, R. Schulz, *Psychiatry, University of Pittsburgh, Pittsburgh*

Circumstances surrounding the death of a loved one can affect surviving family members' bereavement experience. Those who believe their loved one had a 'good death' (e.g., death was a relief, expected) may experience better bereavement outcomes than those who were dissatisfied with their loved one's death experience. This study examined: (1) pre-death factors associated with caregivers' perceptions about the circumstances surrounding their care recipients' death; and (2) whether a better perception of death is associated with indicators of adaptation to bereavement. Participants included 89 informal caregivers (CG) aged 32 - 87 years (M = 63 years) who experienced the death of their care recipient shortly after placing him/her in a long-term care facility. Pre-death measurements included sociodemographic characteristics, depression, and preparedness for death. Post-death measurements (approximately 3 months post-death) included circumstances surrounding death, restorative health behaviors, and complicated grief. A multivariate regression model showed that CGs who were White and CGs who felt more prepared prior to death perceived better circumstances surrounding their loved one's death. CGs who perceived better circumstances surrounding their loved one's death engaged in more restorative health behaviors post-death and reported fewer symptoms of complicated grief. These findings suggest that a better perception of death facilitates behavioral and psychological adaptation to bereavement. These findings raise questions about the specific circumstances surrounding death that may facilitate adaption to bereavement and whether healthcare providers can improve CGs perceptions of a 'good death', possibly by preparing them for the death of their loved one.

PSYCHOLOGICAL VULNERABILITY TO WIDOWHOOD: FINANCIAL STRAIN, WORRY ABOUT CARE, AND SOCIAL ENGAGEMENT

J. Min⁴, L. Xu¹, Y. Li², I. Chi³, 1. University of Texas Arlington, Arlington, Texas, 2. San Diego State University, San Diego, California, 3. University of Southern California, Los Angeles, California, 4. University of Alberta, Edmonton, Alberta, Canada

Objective. This study examines the ways in which the financial, social, and care factors (financial strain, worry about having no caregiver, and social engagement) modify the association

between widowhood and depressive symptoms among older adults in China. **Methods.** Using national representative data from older adults in China in 2000 ($n = 15,115$), Multiple regressions were used in this study to examine the moderating effects of the financial, social and care factors on the association between widowhood and depressive symptoms. We also performed structural equation modeling to test the mediating effects of these factors on such association.

Results. Compared to their married counterpart, widowed older adults show significantly higher level of depressive symptoms ($b = 0.46, p < .001$), higher percentage of worry about having no caregiver ($b = 0.11, p < .001$) and financial strain ($b = 0.10, p < .01$), and lower level of social engagement ($b = -0.07, p < .01$) which results in higher levels of depressive symptoms. Worry about having no caregiver ($b = 0.15, p < .001$) significantly moderates the relations between widowhood and depression.

Discussion. This study extends bereavement and psychological wellbeing research to developing nations by examining several pathways between bereavement and depressive symptoms. The results provide important implications for intervention when working with widowed older adults in China.

AN EMPIRICAL TEST OF ROLE THEORY IN THE RELATIONSHIP BETWEEN WIDOWHOOD AND LIFE SATISFACTION

S. Hye Lim, H. Jun, S. Joo, S. Kim, *Yonsei University, Seoul, Korea (the Republic of)*

The purpose of this study was to test the social role theory in terms of widowhood transition among individuals in middle and later life. In this study, there were two approaches. One was the inter-comparison approach between married and widowhood individuals. The other was the intra-comparison between pre-widowhood and post-widowhood within individuals. For the analyses, data collected across the years 2006 to 2012, from the 1st to 4th wave of the Korean Longitudinal Study of Aging was utilized. The sample was individuals over 45-years-old and who experienced widowhood transition once or who stayed married ($N=5,735$). The dependent variable was life satisfaction. The independent variable was widowhood status as time-varying dichotomous variables. Utilizing the STATA program, the pooled model and the Fixed Effect model were analyzed. In the pooled model, the differences in life satisfaction between the married and the widowed were significant. In other words, widowhood individuals showed lower life satisfaction than the married. In the fixed effect model, however, widowhood was not significantly associated with life satisfaction. These results imply that the social role theory is not supported. That is, it is likely that other time-invariant characteristics among individuals may be associated with low life satisfaction in the context of widowhood transition in middle and later life. Implications and directions for future research are discussed.

A TARGETED AND TAILORED BEREAVEMENT INTERVENTION FOR CANCER CAREGIVERS

R.L. Utz¹, L. Miller², M.S. Caserta¹, D.A. Lund¹, 1. *Sociology, University of Utah, Salt Lake City, Utah, 2. University of Utah, College of Nursing, Salt Lake City, Utah*

Current literature suggests that interventions be targeted to those most at risk and flexible enough to accommodate individual preferences and needs. To explore whether tailoring and targeting modifies the efficacy of an intervention, this project utilizes a sub-sample of older spousal caregivers (median age = 64 years) who were randomized to receive an individually-tailored 14-week bereavement intervention ($n=112$) or usual care where they received only the standard bereavement support provided by hospice ($n=114$). Results from a traditional intent-to-treat model find a moderate effect size: those assigned to the intervention had more favorable bereavement outcomes over time compared to the control group. Further analyses revealed that participants benefitted from the intervention regardless of whether they chose to receive a high or low dosage of the intervention and regardless of whether they were categorized as being at higher or lower risk for adverse bereavement outcomes. Despite the similarity in treatment effects, there was substantial variation in how the intervention was delivered (e.g., total number of intervention sessions ranged from 1 to 19 across individuals). Taken together, these findings suggest that the key to effectively supporting older adults during a difficult life transition such as widowhood appears to be in developing an intervention that meets one's unique needs and preferences. As clinicians and practitioners, we should be careful to not force support when it is not needed or wanted, but be willing to provide high levels of support for others who may desire it. Funded by NCI, P01-CA138317.

DOES SPOUSAL LOSS PREDICT COGNITIVE FUNCTION? RESULTS FROM THE MEXICAN HEALTH AND AGING STUDY.

J. Saenz, B. Downer, M.A. Garcia, R. Wong, *Preventive Medicine & Community Health, University of Texas Medical Branch, Galveston, Texas*

Background: Mortality following spousal loss has received considerable research attention. The cognitive impacts of spousal bereavement remain understudied. In the United States, previous work suggests that bereavement negatively impacts cognitive function. This has not been studied in developing countries such as Mexico. We examine whether widow(er)hood is associated with cognitive function among older Mexican adults and whether this association differs by sex and anticipatory spousal loss.

Method: We use Waves 2 (2003) and 3 (2012) of the Mexican Health and Aging Study including married respondents in 2003. Those who lose a spouse between waves are analyzed as widow(er)s while the continuously married are controls. Cognition is measured through verbal learning, verbal recall, and visual scanning. Models include cognitive function prior to widow(er)hood. Spousal loss is considered unanticipated if one's spouse reports good health prior to death.

Results: Recently bereaved males performed significantly worse on verbal learning tasks, an effect that seemed to diminish with time since widowerhood. The effect of spousal loss on cognitive function for males was stronger when the loss of their spouse was unanticipated (when the wife reported good health prior to death). Spousal bereavement did not seem to affect cognitive function for females regardless of anticipatory status.

Discussion: Our results echo previous work suggesting that spousal loss harms cognitive function, that males are more affected by spousal bereavement, and that elevated risk seems to decline with time since widow(er)hood. The effect of spousal bereavement on cognitive function may be more pronounced when spousal loss is unanticipated.

THE GENDERED EXPERIENCE OF SOCIAL RESOURCES ACROSS THE TRANSITION TO LATE-LIFE WIDOWHOOD

L. Isherwood, *National Institute of Labour Studies, Flinders University, Adelaide, South Australia, Australia*

Widowhood in later life is a transitional event necessitating considerable change and presents differing challenges for men and women. Social resources - close relationships, social support exchange and opportunities for social participation - can assist in successful adjustment to spousal loss. Using the perspective of life course theory, this study sought to understand the gendered experience of social resources during the transition to widowhood.

Semi-structured interviews were conducted with 20 men and women (aged between 85 and 96 years) who had been widowed in later life. Participants were asked about the continuity and changes which had occurred in their social resources both pre- and post-widowhood. The role that these resources played in adjustment to spousal bereavement was also explored. The interview data were analysed thematically using framework analysis.

Four different phases in the transition to widowhood were identified each with differential experiences of contact with the social network, support and social participation. Older men and women experienced different opportunities in the accessibility and mobilisation of their social resources in widowhood. Male participants reported smaller social networks and received less support than female participants during all phases in the transition to widowhood. They also experienced fewer opportunities for social participation and were consequently more likely to be socially isolated. The stronger social resources possessed by older widowed women may assist them in better meeting the challenges associated with spousal bereavement. Potential gender differences should be taken into account in the assessment and planning of supports and services for older widowed adults.

MENTAL HEALTH AND THE RELATING FACTORS AMONG CHINESE OLDER ADULTS WHO LOST THEIR ONLY CHILDREN

D. Wang¹, X. Cao¹, P. Yang², R. Liu², *1. Psychology, Beijing Normal University, Beijing, China, 2. Beijing Hualingyiyang Mental Health Care Center, Beijing, China*

The number of older adults who lost their only children is increasing year by year with the implementation of the birth control policy in mainland China. They would encounter not only the pain caused by the loss of the child but also the pressure imposed by social context. However, few empirical studies have revealed the mental health among these vulnerable people. This study aimed at investigating the mental health status and the factors associated among them.

The sample consisted of 116 older adults who lost their only children (the lost group) and 100 older adults who didn't (the contrast group) from same communities. Participants were asked to complete a set of questionnaires to measure child death-related factors (time and cause of death), physical health (number of disease and self-rated physical health), social support (satisfaction of formal social support, participation in community activity, and marital quality), resilience, and mental health (depression, loneliness, and anxiety).

The findings revealed that, lost group reported more depression and anxiety symptoms than contrast group and females had more depression symptoms than males; Within the lost group, those whose children died of accidents showed worse mental health while those who had higher resilience, marital quality, and better physical health reported lower level of depression and anxiety. Community practices should channel more resources to improve the mental health of older adults who lost their only children. Efforts will be significantly valuable when focusing on enhancing resilience, physical health or marital quality of parents according to the present study.

SURVEYING ELDERLY PATIENTS' WISHES ABOUT ARTIFICIAL NUTRITION DURING END-OF-LIFE CARE IN JAPAN

Y. Yamaguchi¹, H. Mori², M. Ishii¹, K. Yamaguchi¹, S. Iijima³, S. Ogawa¹, M. Akishita¹, *1. Department of Geriatric Medicine, Graduate School of Medicine, The University of Tokyo, Bunkyo-ku, Tokyo, Japan, 2. Nursing Division, The University of Tokyo Hospital, Bunkyo-ku, Tokyo, Japan, 3. Rehabilitation Services Bureau, National Rehabilitation Center for Persons with Disabilities, Tokorozawa-shi, Saitama, Japan*

Because ambiguity is one of the prominent features of Japanese culture, it is crucial to understand how many Japanese elderly persons have strong wishes related to end-of-life care. Ninety-nine consecutive inpatients aged 75 years or older were enrolled in the first survey from 2012 to 2014, after excluding patients with a Mini-Mental State Examination (MMSE) score of 20 or less. The first survey was performed by interviewing them about their wishes related to artificial nutrition and hydration (ANH) during end-of-life care. For the 35 patients who had attended the first survey, we performed the second survey from 2015 to 2016 by handing them the questionnaire comprised of the same items as the first survey. 50.0% of the participants were against ANH at the end stage of their lives on the first survey. In contrast, only 5.3% wished to receive ANH. The answers of the other patients were inconsistent or included "I don't know". Aging and MMSE scores of less than 24 were significantly associated with a higher tendency to decline from participating in the interview. However, the distribution of the interview answers was not associated with age or MMSE scores. Interestingly, 87.5% of the patients who had been against ANH on the first survey selected the same answers on the second survey, while only 20.0% of the other patients selected the same answers as the first survey. In conclusion, many patients did not have definite wishes in Japan. However, most of the wishes against ANH did not change with age.

SESSION 820 (POSTER)

DEMENTIA AND ALZHEIMER'S DISEASE II

IMPLEMENTING PHYSICAL ACTIVITY PROGRAMS FOR PEOPLE WITH DEMENTIA: RESULTS FROM A GERMAN STUDY

M. Reichert, V. Wolter, FK 12, *Institute for Sociology, University TU Dortmund, Dortmund, Germany*

Different studies prove the benefit of physical activity for people with dementia and especially a holistic health approach is an effective strategy. Feasibility and sustainability of physical activity programs are more problematic and often not considered, when implementing them. This project (2014 – 2016) evaluated 73 local partnerships between sports clubs and care service providers which introduced this kind of programs for people with dementia (and their informal carers). The evaluation comprised a multi-method approach: (a) focus groups to analyze the needs and expectations of the two partners involved at three different times, (b) qualitative interviews with people with dementia (n=12) and their carers (n=20) to examine the effects of taking part in the physical activity program and (c) analysis of the user statistics. Results of focus group discussions confirm the importance of a local network and a sustainable finance model to ensure long-term feasibility. People with dementia and their carers emphasize that the experience of social support, fun and break from their daily life routine are the most relevant reasons for participation. Instead, time, place and kind of physical activity are of less importance. The key factor for a successful implementation of physical activity programs or for achieving positive effects for people with dementia and their carers is – besides other favorable framework conditions – a local community network which involves all actors mentioned above. These actors, they are all experts in a particular way, must have the willingness for communication and cooperation in order to complement each other.

THE POSSIBILITY OF COUPLES LIFE STORY PROJECT REDUCING CAREGIVERS BURDEN

M. Ito¹, R. Campbell⁴, A. Kan¹, N. Miyamoto², S. Tsuboyama², Y. Kurokawa³, 1. *Human Care Research Team, Tokyo Metropolitan Institute of Gerontology, Itabashi-ku, Tokyo, Japan*, 2. *Keiseikai institute of Gerontology, Tokyo, Japan*, 3. *Sophia University, Tokyo, Japan*, 4. *University of Michigan, Ann Arbor, Michigan*

In Japan, the older population is growing rapidly and it is estimated that the number of person with dementia will be 7 million in 2025. Over 80% of older people say they prefer to receive caregiving from their spouse, and a quarter of the family caregivers are spouses in Japan. Caring for a spouse with dementia can be very stressful and increase feelings of burden. The couples life story method which was developed by Ingersoll-Dayton helps couples review their life together from the first time they met to the present using photographs to stimulate conversation. We used couple's pictures and a life story board to conduct interviews with couples over 4–5 sessions lasting 1 to 2 hours each. Pre-and post-questionnaires for each spouse were used before and after the tape-recorded sessions; a life story book was produced for each

couple. 13 couples were included to this project. The average age of the caregivers was 79.0(±7.7), and 3 of them were male. The average age of care receivers was 80.2(±6.9), and 10 were male. The average score of MMSE was 14.2(±7.1) in care receivers. Depression and care difficulty was improved significantly after 4–5 session of the couple's life story project. There was no result to show improvement of couples' relationships from statistical analysis. But some couples used the life story book to promote their communication even after this project. This project is recommended to couples to improve spouse caregivers depression and care difficulty.

EATING PERFORMANCE AND ENVIRONMENTAL STIMULATION AMONG OLDER ADULTS WITH DEMENTIA IN NURSING HOMES

W. Liu², Y. Jao², K.N. Williams³, 2. *University of Iowa College of Nursing, Iowa City, Iowa*, 2. *Pennsylvania State University College of Nursing, State College, Pennsylvania*, 3. *University of Kansas School of Nursing, Kansas City, Kansas*

Nursing home (NH) residents with dementia experience increased risk for compromised eating performance due to cognitive and functional decline and behavioral symptoms. Beyond the personal factors, there is a lack of evidence on how environmental stimulation at mealtime influence individuals' eating performance. This study examined the association between environmental stimulation and eating performance among NH residents with dementia. A secondary analysis was completed of 36 baseline eating videos among 19 nursing assistants and 15 residents with dementia in 8 NHs from a communication intervention study. The dependent variable was eating performance (Level of Eating Independence scale). The independent variables were characteristics of environmental stimulation measured by the Person-Environment Apathy Rating-Environment subscale (stimulation specificity, interaction involvement, environmental feedback). Multilevel models were used to examine the association between eating performance and environmental stimulation adjusting for resident characteristics and nesting effects of resident and staff. Eating performance was significantly associated with stimulation specificity (how the stimulation is delivered and tailored to residents) and was not associated with other environmental stimulation characteristics, after controlling for resident characteristics. An environment with more specific stimulation is associated with better eating performance. For each 1 point increase in stimulation specificity, eating performance is increased by 8.78 points (95% CI=.59, 16.97). Environmental stimulation that is personally tailored to residents' needs and preferences and directly offered to residents improves eating performance among residents with dementia. The findings will direct future development and implementation of person-centered mealtime care programs and dining environment arrangements for residents with dementia in NH settings.

PERSONALITY TRAITS AND RISK OF COGNITIVE IMPAIRMENT AND DEMENTIA: NEW DATA AND META-ANALYSIS

A. Terracciano, *Geriatrics, Florida State University, Tallahassee, Florida*

Personality traits are relevant risk factors for dementia because of their widespread impact on individuals' behaviors, lifestyle, and health. We investigated the association between personality traits and risk of cognitive impairment and dementia in a large prospective cohort and in a meta-analysis of the literature. We also tested whether personality traits predict the risk of conversion from cognitive impairment to dementia. Participants were drawn from a national prospective study (N = 13,882), the largest and most representative sample to date to test the association between personality and dementia. Participants completed a brief five factor model personality measure and their cognitive status was tracked for up to 8 years and classified into normal, cognitive impairment not dementia (CIND), and dementia groups. With Cox regression analyses we found that scoring lower on conscientiousness and higher on neuroticism was associated with increased risk of incident CIND and dementia ($p < 0.001$). Low agreeableness was also associated with dementia risk ($p < 0.001$). The association of personality with risk of dementia remained significant after adjusting for age, sex, education, race, ethnicity, smoking, physical activity, obesity, diabetes, hypertension, cholesterol, HDL, Cystatin C, CRP, and Hemoglobin A1c. Among individuals with CIND at baseline, we found that conscientiousness was a significant predictor of conversion to dementia ($p = 0.030$), but there was only a non-significant trend for neuroticism. The meta-analysis of 7 prospective studies (N = 16,311) found consistent evidence that conscientiousness, neuroticism, agreeableness, and to a lesser extent openness, are associated with risk of dementia.

IT TAKES TWO TO CARE: LESSONS LEARNED WHILE ENGAGING WITH EARLY-STAGE DEMENTIA DYADS

G. Stockwell-Smith^{3,1,2}, W. Moyle^{3,1}, U. Kellert^{3,1}, 1. *Menzies Health Institute Queensland, Griffith University, Camp Hill, Queensland, Australia*, 2. *Queensland Health, Southport, Queensland, Australia*, 3. *Menzies Health Institute Queensland, Nathan, Queensland, Australia*

This presentation reports on the recruitment and implementation stages of a community based early-intervention support model for older people with Mild Cognitive Impairment (MCI)/early-stage dementia and their caregivers (the dementia dyad, n=96). Detailed records on non-participation and withdrawal reasons were maintained throughout the study, and intervention acceptability was evaluated using a mixed method analysis. The study findings highlight some key issues regarding the acceptability of early intervention/forward planning approaches to people dealing with a progressive incurable condition. Public impressions of dementia heavily influenced dyad participation in the study, with nearly half (45%) of those who initially expressed interest abstaining. A significant barrier to participation was inter-dyadic disagreement, commonly related to one member's apprehension over involvement in a study for people with dementia. Stigma continued to have an impact post-recruitment. Two dyads in the intervention group and one in the control group withdrew from the study because they found talking about dementia and associated deficits confronting. Among intervention group dyads that completed the intervention (n=35), the majority of dyads (75%) stated they felt better informed and identified tangible actions taken to plan for the

future. A key challenge in intervening early with people with dementia is how to refute stigma myths and accommodate a positive perspective to adjustment to declining function. The significant impact that stigma has on the decision to engage in research activities associated with dementia may prove insurmountable, until dementia treatment options improve.

IMPLEMENTING OBSERVATIONAL PAIN MANAGEMENT PROTOCOL FOR PAIN MANAGEMENT OF RESIDENTS WITH DEMENTIA

J. Liu^{1,2}, C.K. Lai^{1,2}, 1. *The Centre for Gerontological Nursing, Hong Kong, Hong Kong*, 2. *The School of Nursing, The HK Polytechnic University, Hong Kong, Hong Kong*

Objective: To investigate whether the implementation of the Observational Pain Management Protocol (Protocol) can improve pain management for nursing home residents with dementia.

Design: A two-group, single-blinded, cluster-randomized controlled trial

Participants: 128 recruited residents with advanced dementia and pain-related diagnoses from 17 nursing homes were allocated to either the control or the experimental conditions based on the randomized group allocated to their home.

Interventions: The Protocol, which includes assessing, interpreting, and verifying the participants' observed pain scores, initiating pain-relieving interventions according to the observed pain scores, and reassessment, was implemented in the experimental homes for 12 weeks to guide the pain management of the participants. Meanwhile, the control homes continued to employ their usual pain management strategies.

Measurements: These included the use of pain medications and non-pharmacological pain treatments in terms of types and frequency, as well as the participants' observational pain scores (assessed by Chinese-Pain Assessment IN Advanced Dementia).

Results: A significant increase in the frequency (95% CI: -0.13 to -0.09, $p < 0.01$) and type (95% CI: -0.05 to -0.02, $p < 0.01$) of non-pharmacological interventions used was seen in the experimental homes in comparison with the control homes. However, no statistically significant difference in the use of pain medications was observed. A significant reduction in the observational pain score (95% CI: -0.26 to -0.17, $p < .001$) was obtained only in the experimental home.

Conclusion: This study supports the view that the Protocol is of clinical utility in enhancing the use of non-pharmacological pain-relieving interventions among residents with advanced dementia, leading to a reduction in their observational pain-related behaviors.

QUALITY IS PERSONAL: NEGOTIATING CHOICE AND RISK IN COMMUNITY BASED DEMENTIA CARE

D.P. Goeman^{1,2,3}, M. Dickins¹, F. O'Keefe¹, 1. *RDNS Institute, RDNS, St Kilda, Victoria, Australia*, 2. *The University of Newcastle, Newcastle, New South Wales, Australia*, 3. *Monash University, Melbourne, Victoria, Australia*

With a growing population of people with dementia living at home, practitioners working in the community are faced with the challenge of delivering services that provide control

and reflect the choices of this high risk population. The balance between providing older people with the opportunity to be active partners in their care and ensuring that they are not at risk is a difficult one, however it is imperative that we understand the issues that are important to each older person and act accordingly. Despite this, there are currently no gold standard guidelines to assist community health professionals in providing services that address client choices while mitigating risk. This presentation will detail the findings from a study that explored the issue of safety and risk in dementia care, and the creation of a tool that allows health professionals, clients and carers to negotiate the risk to the client. Interviews were used to explore the perceptions of 'healthy' older people, older people with dementia, carers, health professionals and representatives of a community health service organisation. Using case studies from the data, this presentation will report on the development and acceptability of a tool and whether it allows health professionals, clients and carers to negotiate risk while ensuring that clients are active partners in their care.

POSITIVE EXPERIENCES IN DEMENTIA

C. Smits¹, E. Dusee², L. Groen - van de Ven¹, 1. *Windesheim University of Applied Sciences, Zwolle, Netherlands*, 2. *University of Utrecht, Utrecht, Netherlands*

The negative image of dementia hampers empowerment and positive health in persons with dementia, their caring relatives and care professionals. Two pilot projects aim to highlight any positive aspects of living with dementia.

The first project used interviews with five family carers and two persons with dementia. Analyses of the interview transcripts involved content analyses.

The second project expanded on the findings of the first. It involved a multiple case study including four cases (each involving a person with dementia, family carer and care professional). The family carers were invited to take photographs of positive daily aspects (cultural probe). All 12 case members were interviewed, using the photographs as prompts. Interview transcripts were analysed within and cross cases.

The findings of the first project show that the positive experiences of persons with dementia and carers involved social contacts, positive life attitude, meaningful and pleasant activities and daily events, positive management of dementia, personal growth and satisfaction as carer, and a pleasant environment.

The analyses of the second study show that all three parties report positive experiences reflected in three themes: (1) It's the little things that matter, (2) being surrounded by loved ones, and (3) life is what you make of it.

We conclude that people with dementia, their informal and professional carers have positive experiences relating to the enjoyment of small things in life and meaningful and pleasant social interactions. These insights may be used to design educational interventions for the general public and professionals and contribute to a dementia-friendly society.

DISCLOSING RISK FOR AD: ATTITUDES AND PERCEPTIONS IN THE GENERAL PUBLIC

J. Gooblar, *Washington University in St. Louis, Saint Louis, Missouri*

Recent biomedical research has focused on early detection of Alzheimer's disease (AD) pathology in people who do

not yet have symptoms of the disease. This focus represents a shift in current diagnostic practices from detection of cognitive impairment to include detection of disease risk. The current study examines attitudes regarding preclinical risk detection for AD in N=581 individuals aged 19–65 recruited online using Amazon's Mechanical Turk. Participants were randomized to view an educational intervention (varying depth of education) and viewed a videotaped disclosure of hypothetical risk for AD to themselves (varying level of risk). Participants also reported on several individual difference variables (e.g., prior knowledge, experience with AD) as well as their interest in predictive testing and subjective risk of AD. The results of this study show that greater prior knowledge and health literacy was associated with better recall of novel information about preclinical AD. Experience with AD, although not age, was associated with greater interest in predictive testing and higher subjective risk. Participants who were disclosed a hypothetical diagnosis of preclinical AD and who viewed in-depth information about the disease reported lower subjective risk compared to participants who learned only basic information about the disease. These findings have implications for the development of empirically-supported education interventions and disclosure processes for preclinical AD in research settings and in clinical practice.

RLIFE™: AN ONLINE PLATFORM TO SUPPORT THE SOCIAL INTERACTIONS OF INDIVIDUALS WITH DEMENTIA

A. Yurkewich^{1,2,3}, V. Chenel^{1,4,5}, C. McGrath^{1,6}, M. Koch^{1,7}, J. Blumenthal^{1,8}, A. Moreno^{1,5,9}, 1. *AGE-WELL NCE, Toronto, Ontario, Canada*, 2. *Institute of Biomaterials and Biomedical Engineering, University of Toronto, Toronto, Ontario, Canada*, 3. *Toronto Rehabilitation Institute, Toronto, Ontario, Canada*, 4. *School of Rehabilitation, Faculty of Medicine, Université de Montréal, Montréal, Quebec, Canada*, 5. *Centre for Interdisciplinary Research in Rehabilitation (CRIR), Montréal, Quebec, Canada*, 6. *Ontario Shores Centre for Mental Health Sciences, Whitby, Ontario, Canada*, 7. *University of Waterloo, Waterloo, Ontario, Canada*, 8. *Department of Mechanical and Industrial Engineering, University of Toronto, Toronto, Ontario, Canada*, 9. *McGill University, Montréal, Quebec, Canada*

Social connectedness and participation in meaningful activities can help individuals with dementia maintain a sense of belonging, stay independent at home longer, slow cognitive decline, increase life satisfaction, and promote aging in place. However, there is a lack of consolidated resources to support individuals with dementia with the fulfillment of their social needs after a dementia diagnosis. There are some websites and online information boards to support individuals with dementia; however, the amount of information can be overwhelming because it is not adapted to their needs. The demand to increase and facilitate social connectedness for individuals with dementia encourages the development of solutions tailored to this population. The objective of this work is to develop a prototype of an online platform to Reconnect individuals with mild to moderate dementia to Life, through social Interaction and Fulfilling Experiences (*rLife*™). Using a transdisciplinary approach, a prototype was co-created based on the information provided by

different stakeholders (i.e., individuals with dementia, clinicians, technicians, engineers, family caregivers, and researchers). We first identified areas for social interaction and translated them into the conception of a matching algorithm aimed at connecting individuals with dementia to personalized opportunities tailored to their needs, values and preferences. We then defined a non-profit model of operation that utilizes partnerships with dementia-focused organizations to ensure the sustainability of the platform. Future directions include developing the services offered on the platform, and designing and testing the user interface with individuals in our target population.

EVALUATION OF THE MEETING CENTER SUPPORT PROGRAMME FOR PEOPLE WITH DEMENTIA AND THEIR FAMILY CARERS

S. Evans⁵, D. Brooker⁵, R. Drees¹, F. Meiland¹, J. Rymaszewska², D. Szczesniak², R. Chattat³, E. Farina⁴, 1. VU University Medical Center, Amsterdam, Netherlands, 2. Wroclaw Medical University, Wroclaw, Poland, 3. University of Bologna, Bologna, Italy, 4. Fondazione Don Carlo Gnocchi, Milan, Italy, 5. University of Worcester, Worcester, United Kingdom

The Meeting Centre Support Programme (MCSP) is a community-based approach to supporting people with mild to moderate dementia and their families, developed in the Netherlands where they are now widespread. Evaluation studies showed benefits including reduced behavioural and mood problems, delayed admission to residential care, higher levels of carer competence and lower levels of burden. The JPND funded MeetingDem project aimed to implement and evaluate Meeting Centres in the UK, Italy and Poland.

Our evaluation adopted a before and after control group design with matched patient-carer dyads. In each country we compared a minimum of 25 dyads using the MCSP with 25 receiving 'usual care. Baseline data were collected at month 1 with a follow up at month 7. Validated measures were used to assess quality of life, depression, social support and carer competence. Data were also collected on intervention costs and the use of other services in order to allow a cost-effectiveness analysis. Finally, surveys and focus groups were used to evaluate user satisfaction with the MCSP.

Initial findings suggest significant effects for MCSP compared to usual care, including reduced behavioural problems and improved caregiver coping. This presentation will describe the MCSP approach, present the full evaluation findings and consider the potential for wider implementation.

FINDINGS FROM A REAL-WORLD TRANSLATION STUDY OF THE EVIDENCE-BASED "PARTNERS IN DEMENTIA CARE"

D.M. Bass¹, B. Primetica¹, K. Kearney¹, K. McCarthy¹, J.H. Rentsch¹, M. Kunik², J. Miller³, T. Hornick⁴, 1. Center for Research and Education, Benjamin Rose Institute on Aging, Cleveland, Ohio, 2. Houston VA Health Services Research and Development Center of Excellence, Houston, Texas, 3. Greater East Ohio Alzheimer's Association Chapter, Canton, Ohio, 4. Louis Stokes VA Medical Center, Cleveland, Ohio

Numerous non-pharmacological programs for persons with dementia and family caregivers have been found

efficacious in randomized controlled trials. However, few programs have been tested in translation studies to assess feasible and outcomes in less-controlled, real-world implementations. This translation study of the partnership version of *BRI Care Consultation*, "Partners in Dementia Care (PDC)," tested feasibility and outcomes, when delivered via partnerships between Stokes VA Medical Center, Greater East Ohio Alzheimer's Association Chapter, and Western Reserve Area Agency on Aging. The sample was 200 north-east Ohio veterans with dementia and their family caregivers. Data came from the computerized program record and research interviews with caregivers, and veterans who were able. Interviews were conducted before enrollment and 12-months later. Record data showed the program was feasible for regular employees of partnering organizations, with high-levels of fidelity to the evidence-based protocol. Specifically, veterans and caregivers averaged: 15 telephone/computer contacts over the 12 months; 9 and 3 triggered problems in the initial assessment, respectively; and over 11 behavioral action steps to address triggered problems. Similar to past controlled studies, repeated measures ANOVA of pre-post data showed significant changes in various outcomes, especially when veterans were more impaired. Caregivers had significant improvements in: confidence, isolation, physical health strain, unmet needs, informal support, and support service use. Veterans had significant improvements in: embarrassment about memory problems, unmet needs, informal support, and community service use. Encouraging translation-study findings are being used to engage VA's, health systems, and community agencies in discussions about organizational partnerships to deliver PDC.

DEATHS FROM ALZHEIMER'S DISEASE—UNITED STATES, 1999–2014

C.A. Taylor¹, S. Greenlund², L.C. McGuire¹, H. Lu¹, K. Greenlund¹, J.B. Croft¹, 1. Centers for Disease Control and Prevention (CDC), Atlanta, Georgia, 2. Georgia State University, Atlanta, Georgia

Alzheimer's disease (AD) is the sixth leading cause of deaths in the US. Mortality is important to examine because persons with AD might live several years with adverse health effects which places a heavy burden on patients, their families, caregivers, and community. US AD mortality data has been presented at the state level but not counties. We examined AD deaths at national, state, and county levels. Mortality data for 1999 through 2014 from the Centers for Disease Control and Prevention Wide-ranging Online Data for Epidemiologic Research was examined to generate state- and county-level AD statistics. AD was defined using *International Classification of Diseases, Tenth Revision* underlying cause-of-death codes G30.x. Nationally, the age-adjusted AD death rate per 100,000 population significantly increased by 54.5% from 16.5 (44,536 deaths) in 1999 to 25.4 (93,541 deaths) in 2014. Significant increases occurred across the same period for all age groups, sexes, and race and Hispanic origin categories. From 1999 to 2014, AD death rates significantly increased for 41 states and DC. Only one state had a significant decrease in age-adjusted AD deaths (Maine). County-level age-adjusted death rates were aggregated for 2005–2014 to improve stability and ranged from 4.3 to 123.7 per 100,000. Counties with the highest

age-adjusted rates were primarily in the South with additional areas in the Midwest and Pacific Northwest. Increases in the number of AD deaths might be because of improved diagnostic capabilities and improved public knowledge encouraging patients and families to seek a diagnosis or care when symptoms appear.

EFFICACY OF SCHEDULED ACTIVITY ON CIRCADIAN RHYTHMS IN PERSONS WITH DEMENTIA: HEALTHY PATTERNS TRIAL

N.A. Hodgson, *Biobehavioral Health Science, University of Pennsylvania School of Nursing, Cherry Hill, New Jersey*

Over 60% of persons with dementia experience disruptions in sleep wake patterns associated with circadian rhythm disorders. This pilot trial tested whether the Healthy Patterns behavioral intervention demonstrated efficacy in reducing symptoms of circadian rhythm disorders in home dementia patients with sleep disorders. A prospective, two group controlled trial randomized 33 persons with dementia and their family caregiver (dyads) to treatment or attention control conditions. Dyads were interviewed at baseline and 10 days (trial endpoint). Sleep parameters were collected via caregiver report and actigraphic measures. The 4 session intervention involved a cognitively-engaging activity in the morning, a physically-engaging activity in the afternoon and a sensory based activity in the evening. At 10 days, compared to controls, intervention participants were more likely to experience improvements in wakefulness after sleep onset (62% improved versus 20% improved; $p=.042$) and improvements in number of night awakenings (69% improved versus 20% improved; $p=.021$). Total sleep time improved in the intervention but not the control group. Results suggest clinically-relevant benefits in sleep parameters associated with circadian rhythm disorders in home-dwelling persons with dementia. Routinizing the day based on circadian needs into a predictable but engaging schedule may reduce disrupted sleep cycles and may have future potential for scaling the intervention for adult day care or other dementia care settings.

A SOCIAL ROBOT CALLED PARO AND ITS EFFECT ON PEOPLE LIVING WITH DEMENTIA

W. Moyle¹, E.R. Beattie², B. Draper⁴, D. Shum¹, L. Thalib³, C. Jones¹, 1. *Menzies Health Institute QLD, Griffith University, Brisbane, Queensland, Australia*, 2. *Queensland University of Technology, Brisbane, Queensland, Australia*, 3. *Qatar University, Qatar City, Qatar*, 4. *UNSW, Sydney, New South Wales, Australia*

Apathy, agitation, loneliness and depression are common behavioral and psychological symptoms of dementia (BPSD). These symptoms can make life distressing for the person with dementia and can also make it challenging for care staff to meet the needs of the person. In recent years, social robots have been used as a means to reduce BPSD. However, to date, studies have mostly been descriptive or had small samples. This paper presents a cluster-randomized controlled trial with three treatment groups: a robotic animal (PARO), a non-robotic animal (Plush-Toy), and usual care (control). Older people ($n=415$) with a diagnosis of dementia and living in long-term care participated in the trial. The intervention consisted of three individual 15-min non-facilitated

sessions with PARO or Plush-Toy per week for a period of 10 weeks. This allowed both short-term (5-weeks) and long-term follow-up (10-weeks), and sustainability following withdrawal of intervention (15-weeks). Interim analysis found the majority of participants were female ($n=314$), with a diagnosis of Alzheimer's disease ($n=148$), a mean age of 84.9 years and a mean CMAI-SF score of 30.13/70. PARO group experienced significantly higher pleasure than control ($p<.0005$) and Plush Toy ($p<.005$) at end of treatment. Both verbal ($p<.0005$) and visual ($p<.0005$) engagement were also significantly higher in the PARO condition. The majority of participants enjoyed the opportunity to spend time with PARO. This presentation outlines what we have learnt to date about the impact of PARO through the secondary outcomes of interest – sleep duration and activity (step count -Sensewear).

INTEGRATIVE COGNITIVE BEHAVIOR THERAPY FOR PEOPLE WITH MILD ALZHEIMER'S DISEASE: RESULTS OF AN RCT

S. Forstmeier¹, A. Maercker², E. Savaskan³, T. Roth³, 1. *Institute of Psychology, University of Siegen, Siegen, Germany*, 2. *University of Zurich, Zurich, Switzerland*, 3. *Psychiatric University Hospital Zurich, Zurich, Switzerland*

About 90% of all mild Alzheimer dementia (AD) cases experience neuropsychiatric symptoms. Although some research has supported the effectiveness of specific psychotherapeutic approaches for mild AD, there are only few attempts to evaluate a multi-component treatment programme. This randomized controlled trial evaluates the effect of an integrative psychotherapy approach on the health of patients with mild AD and their caregivers. It consists of 25 weekly sessions, including eight modules: goal setting; psychoeducation; engagement in pleasant activities; cognitive restructuring; live review; behavior management; interventions for the caregiver; and couples counselling. 50 participants and their caregivers have been randomized to either the CBT-based intervention group (CBT) or to the control group, which received treatment-as-usual (TAU). Before and after the treatment phase, participants have been assessed. Follow-ups took place at 6, and 12 months post-treatment. The primary outcome was depression in the patient with AD. The secondary outcome measures were apathy, other neuropsychiatric symptoms, functional abilities, quality of life, and quality of the relationship to the caregiver. CBT reduced depression significantly more than TAU (interaction: $F = 5.3$, $p < .05$), with a moderate-to-large effect size ($d = 0.76$). There were also a significant advantage for CBT with regard to apathy ($F = 4.7$, $p < .05$; $d = 0.71$) and quality of the relationship to the caregiver ($F = 4.3$, $p < .05$; $d = 0.77$). There was no advantage with regard to other neuropsychiatric symptoms, functional abilities, and quality of life. The results are very encouraging and stimulate an adequately powered multi-center-study.

PREVENTING LOSS OF INDEPENDENCE THROUGH EXERCISE IN PERSONS WITH DEMENTIA IN THE VA (PLIÉ-VA)

D.E. Barnes^{2,1}, J. Lee^{2,1}, M.A. Chesney^{2,1}, K. Yaffe^{2,1}, G. Abrams^{2,1}, W. Mehling^{2,1}, 1. *Psychiatry and Epidemiology & Biostatistics, University of California, San*

Francisco, San Francisco, California, 2. San Francisco VA Medical Center, San Francisco, California

We have recently developed a novel, multi-modal, group movement program for people with dementia called Preventing Loss of Independence through Exercise (PLIÉ) that is grounded in neuroscience and focuses on abilities that are relatively well-maintained (procedural memory, mindful body awareness, social connection). This randomized, controlled trial (N=120) compares PLIÉ to a waitlist control group for its effects on physical and cognitive function, quality of life and caregiver burden. Study sites are adult day centers that contract with the Veterans Health Administration. Inclusion criteria are mild-to-moderate dementia, English fluency and ability to participate in intervention activities. Study participants are randomly assigned to Group 1 or Group 2 in blocks (20/site, 6 sites). Group 1 participates in PLIÉ for 1 hour, 2–3 days/week for 4 months while Group 2 is placed on a waitlist. Then Group 2 participates in PLIÉ for 1 hour, 2–3 days/week for 4 months. Assessments are performed at baseline, 4 and 8 months. The co-primary outcomes are change in physical performance (Short Physical Performance Battery), cognitive function (Alzheimer's Disease Assessment Scale–cognitive subscale), and quality of life (Quality of Life in Alzheimer's Disease) for affected individuals and caregiver burden (Caregiver Burden Inventory) for caregivers. We have completed site 1 with 19 enrolled and 13 completed (7 Group 1, 6 Group 2). Withdrawals were due to unrelated medical conditions and disease progression. Qualitative data to date suggest noticeable improvements in ability to sit and stand, articulate thoughts, and share experiences with others. Quantitative data collection is ongoing.

EFFECTS OF DANCE MOVEMENT INTERVENTION AND EXERCISE ON ELDERLY WITH EARLY DEMENTIA

R. Ho^{1,4,6}, T. Fong¹, T. Hon¹, B. Li⁴, W. Chan², J. Kwan³, P. Chiu³, L. Lam⁵, 1. *Centre on Behavioral Health, The University of Hong Kong, Hong Kong, Hong Kong*, 2. *Department of Psychiatry, The University of Hong Kong, Hong Kong, Hong Kong*, 3. *Department of Medicine, The University of Hong Kong, Hong Kong, Hong Kong*, 4. *Department of Social Work and Social Administration, The University of Hong Kong, Hong Kong, Hong Kong*, 5. *Department of Psychiatry, The Chinese University of Hong Kong, Hong Kong, Hong Kong*, 6. *Sau Po Center on Aging, The University of Hong Kong, Hong Kong, Hong Kong*

Dementia is marked by progressive deteriorations in memory, spatial navigation and language functioning and disturbances in daily functioning. Non-pharmacological interventions target cognitive impairments, prognosis and psychosocial effects of dementia. Dance-movement intervention (DMT) and physical exercise have shown benefits in cognitive functioning and emotional and social support in dementia. The present study is an ongoing randomized controlled trial (RCT) that investigates the effects of DMT and exercise on physical and psychological well-being of Chinese elderly. The target sample size was 201 elderly with early dementia. Participants were randomized into three groups: (i) DMT, (ii) exercise, and (iii) waitlist-control group. The two intervention groups received an 1-hour intervention, twice a week, for 12 weeks. The participants were assessed before

randomization, post-intervention (3-month), at 6-month and 12-month. Primary outcomes included neuropsychiatric symptoms, psychosocial well-being, cognitive functioning, and daily functioning. So far, 114 participants have been recruited and randomized into the three arms. The majority of them were female (76.9%) with mean age of 80.6 years old (SD = 7.1). The study is on-going and preliminary analysis on data in 30 participants who have finished post-intervention assessment showed a positive trend in improvement in physical function and positive emotions. Depression was not improved in DMT group but the other groups deteriorated. Changes were not statistically significant due to the current small sample but trends aligned with clinical observation. Presentation will focus on the intervention model and more data will be shown. This study is supported by the General Research Fund, Research Grants Council (GRF/HKU17402714H).

GAMIFICATION OF DEMENTIA EDUCATION IN ACUTE CARE

D. Bohl², L. Hung¹, J. Tabamo², S. Sandhu³, S. Vajihollahi³, 1. *Nursing, University of British Columbia, Vancouver, British Columbia, Canada*, 2. *Vancouver General Hospital, Vancouver, British Columbia, Canada*, 3. *Langara College, Vancouver, British Columbia, Canada*

Background: About 40% of older people in general hospitals have dementia, and evidence showed that hospitalization has detrimental effects on people with dementia. Hospital leaders are challenged to engage staff in change of attitudes, knowledge and culture to meet the changing needs of patient population. This poster presents a project of using gamification to achieve the goal of motivating staff engagement and passion to improve care of patients with dementia.

Methods: We used qualitative methods to investigate the benefits and challenges of using gamification in staff education for dementia care. Gamification refers to applying game thinking to non-game context to make learning more exciting, fun and effective. Our intervention focused on game dynamics such as receiving rewards, recognition, social experience and appreciation. Staff received surprise prizes when they completed various games in two fun fairs. These included virtual badges, recognition from clinical leaders and points redeemable for prizes. The fun fairs were videotaped, and the video data were co-analyzed by staff and the researchers in focus groups. Thematic analysis was conducted.

Results: The results of the education intervention included three themes: (a) games reinforced previous learned knowledge in dementia care; (b) healthy competitions among staff created fun learning experiences; (c) collective learning inspired commitment to actions.

Conclusion: Our findings suggest that gamification could tap into both extrinsic and intrinsic motivations and has potential to increase sustained staff behavioural change.

OF SOUND MIND: USING PUBLIC ACCESS TV FOR COMMUNITY OUTREACH AND TO RAISE DEMENTIA AWARENESS

A.C. Bilbrey^{1,2}, F.T. Bockmann³, N. Askari^{2,1}, D. Gallagher-Thompson^{1,2}, 1. *Psychiatry & Behavioral Sciences, Stanford University School of Medicine, Sunnyvale, California*, 2.

Stanford Alzheimer's Disease Research Center, Stanford, California, 3. MidPen Media Center, Palo Alto, California

Every day, Americans spend on average 2.8 hours watching television (TV). After retirement, the time spent watching TV increases. Public-access television (PATV) is a non-commercial media where the general public can create content programming, which is shown through cable TV specialty channels. While there is limited marketing research on the audiences of PATV, Chen and colleagues (2013) found PATV remains relevant, especially for underprivileged populations who have been shown to rely on TV to gather information on health concerns. In a 2009 survey of Spanish speakers in Baltimore City, 82.4% obtain their health information through TV. While abundant information concerning dementia exists for those with access to the internet, there is limited approachable information available through the TV. Of Sound Mind was designed to address multiple needs, including the need for accurate, research-based information about dementia and healthy cognitive aging, which can be scarce on most TV programming. The development of a public access talk show can be split into production and content. Production will contain the steps needed to produce a talk show, including securing a partnership with a local public access studio. Content describes the material being covered, guest recruitment, and establishing credibility. The direct and indirect benefits for the organization producing the talk show are explored. With the inability to gain direct viewership numbers, methods of determining success are reviewed. Finally, the future plans for Of Sound Mind are discussed.

SESSION 825 (POSTER)

DEMENTIA II

PARTICIPATION OF PEOPLE WITH DEMENTIA IN DEVELOPING AN INTERACTIVE WEB TOOL

M. Span¹, M. Hettinga¹, L. Groen - van de Ven¹, J. Jukema¹, R. Janssen¹, M. Vernooij-Dassen², J. Eefsting³, C. Smits¹, 1. *Windesheim University of Applied Sciences, Zwolle, Netherlands*, 2. *Radboud University, Nijmegen, Netherlands*, 3. *Zonnehuis groep IJssel-Vecht, Zwolle, Netherlands*

Involvement of people with dementia is not self-evident. The aim of this study was to gain insight into the ways in which people with dementia participated in developing the DecideGuide, an interactive web tool facilitating shared decision-making in their care networks.

An explanatory case study design was used when developing the DecideGuide. A secondary analysis focused on the data gathered from the participating people with dementia during the development stages: semi-structured interviews (n=23), four focus groups with a total of 18 participants, three usability tests, and a pilot study with 4 participants. Framework analysis was applied to the data.

People with dementia participated especially as informants and advisors in most phases of the development. Four themes proved to be important regarding the impact of the participation by people with dementia: influence on content and design of the DecideGuide, motivation to participate,

time investment, and the balance between challenge and concern.

People with dementia can give essential feedback and, therefore, their contribution is valuable. Other roles than informant and advisor need to be explored. Significant participation of people with dementia takes time that should be taken into account. It is important for people with dementia to be able to reciprocate the efforts others make and to feel of significance to others.

GENDER, PSYCHOTROPIC DRUG USE AND MORTALITY IN OLDER PEOPLE WITH DEMENTIA

G. Boström, J. Brännström, E. Rosendahl, P. Nordström, H. Littrand, H. Lövheim, Y. Gustafson, *Umeå University, Umeå, Sweden*

Psychotropic drugs are commonly prescribed to older people with dementia and have been associated with increased mortality. Behavioral and psychological symptoms of dementia, prescription patterns of psychotropic drugs, and adverse effects from these drugs seem to differ by gender. However, gender differences in mortality risk have not previously been analyzed. Associations between mortality risk and baseline use of antipsychotics, antidepressants, and benzodiazepines were analyzed among people with dementia ≥ 65 years. Participants (n=1037) from four cohort studies were included and followed for 2 years. Cox proportional-hazard regression models were used to analyze associations and gender differences adjusted for confounders. None of the psychotropic drug classes were associated with 2-year mortality in fully adjusted models. Significant gender differences were found in association between mortality risk and antidepressant use ($P=0.047$). When analyzed separately, a reduced risk was found in men, but not in women (hazard ratio [HR] 0.61, 95% confidence interval [CI] 0.40–0.92 and HR 1.09, 95% CI 0.87–1.38, respectively). Significant gender differences were also found in associations between mortality risk and benzodiazepine use ($P=0.029$), with a relatively higher mortality risk in men compared with women. However, no risk was found in separate analyses of men and women. No gender differences were found in mortality risk associated with antipsychotic use.

In conclusion, baseline use of antipsychotics, antidepressants, or benzodiazepines may not be independently associated with increased mortality risk in older people with dementia. Gender may moderate the mortality risk associated with baseline use of antidepressants and benzodiazepines.

LATENT CLASSES OF DEMENTIA COURSE SHOW AN OPTIMISTIC PROGNOSIS FOR THE MAJORITY OF PATIENTS

M. Haaksma¹, J. Leoutsakos², M. Olde Rikkert¹, R.J. Melis¹, 1. *Radboudumc Alzheimer Center, Nijmegen, Netherlands*, 2. *Johns Hopkins University School of Medicine, Baltimore, Maryland*

Dementia is a neurodegenerative syndrome affecting multiple aspects of life. The large heterogeneity in disease course causes high uncertainty about patients' prognosis. Patients may live in fear of rapid cognitive decline, while in fact their disease progresses slowly and vice versa. This study aims to

provide patients with an individualized prognosis by investigating trajectories of cognition and functioning simultaneously over time.

In the Clinical Course of Cognition and Comorbidity study, 331 dementia patients were followed yearly from diagnosis onwards for a maximum of three years. Cognition was measured using the Mini Mental State Examination. Functioning was recorded according to the Disability Assessment for Dementia. We built a parallel-process growth mixture model to jointly model cognitive and functional progression and used the Bayesian Information Criterion to assess model fit.

Three distinct classes of cognitive and functional trajectories were observed: 32% of the patients showed moderate progression speed, 12% declined rapid and 56% exhibited slowly declining trajectories for both cognition and functioning over time. Cognitive and functional rates of decline were highly correlated ($r=0.86$, $p=0.000$).

This study shows that heterogeneity in the course of dementia could be modeled as latent classes of trajectories and that most individuals were members of a class with stable and slow progression. This presents a more optimistic picture of dementia progression as compared to presenting the mean trajectory across the entire population. Relating class membership to baseline variables can help explain the heterogeneity in disease progression.

PEOPLE WITH DEMENTIA AND SOCIAL ROBOTS: BEST FRIENDS FOREVER?

M. Span, C. Smits, M. Hettinga, *Windesheim University of Applied Sciences, Zwolle, Netherlands*

People with dementia want to stay at home for as long as possible. Social robots that offer interaction and companionship may help them to fulfill that wish. This study aims to identify how social robots may help people with dementia to stay at home longer and what these social robots should offer. We aim to do this in co-creation with them.

Sixteen semi structured individual interviews and four separate focus groups with eight people with dementia and eight informal caregivers were conducted. These focused on what is important to people with dementia, their needs in daily life and which help they would like from social robots. The topic list was illustrated by a video clip and photos of two types of social robots that were presented to people with dementia.

Results show that most people with dementia and informal caregivers are positive about the usefulness of social robots in their home environment. Both think that social robots can support people with dementia by providing guidance in daily life. People with dementia see opportunities in using social robots as support for their memory and in managing their daily life. They expect to feel more independent from their informal caregivers. Supportive functions mentioned are: helping people with dementia to structure daily life by giving reminders for appointments and medications, answering repetitive questions, falls detection, answering questions on the whereabouts of a spouse, and making a conversation. Both people with dementia and informal caregivers were interested to participate in further research on social robots.

ACUTE STRESS REACTIVITY LINKS TO QUALITY OF LIFE (QoL) IN AMNESTIC MILD COGNITIVE IMPAIRMENT (MCI)

P. Ren, A. Jacobs, F.V. Lin, *University of Rochester Medical Center, Rochester, New York*

Diminished QoL is a major concern among older adults in Alzheimer's disease associated neurodegenerative processes, such as amnesic MCI. To better assess and improve their well-being, it is important to understand the neural basis of QoL and factors leading to better QoL. In this case-controlled study (MCI, $n = 18$; healthy control (HC), $n = 21$), we examined the relationship between QoL and cognition-demanding acute stress tasks, and the neural mechanism linking these two. Acute stress tasks were the total 20-minute Stroop Word Color task and Dual 1-back task. The discrepancy of amplitude of low-frequency fluctuations (ALFF) of the resting-state functional magnetic resonance imaging administered before and after the tasks was extracted as the neural stress reactivity. The discrepancy of psychological valence and arousal rating was considered the psychological stress reactivity. QoL and ALFF reactivity in three regions (anterior cingulate cortex, medial prefrontal cortex (MPFC), and superior frontal gyrus (SFG)) significantly differed between groups. The associations of MPFC and SFG's reactivity with QoL were not group-specific while the associations of valence and arousal reactivity with QoL were group-specific. Greater arousal reactivity (adaptive coping) was associated with better QoL in HC; lower valence reactivity (maladaptive coping) was associated with worse QoL in MCI. SFG reactivity significantly mediated the association between valence reactivity and QoL for the entire sample. The MCI group may be more sensitive to maladaptive coping. Enhancing SFG, especially among those with MCI, may be a way to intervene in the negative impact of maladaptive stress regulation on QoL.

ENHANCED CARDIOVASCULAR FITNESS ATTENUATES COGNITIVE DECLINE IN ALZHEIMER'S DISEASE

D. Salisbury, M.A. Mathiason, F. Yu, *School of Nursing, University of Minnesota, Minneapolis, Minnesota*

Dementia is an endemic affecting 44.4 million people worldwide in 2013 and will afflict 135.5 million by 2050. Alzheimer's disease (AD) accounts for 60–80% of all dementias and cannot yet be prevented, slowed, or cured. Cardiovascular exercise training may attenuate AD's course through its action on improving cardiovascular fitness which in turn mediates positive changes in brain structure and function. The purpose of this secondary data analysis was to examine the relationship between cardiovascular fitness and cognition in AD. Twenty-seven community-dwelling older adults with mild-to-moderate AD completed a 6-month, moderate intensity cycling intervention, 3 times a week in two pilot studies. Cardiovascular fitness and cognition were assessed using the intermittent shuttle walk test (ISWT) and AD Assessment Scale-Cognition (ADAS-cog), respectively, at baseline and 6 months. Data were analyzed using Pearson's correlation and linear regression. Adjusted for age (79.3 ± 6.9 years), the 6-month change in ISWT has an inverse relationship with the 6-month change in ADAS-cog

($r=-.40$; $p=0.04$), indicating that enhanced cardiovascular fitness was associated with improved cognition over 6 months. The age-adjusted linear regression was also significant ($F(2,24)=3.70$, $p=0.04$, $R^2=0.24$). Predicted change in ADAS-cog = $33.8 - 0.39$ (Age) - 0.88 (change in ISWT). For each additional meter walked in the ISWT at 6 months, a participant's ADAS-cog score improved 0.88 point. In conclusion, enhanced cardiovascular fitness may be essential for cardiovascular exercise to attenuate cognitive decline in individuals with AD. Future studies are needed to replicate these findings and further elucidate the physiological mechanism of exercise-induced neural protection.

PSYCHOMETRIC EVALUATION OF THE EATING BEHAVIOR MANAGEMENT NEEDS SCALE IN NH RESIDENTS WITH DEMENTIA

K. Lee, J. Song, *Korea University, Seoul, Korea (the Republic of)*

This study reports the initial psychometric properties of a recently developed instrument, the Eating Behavior Management Needs Scale (EBMNS), among nursing home residents with dementia. Using a convenient sample of 171 nursing home-dwelling Korean elders with dementia (mean age = 84.35; mean MMSE = 8.44; mean duration of dementia = 60 months), preliminary version of the EBMNS consisting of 31 items with 3 point Likert-type scale was evaluated for content validity, criterion related validity, internal consistency, test-retest reliability, and inter-rater reliability. Through repeated principal component factor analysis with oblimin rotation, the six-factor solution with 24 items for the EBMNS was derived and it explained a total of 63.30% of the variance. Factors were named 'eating behavior associated with cognitive function problem (7 items)', 'eating behavior associated with physical operation and functional problem (5 items)', 'eating behavior associated with BPSD (4 items)', 'excessive eating behavior (2 items)', 'passive eating behavior (3 items)', 'subject influencing factor (3 items)'. The criterion related validity was established by its significant ($<.001$) correlation with Korean Mini Mental State Examination ($r=-.564$), Korean Activities of Daily Living ($r=.602$), Eating Behavior Scale ($r=-.626$), and Edinburgh Feeding Evaluation in Dementia Questionnaire ($r=.734$). Cronbach's alpha for total items was .888 and test-retest reliability and inter-rater reliability was $r=.997$, and $r=.989$, respectively. Although these initial estimates of the psychometric properties of the EBMNS are promising, caution in using the measure is warranted. Therefore, we advise confirmation of these results in an independent random sample and extension of analyses in community samples. Correspondence to jasong@korea.ac.kr.

THE RISK OF ACCIDENTAL INJURY ADMISSIONS AMONG DEMENTIA PATIENTS IN TAIWAN

Y.A. Huang¹, C. Li², C. Huang³, 1. *Kaohsiung Medical University, Kaohsiung City, Taiwan*, 2. *Rush University, Chicago, Illinois*, 3. *E-Da Hospital, Kaohsiung, Taiwan*

Dementia that interferes with people's independent functioning is a significant chronic condition in older adults. In Taiwan, as the number of elderly people is increasing rapidly, dementia has become a major public health issue. Little is known about dementia-related accidental injuries among Taiwanese patients. This study aimed to investigate

differences in accidental injury admissions between people with dementia and those without dementia. The age-standardization admission rate ratio (ASARR) was used for comparison. Data was obtained from Taiwan's National Health Insurance Population-Based Database. Study results showed that dementia patients had lower likelihood of being admitted due to traffic accident (ASARR=0.74), but had higher likelihood of being admitted for accidental falls (ASARR=2.26), burns (ASARR=1.94), homicide (ASARR=1.65), poisoning (ASARR=3.01), and submersion and suffocation (ASARR=3.42). Dementia is a potential risk factor for accidental injuries. The development of prevention and intervention for dementia-related accidental injuries is necessary in the long-term care settings and local community organizations.

ANTICHOLINERGIC BURDEN AND DEMENTIA IN OLDER ADULTS WITH SUBJECTIVE COGNITIVE DECLINE

I. Naharci, U. Cintosun, A. Ozturk, H. Oztin, T. Turker, E. Bozoglu, H. Doruk, *Gulbane Military Medical Academy, Ankara, Turkey*

Data on the effect of anticholinergic burden (ACB) on cognitive status in older adults with subjective cognitive decline (SCD) are limited. Our aim was to study whether ACB increases the future risk of dementia in older adults with SCD.

The analysis was carried out on 1496 older adults. Out of those, 109 older patients had been diagnosed with SCD at baseline and followed up over 36 months were studied. They were divided into two groups according to cognitive status at last visit: group I included the subjects with SCD who did not progress to dementia and group II included those who progressed to dementia. ACB was calculated for each subject by adding the score of each drug and classified as no or low ACB ($ACB \leq 2$) and high ACB ($ACB \geq 3$).

Sixteen (13.8%) of 109 participants with baseline SCD developed dementia. High ACB was present in 17 subjects (18.1%) in group I and 8 subjects (53.3%) in group II ($p=0.003$). The 75-84 and 85+ age groups (HR=3.595; CI:1.117-11.574; $p=0.032$ and HR=12.203; CI:2.889-51.537; $p=0.001$, respectively), hypertension (HR=7.835; CI:1.020-60.189; $p=0.048$), and high ACB (HR=4.312; CI:1.563-11.899; $p=0.005$) were found to be possible risk factors for dementia among subjects with SCD in the univariate model. In the final multivariate cox regression model, subjects with high ACB had a 3.3-fold the risk of the development of dementia.

High ACB is associated with an increased risk of dementia in older adults with SCD.

ANTIPSYCHOTIC MEDICATION IN RELATION TO NATIONAL DIRECTIVES IN PEOPLE WITH DEMENTIA IN SWEDEN

S. Karlsson^{1,2}, I.R. Hallberg¹, P. Midlöv¹, C. Fagerström^{3,4}, 1. *Lund University, Lund, Sweden*, 2. *Halmstad University, Halmstad, Sweden*, 3. *Blekinge Institute of Technology, Karlskrona, Sweden*, 4. *Blekinge Centre of Competence, Karlskrona, Sweden*

The aim of this study was to explore trends in treatment with antipsychotic medication in Swedish dementia care as

reported in the most recent empirical studies on the topic, and to relate these trends to directives and recommendations from national authorities. The study included two scoping review studies and two empirical studies. The scoping studies reviewed published data in electronic databases as well as Swedish recommendations and directives in the field. During the past decade, recommendations have been developed regarding antipsychotic medication in Sweden. These recommendations were generic at first, but have become increasingly specific and restrictive with time. The scoping review showed that treatment with antipsychotic drugs varied between 6% and 38%, and was higher in younger older persons and those with moderate cognitive impairment and living in nursing homes for people with dementia. A trend towards a decrease in antipsychotic use has been seen over the last 15 years. The empirical studies showed that the medication with antipsychotics decreased from 23.4% in 2001 to 11.5% in 2007, for older people in general as well as for older people with dementia. Among older people with dementia, 10% were utilizing antipsychotic medication, with no difference between those cared for at home and those in nursing homes. Directives from Swedish national authorities seem to have had an impact on antipsychotic medication for people with dementia. Treatment with antipsychotic medication has decreased, while other psychotropic medication has increased. National directives may possibly be even more effective, if applied in combination with systematic follow-ups.

THE RUBBER MEETS THE ROAD: INTERACTIVE THEATER TO PROMOTE DRIVING SAFETY FOR PERSONS WITH DEMENTIA

D.K. Pastor⁵, A.L. Jones⁴, T. Arms⁵, M. Pate³, D. Tilley⁴, B. Saypol², 2. *Theater Delta, Chapel Hill, North Carolina*, 3. *Alzheimers North Carolina, Wilmington, North Carolina*, 4. *School of Social Work, University of North Carolina Wilmington, Wilmington, North Carolina*, 4. *North Carolina Nurses Association, Raleigh, North Carolina*, 5. *University of North Carolina Wilmington, Wilmington, North Carolina*

Driving safety for older adults with dementia presents a continuing complex challenge in the community for health care providers. More than 5 million people in the United States suffer from dementia, and their numbers are expected to grow. Evidence-based resources to identify and manage driving risk in older adults with dementia do exist, but the challenges of limited time in primary care and outpatient settings can make application difficult. This innovative project, funded by a Hartford Foundation Change AGENTS Action grant award, focused on interprofessional work to address the educational need for primary care professionals and family caregivers to manage driving safety for their loved ones with dementia. After a live interactive theater performance in April 2016 at a medium sized public university's College of Health and Human Services, post-performance surveys assessed audience members' positive satisfaction with interactive theater as a communication strategy, as well as self-reported knowledge, attitudes and beliefs about driving and dementia. Using a videotape of the theater performance, the research team produced an educational DVD to promote continued driving safety and driving decision making for community-dwelling persons with dementia and their family

caregivers. The DVD will be widely distributed to state-level community partners (Alzheimers North Carolina and Nurse Practitioner Council of the North Carolina Nurses Association), in order to guide and educate advanced practice nurses and social workers caring for this population. This practice change project also forged new sustainable interprofessional community partnerships among educators/researchers and health providers caring for this vulnerable community population.

NATIONAL TRENDS IN ANTIHYPERTENSIVE PRESCRIBING IN OUTPATIENTS WITH DEMENTIA IN THE UNITED STATES

E.C. Tan^{1,2}, J. Bell^{2,3}, C.Y. Lu⁴, S. Toh⁴, 1. *Aging Research Centre, Karolinska Institutet, Stockholm, Sweden*, 2. *Monash University, Parkville, Victoria, Australia*, 3. *Sansom Institute, University of South Australia, Adelaide, South Australia, Australia*, 4. *Harvard Medical School and Harvard Pilgrim Health Care Institute, Boston, Massachusetts*

This study aims to investigate national trends in outpatient antihypertensive prescribing in people with dementia in the United States between 2006 and 2012, and to determine clinical and demographic factors associated with different prescribing patterns. Outpatient visits by people aged ≥ 65 years with documented dementia were analyzed in the National Ambulatory Medical Care Survey (NAMCS) and the outpatient department component of the National Hospital Ambulatory Medical Care Survey (NHAMCS). Complex samples multivariate logistic regression was conducted to estimate temporal trends and adjusted odds ratios (AORs) with 95% confidence intervals (CIs) for factors associated with prescribing of antihypertensives, multiple antihypertensives and different antihypertensive classes. There was a statistically significant increase in the proportion of physician visits by older people with dementia with a documented diagnosis of hypertension from 49.3% (95%CI: 41.3%–57.4%) in 2006 to 55.7% (95%CI: 50.2%–61.2%) in 2012. There were non-significant increases in overall antihypertensive use and the use of multiple antihypertensive classes. Male sex was associated with a higher prescribing of any antihypertensive (AOR 1.37, 95%CI 1.02–1.84) and multiple antihypertensive medications (AOR 1.52, 95%CI 1.14–2.04). Black race (AOR 2.04, 95%CI 1.12–3.71) and Midwest residence (AOR 2.03, 95%CI 1.46–2.82) were associated with a higher prescribing of multiple antihypertensive medications. In conclusion, there was an increase in documented hypertension in physician visits by older people with dementia from 2006 to 2012, but minimal increases in overall antihypertensive use. Various demographic and clinical factors were associated with the prescribing of antihypertensives in people with dementia.

POTENTIAL THERAPEUTIC BENEFITS OF DECREASING A β PRODUCTION THROUGH BACE INHIBITION

L.H. Gold, M.F. Egan, M.S. Forman, T. Dam, Y. Zhang, J.T. Kost, D. Michelson, *Merck & Co., Inc., Kenilworth, New Jersey*

Alzheimer's disease (AD) is a devastating global epidemic with economic and social burden. The amyloid hypothesis

proposes that toxic aggregation of A β peptides, produced via cleavage of Amyloid Precursor Protein by β -secretase (BACE1) followed by gamma-secretase, leads to neurodegeneration. Inhibition of BACE1 reduces A β production, and may slow progression of AD. Verubecestat, a potent BACE1 inhibitor, has been shown to lower CSF A β by as much as 80% in healthy controls and patients with AD after one week of once daily dosing. Based on these results, two ongoing phase 3 studies are evaluating the ability of verubecestat to safely delay disease progression in mild to moderate (EPOCH NCT01739348) and prodromal (APECS NCT01953601) AD populations. However, as amyloid deposition takes place years before AD diagnosis, administering an anti-amyloid therapy even earlier in the disease process, before clinical onset, may be necessary to exploit the full potential of this mechanism. Thus secondary prevention trials in individuals with biomarker evidence of A β pathology or genetic risk but no clinical symptoms, and primary prevention trials, intervening before the appearance of any pathology, have been proposed as important next steps in testing the amyloid hypothesis. A review of learnings from the ongoing verubecestat and other AD studies in the context of addressing the methodological issues and challenges of earlier intervention studies will be presented.

DEMENTIA DUE TO ALZHEIMER'S DISEASE AND BRAIN MORPHOMETRIC ALTERATIONS

J.C. Moriguti, S.R. Silva Filho, A.C. Santos, E. Ferrioli, N.K. Lima, *Internal Medicine, Ribeirão Preto Medical School of University of São Paulo, Ribeirão Preto, São Paulo, Brazil*

Introduction: Dementia due Alzheimer's disease (DAD) is a primary and progressive neurodegenerative disorder. There are atrophy in hippocampus and other basal areas. This work evaluated the brain morphometry of DAD patients in all disease stages, aiming at identifying the structural neurodegeneration profile in every phase. **Methods:** DAD patients above 60 years old (n=44) and age paired controls (n=16) were recruited. The brain images acquired in Achieva 3T magnetic resonance tomograph. Volumetric quantitative data and cortical thickness measurements were obtained by automatic segmentation using Freesurfer®. The volume of each region was normalized considering whole brain volume. **Results:** Brain regions targeted by the disease during the initial stages were found to be altered until in the later stages of the dementia. No correlation was observed between brain cortical volume or thickness, age and years of education. We found an association between cortical volume or thickness and cognitive indexes Mini Mental State Examination ($R^2 < 0.47$), Clinical Dementia Rating and disease duration in years ($R^2 < 0.52$). **Conclusion:** The most affected brain regions suffer atrophy in a linear fashion until the later stages of the disease, what seems contrary to the hypothesized models, which consider a faster degeneration in earlier stages. These regions are closely related to neuronal loss and gliosis. The cortical thickness measurements were less sensible in differentiating the groups than cortical volume, what may be due to the fact that cortical thickness is more dependent of segmentation quality. These findings favor a better understanding of the physiopathological process in the advanced diseases stages.

THERAPEUTIC EDUCATION IN ALZHEIMER'S DISEASE AND QUALITY OF LIFE: THERAD RANDOMIZED CONTROLLED TRIAL

H. Villars¹, V. Gardette^{3,2}, C. Hein¹, A. Perrin¹, E. de Peretti¹, A. Zueras¹, B. Vellas^{1,4}, F. Nourhashemi^{1,4}, 1. *Geriatric department, Toulouse University Hospital, Toulouse, France*, 2. *Inserm U 1027, University Toulouse III, F-31073, Toulouse, France*, 3. *Department of Epidemiology and Public Health, Toulouse, France*, 4. *Inserm U 558, University Toulouse III, F-31073, Toulouse, France*

Therapeutic education is expanding in the management of Alzheimer's disease (AD) patients. However, to date, no study has evaluated its impact on the quality of life of the AD patient him/herself. The THERAD study is a monocentric 12-month randomized controlled trial undergoing since January 2013. 196 dyads (AD patient/ caregiver), have been enrolled (MMSE 11 to 26, living at home and receiving support from a family caregiver), 98 in each group. The two month length intervention was a therapeutic educational programme, addressed to both patients (individual session) and caregivers (group sessions) performed by a geriatric team (geriatrician, nurse, psychologist and social worker) specifically trained to patient education and counselling. The first visit (M0) included the educational diagnoses of the dyad. Between M0 and M2 the primary caregivers received one 3 hours group sessions per week, on the main AD topics (eg caregiver's exhaustion, crisis situations) and at M2, an assessment visit. The control group received routine care. Our primary outcome is the AD patient's quality of life assessed by Logsdon's Quality of Life in Alzheimer's Disease scale (QoL-AD) reported by the caregiver at two months. Secondary endpoints are caregiver's burden (ZBI), depression (GDS) and quality of life (NHP), patient's behavioural and psychological symptoms (NPI), autonomy (ADL, IADL) and self-reported quality of life (QoL-AD). Intention to treat analysis will be performed using linear mixed model. Final results, at the end of 2017, may indicate if such an approach needs to be implemented in the care of AD patients.

THE CHANGING FACE OF MCI A TWO-DECADE COMPARISON IN OVER-65S FROM THREE AREAS OF ENGLAND: CFAS I & II

C. Richardson¹, F. Matthews^{1,2}, B. Stephan¹, L. Robinson¹, C. Brayne², 1. *Newcastle University, Newcastle Upon Tyne, United Kingdom*, 2. *University of Cambridge, Cambridge, United Kingdom*

Much work on identifying individuals at high risk of dementia has focused on the clinical concept of mild cognitive impairment (MCI), which is considered to be an intermediate state between normal cognitive ageing and dementia. How the population with this intermediate state has changed over generations is unknown. This study aimed to estimate the prevalence of MCI in the UK now, as well as investigate any changes in MCI and mild dementia prevalence over two decades using the identical diagnostic criteria in the MRC Cognitive Function and Ageing Study I and II. In addition the incidence of dementia at two years by baseline cognitive status will also be estimated.

The aim was to define the complete population into groups based on their cognitive states. Including all individuals in

CFAS I and II into no cognitive impairment, amnesic-MCI, non-amnesic-MCI, multiple-MCI, other cognitive impairment no dementia, mild and moderate dementia. Cognitive domains from the MMSE and (in full) CAMCOG were used to define the cognitive impairment levels.

Prevalence of each condition was modelled using age, sex terms in logistic regression models. Many of the impairment definitions have reduced in prevalence, as found with dementia, however this was not seen consistently across all definitions.

The incidence of dementia over two years by baseline cognitive state in CFAS I and CFAS II will be estimated together with the change over 20 years to see whether the incidence of dementia has changed within baseline risk group. The impact of these changes on the health of the general population will be discussed.

SESSION 830 (POSTER)

DEPRESSION, ANXIETY, AND PERSONALITY II

WHAT CAUSES LATE-LIFE DEPRESSION?: A QUALITATIVE STUDY AMONG DEPRESSED IRANIAN SENIORS

M. Sadeghipour Roudsari¹, M. Foroughan¹, S. Nedjat², F. Mohammadi¹, 1. *University of Social Welfare and Rehabilitation Sciences, Tehran, Iran (the Islamic Republic of)*, 2. *Tehran University of Medical Sciences, Tehran, Iran (the Islamic Republic of)*

Depression is a major health problem in old age that is closely related to cultural and social context. Studies have shown higher prevalence of geriatric depression in Iran. This qualitative content analysis study aimed to explore psychosocial factors related to experience of late life depression in Iranian older people. This is a qualitative study with directed content analysis approach which took place in Tehran, 2015. First, a systematic search in major English and Persian data banks was performed to develop an analysis matrix. Then, participants with most variation in demographic characteristics were recruited from psychiatric clinics if they met inclusion criteria including 1) age 60 and over and 2) having depression in the previous 6 months. Six men and 6 women participated in this study. Semi structured interviews were performed, recorded, transcribed and analyzed according to the prepared matrix, up to reaching data saturation. Analysis of gathered data showed six main categories 1) transition of values system, 2) role changes, 3) life concerns, 4) inadequacy of social relations, 5) regrets and 6) impaired health and function. Considering recent changes in Iranian community and family structures and impaired social relations and inadequate support in the context of physical and social function decline, Iranian older adults have been more susceptible to geriatric depression. As population of Iran is graying very fast, some context-based interventions such as community alertness and providing more formal support may be helpful in preventing late life depression.

DEPRESSIVE SYMPTOMS, SELF-RATED HEALTH STATUS, AND RETIREMENT STATUS AMONG OLDER ADULTS IN THE U.S.

J. Parajuli, *Sociology and Gerontology, Miami University, Oxford, Ohio*

This study investigated if the association between depressive symptoms and self-rated health status was moderated by the retirement status among older adults aged 65 and above in the United States and tested the following hypotheses: (1) the older adults who are depressed and retired will have worse health compared to individuals who are depressed and not retired (2) the effect of depressive symptoms on self-rated health status among older adults will depend on the retirement status of those individuals. Data was used from the 2012 wave of the Health and Retirement Study. Ordinal regression was conducted to assess the relationship between self-rated health status, depressive symptoms, and retirement status. Interaction terms between depressive symptoms and retirement status were included in the final model. Ordinal regression results revealed that the interactions between depressive symptoms and retirement status were significant in the model ($p < .0001$). The results of interaction effects revealed that having depressive symptoms and being completely retired decreased the odds of having better health compared to having depressive symptoms but not retired; which supported the first hypothesis. Similarly, the significant interaction between depressive symptoms and retirement status imply that the retirement status has a moderating effect on the relationship between self-rated health status and depressive symptoms; which supported the second hypothesis. The results of this study have implications for health policy makers to identify and address factors that lead to depressive symptoms.

A BEHAVIORAL AVOIDANCE TASK FOR HOARDING DISORDER IN OLDER ADULTS

M.E. Dozier^{1,2}, C. Ayers^{2,3}, 1. *SDSU/UCSD Joint Doctoral Program in Clinical Psychology, San Diego, California*, 2. *VA San Diego Healthcare System, San Diego, California*, 3. *University of California, San Diego, San Diego, California*

Hoarding disorder (HD) is functionally and cognitively debilitating, as well as socially isolating, particularly in older adults. There is strong avoidance to the distress of parting with personal possessions in HD. The current study explored the feasibility of a behavioral avoidance task (BAT) for HD by utilizing subjective and behavioral assessments of fear response during a sorting task administered to older adults.

The current study utilized data from 16 older adults (mean age 68, range 60–82) meeting DSM-5 criteria for HD. During the BAT, participants' subjective units of distress (SUDS) were recorded at regular intervals. The number of items sorted and the percent of items discarded were recorded as behavioral indicators of approach-orientation to the task.

Twelve of the 16 participants were able to engage in the task for a full five minutes. The average initial SUDS score was 21 out of 100 with 100 being the most amount of distress. The average peak SUDS score was 39. The average within-session habituation was 14 points. Participants were able to sort an average of 39 items and discard 49% of sorted items. The majority of participants (62%) reported that the task was at least "somewhat similar" to what they

experience when sorting objects in their homes. Participants with higher initial SUDS scores were able to sort more items ($r=.74$, $p=.001$) but did not discard a significantly higher percentage of items ($r=.39$, $p=.14$).

Clinicians treating geriatric HD should consider utilizing a BAT to monitor change in distress and avoidance of sorting/discarding.

IS THERE A RELATIONSHIP BETWEEN BODY POSTURE AND PSYCHOMOTOR RETARDATION IN DEPRESSED OLDER ADULTS?

T. Deschamps¹, A. Sauvaget², S. Bulteau², V. Thomas-Ollivier¹, 1. Laboratory "Movement, Interactions, Performance" (E.A. 4334), University of Nantes, France, Nantes, France, 2. Department of "Addictology & Consultation-Liaison psychiatry", Nantes University Hospital, Nantes, France, Nantes, France

The current study supported the idea that postural control variables, particularly the center-of-pressure velocity-based parameters, could be a relevant hallmark of depression-related psychomotor retardation (PMR). The purposes were twofold: first, it aimed to clearly look at the interplay between the subjective PMR scores and the postural performance in patients with major depressive disorder (MDD), as compared to age-matched healthy controls; secondly, it focused on the impact of a repetitive Transcranial Magnetic Stimulation (rTMS) treatment on depression, PMR objective and subjective evaluations. Sixteen MDD patients (mean age 57.9 ± 13.9 years) were compared to 16 healthy controls adults (mean age 60.7 ± 9.6 years). All participants were asked to maintain standing position on a force platform during two trials of quiet standing balance with eyes open or eyes closed, and two "dual task" trials while backward counting by two from a random number around 100. During the 60-s trials, dependent variables computed from the analysis of center-of-pressure trajectories were recorded. Before and after the rTMS session, the depression level and the PMR were scored with the French Retardation Rating Scale for Depression (ERD). The present results contributed to a deeper understanding of the motor performance that characterizes objectively the depression-related PMR. In fact, significant partial correlations between body posture and ERD scores, and positive effects of rTMS treatment on postural instability in dual task, PMR and depression ($p < 0.05$) validated the view that the assessment of postural performance constitutes an objective marker of PMR in depressed patients.

CHILDLESSNESS AND DEPRESSION AMONG OLDER ADULTS IN LATIN AMERICA AND THE CARIBBEAN

N. Quashie², F. Andrade¹, 1. Kinesiology and Community Health, University of Illinois--Urbana-Champaign, Champaign, Illinois, 2. Chulalongkorn University, Bangkok, Thailand

Rapid fertility declines within Latin American and Caribbean countries since the 1960s have contributed to smaller family sizes among the current cohorts of older adults, and increased the likelihood that future cohorts will not have children. This can have implications for mental health in later life in societies where the family unit is highly valued as a source of welfare. Drawing on data from

the 2000 Survey of Health, Well-Being and Aging in Latin America and the Caribbean (SABE), this study examines the association between parental status and the likelihood of experiencing depressive symptoms among older adults 60 years and over in seven cities of Latin America and the Caribbean ($N=9756$). Estimates from logistic regressions are provided for pooled data, and disaggregated by sex and city. Findings show that compared to the childless, older adults with two or more children had lower odds of experiencing moderate to severe depressive symptoms. Having multiple children was shown to be especially protective to older women in Buenos Aires and Havana, and to older men in Montevideo. Other significant covariates such as being unmarried, uneducated, having no access to independent income, experiencing disability and comorbidity were each positively associated with depression. While children may represent a critical component of the welfare mix for older adults, increasing longevity and changes in family structures that accompany population ageing require broader investments in education and health across the life course to improve individual psychological wellbeing, regardless of family status.

SUICIDAL IDEATION IN MEDICALLY ILL OLDER ADULTS: THE IMPORTANCE OF CONTROL STRATEGIES

A. Fiske^{1,5}, L. Henry⁴, K. Marshall¹, Y. Conwell², C.A. Reynolds³, 1. Department of Psychology, West Virginia University, Morgantown, West Virginia, 2. Geriatric Psychiatry Program, University of Rochester Medical Center, Rochester, New York, 3. Department of Psychology, University of California River, Riverside, California, 4. Heart and Vascular Institute, West Virginia University, Morgantown, West Virginia, 5. WVU Injury Control Research Center, Morgantown, West Virginia

Suicide rates are elevated among older men globally. Suicides in this age group often reflect concerns about threats to the older adult's independence and sense of control. Physical illness and associated functional limitations are common in late life, but most individuals adapt by altering their strategies for exerting control (Heckhausen et al., 2010). Evidence suggests that those who do not adapt may be at risk for depression and suicidal thinking (Fiske et al., 2013). In this pilot study, $N = 7$ adults aged 50–85 with a heart attack or a new diagnosis of heart failure within the past six months were assessed for health-related limitations, control strategies, and affective states at baseline and 6-week follow up. The Wilcoxon sign rank test was used to test the hypothesis that more limited use of control strategies would be associated with greater risk of depressive symptoms, hopelessness and suicidal ideation. At baseline, 87% of participants endorsed clinically significant levels of depressive symptoms (CESDR) and 14% scored above the recommended cutoff on the Geriatric Suicide Ideation Scale. Results indicated that both Selective Primary Control (SPC) strategies and Compensatory Primary Control (CPC) strategies (e.g., getting help from others or modifying the task) were significantly linked to hopelessness and suicidal ideation at baseline. At the 6-week follow up, both SPC and CPC were associated with depressive symptoms and hopelessness. These findings suggest that it may be important to focus

on strategies older adults may use to cope with functional impairments.

OLDER VETERANS' PERCEPTIONS OF ANXIETY SYMPTOMS

C.E. Gould^{1,2}, N. Mashal^{1,2}, A.L. Zapata¹, J.L. Wetherell³, M.K. Goldstein^{1,2}, S.A. Beaudreau^{1,2}, R. O'Hara^{2,1}, 1. VA Palo Alto Health Care System, Palo Alto, California, 2. Stanford University School of Medicine, Stanford, California, 3. UCSD/VA San Diego, La Jolla, California

Although studies have examined anxiety in the general population, few studies examine anxiety among older veterans. To this end, we characterized anxiety in older veterans using mixed methods. We used quantitative measurements of geriatric anxiety (Geriatric Anxiety Scale; GAS) and depression (Patient Health Questionnaire 9-item), and qualitative information about perceptions of anxiety. Twenty veterans aged 60–85 years old participated ($M = 69.5$; $SD = 7.3$ years; 50% White). Veterans were characterized as high and low anxiety based on a median split of GAS scores. As expected, the high anxiety group ($M = 35.36$, $SD = 9.94$) had worse anxiety than the low anxiety group ($M = 6.33$, $SD = 4.38$; $t(18)$, 15.54, $p = .001$). The groups also differed on depression severity ($t(18)$, 15.94, $p = .001$), but not on age ($t(18)$, 1.28, $p = .27$). In the interviews, veterans described what anxiety means to them and identified thoughts, emotions and body sensations associated with anxiety. Responses were transcribed and coded using both inductively and deductively developed codes (Cohen's Kappa = 0.79 to 0.86). Thematic analysis revealed that most anxiety symptoms were universally experienced; however, the high and low anxiety groups differed in appraisals of anxiety and in perceived ability to deal with anxiety. The high anxiety group described being stuck and trapped by anxiety. These findings suggest that anxiety symptoms are dimensional and veterans' ability to cope and manage symptoms varies as a function of symptom severity. Implications for anxiety assessment and treatment in older veterans will be discussed.

SUPPORT IS COMPLICATED: HOW INCREASED SUPPORT AFTER CRITICAL ILLNESS CAN CREATE INCREASED ANXIETY

L. Johnston¹, D. Terp², 1. Social Sciences, Cal Poly University, San Luis Obispo, California, 2. Curry Senior Center, San Francisco, California

This presentation summarizes a mixed methods study of 32 older adult ICU patients as they recovered from critical illness. These results are compared and contrasted to a qualitative study of 50 homebound patients who were recovering from less severe illness. The presentation will offer empirical research combined with practical practice guidance for the range of professionals who assist older adults. The authors are medical social workers who combine ongoing counseling practice with research in order to better understand older adults and their social support system in the home and community. The authors propose and describe a counterintuitive concept; patients who reported more sources of support experienced more anxiety during their recovery from illness. A brief history and literature review examines the difficulties in defining social support. There are many types of support and different patients may need different types of support.

Cultural perspectives will also be examined. For older adults in particular, the ageist stereotypes of Western society can make accessing social support difficult because asking for help is viewed as admitting weakness. In contrast, other cultures view older adults as respected sources of wisdom who are entitled to social support. Three types of support-induced anxiety are identified and described using case vignettes. The importance of informed intervention by all the professionals involved with older adults is highlighted and practical practice suggestions will be provided.

ANXIETY SYMPTOMS AND DRINKING TRAJECTORIES IN LATER LIFE: PROSPECTIVE EVIDENCE FROM THE MIUDS STUDY

S. Kim, C. Grella, University of California, Los Angeles, Los Angeles, California

While literature suggests the higher prevalence of anxiety disorders among older alcohol users, few studies have examined the longitudinal relationship between anxiety symptoms and alcohol consumption in later life. The aim of this study was to determine the effects of late-life anxiety symptoms on their subsequent 18-year alcohol use trajectories. Data were drawn from three waves (wave1 [1995–1996], wave2 [2004–2006], and wave3 [2013–2015]) of the MacArthur Foundation Survey of Midlife Development in the United States ($n=7,108$; mean age= 46.8 at baseline). Symptoms of generalized anxiety disorder (GAD) within the previous 12 months were assessed by using the Composite International Diagnostic Interview–Short Form (CIDI-SF) scale. The amount of alcohol use was measured as the typical number of drinks that participants had on days on which they drank during the past month. Covariates (age, gender, race, income, education, and physical health) were assessed at baseline. Latent growth curve modeling was used to identify the association between anxiety symptoms and longitudinal changes in alcohol consumption adjusting for the covariates measured at baseline. We found that individuals with higher levels of anxiety symptoms tended to have an increase in alcohol consumption over time ($\beta=0.07$, $p<0.05$). The results highlight the role of anxiety symptoms in determining the use of alcohol in later life. Therefore, our findings indicate that on-going efforts to improve mental health, especially symptoms of anxiety, may help older adults to reduce hazardous alcohol consumption.

SESSION 835 (POSTER)

DISABILITIES II

DETERMINANTS OF THE NEED TO CARE FOR ELDERLY BRAZILIANS

D. Nunes¹, T. Brito², T.d. Alexandre³, L.P. Corona⁴, Y. Duarte², M. Lebrao², 1. Nursing, Federal University of Tocantins, Palmas, Tocantins, Brazil, 2. University of São Paulo, São Paulo, Brazil, 3. University of São Carlos, São Carlos, Brazil, 4. University of Campinas, Limeira, Brazil

The presence of functional limitations in the elderly determines the need for care. This necessity represents challenging demands for the family and the health services as it presents a complex group. The objective of the study is to analyze

determinants of the need for care in elderly Brazilians. This was a longitudinal and analytical home-based study, which used the database of the SABE study (Health, Well-being and Aging) in the years 2006 and 2010. The sample consisted of 459 elderly individuals independents (≥ 60 years). It was considered as the need for care, the difficulty of the elderly in the performance of basic and instrumental activities of daily living according to aid demands in these activities. It was used in the analysis Multiple Multinomial regression. Among the independent elderly, the determining factors for minimum need were female (RRR=1.81, CI95%:1.05–3.13), aged 80 and over (RRR=2.84, CI95%:1.17–6.86), impaired physical mobility (RRR=2.94, CI95%:1.02–8.43); for moderate need, aged 80 years and over (RRR=5.58; CI 95%:1.55–20.00) and cognitive decline (RRR=7.83, 95% CI:1.60–38.24); and maximum need, age between 70 to 79 years (RRR=2.60; CI95%: 1.13–5.96) and 80 and over (RRR=5.59, CI95%:1.87–16.62), multimorbidity (RRR=3.50; CI95%:1.32–9.30). Identifying the factors determining the need for care will allow family members, caregivers and health professionals to develop strategies to prevent the establishment of the difficulties in daily activities. Public policies should be developed for caregivers, considering the health and social services as support for the providers of care.

MULTI-YEAR DISABILITY TRAJECTORIES AMONG SURVIVORS AND DECEDENTS

S.M. Albert¹, J.R. Lunney¹, L. Ye¹, D.G. Ives¹, S. Satterfield², A. Newman¹, 1. *Behavioral and Community Health Sciences, University of Pittsburgh, Pittsburgh, Pennsylvania*, 2. *University of Tennessee Memphis, Memphis, Tennessee*

Investigators have identified varying trajectories of disability before death, but it is unclear if disability trajectories among decedents and survivors differ among older adults.

We examined self-reported disability in walking a quarter mile at 6-month intervals beginning 3 years before death among 1020 decedents in the Health, Aging and Body Composition Study (Health ABC). Survivors matched for age and gender were identified and self-reports for each pair were tracked over the same 3-year period (total $n=2040$). Survivor and decedent reports of disability over the 6 assessments were compared using mixed models to calculate the odds of disability for each group adjusted for race, site (Memphis vs. Pittsburgh), and time. In a sensitivity analysis, we assumed that respondents missing self-report status were disabled.

Decedents increased in disability from 48.6% 3 years before death to 78.1% 6 months before death. Among survivors, disability increased from 32.3% to 43.6%. In a logistic regression model the odds of having disability showed a significant month by group (decedents vs. survivors) interaction ($p < .0001$). The monthly increase in odds of having disability was 6.3% among decedents compared to 2.6% among survivors. The two groups did not differ in volatility, that is, switching between disabled and non-disabled status; but African-American respondents showed greater volatility than whites ($p < .0001$).

Trajectories of self-reported disability differ between survivors and decedents. Older adults who died after 3 years were more disabled at the start of follow-up and also had a greater risk of increasing disability over each subsequent 6-month assessment.

CORRELATES OF DISABILITIES AMONG COMMUNITY-DWELLING ELDERLY INDIVIDUALS FROM BRAZIL

T. de Andrade¹, F. Bof de Andrade², 1. *Faculty of Medical Sciences, Belo Horizonte, Brazil*, 2. *Oswaldo Cruz Foundation - FIOCRUZ, Belo Horizonte, Brazil*

Objective: Assess the prevalence of disability and evaluate its association with sociodemographic and general health factors among a representative sample of community-dwelling elderly individuals from Brazil. **Methods:** This was a cross-sectional, population based study, with a probabilistic household sample from Brazil. Sample comprised 11,177 individuals, representing 26,407,830 older adults aged 60 years or more. All participants answered a structured questionnaire informing on disabilities on basic activities of daily living (BADL) and covariates on sociodemographic, life style, general health and use of health services. Individuals reporting difficulty in one or more BADL (bathing, dressing, walking, using the toilet, feeding and moving in and out of bed) were considered disabled. Associations between variables were evaluated by means of prevalence ratios estimated by Poisson regression model. **Results:** The prevalence of disability in BADL was 6.1%. According to the adjusted analysis, the prevalence of disability increased with increasing age and was lower among individuals with more years of education. Elderly individuals with chronic diseases and hospitalization in the previous year had significantly higher prevalence of disability. The prevalence of disability was significantly lower among individuals reporting physical activities. **Conclusion:** There were socioeconomic inequalities in the prevalence of disability in BADL which was also significantly associated with factors related to life style, general health, use of health care.

GREATER PERI-AORTIC ADIPOSE TISSUE IS ASSOCIATED WITH INCREASED TRUNK MUSCLE FAT IN MEN AND WOMEN

R. McLean^{1,2,3}, L.J. Samelson^{1,2,3}, A. Lobergs^{1,2,3}, D. Anderson^{3,2}, U. Hoffmann^{4,2}, C. Fox⁵, M. Bouxsein^{3,2}, D.P. Kiel^{1,2,3}, 1. *Hebrew SeniorLife Institute for Aging Research, Boston, Massachusetts*, 2. *Harvard Medical School, Boston, Massachusetts*, 3. *Beth Israel Deaconess Medical Center, Boston, Massachusetts*, 4. *Massachusetts General Hospital, Boston, Massachusetts*, 5. *Merck Research Laboratories, Boston, Massachusetts*

Age-related muscle fat accumulation and loss of muscle mass, contributors to mobility problems in older adults, may result from ectopic fat producing cytokines that promote satellite cell differentiation into adipocytes. Whether this occurs via systemic or local paracrine effects is unknown. We determined the association of peri-aortic adipose tissue (PAAT) volume with size and fat content of adjacent trunk muscles among 948 participants (56% women) in the community-based Framingham Study. Multidetector CT measured PAAT, and cross-sectional area and attenuation (marker of fat content) of trunk muscles (averaged left and right erector spinae, transversospinalis, and trapezius muscles at T7/T8 levels). Linear regression was used to calculate associations (β) of PAAT with cross-sectional area and attenuation, adjusting for sex, age, height, body mass index (BMI) and physical activity, and further adjustment for abdominal visceral (VAT)

and subcutaneous adipose tissue (SAT) volumes. Mean age was 58 years (range 45–81), mean BMI was 28 kg/m² (range 18–53). PAAT was not associated with cross-sectional area ($\beta=-0.96$, $P=0.37$), but was inversely associated with attenuation ($\beta=-0.31$, $P<0.01$), indicating higher muscle fat content with increasing PAAT. The association remained after adjustment for VAT and SAT. We found that increased fat surrounding the thoracic aorta was associated with greater fat content in nearby trunk muscles, independent of overall obesity and ectopic abdominal fat, suggesting that age-related skeletal muscle fat accumulation may result mainly from local paracrine effects of adjacent fat depots. Cross-talk between neighboring fat and muscle is a potential target for novel muscle function-promoting therapies in older adults.

SARA-OBS CLINICAL TRIAL: BASELINE CHARACTERISTICS OF SARCOPENIA/SARCOPENIC OBESITY IN THE ELDERLY

W. Diah¹, S. Del Signore^{1,2}, L. Daudigny¹, S. Veillet¹, 1. *Biophytis, Romainville, France*, 2. *Bluecompanion Ltd, London, United Kingdom*

Sarcopenia is a key underlying cause of physical frailty, a reversible condition in older subjects, which may lead to mobility disability and dependency. Sarcopenia is characterized by the loss of muscle mass and function. Sarcopenic obesity (SO), an emerging condition affecting older obese individuals, can be defined by fat mass increase associated with the loss of muscle mass and function.

SARA-OBS is a 6-month observational, multicenter, clinical trial aiming to enroll 300 community-dwelling persons aged ≥ 65 years at risk of mobility disability, within 8 investigational sites across Europe and USA. SARA-OBS main objective is to characterize sarcopenia including sarcopenic obesity, by using DXA, according to the criteria of the Foundation of NIH (Studenski et al., 2014) and of the Short Physical Performance Battery (SPPB; Guralnik J et al., 1994).

Patients with SPPB $\leq 8/12$ and DXA ALM/_{BMI} corresponding to FNHI criteria (< 0.789 in men and 0.512 in women) will be included. The primary endpoint will be the 6-minute distance or the 400 m walking test. Secondary endpoints include muscle strength, physical activity through an activity monitoring device; muscle mass and fat mass (measured by DXA). Patient-Reported Outcomes (PROs) will also be collected.

Patients' enrollment will start by the fourth quarter 2016 through a 7-month screening and recruitment phase followed by an observational phase with two visits at inclusion and at 6 months. SARA-OBS data (baseline characteristics, demographics, body composition and functional tests) will pave the way for SARA-INT, the interventional Phase2 trial for the candidate drug Sarconeos (BIO101).

COLLABORATION BY A HEALTHCARE TEAM TO IMPROVE MOBILITY IN HOSPITALIZED OLDER ADULTS—GET UP AND GO

U. Ohuabunwa^{1,2}, R. Walton Mouw², J. Brandt², J. Turner², Q. Jordan², T. Dumas², L. Perdue², C. Osuji², 1. *Emory University, Atlanta, Georgia*, 2. *Grady Hospital, Atlanta, Georgia*

Older adults who are hospitalized are prone to multiple hazards such as falls, and significant functional mobility

decline often resulting in institutionalization, and readmission to the hospital after discharge. Patients are often mobilized late in their hospital stay due to Nursing Staff awaiting clearance from physical therapy. We sought to determine the effectiveness of an early mobilization protocol established to improve mobility and function in hospitalized older adults

Project Setting was a 953 Bed academically affiliated safety net hospital.

Participants included older adults 75yrs and older or patients 65 years and older identified to have 1 or more geriatric syndromes admitted to the Acute Care for the Elderly Service.

All patients were evaluated by Nursing Staff on admission to determine their Get up and Go score ranging from a score of 1 (patient able to get up and go without assistance) to 9 (bed rest ordered). Patients were mobilized early by Nursing based on their Get up and Go scores following the protocol on amount of mobilization required. Physical Therapy and Occupational Therapy also saw the patient early in their hospital stay to evaluate for further functional and mobility needs and implement physical and occupational therapy as needed.

Initial data show a significant improvement in mobility scores for patients based on the Get Up and Go scores on admission and at the time of discharge with lower scores indicating improved mobility. Pre Intervention, the mobility scores on admission were 4.4 and increased to 4.53 at discharge. Post intervention, mobility scores were 4.37 on admission and 3.65 at discharge.

In conclusion, the Get up and Go protocol is a useful mobilization program to improve functional mobility in hospitalized older adults.

COMPARISON OF STATIC BALANCE BETWEEN INSTITUTIONALIZED AND COMMUNITY-DWELLING OLDER ADULTS

M. Scheicher², L. Moreira¹, L. Faber¹, 1. *Physiotherapy and Occupational Therapy, UNESP, Marília, São Paulo, Brazil*, 2. *UNESP, Marília, São Paulo, Brazil*

Falls are common among older people and are a serious public health problem in this population. Studies indicate that about 30% of people over 65 years who live in the community fall annually. For individuals in nursing homes, 50–66% fall each year. One specific condition for risk of falling is the gait/balance disability. Often, institutionalized older patients have fewer opportunities to independently participate in activities and tasks of daily living, having higher deleterious effects in the physiological losses from aging, compromising gait and balance. There are fewer studies showing the balance by a force platform in institutionalized elderly. The aim of the study was compare the static balance between institutionalized and community-dwelling older. Forty two older volunteers participated in the study (21 community-dwelling and 21 institutionalized). The static balance was assessed using a force platform (eyes open and closed base). The parameters used to measure the subject's stability were: total path length (cm), mean velocity (cm/s) and 95% of the ellipse area (cm²). The age of participants was 75.4 ± 7.3 for institutionalized and 72.5 ± 7.1 for community-dwelling older ($p=0.20$). The results showed a significant difference between institutionalized and community-dwelling older:

total path length (77.9 ± 25.05 and 52.7 ± 12.59 , $p=0.0002$), mean velocity (2.60 ± 0.84 and 1.88 ± 0.86 , $p=0.001$) and 95% of the ellipse area (6.5 ± 3.3 and 4.6 ± 2.4 , $p=0.04$). The results showed that the static balance assessed by a force platform of institutionalized older is significantly different of community-dwelling elderly, explaining the greater risk of falls of this population.

SIT TO STAND ACTIVITY: A LITERATURE REVIEW

U.D. Wisnesky, W. Duggleby, S. Slaughter, *Nursing, University of Alberta, Edmonton, Alberta, Canada*

It is common for older adults to have many age related problems such as muscle weakness, slowed performance, fatigue and poor endurance. Focusing on exercises to improve older adults mobility is a potential mechanism to assist their physical capability and performance of activities of daily living. Using Arksey and O'Malley framework a scoping review was conducted to: (1) to explore the breadth of literature on the current state of knowledge about the sit-to-stand activity to improve mobility in the older adult population and (2) to identify gaps for future research. Of 1639 papers, 14 studies met the inclusion criteria, with study dates ranging from 1993 to 2015. The target population of the majority of studies was post-stroke patients. A range of sit-to-stand interventions were described with duration of interventions ranging from two to 24 weeks. The frequency of the sit-to-stand activity ranged from three to seven times/week lasting 15 to 45 minutes on each occasion. Also, the activity was prompted mostly by rehabilitation professionals. Three themes were identified in the studies: (1) positive impact of sit-to-stand activity on patient outcomes; (2) absence of long term follow up in study designs; and (3) gap of theoretical framework guiding the studies. Across most of the studies, participants showed significant improvements in performance of sit-to-stand and motor function, yet most studies lacked adequate methodological rigor and/or experimental design. There was an absence of explicit theoretical frameworks guiding the studies. More research is needed to assess whether the sit-to-stand could benefit groups beyond the post-stroke population.

AMBULATION OF HOSPITALIZED OLDER PATIENTS

F. Kuo, B. King, L. Steege, H. Wang, *UW-Madison, Madison, Wisconsin*

About 65% of older adults will experience functional decline or loss of independent ambulation during their hospital stay. Loss of independent ambulation has been identified as a hospital-associated disability (HAD). Patients at risk for HAD are those with decline in 1 or more ADLs, female, over the age of 75 and use of an assistive walking device. Limited ambulation has been identified as the most preventable cause of HAD. Older adults infrequently walk during their hospital stay. An exploratory study was conducted on an adult medical unit in a Midwest academic hospital. Thirty-seven older adults (mean age=80.73) consented to wear a research-grade accelerometer during their hospital stay (mean stay=61.46 hours). Growth mixture modeling identified the trajectories of cumulative number of steps into two classes, class I ($n=29$, mean growth slopes= 33.4) and class II ($n=8$, mean growth slope=130.1). T-test indicated lower body weight (BW) was statistically significant in the group with high slopes ($p=0.037$). Partial correlation test, controlling

for ambulation assistance, identified a negative correlation between the slope of cumulative number of steps with age ($r = -0.42$, $p = 0.013$), and male ($r_{pb} = -0.336$, $p = 0.026$). Pattern of ambulation within the sample identified 3 time periods of greatest activity, 10am-1pm, 4-6pm and 8-9pm. Decrease in ambulation activity occurred during shift change 3pm, 7pm and after 10pm. High BW, male and need for assistance were correlated with low levels of ambulation. Future intervention studies should target high risk patients who may be at greater risk for HAD.

MANAGING MOBILITY IN VULNERABLE SENIORS (MMOVES) WITH AN INDIVIDUALIZED, HOME-EXERCISE PROGRAM

S. Figueiredo^{3,1}, J.A. Morais^{2,4}, N.E. Mayo^{5,3,4}, 1. *Center for Outcomes Research and Evaluation, Research Institute, McGill University Health Centre, Montreal, Quebec, Canada*, 2. *Faculty of Medicine, McGill University, Montreal, Quebec, Canada*, 3. *School of Physical and Occupational Therapy, McGill University, Montreal, Quebec, Canada*, 4. *Division of Geriatrics, McGill University Health Center, Montreal, Quebec, Canada*, 5. *Division of Clinical Epidemiology, McGill University, Montreal, Quebec, Canada*

After hospitalization, further disability among seniors could be prevented through exercise. Nonetheless, a one-on-one rehabilitation is not realistic for the volume of seniors that are experiencing disability. Currently available educational material for improving disability is so vast and non-specific that passive dissemination may pose a barrier to behaviour change. The aim of this pilot study was to estimate the extent to which an individualized, exercise-focused, self-management program (MMOVES), in comparison to exercise information, is more effective in improving mobility after 6 months among seniors recently discharged from hospital.

The physiotherapy-facilitated intervention consisted of 1) evaluation of mobility capacity; 2) setting short and long term goals; 3) delineation of an exercise treatment plan. In addition, MMOVES participants received an educational booklet to enhance mobility self-management skills and were followed-up with monthly telephone calls. Control group received a booklet with information on exercises targeting mobility limitations in seniors.

Mobility, pain, and health status were assessed at baseline and at 6 months using multiple indicators drawn from DASH, LEFS, SF-36. After imputing missing data, generalised estimating equations (GEE) estimated the odds of response for people receiving the intervention in comparison to the odds of response in the control group. Each person was classified as having made a response, deterioration, or no change on each measure based on change of one level on the ordinal scale.

26 people were randomized to the intervention (mean age 81 ± 8 ; 39% women), 23 were randomized to the control (mean age 79 ± 7 ; 33% women). The OR for the mobility outcomes combined was 3.08 and the 95%CI excluded 1 (1.65 – 5.77). The ORs for pain and health perception favoured the MMOVES group; but, the 95%CI included the null value. Our individualized, exercise-focused, self-management program was more effective than exercise information in improving mobility outcome for seniors.

THE SHORT VERSION OF THE ACTIVITIES-SPECIFIC BALANCE CONFIDENCE SCALE FOR OLDER ADULTS WITH DIABETES

P. Hewston, N. Deshpande, *Queen's University, Kingston, Ontario, Canada*

The Activities-specific Balance Confidence scale (ABC-6) is advantageous in busy clinical or research settings as it can be administered in significantly less time than the original 16-item ABC scale (ABC-16). The purpose of this study was to examine the convergent, discriminant and concurrent validity of the ABC-6 in older adults with diabetes mellitus (DM) with and without diagnosed diabetic peripheral neuropathy (DPN). Thirty older adults (aged ≥ 65) were age- and sex-matched in 3-groups: 10 with DM (DM-group), 10 with diagnosed DPN (DPN-group), and 10 without DM (noDM-group). Balance confidence was quantified with the ABC-16 which includes the six items of the ABC-6. Potential correlates were evaluated in physical and psychological domains. Our results indicated the ABC-6 and ABC-16 balance confidence scores were strongly correlated ($r=0.969$, $p<0.001$; convergent validity). The ABC-6 revealed significant differences in balance confidence between the noDM- and DM-groups ($p<0.001$; discriminant validity) whereas the ABC-16 did not ($p>0.05$). The ABC-6 was moderately but significantly correlated with physical activity level ($r=0.528$, $p=0.017$), mobility ($r=-0.520$, $p=0.027$), balance ($r=0.633$, $p=0.003$) and depressive symptoms ($r=-0.515$, $p=0.020$) in the DM study-groups (concurrent validity). In conclusion, the ABC-6 and ABC-16 had excellent convergent validity and both ABC-scales had similar concurrent validity. However, the ABC-6 was more sensitive to detect subtle differences in balance confidence in older adults with diabetes without diagnosed DPN than the ABC-16. Overall the ABC-6 is a valid assessment tool that may provide a means for early detection of balance and mobility-related declines in older adults with DM without diagnosed DPN.

IDENTIFICATION OF FACTORS THAT INFLUENCE INDEPENDENCE OF COSTA RICAN NONAGENARIANS AND CENTENNIANS

X. Ramirez-Ulate, M. Bolaños-Sanchez, *Hospital Nacional de Geriatria y Gerontologia, San Jose, Costa Rica*

Costa Rica is now dealing with a demographical transition in which it is common to see healthcare users aged 90+. The goal of this study is to document the sociodemographic characteristics, and the medical and functional condition of the ninety and hundred-year-old senior citizens within the sample, as well as to document the most important factors affecting their independence, both in their basic and instrumental activities. The information used was gathered from the CRELES (Costa Rica, Longevity and Healthy Aging Study, as per its Spanish acronym). In this study a survey was administered to a nationally representative sample of 8,000 senior citizens. This is a descriptive and analytical cross-sectional study. In total 278 people over ninety years of age were studied, representing 9.8% of the individuals included in the CRELES study. Among the most important findings was the fact that most participants are female and that 30.9% of them were illiterate. The most frequent pathologies were sleep disorders (51%) and hypertension (44%); 14% reported having no previous pathologies. 24.9% of the individuals had a

BMI of less than 20. 63% of them considered that they had a good to excellent health. Upon assessing their functional conditions, it is clear that 32% of them are completely independent in Basic Daily Activities. Their instrumental activities were positively affected by hypercholesterolemia, in that their degree of independence was higher when this condition was present ($p = 0.088$). These findings should allow better measures to be taken for the early detection of risk factors.

PROPHYLAXIS PROTOCOL FOR SURGICALLY TREATED HIP-FRACTURED ELDERLY IN REDUCING VENOUS-THROMBOEMBOLISM

C. Cheong¹, S. Su¹, Y. Wan¹, C. Tan², Y. Chen², Y. Kang³, M. Ullal¹, 1. *Department of Geriatric Medicine, Khoo Teck Puat Hospital, Singapore, Singapore*, 2. *Department of Orthopaedic Surgery, Khoo Teck Puat Hospital, Singapore, Singapore*, 3. *Department of Pharmacy, Khoo Teck Puat Hospital, Singapore, Singapore*

Venous-thromboembolism(VTE) risk is high in surgically treated hip-fractured patients and could still be 19% despite being on pharmacological prophylaxis. There was no routine practice of giving pharmacological prophylaxis in elderly due to the concern of bleeding risk and lower risk(8.6%) of VTE in Asian populations.

We developed a VTE prophylaxis protocol via inter-departmental collaboration for all hip-fractured elderly admitted to the Hip Fracture Unit. We studied 256 patients with surgically treated hip fractures (mean age 78.6 ± 8.9) who were admitted from November 1, 2014 till October 31, 2015. Mechanical calf-compressors and anti-embolism stockings were used as mechanical methods whereas low-molecular weight heparin or unfractionated heparin were used as pharmacological methods. Prophylaxis was started from the first day of admission except those with absolute contraindications. DVT and pulmonary embolism(PE) were confirmed by ultrasonography and CT pulmonary angiography respectively. We aimed to study the compliance of VTE protocol and VTE risk with appropriate prophylaxis.

All 256(100%) of the patients were given mechanical prophylaxis, with 238(88%) of them on concurrent pharmacological prophylaxis. Seven(2.7%) had DVT and two (0.8%) had PE. One(0.004%) mortality was associated with the VTE-positive group. No complications were reported from the mechanical methods. One(0.004%) heparin-induced thrombocytopenia and one(0.004%) rectal bleeding secondary to undiagnosed sigmoid tumour were reported. No bleeding complications of the wound.

VTE is a serious complication and often underestimated in Asian patients with hip fracture. VTE prophylaxis protocol could improve the compliance and safety of prophylaxis initiation and is effective in reducing VTE occurrence in hip fracture patients.

SELF-REPORTED HEALTH AS A PREDICTOR OF FUNCTIONAL DECLINE IN A COMMUNITY-DWELLING ELDERLY POPULATION

S. Kim^{1,2}, D. Shin³, B. Cho⁴, C. Won², Y. Hong², K. Son⁴, 1. *Seoul National University Bundang Hospital, Gyunggi-do, Korea (the Republic of)*, 2. *Kyung Hee University, Seoul, Korea (the Republic of)*, 3. *Samsung Medical Center, Seoul, Korea (the Republic of)*, 4. *Seoul National University Hospital, Seoul, Korea (the Republic of)*

Purpose: As elderly population is increasing, prediction and prevention of functional decline in the elderly are of great concern. This study aimed to evaluate whether poor self-reported health status (SRHS) could predict functional decline after two years in the elderly population.

Methods: Data from the KLoSA panel, a national representative sample of the aging Koreans, were used. Subjects of investigation were the elderly population aged 65 or more without disability in carrying out activities of daily living (ADL) at baseline. The survey asked respondents about their subjective health status. Setting the respondents who stated their health status 'very good' or 'good' as the reference group, multivariable logistic regression analysis was performed to compare functional decline according to the baseline SRHS.

Results: A total of 2,824 subjects were included in the analysis. Among them, 138 (4.9 %) reported functional decline of at least one of the 7 ADL components after two years. In multivariable logistic regression analysis, SRHS was significantly associated with subsequent functional decline in respondents who chose 'Bad' (odds ratio (OR), 3.32; 95 % confidence interval (CI), 1.71 – 6.44) or 'Very bad' (OR, 4.75; 95 % CI, 2.12 – 10.66). Moreover, poorer SRHS was significantly associated with subsequent impairment in each ADL components. Also, SRHS predicted overall subsequent impairment in the instrumental ADL.

Conclusions: SRHS predicted functional decline after two years in the elderly without baseline disabilities. SRHS can be a good predictor of future functional decline in the elderly population.

LOSS OF INDEPENDENCE IN ACTIVITIES OF DAILY LIVING IN OLDER ADULTS HOSPITALIZED

P.J. Villas Boas, A.P. do Valle, A.F. Jacinto, V.F. Mayoral, M. Garuzi, T. Carvalho, D. Veiga Antonangelo, *Internal Medicine, Sao Paulo State University - Unesp, BOTUCATU, Sao Paulo, Brazil*

Objectives: To describe the changes in activities of daily living (ADL) function occurring before, after hospital admission and discharge in inpatients elderly with medical illness and to assess the effect of frailty on loss of ADL function.

Design: Prospective observational study.

Setting: Brazilian university hospital.

Participants: One-hundred ninety-five patients (mean age 74 years, 59% men).

Measurements: At the time of hospital admission, patients were interviewed about their independence in ADLs (Katz index) 2 weeks before admission (M0), at admission (M1), discharge (M2) and 15 days after discharge (M3) and about frailty (M0) (Cardiovascular Health Study index). Outcome measures included functional decline between M0-M1, between M0-M2, between M0-M3 and between M2-M3.

Results: Eighteen percent of patients were dependent (Katz index < 3) and 38.4% were frailty in M0. The ADL function of 31% of the patients did not decline between M0-M2. Thirty-five percent declined between M0-M3. This included the 17.1% of patients who declined between M0-M1 and failed to recover to baseline function. Fifty-nine percent declined between M1-M2. Twenty-four percent recovered between M2-M3.

The frequency of ADL decline between M0-M3 varied markedly with frailty (OR=5.77, 95% confidence interval 2.23–14.96).

Conclusion: Many hospitalized older people are discharged with ADL function that is worse than their baseline function. Frailty was a risk for losses of ADL function during hospitalization in elderly patients

ARE STATIC AND DYNAMIC BALANCE ABILITIES CORRELATED WITH HANDGRIP STRENGTH IN HEALTHY ELDERLY?

M. Pau, F. Corona, S. Caggiari, C. Fastame, P. Hitchcott, G. Panu, M. Penna, *University of Cagliari, Cagliari, Italy*

Several studies report that basic motor abilities, including muscular strength and static and dynamic balance influence the risk of falls in elderly people. However, the relationship between these features is not fully clear. In this study, we measured static posturography and TUG (performed using force platform and wearable inertial sensors) with handgrip strength (HSG) and determined the correlation between balance and HSG performances.

Twenty-two healthy individuals (10M, 12F, age 68.0 SD 8.3) underwent a 30 s static posturography and instrumented TUG using an inertial sensor attached at the lower lumbar level. The center-of-pressure (COP) time series acquired with the force platform were processed to calculate: sway area, COP path length, maximum COP displacements and velocities in AP and ML directions. For the TUG, acceleration data allows calculating: duration of the trial, duration of sit-to-stand, intermediate turning, final turning and stand-to-sit phases. HSG was measured using a validated dynamometer.

Pearson's product-moment correlations was calculated by setting the significance level at $p=0.05$. We found significant positive correlations of HSG with sway area ($r=0.462$), path length ($r=0.510$) COP displacements and velocities in AP and ML direction ($r=0.576$ and 0.422 for displacements, $r=0.563$ and 0.414 for velocities). Moreover HSG is negatively correlated with TUG duration ($r=-0.604$) and final rotation phase ($r=-0.509$). Such results suggest that HSG is a good predictor of static balance, while muscular strength seems to be less of an influence in dynamic balance tasks like TUG.

SESSION 840 (POSTER)

DISEASES OF AGING AS MEANS TO UNDERSTAND THE AGING PROCESS

PROTEIN MALNUTRITION AFFECTS CARTILAGE QUALITY AND COULD CONTRIBUTE TO OSTEOARTHRITIS DEVELOPMENT

P. Ammann, C. Lavet, *Division of Bone Diseases, Geneva, Switzerland*

Elderly patients frequently suffer from protein malnutrition leading to major alteration of the somatotrophic axis as well as IGF-I local production. IGF-I is a major anabolic agent for cartilage homeostasis. Indeed a decrease of IGF-I induced by protein malnutrition could affect both cartilage and subchondral bone and may contribute to osteoarthritis

development. To address this question, 9 months old rats were pair fed a normal or an isocaloric low protein diet (LP) for 2 months (n=6/group). All animals were euthanized and femurs were collected. Micro-computed tomography allows determination of trabecular and cortical subchondral bone (SB) morphometric parameters as well as hyaline and calcified cartilage thickness, and proteoglycan content estimation. Bioindentation with Bioindenter equipment (CSM Instrument, Switzerland) allows determination of cartilage material level properties (indentation depth and Young's modulus). Systemic IGF-I was decreased in LP group (-18%, p<.001). As expected, in LP group, SB compartment was altered: trabecular SB mass was decreased (-10%, p<.01) as well as SB cortical plate thickness of the medial condyle (-12%, p<.05). Despite no morphologic changes of the cartilage of the medial condyle (thickness tended to decrease by 8% but not significantly), hyaline cartilage biomechanical properties (force, elastic modulus and working energy) were respectively decreased by -47, -58 and -41% (p<.01). We did not observed alterations of proteoglycan. These cartilage degradations are similar to what is observed in early osteoarthritis. We suggest that alteration of the somatotrophic axis induced by protein malnutrition could predispose to osteoarthritis. Since protein malnutrition is frequent in elderly this mechanism could be relevant in human.

REDUCTION OF NFAT1 EXPRESSION IN ARTICULAR CHONDROCYTES LINKS TO THE AGING OF ARTICULAR CARTILAGE

J. Wang, *Orthopedic Surgery, Kansas University Medical Center, Kansas City, Kansas*

Aging is an independent risk factor for osteoarthritis (OA), for which the biological mechanisms are poorly understood. NFAT1 (NFATc2) known to be expressed in cartilage is a member of nuclear factor of activated T cells (NFAT/Nfat) family of transcription factors. This study aimed to investigate the age-related NFAT1 expression pattern and the role of NFAT1 in regulating metabolic activities of articular cartilage in mice. *Nfat1* mRNA and protein were highly expressed in articular chondrocytes in young adult but were significantly reduced in aged mice. The decreased NFAT1 expression was associated with reduced proteoglycan staining, decreased expression of chondrocyte markers, and increased expression of interleukin-1 β in articular cartilage. Forced *Nfat1* expression in chondrocytes from aged mice significantly reversed the abnormal metabolic activities. Methylated DNA immunoprecipitation and chromatin immunoprecipitation assays revealed that reduced NFAT1 expression in articular chondrocytes of aged mice was regulated by epigenetic histone methylation at the promoter region and was correlated with increased DNA methylation at introns 1 and 10 of the *Nfat1* gene. The present study suggests that epigenetically regulated spontaneous reduction of NFAT1 expression results in imbalanced metabolic activities of articular chondrocytes of aged mice, leading to aging-like changes in articular cartilage. Articular cartilage of aged mice, therefore, is an abnormal joint tissue that may predispose the joint to OA under mechanical stress. These

findings may provide new insights into the mechanisms underlying the aging of articular cartilage.

UNDERSTANDING ROLE OF 9P21 GENE DESERT SNPS IN CANCER, AGING, DIABETES, AND CARDIOVASCULAR DISEASES

R. Jayani^{1,2}, Q. Ma¹, D. Notani^{3,1,2}, M.G. Rosenfeld^{1,2},
1. *University of California San Diego (UCSD), La Jolla, California*, 2. *Howard Hughes Medical Institute, La Jolla, California*, 3. *National Centre for Biological Sciences (NCBS), Bangalore, Karnataka, India*

Aging has been largely thought of as a manifestation of metabolic malfunctions and physical and psychological changes accumulating over time in the body. Recent years have seen seminal research that indicates that changing epigenetic landscape of individual cells is also one of the main contributors to the process of aging, that lead to the term "cellular aging". INK4/ARF locus on chromosome 9p21 has been implicated in aging, diabetes, heart diseases and multiple forms of cancer; making it an ideal model to study the basic rules of cellular aging. We identified 33 enhancers in the 9p21 locus, which have been associated to aging-related diseases in multiple GWAs studies. Using techniques like 5C and CRISPR, we have discovered an intricate network of interplay between some of the key enhancers in the locus. We observed that these enhancers make contacts with the INK4/ARF locus by looping and in turn regulate the expression of ANRIL, p14 and p16: important determinants of cellular aging. We also found out that this is a local effect spread over a few adjacent TADs, suggesting that multiple such "regulator domains" might be at work in the genome, to check the cellular aging. The findings of this study will shed light on how to develop new approaches to impact the architectural events and could provide targets to impede the aging process and development of diseases associated with aging, such as coronary artery disease, diabetes, and neuro-degenerative disease.

GENOMIC AND FUNCTIONAL CELLULAR RESPONSES IN HEAVILY TUBERCULOSIS-EXPOSED OLDER ADULTS

D.H. Canaday¹, B. Richardson², J. Pyles², P. Wilkinson², W.H. Boom², H.K. Mayanja³, M. Cameron², 1. *GRECC, Cleveland VA, Cleveland, Ohio*, 2. *Case Western Reserve University, Cleveland, Ohio*, 3. *Makerere University, Kampala, Uganda*

Little known about changes in immune responses to TB that occur with aging. We identified pulmonary TB index cases and enrolled their heavily TB exposed household contacts in Uganda. We studied 26 older (mean age 58, range 50–78) and 17 younger (mean age 23, range 18–30) household contacts. None had active TB. 11 Index cases with active TB were examined also. PBMC were studied at time 0 by RNA-seq transcriptomic analysis. Not surprisingly, pathway-based analysis of young subjects with active TB versus contacts showed upregulation of IL6, complement, and type I interferon response gene (IRGs such as OAS1/2, IFI6/27, IFIT2/3 and IRF7) pathways signifying a coordinated innate immune response. Interestingly, many of the same IRGs expressed in active TB in younger individuals were also upregulated in older highly exposed versus younger highly exposed.

However, this IRG expression was in the context of type II IRG (IFNG), IL12 and other proinflammatory cytokine signaling consistent with higher activation of the inflammasome upon TB exposure in the aged. PBMC were also stimulated with TB and CMV for study by multiparameter flow cytometry. Surprisingly the magnitude and polyfunctional quality of memory CD4+ T cells responding to TB antigens was similar between the age groups measuring TNF, IFN, and IL-2. The polyfunctional profile however was different between T cells responding to TB and CMV supporting a specific phenotype to TB responding cells. Several inhibitory receptors associated with exhaustion (CD160, 2B4, PD-1) have a trend or are higher in CD4+ T cell memory subsets with age.

ALTERED MITOCHONDRIAL QUALITY CONTROL IN MUSCLE OF OLD CACHECTIC PATIENTS WITH GASTRIC CANCER

R. Calvani, M. Lorenzi, A. Picca, F. Landi, F. Tanganelli, M. Bossola, R. Bernabei, E. Marzetti, *Catholic University of the Sacred Heart, Rome, Italy*

Mitochondrial dysfunction has been involved in muscle wasting associated with cancer cachexia (CC). Whether mitochondrial quality control (MQC) is altered in skeletal myocytes during CC is still unclear. The present investigation sought to preliminarily characterize MQC pathways in muscle of gastric cancer patients with cachexia. The study followed a case-control cross-sectional design. Intraoperative biopsies of the *rectus abdominis* muscle were obtained from 18 old patients with gastric adenocarcinoma (nine with CC and nine non-cachectic) and nine controls, and assayed for the expression of a set of MQC mediators. Mitofusin 2 (Mfn2) expression was reduced in cancer patients compared with controls, independent of CC, while fission protein 1 (Fis1) was up-regulated in CC patients relative to the other groups. As a result, the "fusion index" (Mfn2/Fis1 ratio) was lower in patients with CC. The mitophagy regulators PTEN-induced putative kinase 1 and Parkin were down-regulated in cancer patients compared with controls. The ratio between the protein content of the lipidated and non-lipidated forms of microtubule-associated protein 1 light chain 3B was lower in CC patients relative to controls and non-cachectic cancer patients. Finally, the expression of autophagy-associated protein 7, lysosome-associated membrane protein 2, peroxisome proliferator-activated receptor- γ coactivator-1 α , and mitochondrial transcription factor A was unvarying among groups. In gastric cancer patients, cachexia is associated with derangements of the muscular MQC axis at several checkpoints: mitochondrial dynamics, mitochondrial tagging for disposal, and mitophagy signaling. Further investigations are needed to corroborate these preliminary findings and determine whether MQC pathways they may be targeted for interventions.

ESTIMATION OF CAUSAL EFFECTS ON HAZARDS OF MAJOR AGE-RELATED DISEASES USING MENDELIAN RANDOMIZATION

L. He, I. Culminkaya, Y. Loika, K. Arbeev, O. Bagley, A.I. Yashin, A. Kulminski, *Social Science Research Institute, Duke University, Durham, North Carolina*

Elucidating the causal effects of common intermediate phenotypes on the onset of age-related diseases such

as cardiovascular diseases (CVD), diabetes mellitus (DM), Alzheimer's disease and cancer is indispensable for developing prevention and intervention procedures. We conducted a Mendelian randomization study to investigate the causal effects of cardiovascular risk factors including body mass index (BMI), systolic blood pressure (SBP), and lipids on the age-of-onset of various age-related diseases using three large-scale longitudinal cohorts (ARIC, CHS and MESA). We performed a two-stage time-to-event analyses using additive hazard models followed by a meta-analysis using a fixed-effects model, in which we constructed weighted polygenic scores based on genetic markers from previously reported genome-wide association studies as instrumental variables to estimate the causal effects. Our results show that elevated BMI at the baseline increases the hazard of stroke with a meta-analysis p-value of 1.82e-02 (beta=3.11e-04, i.e., one unit increase of BMI is associated with 0.311 extra cases per 1,000 person years). Raised SBP significantly increases the hazards of coronary heart diseases (beta=3.66e-04, p=1.44e-03) and CVD (beta=4.17e-04, p=2.51e-02). We confirm that the association between low-density lipoprotein cholesterol and onset of Alzheimer's disease is due to the pleiotropic effect in *APOE*. Surprisingly, we observe that triglycerides have a significant negative causal effect on the hazard of DM consistently across the three cohorts (beta=-1.88e-05, p=9.93e-03). These findings have important implications in guiding effective intervention strategies to reduce the incidence of these diseases.

INFLUENCE OF ACE INHIBITORS ON FRAILTY AND CARDIAC FUNCTION IN MIDDLE-AGED FEMALE C57BL/6 MICE

A.E. Kane, K. Keller, S.E. Howlett, *Pharmacology, Dalhousie University, Halifax, Nova Scotia, Canada*

ACE inhibitors improve exercise capacity in older adults without cardiovascular disease and in aged rodents. We hypothesized that chronic ACE inhibitor treatment may attenuate frailty through changes in cardiac function. Female C57BL/6 mice (12 months) were given enalapril (40 mg/kg/day; n=10) or control (n=10) for 3 months. Frailty was quantified with the mouse clinical frailty index (FI). Blood pressure (BP) was measured with a tail-cuff and *in vivo* cardiac function was measured using echocardiography. Cardiomyocytes were isolated for field-stimulation and voltage clamp experiments (2 Hz). FI scores were significantly lower in the enalapril group when compared to control mice (0.14 \pm 0.01 vs 0.21 \pm 0.03, p<0.05) after 3 months. BP, heart structure and contractile function were not significantly different between the enalapril and control groups. Field stimulation experiments showed that enalapril treatment increased cell shortening (1.6 \pm 0.2 vs 3.0 \pm 0.5 %, p<0.001), velocity-to-peak contraction (0.068 \pm 0.005 vs 0.133 \pm 0.016 μ m/ms, p<0.001) and $\frac{1}{2}$ relaxation (0.044 \pm 0.005 vs 0.100 \pm 0.016 μ m/ms, p<0.001), with no change in underlying calcium transients. Under voltage clamp conditions both calcium transients (37.6 \pm 3.2 vs 49.0 \pm 3.9 nM, p<0.05) and contractions (5.7 \pm 0.7 vs 8.9 \pm 0.9 %, p<0.05) were increased by enalapril treatment. Calcium current and sarcoplasmic reticulum (SR) calcium content were unchanged. These results show that enalapril attenuates frailty in middle-aged animals, even in

the absence of cardiovascular disease, and suggest that ACE inhibitor treatment may increase calcium release from the SR.

SARCOPENIA AND MORTALITY IN COMMUNITY-DWELLING ELDERLY INDIVIDUALS IN RIO DE JANEIRO, BRAZIL

V.G. Moreira, J.S. Nascimento, R.A. Lourenço, *Internal Medicina, Universidade do Estado do Rio de Janeiro, Rio de Janeiro, Rio de Janeiro, Brazil*

Sarcopenia is a health problem related to aging and changes in body composition, and are associated with poor prognosis for several clinical outcomes. The European Working Group (EWGSOP) define sarcopenia as loss of muscle mass, plus low muscle strength and/or low physical performance. The aim of this study was to determine the association of sarcopenia and mortality in elderly. The sample was composed by 745 community-dwelling individuals, 65 years old and older, living in Rio de Janeiro, Brazil, who participated in FIBRA study. Their health habits, functional capacity, and anthropometric measures were analyzed. The present study diagnosed sarcopenia assessing usual gait speed, grip strength and muscle mass measured through anthropometry. Other covariates were assessed in order to test the independent association of sarcopenia with mortality. 70.3% were female, 61.9% Caucasian; average age: 76.6 (SD±6.9) years. In total, 222 individuals died during the seven years of follow-up (25.0%). Univariate analyses, Kaplan-Meier curves and log-rank test were significantly associated with mortality from sarcopenia ($p < 0.001$). However, in cox-regression multivariate model, after adjustment for other variables, only age, Instrumental Activities of Daily Living and health self-perception were associated with mortality [OR: 9.4 (CI95% 3.6–24.2; $p < 0.001$); 1.7 (CI95% 1.01–3.1; $p = 0.043$); 3.1 (CI95% 1.26–7.59; $p = 0.013$), respectively. In conclusion, in the present study sarcopenia was not associated with mortality.

METABOLIC BIOSIGNATURES OF FRAILITY IN AN ELDERLY SPANISH POPULATION

D. Monleon¹, C. Borrás², F. Garcia-Garcia³, A. Pellin-Carcelen², M. Ingles², M. Dromant², J. Viña², *1. Health Research Institute INCLIVA, Valencia, Spain, 2. University of Valencia, Valencia, Spain, 3. Hospital Virgen del Valle, Toledo, Spain*

Increase in life expectancy actually represent an increased burden of disability. Frailty involves a decreased capacity to respond to demands because of diminishing of functional reserves and precedes disability in most of the cases. Frailty encompasses changes associated with ageing, life styles, chronic diseases and the interactions among them. Recent findings suggest that changes associated with sarcopenia and with the balance between production and use of energy may be among the most relevant factors associated with frailty. Early detection of subclinical changes is key to preventing or delaying the development of frailty. Metabolomics is the systematic study of the unique chemical fingerprints that specific cellular processes leave behind. By measuring metabolic reagents and end products, metabolomics represents a unique molecular phenotype integrating the influence of genotypes, lifestyle and environment. In the present study, we present blood serum metabolomic biosignatures

of robustness, pre-frailty and frailty in a Spanish elderly population from Toledo cohort. Poly and mono unsaturated fatty acids, branched-chain amino acids, trimethylamine and derivatives, and total creatine contribute the most to these specific biosignatures. In addition, inter-metabolites correlations in the frailty subgroup show dramatic differences with respect robustness especially in mitochondrial metabolites and lipids. Our results suggest that metabolic changes, detectable by NMR metabolomics, precede the clinical onset of frailty. This represent a robust, cheap, reproducible and rapid approach that may help in early detection of frailty, better therapeutic and preventive strategies and personalized management of the patient.

THE ROLE OF SKELETAL MUSCLE MYOSTATIN IN SARCOPENIA IN OLDER ADULTS

A.S. Ryan^{1,2}, M.C. Serra^{1,2}, O. Addison^{1,2}, *1. University of Maryland School of Medicine, Baltimore, Maryland, 2. Baltimore VA Geriatric Research, Education and Clinical Center, Baltimore, Maryland*

Myostatin is a key negative regulator of muscle mass in humans and animals, having direct and indirect influences on molecular regulators of atrophy and hypertrophy, thus may impact fitness and physical function. We have shown that myostatin is elevated in conditions of chronic disability (e.g. paretic limb of stroke). Our hypothesis is that myostatin would be elevated in older adults with sarcopenia. The purpose of this study was to examine the role of skeletal muscle myostatin in sarcopenia. Thirty-eight normal-weight to obese (BMI: 33 ± 5 kg/m², $X \pm SEM$, range 21–45 kg/m²) men ($n=21$) and women ($n=17$) aged 45–81 years underwent a VO_2 max test, DXA scan to determine appendicular lean tissue (ALM), and *vastus lateralis* muscle biopsy. Quantitative real time PCR (Q-RT-PCR) was performed using Taqman probes with 36B4 as a reference to determine myostatin mRNA expression. Rates of sarcopenia were determined using (ALM/BMI) and sarcopenia was defined as < 0.789 in men and < 0.512 in women. Subjects had low fitness (VO_2 max: 24 ± 1 ml/kg/min) and on average $41 \pm 1\%$ body fat. The prevalence of sarcopenia in this cohort was 16%. Myostatin mRNA expression tended to be lower (29%) in those without sarcopenia than those with sarcopenia (68 ± 6 vs. 96 ± 18 AU, $P=0.09$). Myostatin expression was not related to age or VO_2 max. While myostatin may be important in muscle atrophy and sarcopenia, further work could address it's implication in other aging cohorts of disability and chronic disease.

INCREASED CORTICAL POROSITY IN WOMEN WITH HIP FRACTURES

M. Lorentzon, D. Mellström, A. Nilsson, D. Sundh, *Geriatric Medicine, University of Gothenburg, Mölndal, Sweden*

Background: Hip fractures cause increased mortality and disability and consume enormous health care resources. Only 46% of hip fracture patients have osteoporosis at the total hip according to dual energy X-ray absorptiometry (DXA) measurement. Cortical porosity increases with ageing and is believed to be important for bone strength.

Objective: To investigate if older women with hip fracture have higher cortical porosity than controls and if this difference is independent of clinical risk factors and areal bone mineral density (aBMD).

Methods: From an ongoing population-based study, we identified 46 women with a prevalent x-ray verified hip fracture and 361 controls without any fracture. Areal BMD was measured with DXA. High-resolution peripheral quantitative computed tomography (HR-pQCT) was used to measure bone microstructure at the manufacturer's standard (ultradistal) site and at 14% (distal) of the tibia length.

Results: Women with a previous hip fracture had lower aBMD at the femoral neck (-11.8%) and total hip (-14.6%) as well as higher cortical porosity at the ultradistal (32.1%) and distal (29.3%) tibia than controls. In multivariable logistic regressions, with covariates (age, height, weight, smoking, physical activity, calcium intake, current treatment with bisphosphonates, oral glucocorticoids, rheumatoid arthritis, heredity for hip fracture, alcohol consumption and femoral neck aBMD), cortical porosity at the ultradistal (Odds Ratio per SD increase (95% confidence interval) 2.70 (1.84–3.95); $p < 0.001$) and distal (1.57 (1.13–2.17); $p = 0.01$) site was associated with prevalent hip fracture.

Conclusion: Cortical porosity was independently of femoral neck aBMD and clinical risk factors associated with prevalent hip fracture in older women.

AGING AGGRAVATES ALCOHOLIC LIVER INJURY AND FIBROSIS BY DOWNREGULATING HEPATIC SIRTUIN1 EXPRESSION

S. Yin^{1,2}, H. Wang^{3,2}, 1. *Anhui Provincial Hospital, Hefei, China*, 2. *NIH/NIAAA, Bethesda, Maryland*, 3. *The First Affiliated Hospital, Institute for Liver Diseases of Anhui Medical University, Hefei, China*

Alcoholic liver disease (ALD) is one of the most prevalent liver disease worldwide. The spectrum of ALD includes fatty liver, steatohepatitis, fibrosis/cirrhosis and hepatocellular carcinoma. The role of chronic ethanol consumption and aging in ALD still remain unclear. We hypothesized that aging may have an interaction effect with ethanol exposure that may down-regulates hepatic SIRT1 protein expression, inducing liver fibrosis and ALD. For our studies, these mice were fed with control or Lieber DeCarli liquid diets containing 5% ethanol for 10 days, followed by a single ethanol binge or fed up to 8 weeks, which included multiple ethanol binges. Liver injury and fibrosis were measured using histology, protein and gene-expression levels. Hepatic stellate cells and hepatocytes were isolated for *in vitro* studies. Results from liver histology from multiple binges revealed that there was more steatosis and fibrosis in the livers from ethanol-fed old mice when compared to the single binge mouse model. Results showed that the chronic ethanol feeding plus one ethanol binge, levels of hepatic protein of SIRT1 were reduced in old mice. Chronic multiple binge ethanol exposed old mice demonstrated more steatosis, neutrophil infiltration and fibrosis when compared to young mice, correlating to the characteristics of ALD. The current results suggest that aging down-regulates hepatic SIRT1 protein expression in hepatocytes from old mice, consequently inducing alcoholic liver injury and fibrosis. These findings will help us to better understand the importance of how aging and alcohol greatly affects the elderly population, and develop ways to help prevent further injury.

AGEING AND DRUG-INDUCED LIVER INJURY: INSIGHTS FROM ANIMAL STUDIES

J. Mach^{1,2,3}, A. Huizer-Pajkos^{1,3}, S. Mitchell⁴, L. Phillips¹, A.E. Kane⁷, R. de Cabo⁴, D.G. Le Couteur^{2,5,6}, S.N. Hilmer^{1,2,3}, 1. *Kolling Institute of Medical Research, Sydney, New South Wales, Australia*, 2. *University of Sydney, Sydney, New South Wales, Australia*, 3. *Royal North Shore Hospital, Sydney, New South Wales, Australia*, 4. *National Institute of Aging, Baltimore, Maryland*, 5. *Centre for Education and Research on Ageing and Anzac Research Institute, Sydney, New South Wales, Australia*, 6. *Concord Hospital, Sydney, New South Wales, Australia*, 7. *Dalhousie University, Halifax, Nova Scotia, Canada*

Elders are thought to be at increased risk of drug induced liver injury (DILI), however there is little empirical evidence to prove it. We aimed to determine the effect of ageing on DILI in male Fischer 344 rats. Young and old rats were treated via intraperitoneal injection with toxic regimens of either acetaminophen (single dose of 800mg/kg) or isoniazid (4 doses daily; low dose regimen: 100, 70, 70, 70mg/kg or high dose regimen: 150, 105, 105, 105mg/kg (3 hours apart) over 2 days) or vehicle controls. After euthanasia, sera and livers were collected for testing. With acetaminophen treatment, higher serum drug levels were observed in old than in young animals, but conversely serum hepatotoxicity markers were elevated in young animals but not old. Hepatic DNA fragmentation was increased in old animals treated with acetaminophen when compared to all other groups. Similarly, with isoniazid treatment, higher levels of hepatotoxic metabolites were observed in old than in young animals, and serum hepatotoxicity markers were elevated in young animals but not in old. Compared to age-matched controls, with isoniazid treatment there was a trend towards increased necrosis in young rats and increased hepatic microvesicular steatosis in old. Toxic isoniazid insults did not cause hepatic DNA fragmentation. In both studies, the activity of hepatic CYP2E1, which generates toxic intermediates from acetaminophen and isoniazid, was significantly reduced in old animals compared to young. Old age affects the pattern and risk of DILI from acetaminophen and isoniazid differently and age-related changes in metabolism probably contribute.

SESSION 845 (POSTER)

ELDER ABUSE, NEGLECT, AND EXPLOITATION

EVALUATING OUTCOMES OF ADULT PROTECTIVE SERVICES IN THE UNITED STATES: WHAT DO WE KNOW?

J.S. Ernst¹, A.E. Navarro², 1. *Wayne State University School of Social Work, Detroit, Michigan*, 2. *University of Southern California School of Medicine, Alhambra, California*

To provide baseline knowledge to aid in development of measurable outcomes and promote program evaluation in Adult Protective Services (APS), a review of quantitative and qualitative research published between 2005 and 2015 was conducted to examine outcomes of APS interventions in the United States. Balancing the need to protect clients with upholding their self-determination, APS investigates reports of abuse, neglect, exploitation, and self-neglect of vulnerable

older adults and adults with disabilities, assesses situations, and offers services to reduce risk for abuse, neglect, and exploitation. In spite of APS's vital role in protecting vulnerable adults, evaluation research that uses clearly defined and operationalized outcomes, which are necessary to examine program impact, is scarce. In addition to risk reduction and increased client safety, other possible outcomes of APS intervention include upholding self-determination for clients capable of making informed decisions. Thirteen published studies met the criteria. The majority were retrospective case reviews that relied on case records, data collected by APS workers, and case management systems. Eight studies used measures of risk reduction or continuation of abuse. Others identified outcomes related to case processes and included investigation outcomes (confirmed or not confirmed), recidivism, provision and refusal of services, and referral to the court or criminal justice system. Based on these findings and principles of program evaluation that encourage use of program theory and logic models, recommendations are provided that aim to encourage APS research that determines what works, for whom, and under what conditions.

ADVANCING POLICY AND PRACTICE IN ELDER ABUSE: MESSAGE FROM STAKEHOLDERS IN HONG KONG

S. Lo¹, M.R. Nolan², B. Penhale³, 1. *The Hong Kong Polytechnic University, Hong Kong, Hong Kong, Hong Kong*, 2. *Sheffield University, Sheffield, Sheffield, United Kingdom*, 3. *University of East Anglia, Norwich, Norwich, United Kingdom*

Elder abuse poses significant threats to older persons' well-being: physically, psychologically and socially, yet the phenomenon has received relatively little attention in Hong Kong despite its ageing population. Any measures intended to address this issue are more likely to be effective if they are informed by the perspectives of both older people and practitioners.

A constructivist grounded theory approach was adopted for this study involving personal interviews and 3 focus groups with seniors, community-nurses and social workers. Participants were initially selected purposively and then theoretical sampling was employed as categories emerged from the data analysis. Data collection ceased when saturation was reached.

Implications for policy and practice changes were derived: 1) The ways in which financial assistance and housing policies currently operate were found to be insensitive to older recipients' dignity and unresponsive to their concerns thereby potentially increasing their risk of being abused; 2) Filial piety appears to be declining and policy-makers need to seriously consider if legislation is needed to ensure that older peoples' needs are met; 3) New policies are needed that enhance the integration of seniors into society and family life; and 4) The older population, families and practitioners need more education and awareness about elder abuse if preventative measures are to be put in place.

The perspectives unearthed by the study are of potentially great value in the development of strategies to counter this problem, thereby helping older people to age with ever greater dignity.

PUBLIC HEALTH AND ELDER ABUSE

C. Thomas, *Committee on National Statistics, National Academies of Sciences, Engineering and Medicine, Washington, District of Columbia*

A dynamic and multidimensional conceptualization of elder abuse--its causes, manifestations, and consequences--can be grounded in a public health framework. A public health model of elder mistreatment is proposed which includes elements of public awareness (including education, training, and media campaigns), detection (processes by which relevant authorities learn that an alleged incident has taken place), and the development of laws and regulations that support intervention and treatment strategies. This model is used as a framework for assessing progress in addressing and preventing elder abuse in selected countries in five regions around the world, according to information provided by key informants in each country. Informants provided detailed information on ongoing activities in identifying and reporting instances of abuse or neglect in their countries, how official entities learn about abuse when it occurs, laws and regulations, if any, and their enforcement. A finding of the study is that in these countries the primary focus has been on promoting public awareness, and to some extent in detecting abuse after it occurs. There has been limited attention to the development of laws and regulations to address elder abuse, and insufficient enforcement of regulations already on the books. The severe consequences for health and well being of elderly victims of abuse are outlined in a review of the literature on the impact of abuse on older adults, including mortality, physical or emotional harm, and institutionalization.

THE STRUGGLE AGAINST THE ABUSE AND MISTREATMENT OF THE ELDERLY IN ISRAEL IN 2016

A. Bitchor, *Or Yehuda Academic Center College, Or Yehuda, Israel*

Surveys held in Israel in 2015 by the Central Bureau of Statistics and the Public Security Ministry found that the number of elderly Israelis – defined as age 65 and over – suffering from violence (by a third party), abuse and mistreatment (by relatives and individuals in their immediate environment) and neglect (by caregivers, service providers, and the public and governmental systems), was higher and graver than in previous years.

Some 830,000 people were included in this national survey and over 60% expressed concern for their physical safety: They said they were afraid to be out at night, and concerned they would be mugged when collecting their monthly social security benefits. The findings also showed a growing concern among the elderly that someone in their immediate surroundings would neglect, mistreat, or abuse them. This is a phenomenon no normative society should be willing to tolerate.

This essay explores this phenomenon, and tries to determine the nature of potential assailants, and where and when they are most likely to strike against the elderly; as well as introduce the "Inverted Focus" model, that seeks to counter this phenomenon on multiple levels, with the goal of eradicating elderly abuse.

ELDER ABUSE AMONG SEXUAL MINORITY OLDER ADULTS IN THE U.S.

Z.D. Gassoumis¹, P. Nash², 1. *Leonard Davis School of Gerontology, University of Southern California, Los Angeles, California*, 2. *Swansea University, Swansea, United Kingdom*

Elder abuse is a serious concern for global public health and for the health and well-being of victimized older adults. To date, there is a paucity of research on the experience of elder abuse among those who identify as lesbian, gay, or bisexual (LGB) or who have engaged in same-sex sexual relationships (SSSRs). Older sexual minorities have been subjected to high rates of lifecourse victimization due to their sexual orientation, and certain sexual minority groups are at heightened risk of intimate partner violence; however, concepts of elder abuse are rarely explored in this population. This paper uses a U.S.-based dataset from the National Social Life, Health, and Aging Project (NSHAP; $n=3,005$) to investigate this phenomenon. Although NSHAP does not ask participants about sexual orientation, it records whether they have ever engaged in SSSRs. While this group does not wholly encompass LGB individuals, it provides initial insights into the elder abuse experiences of a sexual minority population. In total, over 1 in 10 older adults in NSHAP were victims of verbal, financial, or physical abuse. The rates of abuse for those who had engaged in SSSRs, though not significantly different from the overall population, differed qualitatively from the rates of abuse in non-SSSR individuals, both at large and within subgroups. These differences point to populations that might be appropriate targets for elder abuse education and prevention efforts and highlight the importance of collecting information on both sexual minority status and elder abuse experiences in large aging surveys.

AGE EFFECTS ON CONSUMER'S EVALUATION OF RISK AND BENEFITS IN SWEEPSTAKES SCAMS

S. Wood¹, L. Klapatch², P. Xi², M. Liu³, 1. *Psychology, Scripps College, Claremont, California*, 2. *Claremont Graduate University, Claremont, California*, 3. *U California, San Francisco, San Francisco, California*

Advance-fee fraud schemes are based on the concept that the victim will be promised a substantial benefit, such as a sweepstakes winning, but must pay a fee before the victim can receive the benefit. With the global population growing older, sweepstakes scammers have been targeting older adults' wealth, and the scam becomes one of the top 10 senior scams. A laboratory-based approach was developed to study the very initial steps of the advance fee scam with an emphasis on evaluation of risk and benefit assessment. Three-hundred-and-two adults (age range 18–83), recruited on Amazon's Mechanical Turk, were randomly assigned into one of the three conditions (low, medium, or high activation fee), informed to read a lottery-winning letter, then were asked to answer some questions about its content. Overall, we found 27.2% participants indicating willingness to contact the sweepstakes company in order to "activate" the winnings. Age and activation fee amount predicted contact likelihood in the same regression model, such that older adults were less likely to comply ($b=-.032$, $p=.001$), while high activation fee deterred participants from calling ($b=-.384$, $p=.010$). However, both effects disappeared when

quantitative ratings of risk and benefits were entered into the model. Assessment of higher risk discouraged contact ($b=-.583$, $p<.001$), but higher benefit assessment was associated with contact ($b=.407$, $p<.001$). Participants were often aware that many of these pitches are scams, but unaware that the main goal of the scammers is to obtain contact information for future requests.

SCREENING AND ASSESSMENT OF ELDER ABUSE: AN EVALUATION OF NICE TOOLS

L. McDonald¹, A. Hussain¹, R.M. Mirza¹, E. Relyea¹, M. Beaulieu², G.M. Gutman³, C. Klinger⁴, B. MacDonald⁴, 1. *Social Work, University of Toronto, Toronto, Ontario, Canada*, 2. *Universite de Sherbrooke, Montreal, Quebec, Canada*, 3. *Simon Fraser University, Vancouver, British Columbia, Canada*, 4. *Institute for Life Course and Aging, University of Toronto, Toronto, Ontario, Canada*

Elder abuse (EA) has various dimensions, including physical, sexual and psychological abuse, which make screening and assessment challenging. As part of a larger project, the National Initiative for the Care of the Elderly (NICE) developed evidence-based tools to address these challenges. However, as no formal evaluation of these instruments has been conducted, the current study examines and evaluates the impact of NICE EA tools. Participants with NICE membership were randomly sampled ($n = 438$: 79.7% practitioners; 7.5% students; 4.5% older adults/informal caregivers; and 8.2% other) and asked to complete a telephone survey to assess the instrumental impact (use of tools), conceptual impact (impact of knowledge in tools), and symbolic impact (whether the tools confirmed actions/decisions) of the tools. Of 438 participants, 74 reported using EA tools the most, with 46% of these users indicating that the tools had an instrumental impact (i.e., information in the EA tool changed their daily work practices and/or they adopted ideas/actions from the tool). Additionally, 31% indicated that the tools had a conceptual impact, as the tools increased their knowledge of EA and influenced their work practices. Finally, 45% reported the EA tools confirmed their actions at work and helped justify their decisions to co-workers and clients. These results suggest that NICE EA pocket tools have a conceptual, instrumental, and symbolic impact on improving knowledge and practices related to EA among multiple stakeholders. Screening tools, such as the ones developed by NICE, may help raise awareness to the possibility of elder abuse.

SYSTEMATIC REVIEW AND META-ANALYSIS OF ELDER ABUSE AMONG WOMEN

Y. Yon¹, C. Mikton², Z.D. Gassoumis¹, K.H. Wilber¹, 1. *Gerontology, University of Southern California, Langley, British Columbia, Canada*, 2. *World Health Organization, Geneva, Switzerland*

Elder abuse among older women is a significant problem. Developing a better understanding of the extent of the problem is an important step to violence prevention. We conducted a systematic review and meta-analysis of all existing prevalence studies to determine the extent of the abuse against older women and to disentangle the wide variations in prevalence estimates by investigating the associations

between prevalence estimates and the studies' demographic and methodological characteristics. A total of 50 studies were included in the meta-analysis. The combined prevalence for overall elder abuse in the past year was 14.1% (95% CI: 11.0–18.0). Pooled prevalence for psychological abuse was 11.8% (95% CI: 9.2–14.9%), neglect was 4.1% (95% CI: 2.7–6.3%), financial abuse was 3.8% (95% CI: 2.5–5.5%), sexual abuse was 2.2% (95% CI: 1.6–3.0%), and physical abuse was 1.9% (95% CI: 1.2–3.1%). The studies included for meta-analysis for overall abuse were heterogeneous indicating that significant differences among the prevalence estimates do exist. Significant associations were found between prevalence estimates and the following covariates: WHO regions, countries' income classification and studies' sample size. Together, these covariates explained 37% of the variance. More work is needed to understand the variation in prevalence rates and implications for prevention.

RISK AND PROTECTIVE FACTORS FOR ELDER FINANCIAL EXPLOITATION BY FAMILY POWER OF ATTORNEY AGENTS

B.A. Steinman¹, A.E. Betz-Hamilton⁶, C.R. Bolkan², C. Jasper³, M.S. Stum⁴, P.B. Teaster⁵, V. Vincenti¹, 1. *Human Development and Family Science, University of Wyoming, Laramie, Wyoming*, 2. *Washington State University, Vancouver, Washington*, 3. *University of Wisconsin, Madison, Wisconsin*, 4. *University of Minnesota, St. Paul, Minnesota*, 5. *Virginia Polytechnic Institute & State University, Blacksburg, Virginia*, 6. *Eastern Illinois University, Charleston, Illinois*

Elder Financial Exploitation (EFE) by a family member POA agent is a form of elder mistreatment perpetrated by family members appointed by an older adult to manage health care, financial decisions, or both. Survey and interview data from 60 participants compared POA agent experiences from two types of families: those with successful POA experiences absent EFE and those experiencing EFE by a POA agent. Prior to the identification of EFE, the majority of older adults experienced declines in physical and cognitive functioning; many exhibited poor financial practices prior to invoking POA authority. The majority of exploiting POA agents were financially dependent upon the older adult and exhibited narcissistic behaviors. Experiences of participating family members (typically an adult child of elder/non-perpetrator) suggested risk factors for exploitation, including an elder's declining physical and cognitive health, POA agent's financial dependence on the older adult, heightened sense of entitlement to the elder's resources, geographic proximity to the elder, and low quality family relationships and functioning. Protective factors included the POA agent's integrity and accountability and communication with family members, high levels of family functioning, and positive family relationships. Findings suggest the importance of estate planning considering personality, values, and family relationships in selecting POA agents, and inclusion of accountability and checks and balances as early as possible as well as maintenance of clear communication to all family members pertaining to the appointment and accountability of the POA agent. These findings provide insight into factors to target in needed EFE prevention and intervention efforts.

SYSTEMATIC REVIEW AND META-ANALYSIS OF ELDER ABUSE PREVALENCE

Y. Yon¹, C. Mikton², Z.D. Gassoumis¹, K.H. Wilber¹, 1. *Gerontology, University of Southern California, Langley, British Columbia, Canada*, 2. *World Health Organization, Geneva, Switzerland*

Background. Elder abuse is a public health problem and gaps remain in estimating its prevalence. We conducted a systematic review and meta-analysis with the aim to quantify the extent of the problem and to disentangle the variations in prevalence estimates by investigating the associations between prevalence estimates and the studies' demographic and methodological characteristics.

Methods. We employed a 4-step comprehensive search strategy including a 14 electronic database search to identify studies that reported elder abuse prevalence. For the analysis, we examined studies reporting abuse occurring within the past year.

Findings. Of the 38,544 studies initially identified, 52 were eligible for inclusion. These studies were geographically diverse in 28 countries. Prevalence rates for overall elder abuse were reported in 43 studies with the pooled prevalence of 15.9% (95% CI 12.8–19.5%). Pooled estimates for psychological abuse is 11.6% (95% CI: 8.1–16.3%), financial abuse was 6.8% (95% CI: 5.0–9.2%), neglect was 4.2% (95% CI: 2.1–8.1%), physical abuse was 2.6% (95% CI: 1.6–4.4%), and sexual abuse was 1.6% (95% CI: 1.1–2.2%). The studies included for meta-analysis on overall abuse were heterogeneous with significant associations between prevalence estimates and the following covariates: sample size, income classification and method of data collection. No gender difference was found in the prevalence estimates.

Interpretation. Findings showed that elder abuse is a major problem. Robust studies are absent for most regions of the world, particularly in low- and middle-income countries. Gender symmetry of abuse prevalence is discussed and intervention programs need to be focused on both genders.

FINANCIAL EXPLOITATION: LESSONS LEARNED FROM A STUDY OF PEOPLE HOLDING LASTING POWERS OF ATTORNEY

M.L. Gilhooly¹, G. Dalley¹, K.J. Gilhooly^{1,3}, P. Harries¹, M. Sullivan¹, M. Levi², 1. *Department of Clinical Sciences, Brunel University London, Uxbridge, England, United Kingdom*, 2. *Cardiff University, Cardiff, Wales, United Kingdom*, 3. *University of Hertfordshire, Hatfield, England, United Kingdom*

Financial exploitation of older and vulnerable people appears to be increasing in the UK. The aim of this study was to investigate the nature and extent of financial abuse of individuals lacking mental capacity. There were three components to the study, (1) a case study of a London borough, (2) an online survey and (3) an analysis of cases referred to the Court of Protection in which people holding lasting powers of attorney were thought to have been financially exploiting the donor. This paper is concerned with the third component of the study. The Court of Protection cases were obtained from public records. Sixty three cases were analysed in relation to (a) Applicant to the Court, (b) Respondent to the case, (c) Grounds for making the application, (c) Object of the application – e.g. appointment of deputy; revocation,

(d) Evidence of possible financial abuse, (e) Evidence of intra-family dispute, (f) Outcome. Triggers for suspicion of financial abuse included care home fees arrears and failure to provide personal allowance, failure to submit account to the Office of the Public Guardian, and co-mingling of funds. This paper will, in addition, describe cases. For example, a son holding a lasting power of attorney not only gifted himself large sums of his mother's money, but charged her estate £400 every time he visited. The senior judge hearing the case made his view clear by describing this behaviour as 'repugnant'.

NEW FORMS OF ELDER ABUSE FROM RURAL AND URBAN ZAMBIA

I. Kabelenga^{1,3}, R.K. Sishimba², 1. *University of Zambia, Lusaka, Zambia*, 2. *Senior Citizens Association of Zambia (SCAZ), Lusaka, Zambia*, 3. *University of Lapland, Rovaniemi, Finland*

Aim: The aim of this paper is to add new forms of elder abuse to the existing scientific literature on elder abuse.

Philosophical foundation of the study: Social constructionism guided this study.

Methodology: The study utilized qualitative research that included 31 one-on-one in-depth interviews and 7 focus group discussions. This was undertaken for the period of five months (August to December, 2014) in two districts of Zambia – one rural and one urban with community leaders. The data were analyzed using a grounded theory methodology to determine recurring themes that were mentioned by the informants.

Results: The study results indicate that besides physical, financial/material, verbal and neglect abuses as widely shown in the available literature on elder abuse, two additional types of elder abuse are also taking place in Zambia. These are spiritual abuse and political abuse.

Conclusions: The study concludes that elder abuse does not exist in six many forms as widely reported in world reports such as those produced by World Health Organization. Rather, it exists in many forms which differ from society to society. On the basis of this, the study argues that besides the common typologies of elder abuse that have dominated existing literature, two typologies of elder abuse should be added to the existing literature. These are spiritual abuse and political abuse. This is because they suggest new ways of thinking about the problem of elder abuse.

RECENT DEVELOPMENT OF OMBUDSMAN PROGRAMMES FOR THE ELDERLY CARE FACILITIES IN KOREA

J. Kim², S. Lee¹, T. Park¹, K. Kwon¹, 1. *Seoul Cyber University, Dept. of Social Welfare, Seoul, Korea (the Republic of)*, 2. *Catholic University of Pusan, Busan, Korea (the Republic of)*

Recently, the Ombudsman program has been introduced to prevent elder abuse in elderly care facilities. However, the program has no coercive powers in Korea. As a result, many care workers and elderly people witness and experience elder abuse cases (mainly verbal aggression, ignoring requests and threatening communication) in the long term care facilities. Thus, this study is to review the policy development of

Ombudsman programs in long term care facilities in East-Asia countries. Secondly, this paper investigates care workers' experiences of Ombudsman programmes and elder abuse cases where some elderly care facilities have already operated the program. Thirdly, the research examines the Ombudsman system in terms of official approval, mandatory implementation, the right of investigation, professionalism, and the functions of coordination, guidance and recommendation. To collect data to develop the Ombudsman programs we conducted FGIs, using the Delphi technique, with 45 experts in geriatric social work institutions and long term care facilities. Finally, this research suggests that 'Elderly Ombudsman Agency', as a state organization, should be established to investigate elder abuse screening affairs.

WHEN IT'S FAMILY: EXAMINING ENTITLEMENT AS A RISK FACTOR FOR ELDER FINANCIAL EXPLOITATION

M.S. Stum¹, R. Kilderia^{1,3}, M. Peterson², 1. *Family Social Science, University of Minnesota, St. Paul, Minnesota*, 2. *Minnesota Elder Justice Center, St. Paul, Minnesota*, 3. *School of Social Work, St. Paul, Minnesota*

Elder family financial exploitation (EFFE) is widely recognized as the fastest growing and most common form of elder abuse internationally. A sense of entitlement to an elder's resources has been identified as a motivator for exploitation, but remains relatively unexplored. This study contributes needed conceptual and practical clarity and understanding of entitlement within the context of diverse intergenerational families and societies. An innovative three point spectrum of entitlement norms, beliefs, and behaviors is proposed integrating concepts from social exchange and interpersonal social justice theories, and findings from a systematic review of empirically based international EFFE literature (2000+). At one end of the spectrum, normative entitlement includes a range of intergenerational resource sharing and exchange obligations and expectations (money, time, housing). On the other end of the spectrum, exploitative entitlement includes identifiable financial exploitative behaviors, and narcissistic personality disorders. The middle of the spectrum includes justified entitlement, when entitlement beliefs serve as excuses for misuse of resources and inappropriate behaviors. Two common justification examples include feeling entitled to an inheritance (just taking what's mine now), and to compensation for caregiving or other types of support (it's only fair). The entitlement spectrum can be used to help conceptually inform EFFE research agendas, train practitioners, and develop family-focused prevention tools for assessing a range of entitlement norms and beliefs during estate planning processes. Policy implications include impacting entitlement social norms and practices (e.g. remove incentives for a sense of inheritance entitlement in United States Uniform Probate Code and state statutes).

ELDER FINANCIAL EXPLOITATION: PERSPECTIVE FROM THE FINANCIAL SERVICES INDUSTRY

S. Skees, M. Tucker, *Wells Fargo Advisors, St. Louis, Missouri*

The Elder Client Initiatives (ECI) team at Wells Fargo Advisors (WFA) is dedicated to addressing suspected

financial abuse of WFA clients in all 50 states who are older adults (age 60+) and vulnerable adults (18–59). It is an interdisciplinary team with backgrounds in law, social work and risk management. The ECI team determines whether cases are appropriate for referral to Adult Protective Services and/or other authorities.

Much of the current research on elder financial abuse is based on self-reported measures. The nature of the ECI team has allowed for the collection of a unique dataset containing over 2,000 cases. Three Chi Square tests were conducted. The analysis of case type versus gender and case type versus assets under management yielded no statistically significant results. However, in the third analysis of case type and age, statistically significant results were found. Results revealed that those WFA clients who were referred to the team who were between the ages of 60–69, while less likely to be victims of exploitation by their family members, were more likely to be victims of scammers. Individuals between 70–79 were more likely to be referred concerns about diminished capacity, and those between 80–89 were more likely to be victims of exploitation by a family member.

These findings shed light on the complex issues facing the financial services industry. The findings of this research will inform further research efforts as ECI continues to engage in evidence-informed practice and to coordinate efforts with aging services providers.

A STUDY OF DIFFERENCES IN PERCEPTIONS OF ELDER ABUSE AMONG PROFESSIONAL STAFF MEMBERS

A. Katsumata¹, N. Tsukada², 1. *Rehabilitation Institution, Tokyo, Japan*, 2. *Nihon University, Tokyo, Japan*

The purpose of this study was to examine differences in perceptions of elder abuse among older couples between professional staff at the Community Comprehensive Support Centers (CGSCs) and DV counseling staff at DV Support Centers and Women's Support Centers and to identify effective supports for the victims of elder abuse. Two datasets collected in 2010 were merged and used for this study: (1) Data for professional staff were collected from nationwide survey of 4,042 CGSCs where a structured questionnaire survey was provided to a randomly selected 1,282 CGSCs (N=621). (2) Data for DV staff were collected from nationwide survey where a structured questionnaire survey was provided to all 358 DV Support and Women's Support Centers (N=237). The responses to the same 10 questions were analyzed. Preliminary analyses revealed statistically significant differences in perceived causes of elder abuse and important supports to solve elder abuse among the two different sets of staff. For example, elder abuse professional staff tend to see causes of elder abuse among older couples as "caregiving stress," "victims' personality," and "dementia of the victims," on the other hand, DV staff perceived causes of elder abuse as "abusers' tendency to control with power." Moreover, while 74.5% of the DV staff felt coordination among the two staff was important, 25.5% of DV support staff did so. Thus, it is imperative that both professional staff recognize differences in their perceptions and that their knowledge and resources through coordination be exchanged to solve elder abuse cases effectively and efficiently

SESSION 850 (POSTER)

END OF LIFE

CARE NEEDS BY END-OF-LIFE STAGE AMONG NON-CANCER PATIENTS AT HOME

J. Lee¹, H. Lee¹, Y. Park², J. Jang², J. Choi², K. Lim², W. Choi², J. Lee¹, 1. *The Catholic University of Korea, Seoul, Korea (the Republic of)*, 2. *Seoul St. Mary Hospital, Seoul, Korea (the Republic of)*

This study aimed to explore multidimensional care needs for non-cancer patients by end of life stage and palliative performance scale (PPS). A retrospective study design was used. Home care nurses were asked to review medical and nursing records and to respond structured questionnaire. 115 participants who were at the ages of 40 or over, continuously received home care nursing throughout stable (between the beginning stage and one week before the death) and near death (one week before to the death) at Seoul St. Mary Hospital in Korea, and died from September 1, 2014 to December 31, 2015 were analyzed. Care needs for 'coordination among family or relatives' and 'support for fundamental needs' areas were significantly more important in the stable stage than in the near death stage. The 'Loss, grief care' area was significantly more important in the near death stage than in the stable stage. As patient's initial PPS was lower, the level of importance for care needs was higher especially on 'management of physical symptoms' and 'psychological support' areas in the stable stage and 'coordination among family or relatives' area in both stages. Future palliative intervention need to develop based on patients-centered assessment of PPS and care needs to ensure quality of life for non-cancer patients who receive home care. Moreover health care professionals should focus on continuous and holistic tailoring end of life care through advance care planning for non-cancer patients.

PALLIATIVE CARE FOR TERMINALLY ILL OLDER PATIENTS IN NORTHEAST THAILAND

A. Nuttamonwarakul, *Institute of Geriatric Medicine, Department of Medical Services, Nonthaburi, Thailand*

Aim: The aim of this study was to explore the existing palliative care of terminally ill older patients in Northeast of Thailand.

Material and methods: The study consisted of a cross-sectional quantitative with questionnaire to survey in the government hospitals with over of 120 beds and qualitative interviews with a group of practitioners discussion to explore care model of terminally ill older patients. Include the review of current situation on terminal care of Thai elderly from the literatures.

Results: In quantitative interviews, the total number of completed and returned questionnaires showed 43% suffer from cancer, 57% suffer from non-cancer, 44% die in hospital and 56% discharge to home. Percentages and mean values were assessed using the Fisher's exact test to determine the correlation of variables. Participants in qualitative interviews using the content analysis, the work was in Northeast areas. In Northeast of Thailand, palliative care of

older patients are part of regular health care in the hospitals. Their services cover physical comfort, psychological wellbeing, social functioning and spiritual wellbeing. In community, the current results showed both formal and informal care of terminally ill older patients.

Conclusions: The findings from the present study showed difference types of palliative care for terminally ill older patients between hospital-based and home-based care. However, home care was proper in the elderly patients with end stage who were in strong community and had networking in each level of the hospital.

RESULTS FROM A SCOPING REVIEW ON END-OF-LIFE NEEDS OF LGBT OLDER ADULTS

A. Stinchcombe^{5,6,1}, J. Smallbone², K. Kortess-Miller^{3,4}, K. Wilson², 1. *School of Psychology, University of Ottawa, Ottawa, Ontario, Canada*, 2. *Adult Development and Aging within the Department of Family Relations & Applied Nutrition, University of Guelph, Guelph, Ontario, Canada*, 3. *Centre for Education and Research on Aging and Health (CERAH), Lakehead University, Thunder Bay, Ontario, Canada*, 4. *School of Social Work, Lakehead University, Thunder Bay, Ontario, Canada*, 5. *Department of Health Sciences, Lakehead University, Thunder Bay, Ontario, Canada*, 6. *International Longevity Centre (Canada), Ottawa, Ontario, Canada*

Lesbian, gay, bisexual, and transgender (LGBT) older adults face a number of challenges with respect to access to healthcare especially towards end-of-life. Using a systematic search and scoping review approach, the purpose of this review was to determine the healthcare needs of LGBT older adults nearing end-of-life as well as the factors that contribute to a good death experience among older adults who identify as LGBT. A systematic search of electronic databases for articles published between 2005 and 2016 as well as screening for relevance resulted in 25 results. The data were charted and grouped according to the themes of: social support and chosen family, intimacy, health status, fear of discrimination and lack of trust, lack of knowledge and preparedness, and cultural competence in the healthcare system. The results suggest a role for health and social service workers in contributing to a positive care experience for LGBT older adults by becoming knowledgeable about the unique needs of this population and being unassuming and accepting of individuals' sexuality.

STATUS OF IMPLEMENTING GRIEF CARE IN NURSING HOMES IN JAPAN

N. Morisaki, *Himeji University, Himeji, Hyogo, Japan*

The purpose of this research was to clarify the implementation status of grief care in nursing homes in Japan.

The subjects of this research were nurses who work in nursing home in Japan. It was investigated using a questionnaire. The question items included sex, age, years of nursing experience, participation in grief care study sessions, and implementation status of the grief care.

Responses were obtained from 120 nurses. The breakdown of subjects' sexes was 5.0% men and 95.0% women. Those in their 40s and 50s comprised 67.5%. Those with 10 to 20 years of nursing experience comprised 33.3%.

Of respondents, 54.2% of nurses had participated in grief care study sessions. Regarding implementation of grief care, respondents answered in the following ways: "The mental process of mourning is explained to the family of the person who passed away" 50.0%, "When the family of the deceased person leaves the nursing home, words of consolation are offered" 96.4%, "I attend the funeral" 37.8%, "Spiritual care is given to the family thought to have elevated need for it" 11.9%, "I feel a sense of achievement in the current status of grief care" 67.0%, and "It is necessary to perform a family's mental care as an organization" 76.9%.

The result of the analysis shows that "The mental process of mourning is explained to the family" was related to age ($p < 0.01$), and "I feel a sense of achievement in the current status of grief care" was related to participation in grief care study sessions ($p < 0.05$).

AGREEMENT ON SEVERITY OF DEMENTIA AND PRESENCE OF ADVANCE CARE PLAN IN NURSING HOME RESIDENTS

N.J. Van Den Noortgate^{1,2}, R. Piers¹, R. Botterman¹, L. Van den Block², 1. *Ghent University, Ghent, Belgium*, 2. *End-of-Life Care Research VUB-UGent, Brussels, Belgium*

Background: Dementia and especially the stage of dementia is often underdiagnosed. The white paper on dementia of the European Association on Palliative Care identified the recognition of severe dementia as a pitfall for high quality palliative care.

Methodology: Data from a retrospective cross-sectional study at 241 deceased residents in a random clustered sample of 134 NH in Flanders. Clinical judgment of nurses ($n=228$) and physicians ($n=127$) as well as the Global Deterioration Scale (GDS) and Cognitive Performance Scale (CPS) was investigated. Analyses were made using SPSS version 21.

Results: Nurses were more aware of the diagnosis of dementia than physicians (OR = 5,39; CI: 1.89–15.30). There was a significant correlation between the GDS stage 7 and clinical judgement of the nurse ($r=0.76$, CI: 0.69–0.83) and the physician ($r=0.64$, CI: 0.51–0.76). The correlation between nurses and physicians regarding the stage of dementia was 0.42 ($p < 0,001$) at admission and 0,23 ($p < 0,050$) at death. Care planning was done with 18.7% of the residents and with 70.1% of the relatives. There was no significant correlation between the agreement on the stage of dementia and the presence of an advance care plan.

Conclusion: The stage of dementia is not always recognized by physicians visiting nursing home residents resulting in a low agreement between nurses and physicians on the stage of dementia. The agreement on the stage of dementia seems not to be related with the presence of a care plan at the end of life.

SPEECH-LANGUAGE PATHOLOGISTS' VIEWS ABOUT ASPIRATION RISK AND FEEDING IN ADVANCED DEMENTIA

C. Berkman¹, C. Vitale², 1. *Graduate School of Social Service, Fordham University, New York, New York*, 2. *University of Michigan, Ann Arbor, Michigan*

Recent dementia practice guidelines recommend against feeding tubes and use of thickened liquids in patients with

advanced dementia. Speech-language pathologists (SLPs) often evaluate swallowing problems in such patients. The study aim was to characterize circumstances under which SLPs recommend continued oral feeding in patients with advanced dementia at high risk of aspiration. A national probability sample ($n=731$) completed a mail survey. Participants who responded there were circumstances in which they recommend oral feeding despite high aspiration risk ($N=509$, 70.0%) were asked to describe the circumstances under which they do this. Two main categories of reasons were given: 1) patient or family wishes; and 2) SLP judgment. Reasons in the first category were: patient previously expressed preference to continue eating; patient has advance directive opposing tube feeding; family opposes tube feeding and/or wants to feed patient; family understands risks involved and/or is willing to be educated about safe diet and swallow guidelines. Reasons in the second category included: patient's medical status makes him/her a good candidate for oral feeding; patient is at the end of life and safety is not a major concern; reasonable risk if specified protocol is followed and staff are trained in safe feeding; pleasure of feeding maximizes quality of life; family understands risks of feeding; patient is a poor candidate for feeding tube; consulting physician approves. Continued education about palliative approaches, including comfort feeding, avoidance of long-term use of thickened liquids and tube feeding in advanced dementia is needed to increase use of evidence-based practices by SLPs.

THE MEANING OF EXISTENTIAL LONELINESS AS NARRATED BY FRAIL OLDER PEOPLE

M. Sjberg^{1,3}, I. Beck^{1,2}, B. Rasmussen^{2,4}, A. Edberg¹, 1. Department of Health and Society, Kristianstad University, Kristianstad, Sweden, 2. The Institute for Palliative Care, Lund University and Region Skåne, Lund, Sweden, 3. The Faculty of Health and Society, Department of Care Science, Malmö University, Malmö, Sweden, 4. The Faculty of Medicine, Department for Health Sciences, Lund University, Lund, Sweden

Aging often bring about several losses, such as loss of bodily functions but also losses of significant others who pass away. Older people being in the last period in life are particularly vulnerable as they often live with complex symptoms and problems and are dependent on others. Existential loneliness, a deeper sense of loneliness, seems to occur in relation to threatening life events and losses, but there is still limited knowledge about frail old people's experience of existential loneliness. The aim of the study was to illuminate the lived experience of existential loneliness as narrated by frail old people. The study had a qualitative descriptive design based on 21 interviews with persons 75 years and older receiving long-term care and service, using a phenomenological hermeneutical analysis. The interviews were rich of narratives about situations that was connected with a deep feeling of loneliness. The findings showed that existential loneliness meant Being trapped in the own body, Not being able to share, Being invisible, Lacking purpose and meaning and a Longing for serenity. The findings are important in order to highlight older people's existential needs and to guide health professionals to discover and encounter existential loneliness among their patients.

ADVANCE CARE PLANNING: PSYCHOSOCIAL TRAINING TARGETS TO ENHANCE END-OF-LIFE COMMUNICATION

B.A. Bensadon, *Integrated Medical Sciences, Charles E Schmidt College of Medicine, Florida Atlantic University, Boca Raton, Florida*

The urgent need to improve the quality of death and dying in America is well documented. Historically, physicians have "learned" how to approach these topics on their own, often as senior medical students or interns. Advance care planning (ACP) has been offered as a potential solution but related physician communication is not yet standard in terms of frequency or optimal in terms of quality. While the Centers for Medicare and Medicaid have recently approved financial reimbursement of ACP discussion, related training remains rare, highly variable, and institution-specific, causing some to warn the nation has put the proverbial *cart before the horse*.

To evaluate ACP training needs, 3rd year medical students and 1st year medical residents completed a survey measuring their personal experiences, comfort level, and self-efficacy—all psychosocial factors-- relevant to ACP communication. Data from 120 surveys (49 medical students, 71 interns) were analyzed. Student and intern responses were similar. Less than half ($n = 51$) of respondents knew whether their parents had advance directives and only 8 reported completing their own. 87 believed physicians must *always* inform patients of limited prognoses (< 6 months) but only 14 believed this occurs. Frequency of prior experience delivering bad news to patients was significantly correlated with their comfort level doing so ($r = .48$, $p < .001$) and their confidence in discussing end-of-life (EOL) care preferences ($r = .37$, $p < .001$). Results suggest experience discussing ACP and EOL increases learners' comfort and confidence, and thus may enhance their skill in such communication. Related biopsychosocial training is imperative.

MEDICAL INTERVENTIONS AND PALLIATIVE CARE: WHAT TO DECIDE IN ADVANCED DEMENTIA?

A. Loizeau¹, S. Eicher¹, N. Theill¹, M. Martin^{2,1}, F. Riese^{3,2,1}, 1. University of Zurich, Center for Gerontology, Zurich, Switzerland, 2. University of Zurich, University Research Priority Program 'Dynamics of Healthy Aging', Zurich, Switzerland, 3. Psychiatric University Hospital Zurich, Division of Psychiatry Research and Psychogeriatric Medicine, Zurich, Switzerland

About two-thirds of people with dementia die from pneumonia and one-third from dehydration. The DemFACTS study aimed to develop and test decision supports called fact boxes, in order to inform decision-makers, who have to make burdensome treatment decisions at the end-of-life of people with dementia and either pneumonia or insufficient fluid intake.

The study employed a randomized, controlled, pre-/post-intervention design. Relatives of people with dementia ($n = 103$), professional proxies ($n = 77$) and physicians ($n = 74$) evaluated the newly developed fact boxes. At pre-test, participants were asked to make two fictional decisions concerning burdensome medical interventions in advanced dementia based on case vignettes. Four weeks later, at post-test, the intervention group received two fact boxes in addition to the two case vignettes, whereas the control group

only received the case vignettes. The fact boxes' effect on decisional conflicts (primary outcome), additional decision outcomes, knowledge transfer, and the appropriateness of the fact boxes (secondary outcomes) were assessed. Notably, an expected pre-post reduction in decisional conflicts constituted the central hypothesis of this study.

The fact boxes could reduce the decision-makers' decisional conflicts and enable them to better understand the treatment decisions. Improving knowledge transfer in palliative care decision-making could have a major impact on how decision-making aids in this field will be shaped in the future.

ASSOCIATIONS BETWEEN TIMING OF PALLIATIVE CARE CONSULTS AND FAMILY EVALUATION OF CARE AMONG VETERANS

M. McDarby^{2,3,1}, J. Carpenter^{2,3}, M.T. Ersek^{2,3}, J. Thorpe^{2,4}, D. Smith^{2,3}, M. Johnson^{2,3}, 1. *Washington University in St. Louis, Department of Clinical Psychology, Clayton, Missouri*, 2. *Corporal Michael J. Crescenz VA Medical Center, Philadelphia, Pennsylvania*, 3. *University of Pennsylvania School of Nursing, Philadelphia, Pennsylvania*, 4. *University of Pittsburgh School of Pharmacy, Pittsburgh, Pennsylvania*

Palliative care consultations (PCC) improve end-of-life (EOL) care but often occur late in an illness trajectory. There is limited evidence about the optimal timing of PCC to enhance patient outcomes. The purpose of this analysis was to examine the associations between PCC timing and bereaved families' evaluation of care in the last 30 days of life. The retrospective, observational analysis included 5,592 patients whose first PCC occurred before admission to and death in a Veterans Administration (VA) inpatient hospice unit. Data were collected between October 2011 and September 2014. Outcomes included an overall rating of care and three factor scores (Respectful Care and Communication, Emotional/Spiritual Support, Information about Death Benefits) from the Bereaved Family Survey (BFS), a national, validated quality improvement measure used in the VA. We used multi-variate logistic regression models clustered by facility and controlled for potential confounding variables found to be associated with the outcomes. Family members of Veterans whose first PCC occurred 31–180 days prior to death were more likely to rate overall care as excellent compared with those whose PCC occurred 0–3 days prior to death (AOR=1.56; 95%CI, 1.25–1.95). Respectful Care and Communication and Emotional/Spiritual Support also were significantly higher when the first PCC occurred 31–180 days prior to the Veteran's death ($\beta = 0.53$; 95%CI, 0.29–0.76 and $\beta = 0.31$; 95%CI, 0.04–0.57, respectively). Earlier PCC is associated with greater family satisfaction with EOL care. Strategies aimed at conducting PCC earlier in life limiting illness are needed.

TIL DEATH DO US PART: THE INFLUENCE OF ONE SPOUSE'S DEATH ON THE SECOND SPOUSE'S DEATH

E. Abdoler¹, A. Kelley², K. Ornstein², L. Diaz-Ramirez¹, J. Boscardin¹, A.K. Smith¹, 1. *Medicine, University of California, San Francisco, San Francisco, California*, 2. *Mount Sinai School of Medicine, New York City, New York*

It is unknown how the medical intensity of a spouse's death impacts the widowed spouse's preparation for and intensity

of death. We examined the end-of-life experiences of spousal pairs in the Health and Retirement Study, a nationally representative (US) longitudinal survey. Measures of medical intensity were: (1) low medical intensity death (hospice for 3+ days before death); (2) high medical intensity death (ICU hospitalization during last 30 days of life); and (3) preparation for death (engagement in advance care planning [ACP]). We examined how the medical intensity of the first spouse's death affected the medical intensity of the widowed spouse's death using multivariable logistic regression, adjusted for age at death, months between spouse's deaths, year of death, gender, race/ethnicity, comorbidities, ADL dependence, education, and net worth. There were 2126 spousal pairs. Hospice use in the first spouse increased the odds of hospice use (aOR 1.63, 95% CI 1.20–2.20) and decreased the odds of ICU use (aOR 0.69, 95% CI 0.51–0.92) in the widowed spouse. However, ICU use in the first spouse increased the odds of ICU use in the widowed spouse (aOR 1.78, 95% CI 1.29–2.46) but had no effect on the widowed spouse's use of hospice. The first spouse's engagement in ACP, and not manner of death, increased the widowed spouse's odds of engaging in ACP (aOR 2.94, 95% CI 2.08–4.15). Widowed spouses tend to experience deaths with similar medical intensity to their spouses. Physician engagement in ACP and end-of-life decision-making may have impact beyond that of individual patients.

A LITERATURE REVIEW ON THE DECISION-MAKING PROCESS OF OLDER ADULTS FOR END-OF-LIFE CARE

H.K. Park, C.C. Hendrix, *Duke University, Durham, North Carolina*

The increasing number of chronically-ill older adults makes it mandatory to understand how personal values and preferences interplay in the patient's decision-making for end-of-life (EOL) care. Therefore, a systematic literature review was conducted on the process of how older adults navigate through their internal preferences and external influences in EOL decisions.

Method: The following search engines were used: ABI, CINAHL, PsycINFO, PubMed, and SocINDEX. Search terms included "terminal care", "terminally ill patients", "decision-making", "choice behavior", "process", "mechanism", and "communication". Age group 65 and above was used as a search filter. Overall, 1,324 articles were selected, of which 256 articles were duplicates. After review of titles and abstracts, 15 articles were finally selected: 4 review papers, 10 qualitative studies, and 1 pilot study.

Findings: Selected articles described the factors affecting EOL decision-making rather than the process. Studies focused on varied terminal diseases as well as aspects in EOL care such as physical, psychological, or religious support. Studies have also defined decision-making in varied ways. Majority of the studies identified concepts to describe the complexity of EOL decision-making such as "double effect of ethic principle", "moral responsibility", "cascade of decisions". The wide variability in the definition of decision-making, management preferences in EOL care, and terminal diseases in the articles reviewed made it difficult to synthesize the process in EOL decision-making for older adults.

Conclusion: Further studies are needed to explore how varied factors interplay in the decision-making process of older adults in EOL care.

MEASURING STAFF PERCEPTION OF END-OF-LIFE EXPERIENCE OF OLDER ADULTS IN LONG-TERM CARE

N. Cornally¹, A. Coffey¹, D.W. Molloy¹, R. O’Caoimh^{1,2}, R. O’Sullivan¹, C. McGlade¹, 1. *University College Cork, Cork, Ireland, Ireland*, 2. *NUI Galway, Galway, Ireland*

Background: Quality of dying and death receive far less attention than quality of life. Measuring the quality of care at end-of-life (EOL) in long-term care (LTC) is essential, to ensure high standards.

Methods: A questionnaire measuring Staff Perception of their patient’s End of Life Experience (SPELE) was developed. Content Validity (CVI) was assessed by a panel of experts and piloting was conducted with dyads of healthcare assistants (n=15) and nurses (n=15).

Results: The SPELE captures facets of the quality of the death and dying experience from healthcare staff’s perspective. Good group inter-rater reliability was observed among subscales. One exception was the pain and symptom experience scale. Kappa values showed little agreement between nurses and healthcare assistants for certain symptoms, including pain.

Conclusion: Further testing of the questionnaire is underway in a large multi-centre randomised control trial in Ireland. To date the tool is described as a useful mechanism to enable researchers and clinicians to explore quality of care at EOL.

SESSION 855 (POSTER)

FALLS I

SLEEP APNEA, FALLS AND SARCOPENIA IN OLDER ADULTS: PRELIMINARY RESULTS FROM FALL-AGING- SLEEP STUDY

A. Monti¹, M. Doulazmi, A. Breining⁴, V. Nguyen-Michel¹, E. Pautas¹, J. Mariani¹, K. Kinugawa¹, 1. *AP-HP, DHU FAST, GH Pitie-Salpêtrière-Charles Foix, Paris, France*, 2. *Sorbonne Universités, UPMC University Paris 6, Paris, France*, 3. *CNRS, UMR 8256 Biological Adaptation and Aging, Paris, France*, 4. *Assistance Publique des Hôpitaux de Paris, Acute geriatric care, Pitié-Salpêtrière-Charles-Foix Hospita, Ivry Sur Seine, France*, 5. *Assistance Publique des Hôpitaux de Paris, Functional explorations laboratory, Pitié-Salpêtrière-Charles-Foix Hospital, Ivry Sur Seine, France*

Objectives: Sleep disturbances increase the risk of falls among older people. We aimed to examine prevalence of falls and sarcopenia among older patients with and without sleep apnea (SA).

Methods: Acute care setting patients aged ≥ 75 were proposed to participate to the FALL-A-SLEEP Study since March 2015. Subjective sleep questionnaires (e.g Epworth Sleepiness Scale (ESS)), nocturnal polygraphy (SA defined by $AHI > 15/hr$), handgrip strength and short physical

performance battery (SPPB), Dual Energy X-ray absorptiometry (skeletal muscle mass (SMI)), were performed in a stabilized medical situation.

Results: Complete evaluation was available for 45 patients (mean age 81.9 years, 33 women). Between SA (n=28, mean $AHI=39.7/hr$) and non-SA (n=17, mean $AHI=4.6/hr$) patients, nap was more frequent among SA patients (65.51% vs 29.41%, p-value=0.023) but ESS (5.9 vs 4.9, p-value=0.275) was not different. ADL (5.56 vs 5.71, p=0.883), Charlson score (1.7 vs 2.47, p=0.301), and Rockwood score (4.37 vs 4.29, p=0.861) were not different. Falls (77.7% vs 56.25%, p-value = 0.137), mean SPPB score (5.3/12 vs 7.3/12, p-value=0.0771), SMI (7.03kg/m² vs 6.17, p-value = 0.603), mean handgrip (17.83kg vs 17.97, p-value = 0.799) and sarcopenia defined by EWGSOP (60.9% vs 61.5%, p-value = 0.96) were not statistically different between SA and non-SA patients. CRP level at the entrance to the hospital (47.44 vs 31.53, p-value= 0.016), duration to get up and sit down 5 times (21.15s vs 12.73s, p-value= 0.05), were statistically different.

Conclusions: These preliminary data showed that older SA patients do not present more falls and sarcopenia. Inclusion is ongoing.

FALLS AND SUBSEQUENT ADVERSE DRUG EVENTS AMONG ELDERLY—A REGISTER-BASED MATCHED CASE-CONTROL STUDY

C. Rausch^{3,2}, L. Laflamme³, S.E. de Rooij¹, U. Bültmann², J. Moller³, 1. *University Medical Center Groningen, Department of Internal Medicine Groningen, University Center for Geriatric Medicine, Groningen, Netherlands*, 2. *University of Groningen, University Medical Center Groningen, Community and Occupational Medicine, Groningen, Netherlands*, 3. *Karolinska Institutet, Department of Public Health Sciences, Stockholm, Sweden*

Epidemiological studies on the association between geriatric conditions like falls and subsequent adverse drug events (ADE) remain scarce among unselected community dwelling populations. This study investigates the sequential association between serious injurious falls and ADEs among older people, considering co-morbidity and prescribed medications.

A matched case-control study of Swedish residents 60 years and older was conducted. Cases with ADE were extracted from the National Patient and Death Registers from January 2006 to December 2009. Each case was matched with four controls by sex, age and residential area. Episodes of injurious falls were extracted from the NPR and information on dispensed medications during the four month period prior to index date from the Swedish Prescribed Drug Register. Effects were estimated with odds ratios (OR) and 95% confidence intervals (CI) using conditional logistic regression and adjusting for confounders, including comorbidity.

We found a three-fold increased risk of a new ADE in the six-month period after an injurious fall (OR 3.03; 95% CI, 2.54 – 3.74). This increased risk was highest in the one to three week period after the fall injury, but remained high over the whole period. The risk was higher among the 60–79 year olds than 80+ year olds. Those with an ADE one

to three weeks following a fall injury tended to be more comorbid and have a higher number of medications.

Severe injurious falls increase the future risk of new ADEs among older people, marking injurious falls as potential point for the prevention of ADEs.

FLUID SHIFTS IN OLDER WOMEN AT HIGH ALTITUDE PROMOTE HYDRATION AND MAINTAIN POSTURAL BLOOD PRESSURE

M.J. Benton¹, M. Schlairet², A.L. Silva-Smith¹, 1. *Nursing, University of Colorado Colorado Springs, Colorado Springs, Colorado*, 2. *Georgia Baptist College of Nursing of Mercer University, Atlanta, Georgia*

Worldwide, approximately 32 million older adults live at high altitude, placing them at risk for dehydration that can dangerously lower blood pressure and increase risk for falls. To evaluate this risk, 17 older women living at high altitude (≥ 1800 m) were pair matched with 17 women living at low altitude (≤ 75 m). Hydration, body composition, and postural blood pressure (lying, sitting, standing) were measured midday on Day 1 (well hydrated) and early morning on Day 2 (fasting). There were no differences between HA and LA in age, weight, BMI, body composition, and total body water. However, the relative amount of water in the intramuscular compartment was greater in HA compared to LA on Day 1 ($26.5 \pm 0.4\%$ vs. $24.8 \pm 0.3\%$, $p \leq 0.01$), and again on Day 2 ($26.2 \pm 0.3\%$ vs. $24.7 \pm 0.3\%$, $p \leq 0.01$). Furthermore, overnight changes in total water and relative intramuscular water were greater for HA compared to LA ($-0.9 \pm 0.2L$ vs. $-0.5 \pm 0.8L$; $-0.3 \pm 0.08\%$ vs. $-0.08 \pm 0.06\%$; $p \leq 0.05$). On Day 2, postural systolic and diastolic blood pressures were higher in HA compared to LA in the sitting (SBP: 137.18 ± 5.5 mmHg vs. 123.19 ± 5.0 mmHg, $p \leq 0.07$; DBP: 78.5 ± 2.8 vs. 69.4 ± 2.4 mmHg, $p \leq 0.05$) and standing (SBP: 130.4 ± 4.9 mmHg vs. 111.3 ± 4.3 mmHg, $p \leq 0.01$; DBP: 79.7 ± 2.6 mmHg vs. 67.9 ± 2.4 mmHg, $p \leq 0.01$) positions. In this group of older women, those living at high altitude conserved greater amounts of body water within muscle. This intramuscular water may serve as a reservoir that provides a physiologic buffer to maintain hydration and blood pressure when intake is restricted and risk for dehydration is elevated.

COMBINED ASSOCIATION OF PHYSICAL FRAILTY AND SOCIAL ISOLATION WITH FALLING IN OLDER ADULTS

T. Hayashi¹, T. Makino¹, H. Umegaki¹, X. Cheng¹, H. Shimada², M. Kuzuya¹, 1. *Nagoya University, Nagoya, Japan*, 2. *National Center for Geriatrics and Gerontology, Obu, Japan*

The aim of this study was to examine the association of the combination of physical frailty and social isolation with falling in community-dwelling older people. The study used baseline data on participants in the Toyota Prevention Intervention Cognitive decline and Sarcopenia (TOPICS). Participants in this cross-sectional study were 408 older adults (52% male, mean age = 72.3 ± 4.7 years). Physical frailty status was categorized as non-frail and pre-frail/frail based on the Fried frailty criteria (slow walking speed, muscle weakness, exhaustion, low activity, and weight loss). Social isolation was examined using the

Lubben Social Network Scale (LSNS-6), and scores of less than 12 points indicated social isolation. Participants were divided into 4 groups depending on pre-frail/frail status and social isolation, and experiences of multiple falls over the past year were compared between the groups. Participants were classified into control ($n = 202$), physical frailty (PF; $n = 122$), social isolation (SI; $n = 45$), and PF with SI (PF+SI; $n = 39$) groups. A total of 46 (11.3%) participants reported multiple falls. Logistic regression analysis showed that PF and SI were not independently associated with falling (PF: OR 1.91, 95% CI 0.82–4.45, SI: OR 2.45, 95% CI 0.89–6.75), and PF+SI had a significant association with falling compared with the control group (OR 2.94, 95% CI 1.03–8.41) after controlling for confounding factors. Our findings support the assertion that physical frailty and social isolation are concurrently associated with falling.

COACHING TO REDUCE SEDENTARY TIME IN OLDER PEOPLE WITH FALLS: RANDOMIZED CONTROLLED STUDY PROTOCOL

K. Khaw^{1,2}, C. Smyth^{1,2}, O. Theou³, M. Chehade⁴, R. Visvanathan^{1,2}, 1. *Aged and Extended Care, The Queen Elizabeth Hospital, Woodville South, South Australia, Australia*, 2. *Adelaide Geriatrics Training and Research with Aged Care (G-TRAC) Centre, Adelaide, South Australia, Australia*, 3. *Dalhousie University, Halifax, Nova Scotia, Canada*, 4. *Discipline of Orthopaedics and Trauma, Royal Adelaide Hospital and University of Adelaide, Adelaide, South Australia, Australia*

Sedentary behavior, assessed by self-reporting, has been associated with increased risk of falls. Studies have shown that among the oldest old, they are more likely to be sedentary (>10 hours/day). Standardized supervised exercise interventions do not necessarily reduce the level of sedentary behavior in daily life. The aim is to evaluate an individualized coaching intervention based on accelerometer feedback to reduce sedentary behavior in older people (age ≥ 65 years) living in the community who had a recent fall. Participants will be randomized to either the intervention or control groups in a 12-week feasibility study. In both groups, ActivPAL® accelerometer (35x53x7mm, 15g) will be attached to the mid-thigh of the participants (dominant side) for 7-days at week 0, 6 and 12. To reduce sedentary time, the intervention group will be: (a) presented with the objective information regarding their physical activity levels based on the ActivPAL® accelerometer recordings, (b) educated about the benefits of exercise (using Choose Health: Be Active booklet), (c) face-to-face goal-setting sessions (at weeks 1 and 6) and (d) fortnightly follow-up phone calls. The intervention is based on self-determination theory, which addresses psychological needs in order to modify behavior. The control group will be given the Choose Health: Be Active booklet. Primary outcome is change in sedentary duration. Secondary outcomes assessed include gait speed, Short Physical Performance Battery and Falls Efficacy Scale. The effect of the intervention on sedentary duration and secondary outcomes will be assessed by 2-sided *t*-test. Primary analyses will be performed by intention-to-treat principle.

ASSOCIATION BETWEEN DEPRESSIVE SYMPTOMS, RECURRENT, AND SINGLE FALLS FROM PREVQUEDAS BRAZIL

A. Passos, M.Z. Magalhes, E.Y. Ishigaki, S. Paschoal, M. Perracini, L.E. Gracez Leme, *Hospital das Clinicas USP, Sao Paulo, Brazil*

Introduction: Depressive symptoms are associated with falls in a variety of studies in developed countries. **Objectives:** 1) To examine the association between abnormal 15-item GDS score, single and recurrent falls in community-dwelling older adults in a developing country. 2) To check if recurrent fallers have greater scores in 15-item GDS, examining if it has any association with age, ethnicity, genre, and numbers of medications used.

Methods: Transversal data analyzed was extracted from Prevquedas Brasil, a Multicenter parallel-group randomized controlled trial that evaluates the effectiveness of a multifactorial falls prevention program in reducing the rate of falls in community-dwelling older people. **Statistical Analysis:** Pearson Chi-square test used to compare positive screening for depressive symptoms (GDS >5) and fall events (single or recurrent). Sociodemographic variables were analyzed by logistic regression. Stata® software was used.

Results: 402 participants (mean age 73.8 ± 7.1 years; 88.1% women; 59.8% white). Recurrent falls have association with GDS >5 (92 vs. 28, $p=0.008$). The mean GDS score is greater for recurrent fallers than to non-recurrent fallers ($p<0.001$). After logistic regression for sociodemographic variables and medications, elderly with GDS >5 had twice more chance to be a recurrent faller (OR 2.0, 95%IC 1.2–3.3; $p=0.007$), compared to GDS ≤ 5 .

Conclusions: Abnormal 15-item GDS and its greater scores are associated with recurrent fallers in elderly from a developing country.

30-SECOND SITTING PAUSE IMPROVES BALANCE

E. Johnson, N. Daher, A. Albalwi, F. Al-Dabbak, *Loma Linda University, Loma Linda, California*

Background and Purpose: Falls in older adults are common and often take place in the home when getting up at night to use the restroom. Longer sitting pause times, prior to standing, might improve postural stability after standing from a supine position. The purpose of this investigation was to measure the effects of sitting pause times on standing postural sway velocity immediately following a supine-to-standing transfer in a dimly lit room in older adult females. **Methods:** Eighteen females aged 65–75 participated in the study. On each of 2 consecutive days, study participants lay on a mat table with their eyes closed for 45 minutes prior to performing a supine-to-standing transfer in a dimly lit room. Randomly assigned sitting pause times of 2 seconds and 30 seconds preceded the transfers. **Results:** Mean standing postural sway velocity was significantly less after a 30 second pause time compared to a 2 second pause time ($p=.001$). **Conclusions:** Total mean standing postural sway velocity was less when study participants performed a sitting pause of 30 seconds prior to standing in a dimly lit room. These results support our previous pilot study findings published in the *Journal of Geriatric Physical Therapy* and provides evidence that longer sitting pause times improve standing

postural stability and may contribute to reduced fall risk after waking at night in older adults.

INTERDISCIPLINARY APPROACH TO FALL PREVENTION—RESEARCH, PRACTICE, AND POLICY

M. Wingood¹, M. Renfro^{2,3}, K. Cameron⁴, 1. *University of Vermont-Medical Center Inpatient Rehab, Colchester, Vermont*, 2. *University of Montana, Missoula, Montana*, 3. *MonTECH/ Rural Institute for Inclusive Communities, Missoula, Montana*, 4. *National Council on Aging, Arlington, Virginia*

Research demonstrates that falls are multifactorial and require an interdisciplinary treatment approach. Interdisciplinary evidence-based fall prevention (EBFP) programs are effective with a great return in investment. This presentation will educate the participants about the evidence in interdisciplinary EBFP, how to implement it in your practice, and what policy changes are needed to ensure that our older adults are supported to successfully age-in-place. We will examine interdisciplinary EBFP around the United States and identify strengths and opportunities for improvements in each. Success is reflected in reducing fall risk, falls, fall injuries, and assuring sustainability of the clinic through financing options. Organizational structure, payer systems and public policy will be reviewed and an outline provided to assist the professional with developing an action plan.

CHARACTERISTICS OF LIFT-ASSISTS PROVIDED TO OLDER ADULTS BY PARAMEDIC SERVICES

A. Zecevic¹, D. Carter², M.A. Bauer¹, 1. *Western University, London, Ontario, Canada*, 2. *Middlesex-London EMS, London, Ontario, Canada*

Lift-assist is defined as a paramedic response to an emergency (9-1-1) call that resulted in patient's refusal of transportation to the hospital. Lift-assists represent 5% of all EMS calls and often involve recurrent fallers requiring additional paramedic care within 30 days. The purpose of this study was to determine characteristics of lift-assists provided by paramedics to older adults. Anonymized data was extracted from the Ambulance Call Reports database for a Regional Paramedic Centre in Ontario, Canada for one year (2015). Inclusion criteria were: refusal of services, lift-assists, patients ≥ 65 years, and multiple choice responses only; paramedics' written comments were excluded. Data was analyzed using descriptive statistics, regression and cluster analysis. A total of 798 lift-assists were identified (50% male). We found that: The greatest number of calls occurred on Friday (18%), Saturday (15%) and Monday (15%); Two thirds (68%) of lift-assists happened during the day (06:00-21:00) and 32% at night (21:-06:00); Most frequent locations were 'apartment/condo' (46%) and 'house/townhouse' (45%), while 5% of calls came from nursing homes; On average, paramedics spent 32 minutes on scene. In 2015, paramedics spent almost 24 days responding only to lift-assists. Four clusters with seven attributes best described the sample. These results suggest that paramedic lift-assists are used equally by both genders, in specific areas of the city, and during peak activity hours. Alternative models of care, such as "community paramedicine" should be considered for the management of non-urgent, low-acuity illnesses and injuries to minimize non-essential health care spending.

RELIABILITY AND VALIDITY OF HEALTH IN MOTION® FALLS SCREENING TOOL

B. Walker², S. Flynn¹, R. Johnson¹, 1. *Blue Marble Game Company, Los Angeles, California*, 2. *University of Indianapolis, Indianapolis, Indiana*

Falls are costly, affect independence, and are a leading cause of injury in adults over the age of 65. Awareness of fall risk and engaging with healthcare systems prior to the first fall, annual visit, or hospital stay could have a significant impact on quality of life and healthcare costs. Clinicians use the FRQ, 30STST, and OLST to measure balance and lower extremity strength, predict falls and increase fall risk awareness. This randomized trial design study measured the validity and reliability of the FRQ, 30STST and OLST when performed by a clinician using standard methods and by using self-report and sensor tracking versions of Health In Motion® (Blue Marble Game Co, Altadena, CA) a guided software program for fall prevention. Fifteen community-dwelling adults aged 63–80 completed the study. Compared with clinician 1) the self-report and sensor FRQ, 30STST and OLST had statistically significant moderate to excellent concurrent validity; 2) the self-report PHQ2 had statistically significant excellent concurrent validity; 3) the self-report and sensor FRQ, 30STST and OLST were statistically significantly reliable. Health in Motion was found to be a reliable and valid screening tool for identifying falls risk and could provide early detection of fall risk if used in the home prior to a fall.

GAIT SPEED, COGNITIVE IMPAIRMENT, AND DUAL TASK CONDITIONS IN FALLERS AND NON-FALL CONTROLS

L. Minet^{1,2,3}, K. Thomsen^{1,2}, J. Ryg^{1,2}, L. Matzen², C. Ytterberg^{4,5,1}, K. Andersen-Ranberg², T. Masud^{6,2}, 1. *Institute of Clinical Research, University of Southern Denmark, Odense, Denmark*, 2. *Odense University Hospital, Odense, Denmark*, 3. *University College Lillebaelt, Odense, Denmark*, 4. *Karolinska Institutet, Stockholm, Sweden*, 5. *Karolinska University Hospital Huddinge, Stockholm, Sweden*, 6. *Nottingham University Hospitals NHS Trust, Nottingham, United Kingdom*

Abnormal gait is an established falls risk factor and gait speed (GS) of <0.6m/s is associated with falls (Quach, JAGS, 2011). Cognitive impairment (CI) and dual task conditions (DT) have been linked to impaired gait. This case-controlled study in women explored the relationship between GS, CI and DT in a group of fallers recruited from a falls clinic [FALLCLIN] (n=114) and from age matched faller (FALLCON) (n=97) and non-faller [NOFALL] (n=90) community controls.

The overall median age (range) was 80 years (75–86) and 74/301 (24.6%) had CI. In the cognitively normal women (MMSE≥25) the median (IQR) GS (m/s over 4m) in the FALLCLIN, FALLCON and NOFALL groups were 0.86 (0.63–1.06), 1.11 (0.87–1.33) and 1.30 (1.06–1.58) [p≤0.001], and under DT conditions (counting backwards) were 0.67 (0.46–0.80), 0.79 (0.63–0.98) and 1.04 (0.82–1.28) [p≤0.001] respectively. In the CI women (MMSE<25) the median GS in the FALLCLIN, FALLCON and NOFALL groups were 0.66 (0.56–0.79), 0.68 (0.62–1.04), 1.12 (0.85–1.35) [p≤0.001]; and under DT conditions were

0.46 (0.38–0.65), 0.49 (0.36–0.79) and 0.72 (0.53–0.89) [p=0.006] respectively.

In conclusion, GS was slower in the faller groups, in those with CI and when DT conditions were present. In the presence of both CI and DT conditions, the GS in the faller groups were very low and in the range known to be associated with increased falls risk. GS in normal and under DT conditions may be useful biomarkers for falls risk in cognitively impaired older people and further research is needed to explore if DT training can improve GS.

EXERGAME TECHNOLOGY AND INTERACTIVE INTERVENTIONS FOR ELDERLY FALL PREVENTION: A LITERATURE REVIEW

S. Xiong¹, L. Guo^{1,2}, 1. *Korea Advanced Institute of Science and Technology (KAIST), Daejeon, Korea (the Republic of)*, 2. *China University of Geosciences, Wuhan, China*

Falls and fall related injuries present a substantial health problem among the older population. Training balance and promoting physical activities in the elderly can contribute to fall-prevention. Due to the low adherence of conventional physical therapy, fall interventions through exergame (exercise+game) technologies are emerging. This study synthesizes the available research reported on exergame technology and interactive interventions for fall prevention in the elderly population. Twenty-five relevant publications identified from five major electronic databases (Scopus, ScienceDirect, PubMed, Web of Science and Proquest) were critically reviewed and analyzed. Results showed that the most common exergaming device for fall intervention was the Nintendo Wii, followed by Xbox Kinect. Even though the exergame intervention protocols and outcome measures for assessing the intervention effects varied, the most frequently used outcome measures were the score of Berg Balance Scale for the postural balance performance, the time to complete Timed Up and Go Test for human gait and mobility performance, and the rating of Falls Efficacy Scale for self-perceived risk of falling. This study revealed that the interactive exergame interventions improved physical or cognitive functioning in the elderly. However, it remains inconclusive whether or not the exergame-based intervention for elderly fall prevention is superior to conventional physical therapy. The effect mechanism of the exergaming on elderly's balance ability is still unclear. Further studies are needed to establish a standardized test protocol, to define the optimal intervention treatment, and to design tailored exergame interventions to the elderly for enhanced intervention effectiveness, enjoyment, and safety.

NUTRITIONAL STATUS AND MOBILITY IN ELDERLY FALLERS FROM PREVQUEDAS, BRAZIL

E.Y. Ishigaki¹, M. Zambone¹, A. Passos¹, S. Paschoal², M. Perracini³, L. Leme¹, 1. *Orthopedic Geriatric, University of Sao Paulo, São Bernardo do Campo, São Paulo, Brazil*, 2. *Prefeitura de São Paulo, São Paulo, Brazil*, 3. *UNICID, São Paulo, Brazil*

Introduction: Obesity has recently been thought as a risk factor for falls in elderly. The relative risk of fall is 1.4 times greater in obese elderly. This is partly explained by the negative influence of obesity in mobility. Objective: To check whether the obese elderly fallers have worse mobility in

comparison with non obese ones and find the probability of obese elderly fallers have worse mobility than the non obese ones after analysis of covariance. Methods: Transversal data was extracted from Prevquedas Brasil which is a Multicenter parallel-group randomized controlled trial that evaluates the effectiveness of a multifactorial falls prevention program in reducing the rate of falls in community-dwelling older people. Obesity was determined using Body Mass Index (BMI) formula. All those with BMI >27kg/m² were considered obese. Mobility was checked by Gait Speed Test (GST) and Timed up and go Test (TUGT). Statistical Analysis: Obese and non-obese mobility were compared using Test t- logistic regression as used to measure association between obesity and mobility, adjusted for gender, age and depression, using STATA 14, P-value < 0.05 was considered statistical relevant. Results: Transversal Analysis of 403 people, 355 women and 48 men, mean age 73,59 ± 7,14 and 75 ± 6,85, respectively. Prevalence found was 3.14 falls/person/year. BMI 39,08 ± 10,30 kg/m², 61,1% were obese. The score time to the TUGT was higher in obese (p=0.018) and the probability of being obese elderly slowest is 70% (OR 1,77, 95%IC; p=0.031).

Conclusion: There is correlation between obesity and functional impairment and worse mobility.

SESSION 860 (POSTER)

FAMILY AND INTERGENERATIONAL RELATIONSHIPS II

IMPACT OF CARING FOR GRANDCHILD ON DEPRESSION FOR KOREAN OLDER ADULTS: HEALTH AND INCOME AS MODERATOR

Y. Shin, J. Ha, *Seoul National University, Seoul, Korea (the Republic of)*

This study considers role enhancement and role strain theory as complementarity hypotheses and hypothesizes that the effect of caring for grandchildren on depression for older adults depends by the level of health and income.

Analyses were based on data from the 2010(Time 1, T1) and 2012(Time 2, T2) waves of Korean Longitudinal Study of Ageing(KLoSA). This study used an analytic sample of 5,018 older adults who are aged 49 through 85 and had one or more grandchild, in order to examine how (1) caring for grandchildren at an earlier time point(T2, 2011 October 2012 September) affects older adults' depression at a later time point(T2, 2012 September), controlling for the outcomes at T1. Also This study investigated (2) whether the level of health (perceived health status, the number of chronic health conditions) and income moderated the effect of caring for grandchildren on older adults' depression. This study used multivariate regression models (lagged effect models) controlling for older adults' depression at time 1(T1), including interaction terms.

The results showed that the effect of caring for grandchildren on older adults' depression was not significant. Whereas the effect of taking care of grandchildren on depression level of grandparents was significantly moderated by perceived health status and the number of chronic health conditions,

that was not significantly moderated by income level of older adults.

These findings enhance our understanding of older adults caring for grandchildren. The results of this study indicate that older adults caring for grandchildren are not one group. They differ by level of health, but not by income level of them. So there should be support for older adults taking care of grandchildren with weak health conditions to prevent their depression.

VERY OLD ADULTS AND THEIR CHILDREN: QUALITATIVE FINDINGS ON SUPPORT EXCHANGES

C. Meystre¹, D.S. Jopp¹, J. Darwiche¹, K. Boerner², C. Salaün¹, C. Lampraki¹, D. Spini¹, *1. Institute of Psychology, University of Lausanne, Lausanne, Switzerland, 2. University of Massachusetts Boston, Boston, Massachusetts*

The number of very old people is increasing dramatically in most industrialized countries. The possibility to stay at home is of key importance for this population, and their children often make this possible. However, little is known about the nature of the relationship between very old parents and their old children, and the implication of the quality of this relationship. The present study drew on data from a Swiss sample of 20 of dyads, composed of very old people (aged above 95 years) and the child involved in their care. To examine the quality of the relationship and the support the members of the dyads provide to one another, they were asked to participate in an interaction task (e.g., Suhr, Cutrona, Krebs, & Jensen, 2013). Specifically, the very old parent had to describe a difficult everyday life situation and to discuss it with the child for 10 minutes. Then roles were reversed. The videotaped dyadic interaction was analysed using the Social Support Behavior Code (SSBC; Suhr et al., 2013), which assesses 25 individual support behaviors. The results indicate various support types, ranging from positive (e.g., emotional, information) to negative (e.g., criticism). We also found that dyads ranged in the amount to which the support was reciprocal; yet, with poorer health and increasing age, support exchange became more unbalanced. Findings suggest the usefulness of the chosen task for the assessment/coding of dyadic interactions in very advanced age. Future studies should investigate the relationship between support exchange and well-being/mental health outcomes.

MARITAL ATTACHMENT AND SPOUSAL SUPPORT AMONG OLDER COUPLES

W. Ye, D. Wang, T. Wu, *School of Psychology, Beijing Normal University, Beijing, Beijing, China*

This longitudinal study mainly explored the relationship between marital attachment and spousal support experience among older couples. There were 95 older couples from communities of Beijing, with age ranging from 60 to 83 years old at the first time of investigation, who were assessed twice across two years. At the first wave (T1), the participants completed the demographic information sheet, Older Adults' Marital Attachment Scale and some screening scales including the Geriatric Depression Scale and Clock Drawing Test. At the second wave (T2), besides T1 measures, the participants reported the life events happened during the two-year interval and various aspects of spousal

support while confronting those events. Results of Actor-Partner Interdependence Model Analysis indicated that an individual's spousal supports were affected by both the individual's and his/her partner's attachment at T1. Both husbands and wives' spousal support benefited from their own attachment security or were harmed by their own insecurity. Furthermore, the spousal supports reported by wives were mainly affected by their own attachment, while those of husbands were mainly affected by their wives' attachment. In addition, the change of attachment across the interval was affected by both the individual's and his/her partner's spousal support. Effective support of both sides could contribute to individual's attachment security and vice versa. These results provide evidence that marital attachment and spousal support are influenced by each other, thus forming a dynamic cycle.

PARENTS' PSYCHOLOGICAL PROCESS OF CAREGIVER-RECIPIENT ROLE REVERSAL FROM CHILDREN'S PERSPECTIVES

N. Toyokawa¹, N. Darling², T. Toyokawa³, 1. *California State University San Marcos, San Marcos, California*, 2. *Oberlin College, Oberlin, Ohio*, 3. *Pacific Lutheran University, Tacoma, Washington*

The magnitude of intergenerational ambivalence tends to increase when the expected roles of parents as a caregiver and children as a care recipient become reversed as parents age (Lüscher, 2002). However, little is known about the psychological process of this role reversal, particularly the negotiation of parents' autonomy and adult children's authority over parents' autonomy. This pilot study explored the process of parents' information control about their everyday life to maintain their autonomy. Sixteen adult children were invited to focus groups ($M_{age} = 53$, $SD = 6.1$, Males = 3) through local churches. Content analysis (Weber, 1990) revealed that participants believed that their parents were unwilling to disclose six kinds of issues: use of medication, new physical symptoms, financial aids to own children, the content of their living wills, death preparation, and presence of debts. For reasons for parents' unwillingness to talk about these issues, participants provided several points. First, their parents wanted to maintain autonomy by strategically managing information on their medication use and property management to maintain autonomy. Second, parents did not want to disclose their new disease symptoms until the symptoms got serious to avoid being caregiving burden of their children and/or disliked to go through extra-medical exams. Third, because of death anxiety, certain topics were taboo for adult children to talk about (e.g., death preparation). These findings suggest that parents' psychological process during role reversal between aging parents and adult children include not only parents' information control but also parents' anxiety of aging and death.

MIGRATION AND INTERGENERATIONAL RELATIONSHIPS IN CHINESE FAMILIES

J. Liu¹, M. Guo², L. Xu³, W. Mao⁴, I. Chi⁵, 1. *School of Social Work, Columbia University, New York, New York*, 2. *University of Iowa, Iowa City, Iowa*, 3. *University of Texas at Arlington, Arlington, Texas*, 4. *University of Nevada at*

Reno, Reno, Nevada, 5. *University of Southern California, Los Angeles, California*

Objectives: Internal and international migration influences family relations momentarily by increasing geographic distance and reshaping interactions between migrants and their families in sending areas. This study examined how geographic distance (co-residence, in the same city, in different cities, and in different countries) between older parents and adult children is associated with intergenerational relationships in Chinese families.

Methods: Data were derived from a cross-sectional survey of 330 elders in Beijing who had child(ren) living in another city or country. Information of 708 children was reported by the respondents. Intergenerational support (physical care provided by children for parents, monetary support between parents and children, babysitting assistance from parents for children) and emotional relationships (closeness and conflict) between the respondents and each child they had were assessed. Socio-demographic characteristics of both older adults and their children and elders' health status were controlled for in the two-level regression models.

Results: Transnational livelihood was associated with lower probabilities of receiving both family care and monetary support from children. Older parents perceived lower levels of emotional closeness and conflict relationships with the children migrated to other cities or countries than that with proximate (co-residence and in the same city) offspring. Physical care provided by children for parents and monetary support from parents to children were related to higher level of emotional closeness.

Conclusion: This study showed that geographic distance across countries may weaken intergenerational support and emotional bonds, indicating the needs of programs and interventions to empower migrant families in both sending and receiving areas.

PREVALENCE AND PROFILE OF GRANDPARENTS PROVIDING OCCASIONAL GRANDCHILD CARE IN THE U.S.

Y. Lee, *Syracuse University, Syracuse, New York*

Objectives. This research draws from social contingency theory to explain the relationship between women's labor force participation and the prevalence of grandchild care among grandparents with at least one grandchild in the U.S.. Particular attention is given to grandparent gender by child gender interactions.

Methods. The data was collected from the Health and Retirement (HRS) Study 2008 (wave 9). The source of the data was both the University of Michigan HRS and RAND HRS files. The analysis is based on the total number of 11,981 grandparents and 23,106 adult-children.

Results. Supporting the hypothesis, daughters receive the most grandchild care from grandparents then sons, and more grandmothers provide grandchild care to daughters than to sons.

Discussion. The results highlight the important influence of women's labor force participation on the occasional grandchild care prevalence and profile in the U.S.. In conclusion, contingency can influence grandparents, even in this individualistic country, provide intergenerational support

when family's needs arise due to economic conditions or employment.

LIVING ARRANGEMENTS AND SUBJECTIVE WELL-BEING AMONG OLDER ADULTS IN CHINA

X. Ye¹, D. Burnette², Z. Cheng¹, 1. *Institute of Population Research, Beijing, Beijing, China*, 2. *School of Social Work, Virginia Commonwealth University, Richmond, Virginia*

As a result of demographic transition and society revolution, living arrangements of older adults in China showed new characteristics. The research investigated the relationship between living arrangements of the elderly and their subjective well-being. Data came from the Sampling Survey on the Living Conditions of the Elderly in Urban and Rural Areas in Beijing, China (2015), a representative sample of those 60 and older. The analytic sample size was 3289. The subjective well-being was measured by a 5-point scale consisting of the following responses: very happy, happy, so-so, unhappy, very unhappy. We used ordered logistic regression. 78.43% of the older adults felt happy or very happy with their life. Most of the elderly only lived with spouse (44.01%), followed by those lived in three-generation families (20.92%) and those lived in two-generation families (18.31%). After controlling the demographic and socioeconomic variables, compared to living in two-generation families with adult children, older adults only living with spouse or living in three-generation families with grandchildren tended to have better subjective well-being. In the study, three-generation families could be a better choice for the elderly, which is in line with Chinese traditional value. But the elderly living only with spouse may experience more privacy and independence that are more highly valued in the aging process nowadays. Ongoing research could explore more evidence of the variation trend of living arrangements and how to build better household context for the elderly.

IT'S AN INTIMACY CRITERION: RELATIONSHIPS IN LATE LIFE FROM A PERSONAL COMMUNITIES APPROACH

M. Torrejon, *Sociology, University of British Columbia, Vancouver, British Columbia, Canada*

The literature on social capital, social support and social networks usually describes the resources available in the network of the older person. Although some of that literature includes the concept of emotional support or measures to recognize emotional closeness, the studies rarely recognize the emotional nuances and the subjective meaning of those relationships. This paper seeks to explore the diversity of ties that form older people's emotionally close network of relationships or personal communities, as defined by Pahl and Spencer (2010), and the meanings and more subtle functions of these personal relationships in late life. I draw upon 40 qualitative interviews conducted with Chilean men and women between 60 and 74 years old to examine how they define and identify personal ties considered important to them. The interviews were aided by a method of mapping personal relationships that was suitable to elicit the identification of people who were relevant for reasons beyond the help exchanged. The interviews were analyzed using a thematic analysis and the

personal communities were classified using a typology proposed by Spencer and Pahl (2006). The personal communities approach proved useful to analyze the composition of older people's network of close relationships and to recognize the different manners in which family members and friends are relevant in late life. A particular contribution of this paper is a proposed complementary typology based on the distinction between 'clustered' and 'hierarchical' personal communities. This distinction gives additional information to depict and define emotional closeness and represent suffusion of personal relationships.

LIVING ARRANGEMENTS, CARING FOR GRANDCHILDREN, AND DEPRESSIVE SYMPTOMS AMONG GRANDPARENTS IN CHINA

Z. Cheng, X. Ye, *Institute of Population Research, Peking University, Beijing, China*

This paper investigated the relationship between living arrangements, caring for grandchildren and depressive symptoms among grandparents. Data came from the Chinese Health and Retirement Longitudinal Study (CHARLS, 2011–2012) baseline data, a sample of those 45 and older. The analytic sample contained 5,473 grandparents with grandchildren aged under 16. The CESD-10 was used to measure depressive symptoms with a score from 10 to 40. We used Multiple Linear Regression. 42.69% rural and 48.01% urban grandparents provided care for their grandchildren. More grandparents provided care of high intensity (≥ 48 weeks/year). After controlling demographic and socioeconomic variables, rural grandparents co-residing with grandchildren tended to have less depressive symptoms compared to rural grandparents not co-residing with grandchildren. And rural grandparents providing care tended to have less depressive symptoms compared to rural grandparents providing no care. But when co-residing with grandchildren and providing care of high intensity, rural grandparents were likely to have more depressive symptoms. For urban grandparents, co-residing with grandchildren compared to not co-residing with grandchildren contributed to their less depressive symptoms. But after controlling frequency of visiting from adult children and some other variables, the association between caregiving intensity, interaction term for caregiving intensity and co-residing living arrangements and depressive symptoms among grandparents were not statistically significant. But urban grandparents living in skipped generation households had more depressive symptoms. Grandchildren could be a critical emotion support to their grandparents. However, grandparents co-residing with grandchildren and providing care of high intensity or living in skipped generation households tend to have negative mental health.

UNION FORM IN LATE-LIFE INTIMATE RELATIONSHIPS

T.M. Bildtgård¹, P. Öberg², 1. *Social work, Stockholms Universitet, Stockholm, Sweden*, 2. *University of Gävle, Gävle, Sweden*

Family theory has suggested a radical transformation of intimacy in large parts of the Western world over the last 50 years. Given this development, how can we best explain union form in older people's relationships: In terms of the traditional values they were brought up

with (cohort)? In terms of the historical context in which the relationships were initiated (period)? Or in terms of the life-phase in which the relationships were initiated (age)? All of these hypothesis have been suggested by prior research. The purpose of the paper is to test these hypotheses empirically. The study is based on a quantitative survey of 60–90 year old Swedes (response rate 42%), focusing a subset of respondents (n=702) who are currently either married, cohabiting or LAT. The data are analyzed using logistic regressions. The results showed no significant support for the cohort hypothesis. The analysis gave strong support for the historical hypothesis – union form was significantly correlated with the year the relationship was initiated. It also gave significant support for the life phase hypothesis – older people tend to prefer LAT relationships – but only after they were allowed by the normative historical context. The results are discussed in relation to explanations suggested by earlier research regarding union form in older couples.

GENERATIONAL SOLIDARITY IN EUROPE

A. Tur-Sinai¹, D. Halperin², R. Katz², A. Lowenstein¹, 1. *University of Haifa, Haifa, Israel*, 2. *The Max Stern Yezreel Valley College, Yezreel Valley, Israel*

This study explored various dimensions of generational relationships between older parents and their adult children using the latest waves of SHARE (Survey of Health, Ageing and Retirement in Europe). Intergenerational solidarity model served as the main conceptual framework. Analyses yielded four family relationship types present in all countries, albeit with different frequencies. Around half of the respondents in the comparing countries were identified with close ties and flow of support. Four conclusions were drawn: (1) importance of personal resources; (2) cultural differences and meanings for families; (3) highlighting within-country difference; and (4) strength of intergenerational solidarity. Using a cross-sectional and longitudinal analysis among parents and their adult children revealed the importance of understanding generational relationships in the current era, characterized with higher longevity and changing family structures. Implications for theory, research and policy are discussed.

CHANGES IN LIVING ARRANGEMENTS OF VIETNAMESE OLDER ADULTS

Q.T. Trinh^{1,2}, H.L. Kendig^{1,2}, V. Yiengprugsawan^{1,2}, 1. *Centre for Research on Ageing, Health and Wellbeing (CRAHW), The Australian National University, Canberra, Australian Capital Territory, Australia*, 2. *ARC Centre of Excellence in Population Ageing Research (CEPAR), Canberra, Australian Capital Territory, Australia*

The living arrangements of older adults, which are central to intergenerational support systems in Vietnam, are changing as a result of rapid population ageing and evolving family structure, social norms and values, and socio-economic development. This paper reports on the determinants and consequences of changes in living arrangements of Vietnamese people aged 60 and older using data from the Vietnam National Ageing Survey 2011 and Regional Ageing Surveys 1997 (n= 4,559). The results indicate that a majority are living in multigenerational households but this has declined from 56% to 45% between 1997 and 2011. There have been increases of those living only with a spouse (7.5%

to 18%) and living alone (4.3% to 9.4%). Those at more advanced ages were more likely to live alone or in multigenerational households in 1997 but they tended to live with a spouse or adult child in 2011. Having paid work was associated with living alone only in 2011. Additionally, having a son increased the likelihood of living in a multigenerational household, with a spouse, and/or with children in 1997. Other significant influences were health status and urban versus rural residence. The changes indicate overall stability of households but a trend towards Western patterns of modified extended families. This has significant implications on patterns of intergenerational support exchange as well as living standards and subjective well-being. While the family remains crucial for older adults in Vietnam, the evolving responsibilities of social welfare and care for them, especially those living alone, will be increasingly challenging.

REASONS FOR LIVING WITH AND WITHOUT CHILDREN AND LIFE SATISFACTION AMONG KOREAN OLDER ADULTS

J. Kim¹, S. Kim¹, M. Lee², J. Kang³, 1. *Sungkyunkwan University, Seoul, Korea (the Republic of)*, 2. *Chung Ang University, Seoul, Korea (the Republic of)*, 3. *Yonsei University, Seoul, Korea (the Republic of)*

Living arrangements of Korean older adults have rapidly changed, from 81% living with children in 1966 to 34% in 2010 and from 7% living without children in 1966 to 60% in 2010. Using the 2013 Social Statistics Survey conducted by the Korea National Statistical Office (N=7,020), we examine how the reasons for living with or without children may influence older adults' life satisfaction. For those living with children, their reasons include difficult health and economic situations (47%) their children's difficult health and economic situation (25%), providing childcare and housework (11%), preference (14%), and their children being students (1%). On the other hand, those who live without children listed the following reasons: comfort (33%), feasibility of living independently (26%), avoiding being a burden to their children (23%), children's work or studies (16%), and conflict with their children (1%). Using logistic regression, of those who live with their children, those with reasons other than preference and their children being students are less likely to be satisfied. Of those who live without children, compared to those who find it comfortable to live alone, those who responded as being economically and physically able to live independently are more likely to be satisfied, but those who are avoiding burdening their children are less likely to be satisfied. Our findings suggest the importance of reasons for living arrangements, not living arrangements itself on life satisfaction of older adults.

TIES WITH ADULT CHILDREN AND LONGITUDINAL PARENT-CHILD RELATIONSHIP SATISFACTION OF KOREAN RETIREES

H. Chai¹, S. Joo², 1. *Human Development and Family Studies, The Pennsylvania State University, University Park, Pennsylvania*, 2. *Yonsei University, Seoul, Korea (the Republic of)*

Transition into retirement opens up an opportunity to focus more on family relationships, and relationships with adult children is considered an important contributor of

well-being after retirement. However, not many studies have looked at the longitudinal association between ties with children and well-being among the retirees. Therefore, using four waves (2006, 2008, 2010, and 2012) of the Korean Longitudinal Study of Aging (KLoSA), this study examined how parent-child relationship satisfaction changes over time after retirement and how ties with adult children are associated with the longitudinal change in relationship satisfaction. The sample included in this study were Korean adults aged 45 years or older who retired between 2005 and 2006 before the baseline survey ($N = 233$).

The results showed that parent-child relationship satisfaction decreases over 6 years after retirement, and that receiving support from children and having frequent contact with children measured at Wave 1 have positive associations with the initial level of parent-child relationship satisfaction. Interestingly, the results also showed that income level moderates the relationship between ties with children and parent-child relationship satisfaction. For low-income retirees, those with higher levels of contact and support had higher level of parent-child relationship satisfaction across time. However, for high-income retirees, the level of parent-child relationship satisfaction did not differ by the levels of contact and support. These results show that having strong ties with adult children is important for Korean retirees' parent-child relationship satisfaction soon after retirement, especially for low-income retirees.

INTERGENERATIONAL SOLIDARITY AND PARENT-CHILD DISCUSSION ON END-OF-LIFE CARE IN JAPAN

R. Hirayama, C. Shimada, T. Wakui, K. Nakazato, *Tokyo Metropolitan Institute of Gerontology, Tokyo, Japan*

In Japan, because of the familistic climate surrounding the institutionalized practices of end-of-life care, adult children are expected to know about their parents' wishes regarding the end of their lives so as to fulfill the role of surrogate decision maker for parents. Guided by the intergenerational solidarity model, our aim in this study was to identify arrays of the attributes of parent-child relationship, or dimensions of solidarity, that might lead Japanese adult children to engage in discussions with their aging parents about end-of-life issues. Our data were from an online survey using a sample of Japanese adult children who had at least one living parent aged 65 or older. Of these, we focused on adult children whose parents were not in need of care ($N = 849$). A latent class analysis revealed four types of parent-child relationships that varied in six dimensions of solidarity, and likelihood of end-of-life discussion differed significantly across relationship types. In sum, results suggest that combination of these dimensions, rather than isolated aspects of relationships, matters for parent-child discussion on end-of-life issues. For example, residing with parents (i.e., greater structural solidarity) made it likely for adult children to engage in such discussions only when they had a confidant relationship with parents (i.e., a high level of affectional solidarity). Our findings point to the need for a holistic approach to parent-child relationships; that is, to understand how relationship attributes *combine* to differentiate Japanese adult children's motivation to converse with their aging parents on end-of-life issues.

DIFFERENCES IN HEALTH OUTCOME AMONG MARRIED, NEVER-MARRIED, AND SEPARATED OR DIVORCED ELDERLY IN JAPAN

K. Nonaka¹, M. Hasebe¹, T. Koike², H. Suzuki¹, T. Fukaya¹, Y. Fujiwara¹, *1. Tokyo Metropolitan Institute of Gerontology, Tokyo, Itabashi-Ku, Japan, 2. Kyushu Sangyo University, Fukuoka, Japan*

The proportion of people who are never-married and separated/widowed is rapidly increasing in Japan, and it will increase to 42% of the total population by 2030. The purpose of this study is to examine whether there are any differences in the probability of decline in IADL among married, never-married, and separated/widowed elderly, in relations with demographic characteristics, physical and cognitive health status, and social networks.

We used survey data from a 4-year longitudinal study of elderly aged 65 years and older living in A city, located in a suburb of Tokyo, Japan. A sample of 1686 subjects who answered both a baseline study (T1) conducted in 2008 and a follow-up study (T2) conducted in 2012 were divided into three groups: "married" (55%), "never-married" (13%), and "separated/widowed" (32%).

One-way ANOVA showed that there were no differences in IADL among the three groups at T1. Separated/widowed subjects tended to have higher scores in intellectual activities ($F=7.67$, $p<.01$) and more frequent non-face-to-face and face-to-face contacts with friends than the other two groups ($F=7.95$, $p<.01$; 19.46 , $p<.01$ respectively). A logistic regression analysis revealed that separated/widowed subjects were more likely to reduce IADL compared with never-married persons (OR: 2.29; 95%CI: 1.31–4.01).

Previous studies have reported poorer health among unmarried persons compare with married persons. The result indicates that never-married persons may be able to maintain IADL through managing their daily chores. On the other hand, separated/widowed persons have higher risks for reducing IADL despite their higher ability in intellectual activity and larger social networks.

INDIVIDUALS, FAMILIES, OR THE STATE: WHO SHOULD PROVIDE SINGAPOREANS' LATER LIFE INCOMES?

D.A. Street¹, K.T. D'Amuro², Y. Yang¹, *1. Department of Sociology, SUNY at Buffalo, Buffalo, New York, 2. SIM-UB, Singapore, Singapore*

New challenges for individuals, families and the state are emerging in Singapore's rapidly changing and ageing population. Who should be responsible for meeting the needs of future older Singaporeans? What roles will individuals, families and the government play? Using data ($N=421$) from a survey of purposively sampled Singaporeans aged 30–64 in multivariate statistical models, we analyze factors shaping working aged Singaporeans' expectations about financial support in old age. Our models indicate that working aged Singaporeans with traditional orientations/"Asian values" are significantly more likely to expect future financial support from their families, while optimism about social mobility prospects and preferences for private living arrangements are significantly associated with expectations of self-reliance. Finally, Singaporeans pessimistic about prospects for social mobility and who worry that retirement will never

be possible are significantly more likely to respond that the government should provide more support for future elderly Singaporeans. Our findings show that both material and cultural factors such as social mobility, individualism, and Asian values that are responsive to the rapid social, cultural, and economic changes in which they are embedded influence which social entity—individual, family, or state—working Singaporeans believe should be most responsible for providing financial security in old age.

SATISFACTION WITH FAMILY RELATIONS AND EXCHANGES OF SUPPORT OF ELDERLY THAT ARE CARING FOR OTHER ELDERLY

A.S. Lins, A.L. Neri, L.D. Flesch, *University State of Campinas, São Paulo, São Paulo, Brazil*

This study aimed to investigate relationships between Satisfaction with family relations, household arrangements and exchanges of support, as evaluation of elderly caregivers of other elderly people. A convenience sample of 148 caregivers elderly were selected in health services (public and private), 77% women, mean age 69.8 ± 7.1 , spouses, 62.2% and 85.8% lived together. The sample with the target of care was submitted to APGAR of family, questionnaire on exchanges of support material, instrumental and emotional, and items that assessed sufficiency of support received and the ability to offer them. We used the chi-square test, Fisher's exact test and multivariate logistic regression, with discretion of stepwise selection of variables. Among those who scored higher in satisfaction with family relations, the majority were women and spouses of the targets of care. Low emotional support was associated significantly with low satisfaction with family relations. Higher rates of reciprocity occurred in emotional support and the smaller ones in support instruments. The caregivers who consider that were able to provide support instrumental, but with burden, they pointed down liens with the family relationships than those who thought they could do it without burden. Those who only offered and don't received emotional support were four times more likely to score for low satisfaction than those offered and received emotional support. The results showed that the effectiveness in the exchanges of support, especially the emotional support, influences the satisfaction with family relationships and the act of caring. We use the convoy model to describe the factors.

SESSION 865 (POSTER)

FRAILITY II

CLINICAL FACTORS ASSOCIATED WITH PHYSICAL FRAILITY IN THE COMMUNITY-DWELLING OLDEST OLD

J.A. Sousa¹, M.H. Lenardt², C. Grden¹, *1. State University of Ponta Grossa, Ponta Grossa, Paraná, Brazil, 2. Federal University of Paraná, Curitiba, Paraná, Brazil*

This is a cross-sectional study that aimed to present a predictive model of physical frailty in the oldest old and investigate the association between this syndrome and the clinical characteristics of this group. The research was conducted

with 243 Brazilians aged 80 and older living in the local community with the cognitive ability to participate in the study. For those with cognitive impairment, we invited the family caregiver to participate. Physical frailty was assessed using structured forms, scales, and physical tests. Descriptive statistics, and univariate and multivariate logistic regression (forward stepwise) were used to create prediction models of physical frailty for those living in the community. We evaluated each model using deviance analysis, predictive value, specificity and sensitivity, and presented the most parsimonious model. Of the 243 oldest old, 14.81% were frail, 63.79% pre-frail and 21.40% not frail. There was a significant association between physical frailty and the variables hospitalization ($p=0.045$) and antidiabetic drugs ($p=0.024$). Relationships were found between fatigue/exhaustion and number of diseases ($p=0.056$), fatigue/exhaustion and falls ($p=0.038$), gait speed and falls ($p=0.023$), and hand grip strength to hospitalization ($p=0.023$). The predictive model of frailty elected for this study was composed of the following variables: cardiovascular diseases, metabolic diseases, musculoskeletal diseases, dyslipidemia, ear diseases, other diseases, hospitalization, falls, medication use and number of medications. It is inferred that clinical variables interfere in the development of physical frailty syndrome in the oldest old community.

PREDICTIVE ACCURACY OF FRAILITY MEASURES: OVERVIEW OF REVIEWS

J.A. Apóstolo¹, C. Holland², E. Bobrowicz-Campos¹, M. Vollenbroek-Hutten³, M. Marcucci⁴, S. Santana⁵, R. Cooke², A. Cano⁶, *1. Nursing School of Coimbra, Coimbra, Coimbra, Portugal, 2. Aston Research Centre for Healthy Ageing (ARCHA), Aston University, Birmingham, United Kingdom, 3. University of Twente, Telemedicine group, Eschedede, The Netherlands and Ziekenhuisgroep Twente, Almelo, Netherlands, 4. Geriatric Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico & Dept. of Clinical Science and Community Health, University of Milan, Milan, Italy, 5. Department Of Paediatrics, Obstetrics, And Gynaecology, Universitat de València, Valencia, Spain*

Frailty is an age-related state of high vulnerability to adverse health outcomes after a stressor event, predisposing individuals to progressive decline in different functional domains. A scoping search identified a large number of relevant systematic reviews (SRs) on predictive ability of frailty measures in older adults. Aiming to summarise this set of evidence an overview of reviews, based on the Joanna Briggs Institute (JBI) methodology, was conducted. This project "664367/FOCUS" was funded under the European Union's Health Programme (2014–2020). The studies considered as eligible for inclusion were quantitative SRs including older adults aged 60 years or more, recruited from any type of setting. Timeframe for searching was from January 2001 to October 2015. Of 420 records identified through searching in databases, 20 full-texts were assessed for inclusion criteria and 10 were included. Then 10 were assessed for risk of bias, using JBI critical appraisal checklist for systematic reviews and research synthesis. From those, three SRs conducted in

community and emergency department settings and describing eight screening tools and eight frailty indicators were included. Between frailty measures applied to community dwelling older people, Frailty Index, gait speed and physical activity were shown to be the most powerful predictors of future adverse health outcomes. No suitable tool for assessing frailty appropriately in emergency departments was identified. Future research is required to investigate whether psychometric properties of available frailty measures are generalizable to health care settings other than primary care. There is a need for tools for use in emergency departments.

VALIDATING A MEDICARE CLAIMS-BASED MODEL TO CLASSIFY PHENOTYPIC FRAILTY IN OLDER ADULTS

C.C. Cuthbertson¹, J.L. Lund¹, T. Sturmer¹, K.R. Faurot¹, K.J. Bandeen-Roche², M. Jonsson Funk¹, P. Palta¹, A. Kucharska-Newton¹, 1. *Department of Epidemiology, University of North Carolina at Chapel Hill, Chapel Hill, North Carolina*, 2. *Johns Hopkins University, Baltimore, Maryland*

Medicare claims are increasingly used for epidemiologic studies in older adults. Claims capture longitudinal healthcare utilization (diagnoses, procedures, and medication dispensing), but lack clinical measures including frailty, which may confound or modify observed associations. Researchers previously developed a Medicare claims-based model (MCBM, 20 diagnoses, procedures, and durable medical equipment indicators) to predict severe dependence in activities of daily living as a proxy for frailty. Using Medicare claims linked with clinical data from Atherosclerosis Risk in Communities (ARIC) cohort participants (2011–2013), we assessed the validity of the MCBM to predict phenotypic frailty (PF), derived from cohort data. We described the prevalence of MCBM indicators (e.g., skin ulcer) among participants classified as frail, pre-frail, or robust and computed measures of model discrimination (c-statistic), calibration (Hosmer-Lemeshow test), and predictive validity (mortality using Cox proportional hazards models). Of 3,146 participants (median age: 75, 60% women, 22% Black), 7% were frail. The prevalence of MCBM indicators was highest among frail participants. The mean predicted probability of MCBM-derived frailty was 6.9% (range: 0.4%–78.4%). Model discrimination for prediction of PF was fair (c-statistic=0.744), while calibration was good (p-value=0.51). The crude hazard ratio (HR) for mortality (n=71, maximum follow-up=18 months) comparing older adults with high (>20%) versus low (<5%) predicted probability of MCBM-derived frailty was HR=8.9 (95%CI: 4.1,18.9) and was independent of age, sex, and race (adjusted HR=8.9 (95%CI: 3.4,23.1)). The existing MCBM classifies PF with reasonable accuracy. Efforts to improve PF classification using Medicare claims will enhance their validity for use in epidemiologic studies of older adults.

A MULTIFACTORIAL INTERVENTION FOR IMPROVING FRAILTY STATUS: EXPLORING SHORT- AND LONG-TERM EFFECTS

S. Seino¹, A. Kitamura¹, M. Nishi¹, H. Murayama², M. Narita¹, Y. Yokoyama¹, Y. Nofuji³, S. Shinkai¹, 1. *Tokyo Metropolitan Institute of Gerontology, Itabashi, Japan*, 2. *The University of Tokyo, Bunkyo, Japan*, 3. *Japan*

Association for Development of Community Medicine, Chiyoda, Japan

This study examined the short- and long-term effects of a multifactorial intervention on frailty using a randomized, crossover trial with a follow-up survey within the Hatoyama Cohort Study. Seventy-seven pre-frail or frail older adults were randomly allocated to an immediate intervention group (IIG, n=38) or a delayed intervention group (DIG, n=39). The IIG participated in the twice-weekly multifactorial intervention class consisting of resistance exercise, nutritional, and psychosocial programs. The DIG was provided no intervention for the initial 3-month period, and both groups were crossed over for the latter 3-month period. Pre-frail and frailty were determined by the Check-List 15 (CL15) score, which was validated against Fried's frailty criteria. Intervention effects on the CL15 score and frailty status were examined for the two 3-month periods (Analysis 1). A propensity score-matched analysis was performed to balance the baseline characteristics between the participants (IIG and DIG) and non-participants of the intervention within the same cohort, and follow-up was conducted 6 and 16 months after the intervention (Analysis 2). As compared with DIG, IIG exhibited significant reductions in the CL15 score (-0.36; 95% confidence interval: -0.74, -0.03) and prevalence of frailty (-23.5%; -40.4%, -6.7%), but not in pre-frailty at 3 months, which persisted at 6 months. The DIG exhibited almost similar intervention effects in the latter 3-month period. Analysis 2 showed that CL15 scores further reduced significantly in participants who received the multifactorial intervention, with a significant group-by-time interaction (P=0.036). In summary, this multifactorial intervention was effective in improving frailty status on a short- and long-term basis.

SOCIAL FRAILTY: A MOST IMPORTANT RISK FACTOR OF FRAILTY AND SARCOPENIA IN COMMUNITY-DWELLING ELDERLY

T. Tanaka^{1,2}, K. Takahashi², U. Suthutvoravut¹, Y. Yoshizawa³, M. Fujisaki², M. Akishita¹, K. Iijima², 1. *Geriatric Medicine, The University of Tokyo, Tokyo, Japan*, 2. *Institute of Gerontology, The University of Tokyo, Tokyo, Japan*, 3. *School of Nursing, Tokyo Women's University, Tokyo, Japan*

Aim: To examine the association between social frailty and new onset of frailty and sarcopenia, which are defined by Cardiovascular Health Study index and Asian working group of sarcopenia, respectively, in Japanese community-dwelling older adults.

Methods: Large-scale longitudinal surveys were performed in annually from 2012 to 2014. The inclusion criteria consisted of randomly selected community-dwelling older adults aged ≥65 years who were non eligible for long-term care and were robust group at baseline assessment. 1,211 elderly were included in this study. Social frailty were operationally defined using a deficit accumulation model referred to previous study in Japan. Cox proportional hazard modeling were used to identify the associations between social frailty and onset of frailty and of sarcopenia.

Results: 9.7% of participants experienced having frailty, and 5.5% experienced having sarcopenia during the follow-up period. Baseline prevalence of social prefrailty (1/5score)

was 31% and it of social frailty ($\geq 2/5$) was 20%. Although there were no significant association with social prefrailty, those who with social frailty were found to be significantly at risk of future frailty and sarcopenia (hazard ratio 2.25, 95% confidence interval 1.3–3.9 for frailty; hazard ratio 1.55, 95% confidence interval 1.1–2.8 for sarcopenia, respectively), although adjusted by confounding factors (such as age, instrumental activity of daily living).

Conclusion: Our research showed strong impact of social frailty on the risk of new onset of frailty and sarcopenia in disability-free community-dwelling older adults. Therefore, to prevent physical frailty in community setting, early interventions for social frailty via multi-dimensional approaches may be indispensable.

LOW BODY MASS INDEX IS ASSOCIATED WITH HIGHER COMPLEXITY OF CARE IN OLDEST OLD MEN WITH DYNAPENIA

Y. Wang¹, C. Liang^{1,2,3}, M. Chou^{1,2}, Y. Lin^{1,3}, H. Lam¹,
1. Center for Geriatrics and Gerontology, Kaohsiung Veterans General Hospital, Kaohsiung, Taiwan, 2. Aging and Health Research Center, Institute of Environmental and Occupational Health Sciences, National Yang-Ming University, Taipei, Taiwan, 3. Division of Neurology, Department of Internal Medicine, Kaohsiung Veterans General Hospital, Kaohsiung, Taiwan

The association between BMI and health outcomes are still controversial in oldest old people. However, there are more evidence for the relationship between physical performance or dynapenia and poor outcomes. We recruited 344 men aged over 80 years old from a Veterans home in Taiwan to examine the interrelationship between BMI, dynapenia and complexity of care needs. Complexity of care was evaluated by the Resident Assessment Protocol (RAP) triggers derived from MDS. All subjects were classified into high or low complexity of care needs groups based on our previous study (high complexity of care needs: ≥ 4 RAP triggers; lower: < 4 RAP triggers). Dynapenia defined by the dynapenic components of EWGSOP (DEWGSOP) using the variables of lower handgrip or slower gait speed (Cutoff point defined by Asian Working Group for Sarcopenia) without muscle mass. Triggers of risk of delirium ($P=0.042$), cognitive loss ($P=0.032$), poor communication ($P=0.002$), poor psychosocial well-being ($P=0.007$), low mood states ($P=0.017$), and use of psychotropic drug use ($P=0.013$) had lower mean BMI. Lower BMI is significantly associated with higher mean of MDS-based triggers (residents with $BMI < 18.5$: 5.4 ± 2.4 ; with $18.5 \leq BMI < 25.0$: 4.8 ± 2.3 ; with ≥ 25.0 : 4.1 ± 2.1 ; $P=0.022$) among oldest old men with dynapenia. Comparing to the residents with $BMI \geq 25.0$, the residents with BMI between 18.5 and 25, and lower than 18.5 had higher complexity of care needs (OR 1.793, 95% CI 1.041 – 3.091, $P=0.035$ and OR 4.182, 95% CI 1.291 – 13.543, $P=0.017$) after adjusting for age, educational group and CCI.

SLEEP DISORDERS ARE ASSOCIATED WITH THE PRESENCE OF FRAILITY IN OLDER ADULTS

B. Manrique-Espinoza¹, A. Salinas¹, K. Moreno-Tamayo¹, O. Rosas-Carrasco², 1. Statistics, National Institute of Public Health, Cuernavaca, Morelos, Mexico, 2. National Institute of Geriatrics, Ciudad de Mexico, Mexico

Frailty is a geriatric syndrome characterized by reduced functional reserve, which results in adverse health outcomes such as disability and premature death. Meanwhile, sleep disorders are frequent in the elderly, and their presence is associated with poor physical health. The quality of sleep is important for normal functioning of metabolism and hormonal processes. The aim of this study was to evaluate whether a low quality of sleep is associated with the presence of frailty in a sample of older adults living in rural areas. For this study, the follow-up measurement (2013) of the longitudinal *Rural Frailty Study* in Mexico was used. The analytical sample was composed of 591 older adults aged 70 and plus. Frailty was assessed using the criteria of the Cardiovascular Health Study, and the variable of sleep disorder was built through the scale of Pittsburgh. Logistic regression model, adjusted for demographic and health covariates, in which an interaction term was included between sleep disorder and sex, was used. Prevalences of sleep disorders were 20% (16.8 in men and 21.8 in women) and 11% for frailty. Sleep disorder was significantly associated with the presence of frailty in women (OR = 3.24, $p < 0.01$) but not in men (OR = 0.76, $p = 0.66$), after controlling for covariates. Sleep disorder is an important risk factor to the presence of frailty. These results highlight the need to consider sleep problems in comprehensive geriatric assessment of the elderly. More studies are needed to understand the mechanisms of this association.

ASSOCIATION BETWEEN THE RISK OF VIOLENCE AGAINST THE ELDERLY PERSON AND THE FRAILITY SYNDROME

D.M. Tavares¹, M.S. Belisário¹, F.A. Dias¹, M. Pegorari², M. Mapelli³, P.C. Ferreira¹, 1. Education in Nursing and Community Health, Federal University of Triangulo Mineiro, Uberaba, Minas Gerais, Brazil, 2. Federal University of Amapa, Macapá, Brazil, 3. North Institute of Minas Gerais, Almenara, Brazil

This study had the objective of checking the association between the risk of violence against the elderly person and the frailty syndrome. This is a population-based study, with a cross-sectional design, carried out with 705 Brazilian elderly citizens living in Uberaba, Minas Gerais. We used a structured questionnaire to characterize the socioeconomic, clinical and health data, besides the Fried frailty phenotype and the Conflict Tactics Scale. Data were submitted to descriptive analysis, chi-square test and logistic regression ($p < 0.05$). Project was approved by the Research Ethics Committee. We have found that 15.9% of the elderly were frail, 52.2% pre-frail and 31.9% non-frail. In relation to violence, 20.9% reported episodes of verbal aggression, 7.9% physical aggression and 21.1% physical and/or verbal aggression. Regardless of the type of aggression, there was a prevalence of pre-frails; regardless of the type of aggression, the proportion of frail elderly was greater than the one that did not report aggression. The frailty condition was associated with higher odds ratios for physical and/or verbal (OR=1.82; 95%CI:1.08–3.07; $p=0.024$), physical (OR=2.52; 95%CI:1.22–5.20; $p=0.013$) and verbal aggressions (OR=1.85; 95%CI:1.10–3.12; $p=0.021$), even after adjusting the variables related to age, gender, diseases, medicines, and functional disability

in basic and instrumental activities of daily living. The outcomes of this study add knowledge to this issue, taking into account the analysis of some variables poorly explored in the scientific literature, frailty and violence against elderly people, in addition to being able to support the proposition of preventive interventions and behaviors directed for both conditions.

FRAILTY AND ITS RELATION TO MORTALITY IN ELDERLY WHO LIVED IN A BRAZILIAN COMMUNITY

R.A. PartezaniRodrigues¹, M.A. Diniz¹, J.S. Fhon¹, V.J. Haas², S.C. Fabricio-Wehbe¹, V.C. Almeida¹, S.B. Giacomini¹, 1. *Ribeirão Preto College of Nursing, University of São Paulo, Ribeirão Preto, São Paulo, Brazil*, 2. *Federal University of Triângulo Mineiro, Uberaba, Brazil*

Frailty is a geriatric syndrome caused by multiple factors and is associated with hospitalization, institutionalization and death. **Objective:** to analyze the evolution of frailty and its relationship with mortality in an elderly Brazilian community. **Methods:** Prospective study with a sample of 515 elderly living in the community were evaluated at two moments, with a mean follow-up period of 5.6 years. **Results:** During the first moment, in 2007/2008, the prevalence of frailty was 17.6%, during the second moment, 50.4%. In this period, 24.7% died during follow-up and of these, 45.7% were frail according to Edmonton Frail Scale (EFS). In survival analysis we observed that the frail elderly had lower survival rate. In the adjusted analysis the risk of death was significantly higher among the elderly (HR=2.34, 95% CI 1.62–3.38) and frail elderly (HR=2.21, 95% CI 1.37–3.58). **Conclusion:** Frailty evaluated in 2007/2008 showed a significant predictive value for death.

PREVALENCE OF FRAILTY IN OLDER ADULTS FROM CURITIBA, PARANÁ, BRAZIL: COMPARISON OF TWO INSTRUMENTS

J. Melo Filho¹, A.S. Wojciechowski¹, N.B. Moreira¹, S. Biesek^{2,1}, A.L. Rodacki¹, A.R. Gomes¹, 1. *Physical Education Department, Federal University of Paraná, Matinhos, Paraná, Brazil*, 2. *Centro Universitário Autônomo do Brasil – UniBrasil, Curitiba, Brazil*

Older adult's frailty is marked by individual's vulnerability to increase dependence and/or mortality when exposed to stressors. The aim was to analyze the prevalence of frailty in older adults from Curitiba, Parana, Brazil and to compare two frailty assessment methods. This cross-sectional study included 815 elderly (157 men 70.9±7.6 years-old; 27.6±4.4 kg/m² and 658 women 70.8±7.0 years-old; 28.4±5.3 kg/m²). Frailty was assessed by the Fried Phenotype: unintentional weight loss; exhaustion; low activity; slowness; weakness; score ≥3 frail; 1 or 2 prefrail and 0 not frail; and by the Clinical-Functional Vulnerability Index (CFVI-20): age; health self-perception; activities of daily living; cognition; mood/behavior; mobility; communication and presence of multiple comorbidities; maximum score 40 points; being 0–6 low vulnerability; 7–14 moderate vulnerability and ≥15 high vulnerability. The prevalence (absolute and relative) and the correlation of Spearman was used to determine between

the methods (p<0.05). The frailty's prevalence from Fried Phenotype method was frail 6% (n=49); prefrail 55.8% (n=455) and not frail 38.25% (n=311). Frailty's prevalence from CFVI-20 method was: high vulnerability 14.8% (n=121); moderate vulnerability 34.75% (n=283) and low vulnerability 50.4% (n=411). The correlation between the methods was: frail and high vulnerability (r=0.2; p=0.0001); pre-frail and moderate vulnerability (r=0.12; p=0.0001) and not frail and low vulnerability (r=0.28, p=0.0001). Prevalence of frailty observed was similar to the international literature, although differences between methods were almost two-fold. Frailty's assessment obtained from different methods showed low correlation. Thus, caution is required while comparing results derived from these approaches.

CHALLENGES OF MEASURING FRAILTY IN EMERGENCY DEPARTMENTS AND PROPOSED SOLUTIONS

M. Cardona-Morrell¹, M.R. Kristensen³, M. O'Sullivan², A.A. Ekman⁴, H. Skjot-Arkil⁵, H.H. Nygaard⁴, M. Cardona-Morrell¹, 1. *The Simpson Centre for Health Services Research, The University of New South Wales, Liverpool, New South Wales, Australia*, 2. *Cork University Hospital, Cork, Ireland*, 3. *Odense University Hospital, Odense, Denmark*, 4. *Bispebjerg og Frederiksberg Hospital, København, Denmark*, 5. *Hospital of Southern Denmark, Aabenraa, Denmark*

Frailty is associated with longer length of stay and adverse outcomes in elderly hospitalized patients, including early re-hospitalization and 12-month mortality. Identifying these risk levels on presentation at emergency departments is crucial to deliver family education, plan care, arrange referrals, and anticipate complications. Many instruments are available covering objective and subjective parameters. Our multi-center cohort study of 2,749 elderly patients in Australia, Denmark and Ireland used Fried's, Rockwood's, SUHB's and Rylance's frailty scores to predict outcomes at hospital discharge and 3-months. The exacerbation of chronic illness, poor recall, different timeframes for the estimates before presentation, absence of an informant for incompetent patients, organizational limitations and stresses of the emergency environment, and hospital policies about stretcher use on transfer impacted on our ability to reliably measure some of the parameters. Analysis showed substantial inconsistencies in the classification into pre-frail, frail or robust by different instruments on admission. Telephone administration of the frailty instruments at follow-up yielded incomplete or inexact scores due to reliance on self-report or proxy-report rather than direct observation. We concluded that doctors would have limited time to accurately assess all objective parameters during routine care. Emergency/aged care nurses and physiotherapists are best placed to conduct these measurements given their familiarity with the frailty components, training in recognizing physical abilities of patients, ongoing opportunity at the bedside, frequent visual assessment, and communication with patients/ caregivers. Fried's and Rylance's instruments were affected by many practical limitations. Telephone assessment on follow-up is not recommended to document decline or improvement over time.

ANTHROPOMETRIC MEASUREMENTS OF APPENDICULAR SKELETAL MUSCLE MASS IN OLDER PEOPLE: A SCOPING REVIEW

K. Umapathysivam, C. Tufanaru, R. Visvanathan, S.C. Yu, *University of Adelaide, Adelaide, South Australia, Australia*

Sarcopenia is an age-related loss of muscle mass and strength, a highly prevalent issue for older people and constitutes a major health problem. The measurement of appendicular skeletal muscle mass (ASM) in diagnosing sarcopenia can be challenging. Despite a clinical need to identify sarcopenia, there is still a lack of bedside clinical tools to screen for low appendicular skeletal muscle mass (ASM). The gold standard tools used to determine ASM are expensive, invasive, and complex requiring highly trained staff, therefore, anthropometric prediction equations (PEs) were developed for usage in a clinical and community environments, to estimate ASM.

Thus the objectives of this scoping review were as follows:

1) To map the disparate international literature on the diverse anthropometric variable parameters included in predictive equations for estimating ASM.

2) To map the development of the anthropometric prediction equations for used in estimating ASM.

This scoping review was undertaken in accordance with the Joanna Briggs Institute's methodology. Ten studies were included. Eight studies involved community dwelling healthy older people and two studies focused on hospitalized older patients. The most common anthropometric variable parameters included in PEs for ASM were body weight, height and BMI. Regression analysis was used to determine predictive equations for DEXA derived ASM. Included studies reported the use of Bland-Altman analysis for measurement agreement. It was concluded that it is possible to define the range of anthropometric parameters used in estimating ASM and to identify parameters that can be used with ease in clinical practice.

SELF-REPORTED FRAILITY AT DISCHARGE IS ASSOCIATED WITH READMISSION AND MORTALITY IN OLDER PATIENTS

J. Andreasen^{1,2}, M. Aadahl^{3,4}, E.E. Sorensen^{2,5}, H.H. Eriksen⁶, H. Lund^{7,8}, K. Overvad^{9,10}, 1. *Department of Physiotherapy and Occupational Therapy, Aalborg University Hospital, Hobrovej 18–22, Aalborg, Denmark*, 2. *Department of Clinical Medicine, Aalborg University, Sdr. Skovvej 15, Aalborg, Denmark*, 3. *Research Centre for Prevention and Health, The Capital Region of Denmark, Rigshospitalet- Glostrup Hospital, Ndr. Ringvej 57, Afsnit 84/85, Glostrup, Denmark*, 4. *Department of Public Health, Faculty of Health Sciences, University of Copenhagen, Copenhagen, Denmark*, 5. *Clinical Nursing Research Unit, Aalborg University Hospital, Sdr. Frailty in elderly is associated with higher risk of rehospitalization and death. The objective of this study was to assess whether self-reported frailty at hospital discharge in acutely admitted older medical patients, using a multidimensional questionnaire, was associated with unplanned readmission or death within six months after discharge. Secondly, to assess whether physical function was similarly associated.

A cohort study was conducted in seven medical departments and two acute medical units at Aalborg University Hospital, Denmark, including acutely admitted patients aged 65+. The Tilburg Frailty Indicator (0–15 points), Timed-Up-and-Go and grip strength were measured. Associations were assessed by Cox Regression, with first unplanned readmission or death as outcome and frailty as primary exposure variable, including the covariates gender, age and comorbidity.

Of the 1,328 included patients, 50% were readmitted or died within six months. When adjusted for gender, age and comorbidity there was a 72% higher risk of readmission or death if Tilburg Frailty Indicator scores were 8–13 points compared to 0–1 points (Hazard ratio 1.72, CI 1.25;2.35). A Timed-Up-and-Go score between 12.0 and 23.9 seconds compared to 4.0 to 7.9 seconds was associated with a 83% higher risk of readmission or death (Hazard ratio 1.83, CI 1.35;2.49). Grip strength was inversely associated with the outcomes.

Self-reported frailty assessed by The Tilburg Frailty Indicator at hospital discharge was directly associated with risk of readmission or death within six months. Similarly, higher Timed-Up-and-Go and lower grip strength scores were associated with higher risk of readmission or death.

ESTIMATION OF PREVALENCE OF SARCOPENIA BY USING BIA IN CHINESE COMMUNITY-DWELLING ELDERLY PEOPLE

H. Wang¹, S. Hai¹, J. Zhou², Y. Yang², P. Liu¹, B. Dong¹, 1. *Center of Gerontology and Geriatrics, West China Hospital Sichuan University, Chengdu, Sichuan, China*, 2. *Chengdu Medical College, Chengdu, China*

Sarcopenia is the loss of muscle mass as well as muscle function (defined by muscle strength or physical performance) with aging, but one of the major challenges in research is the accurate measurement of body composition, such as appendicular skeletal muscle (ASM). Although Asian Working Group for Sarcopenia (AWGS) also established the consensus on sarcopenia diagnosis, there has been no epidemiological survey that used AWGS definition to estimate the prevalence of sarcopenia in China. A total of 944 community-dwelling elderly adults aged 60 years or older were recruited in the cross-sectional study. The appendicular skeletal muscle (ASM) was measured by using DXA as a criterion method to validate a standing octapolar multifrequency BIA (InBody 720), followed by a further estimation on the prevalence of sarcopenia according to the AWGS definition. There was no significant difference between DXA and BIA measured ASM by Bland-Altman analysis. Therefore, BIA is suitable for body composition monitoring (ASM) in elderly Chinese as a fast, non-invasive and convenient way; it may be a better choice in large epidemiological studies in Chinese population. The prevalence of AWGS-defined sarcopenia was 12.5% in elderly women and 8.2% in elderly men, and increases with age in a sample of Chinese community-dwelling elderly.

PREVALENCE OF FRAILITY IN TAIWANESE ELDERLY: A COMPARISON OF TAIWAN URBAN AND RURAL AREAS

W. Wu, S.C. Hu, *College of Medicine, NCKU, Tainan, Taiwan*

Background: Frailty has begun to draw attention in recent years because it predicts adverse health outcomes for aging populations. However, the prevalence of frailty in Taiwan is not yet completely confirmed. This study aimed to compare the different prevalence of frailty among Taiwanese older adults in two areas: urban and rural. **Methods:** Data were obtained from Taiwan Longitudinal Study in Aging (TLSA) 2003. After excluding those who living in long-term care institutions and unknown living area, a total of 2,653 older adults (aged ≥ 65 years, 48% female, 41% urban residents) was recruited as the study sample. Frailty index (FI) was constructed by Rockwood's multiple-deficits approach, and the presence of 36 criteria from 3 dimensions was used: 16 of chronic disease history, 5 of functional assessment, and 15 of geriatric syndromes. The FI was calculated as the proportion of the number of deficits, and a cut point of ≥ 0.25 will be defined as frail. **Results:** Among all the participants, 1,109 (42%) were classified as frail; over a half were female and 43% were from rural area. Without doubt, prevalence of frailty increased with age in two areas. Compared with genders, female always had higher prevalence than male in three age strata, and the highest was over 85-year female rural population ($n = 108$, 83.72%, FI mean = 0.27). **Conclusions:** This comparison illustrated the different frailty and severity among gender, age, and area in Taiwan.

ADHERENCE TO THE MEDITERRANEAN DIET AND FRAILITY STATUS IN SPAIN. DATA FROM THE TSHA STUDY

C. Sanchez-Puelles, J. Carnicero, L. Rodríguez-Mañas, *University Hospital of Getafe, Getafe, Madrid, Spain*

Nutrition is one of the main factors related to frailty, but very few studies have assessed the association between Mediterranean Diet-MD and frailty, although MD is discussed as one of the healthiest eating patterns and the adherence to this type of diet is related to the prevention or treatment of several diseases. The present study assesses the potential association between adherence to MD and frailty in a cohort composed by community-dwelling older adults, the Toledo Study of Healthy Aging, Spain, whose characteristics have been broadly described elsewhere. The sample consists of 2327 participant (mean age 76 years). The incidence of frailty was assessed using three different criteria: Fried (9.88%), Frailty Index (10.07%) and Frailty Trait Scale (10.23%). Adherence to the Mediterranean diet was determined by the Predimed questionnaire (0–6 points non-adherence, 7–14 points adherence). The results show low adherence to the Mediterranean Diet (91% of the sample got a score between 2–4). Food pattern varied by: gender, being men those with greater adherence (P -value < 0.05), and age, where adherence to Mediterranean Diet declines with age (P -value < 0.01). Overall the frail population had a different nutritional pattern (P -value < 0.01) with a lower adherence to Mediterranean Diet (P -value < 0.01), and a lower consumption of foods rich in antioxidant in frail people. These differences were independent of tool used to assess frailty.

Accordingly, Mediterranean Diet is associated to frailty, with an outstanding role for some of their components.

Supported by Grant RD12/0046; ISCIII, Ministerio de Economía y Competitividad

PREVALENCE OF FRAILITY IN CHINESE OLDER PEOPLE: A CROSS-CULTURAL STUDY

R. Yu^{1,2}, W. Wu³, J. Leung⁴, S.C. Hu³, J. Woo^{1,2}, 1. *Department of Medicine & Therapeutics, Faculty of Medicine, The Chinese University of Hong Kong, Shatin, Hong Kong*, 2. *The Chinese University of Hong Kong Jockey Club Institute of Ageing, Shatin, Hong Kong*, 3. *Department of Public Health, College of Medicine, National Cheng Kung University, Tainan, Taiwan*, 4. *The Chinese University of Hong Kong Jockey Club Centre for Osteoporosis Care and Control, Shatin, Hong Kong*

Methods: Data were derived from two population-based studies, the Mr Os and Ms Os (Hong Kong) studies ($n=4000$) and the Taiwan Longitudinal Study on Aging (TISA, $n=2653$). Older people aged 65 years and older living in the community were invited to respond to a structured questionnaire. Frailty Index (FI) was constructed from 36 variables covering medical and drug histories, geriatric syndromes, assessment of physical and cognitive functioning, psychological wellbeing, and nutritional status. Frailty was defined as the index ≥ 0.25 . The ratio of FI to life expectancy at birth (LE) was used as an indicator of compression of morbidity.

Results: The weighted average prevalence rate of frailty was 41.8% and the rates were more prevalent in Taiwan urban and Taiwan rural areas (40.5% and 42.7% respectively) compared to Hong Kong (15.2%, $P<0.05$). Frailty increased with age: 65–74 years 9.6%–30.4%; 75–84 years 19.4%–48.8%; older than 85 years 24.7%–77.0% ($P<0.05$). Prevalence of frailty were statistically higher in women (ranged from 21.1%–54.3%) than in men (ranged from 9.4%–31.7%, $P<0.05$) and the differences were found in all age groups ($P<0.05$). The ratios of FI/LE were higher in Taiwan urban and Taiwan rural areas (both 0.25) compared to Hong Kong (0.17, $P<0.05$).

Conclusion: This comparison provides better understanding of levels in the health of older people and provides useful data to inform government policies. Further analyses are needed to compare the role of personal, environmental, and health and social care systems in contributing to frailty across the study populations.

SESSION 870 (POSTER)

GERONTOLOGY AND GERIATRICS EDUCATION II

THE EFFECT OF A KOREAN FUNCTION-FOCUSED CARE PROGRAM AMONG OLDER ADULTS IN LONG-TERM CARE FACILITIES

D. Jung, J. Byun, M. Lee, *Ewha Womans University, Seoul, Korea (the Republic of)*

The purpose of this study was to develop Korean Function-Focused Care Program (K-FFCP) to manage older adults' functions in restorative care, ultimately, evaluate the

program's effectiveness. The study design was pretest-posttest design with nonequivalent control group were assigned. Two nursing facilities located in Seoul as a treatment group and as a control group, respectively. The number of participants in the experimental group was 23 and control group had 20 participants with a total 43 participants enrolled in the study. The K-FFCP consisted of education for nurse and care workers and self-training for older adults for 6 weeks. The details about the developed K-FFCP include six components such as eating, dressing, bladder training, walking, using adaptive equipment, and exercise. The data of cognition (K-MMSE), physical function (K-ADL), physical capability (PCS), depression (CSDD), anxiety (RAID), grip strength, fear fall were collected. The K-FFCP effects for older adults were measured a total of 3 times (before intervention, after intervention, 6 weeks after intervention). The collected data were analyzed using Statistical Analysis System (SAS version 9.3 TS Level 1M0) program, which utilized Generalized estimating equations (GEE). According to the results, the K-ADL and PCS in experimental group showed significant increase group-time interaction. Thus, the K-FFCP showed its effectiveness in managing and improving older adults' physical function. Ultimately, the results of this program can work as a corner stone in increasing quality of life for older adults.

CAN MATURE-AGE NONTRADITIONAL STUDENTS SUCCEED IN AN ONLINE BACHELOR OF DEMENTIA CARE PROGRAM?

L. Goldberg, A. Canty, A. King, A. Price, A. Carr, J. Ziebell, J. Westbury, K. Elliott, *Wicking Dementia Research and Education Centre, University of Tasmania, Hobart, Tasmania, Australia*

An important strategy to increase knowledge, skills, and confidence of the workforce providing a range of care to people with dementia is access to contemporary evidence-based education. This paper outlines the innovative, fully online Bachelor of Dementia Care degree offered by the Wicking Dementia Research and Education Centre at the University of Tasmania (Australia). It presents an exploratory single-case study of 65 students in the first degree cohort: 31 students had previous university-level experience, 34 did not. All passed the units in which they had enrolled. Students with previous university-level experience showed significantly superior performance ($p < .05$) in only 3 of the 15 units all students had completed to date. Further, the average across-unit grade for students in both groups was no lower than a Credit (60–70%). As judged from comments on University surveys, discussion boards, and requests for help, students with no previous university-level experience needed time to adapt to the culture of university-level study, understand the nuances of ethical academic writing, and learn how to balance the intensity of studying over consecutive semesters with work and family responsibilities. These differences highlight the importance of scaffolding learning and providing step-by-step guidance for all students, but particularly those with no previous university-level experience. Findings give credence to the institutional and student support, curriculum planning, unit structure, and methods of presentation that are integral to this online degree to provide a successful online learning experience for mature-age non-traditional students.

FRAILITY STATUS AND ITS ASSOCIATED FACTORS AMONG INDONESIAN ELDERLY PEOPLE

S. Setiati¹, S. Aryana², E. Seto¹, S. Sunarti³, N. Widajanti⁴, L. Dwipa⁵, R. Istanti¹, 1. *Faculty of Medicine Universitas Indonesia - Division of Geriatrics Internal Medicine Department - Cipto Mangunkusumo National Hospital, Jakarta, Jakarta, Indonesia*, 2. *Faculty of Medicine Universitas Udayana - Division of Geriatrics Internal Medicine Department, Bali, Bali, Indonesia*, 3. *Faculty of Medicine Universitas Brawijaya - Division of Geriatrics Internal Medicine Department, Malang, East Java, Indonesia*, 4. *Faculty of Medicine Universitas Airlangga - Division of Geriatrics Internal Medicine Department, Surabaya, East Java, Indonesia*, 5. *Faculty of Medicine Universitas Padjajaran - Division of Geriatrics Internal Medicine Department, Bandung, West Java, Indonesia*

Frailty puts the elderly in risk of getting adverse health outcomes. Genetic factors, aging, life style, and commorbidities are important risk factors of frailty. It is important to know other related risk factors of frailty in elderly, especially in outpatient setting in order to prevent incidence of frailty. Unfortunately, study about frailty among elderly population in Indonesia is limited. The aim of this study is to obtain prevalence of frailty status and its associated factors among Indonesian elderly population.

This multicenter cross-sectional study was conducted at Geriatric Clinic of several hospitals in Indonesia (Jakarta, Malang, Surabaya, Bali, and Bandung) among 448 elderly patients aged 60 years old and above. Frailty was diagnosed using questionnaire of Frailty Index-40 item. Data on social demographic, functional status (ADL Barthel index), nutritional status (MNA questionnaire), and polypharmacy of each subject were collected. Logistic regression was used to obtain factors associated with frailty status.

Frailty status of subjects were 13.2% robust, 61.6% pre-frail, and 25.2% frail. Bivariate analysis showed that age (OR 2.83; 95% CI 1.69 – 4.73), nutritional status (4.55; 95% CI 2.88–7.20), functional status (OR 3.97; 95% CI 2.54–6.20), and polypharmacy (OR 1.82; 95% CI 1.05–3.15) were associated with frailty status. Logistic regression analysis showed that age (OR 2.72; 95% CI 1.58 – 4.76), functional status (OR 2.89; 95% CI 1.79–4.67), and nutritional status (OR 3.75; 95% CI 2.29–6.13) were associated factors of frailty status.

The conclusion of this study is that the factors associated with frailty status were age, functional status, and nutritional status.

FUNCTIONAL FITNESS, ANTHROPOMETRICS, AND PHYSICAL ACTIVITY IN OLDER ADULTS FROM AMAZONAS, BRAZIL

M.A. Faber², A.B. Lima¹, R.P. Lima¹, D.L. Freitas^{3,4}, E.R. Gouveia^{3,5}, 1. *Science of School Health, University of the State of Amazonas, Manaus, Amazonas, Brazil*, 2. *Faculty Idaam, Manaus, Amazonas, Brazil*, 3. *University of Madeira, Funchal, Portugal, Ilha da Madeira, Portugal*, 4. *University of Essex, Colchester, United Kingdom*, 5. *University of Geneva, Geneva, Swaziland*

This study aimed to describe the variation of functional fitness (FF), external morphology and body composition (BC) according to gender, age, and level of physical activity

(PA) in older adults from the city of Borba, Amazonas, Brazil. The sample consisted of 233 participants (97 men and 136 women) distributed across 5 age cohorts (60–64, 65–69, 70–74, 75–79 and >80 years). The FF was assessed using Senior Fitness Test. PA was estimated by the modified Baecke questionnaire. Anthropometric measures followed the ISAK protocol. Independent sample t-test showed no statistically significant differences in FF between men and women, except in upper limbs strength (favoring men) and shoulder flexibility (favoring women). Men were higher, heavier and had higher bone diameters, circumferences, and fat-free mass than women. Opposite results were found for fat mass (FM). One-way between-groups ANOVA revealed in both sexes, age cohorts differences in all FF components, favoring the younger cohorts, except for flexibility. Similar results were seen for anthropometric measures and FFM. No statistically significant differences were seen in FF components, neither in the anthropometric measures nor BC, between PA groups (low, medium and high), with one exception: flexibility in women. These results can be used as a general health index for this group/sub-population from a specific environment. Longitudinal studies, as well as, more objective measures, are badly needed to achieve a deeper understanding of these relationships in this specific population.

FEASIBILITY, SAFETY, AND OUTCOMES OF PLAYING KINECT ADVENTURES GAMES FOR ELDERLY: A PILOT STUDY

J.R. Bacha, T.B. Freitas, K.G. Silva, G. Gomes, L. Viveiro, E.M. Varise, C. Torriani-Pasin, J. Pompeu, *Department of Physical Therapy, Speech Therapy and Occupational Therapy, School of Medicine, University of Sao Paulo, São Paulo, São Paulo, Brazil*

Objective: To evaluate the feasibility, safety and outcomes of a training based on Kinect Adventures games in community dwelling elderly. **Methods:** We selected 18 community dwelling elderly, mean age 70.41 (5.43) years. Participants underwent 14 training sessions of training of one hour of duration, twice a week, in which they played four Kinect Adventures games. The subjects were assessed before and after training. The feasibility was assessed through a satisfaction questionnaire. Security was evaluated by recording adverse events during interventions. The outcomes of postural control and gait were the Mini-Balance Evaluation Systems Test (Mini BESTest) and the Dynamic Gait Index (DGI), respectively. **Results:** All participants scored the higher level of the satisfaction questionnaire. There were no adverse events during interventions. The intervention promoted improvement on postural control (Mini BESTest median before training = 28 and after training = 30.5; Wilcoxon test, $p = 0.013$) and gait (DGI median before training = 23 and after training = 24; Wilcoxon test, $p = 0.033$). **Conclusion:** The training based on Kinect Adventures Games was feasible, safe and promoted improvement on postural control and gait of community dwelling elderly.

RELATIONSHIP OF NUTRITIONAL STATUS AND FUNCTIONAL CAPACITY IN ELDERLY PATIENTS

S. Kanwal, W. Qidwai, K. Nanji, *Aga Khan University Hospital Karachi, Karachi, Sindh, Pakistan*

Rising elderly population poses a great challenge in terms of the health care burden due to various social and biological

influence so our older individuals is at risk of malnutrition and subsequently impairment in their functional activity and affects quality of life.

This was analytical cross-sectional conducted from January-July 2015. We evaluated functional and nutritional status by using KATZ scoring and MNA Scale in elderly >60 years in sample size of $n=200$. Individuals presented to Family medicine clinics of Aga Khan University hospital Karachi, were recruited via non probability consecutive sampling. Data double entered in SPSS 19. To assess the correlation between nutritional status and functional status Spearman's rank Correlation Coefficient was applied.

Mean age was (68.3 years \pm 7.0 SD) male proportion was (54%) $n=109$. According to checklist 33.5% ($n=67$) were at risk of malnutrition, and 35.5% were functionally impaired ($n=71$). Spearman correlation between functional and nutritional status was found to be $\rho=0.65$ with $p\text{-value}=0.039$. Both are also significantly associated with variables like age and educational status $p\text{-value}=0.000$ and $p=0.049$ respectively. Hypertension 67% ($n=134$) and diabetes 50% were found to be most prevalent diseases in elderly. Polypharmacy was prevalent in 37.5% ($n=75$).

Our study indicates that there is a significant positive correlation between nutritional and functional status. This needs to be addressed in a developing country like Pakistan, however this is a small cross-sectional study in one setting, further large studies will be required to assess the relationship.

EDUCATIONAL NEEDS OF HEALTHCARE PROFESSIONALS IN THE FIELD OF GERONTOLOGY IN BULGARIA

P. Balkanska-Georgieva, N. Georgiev, E. Ivanov, S. Mladenova, A. Vodenicharova, A. Yanakieva, *Medical University of Sofia, Faculty of Public Health, Sofia, Bulgaria*

Challenges for geriatric care in Bulgaria are significant. Our country is the second most rapidly aging nation in the Eastern region of Europe. In this connection, the logical question is: are the health professionals prepared to meet the demographic challenges of aging? In search of answers to these questions was done a large study. *The aim of the study* was to explore the specific problems of occupational health professionals in providing medical and social assistance for old people and clarify their educational needs in the gerontology and geriatric practice. *Object of Study and Methods:* Respondents are 1875 people in 10 cities across Bulgaria: 940 healthcare professionals and 935 persons over 60 years, consumers of health care, of which 385 people from their homes for the elderly. The following methods were used: documentary method; inquiry method; Delphi method; statistical methods. *Research Results:* Determined are the main reasons for the difficulties of health professionals in taking care for their patients. There were missing or insufficient knowledge of gerontology and geriatric care in half of the respondents. Educational needs in medical gerontology are in the following areas: specific manifestations of disease in old patients, age changes in mentality and behavior, communication skills for working with elderly, training in health care for chronically ill and their families, aging prophylaxis. Based on the survey data, recommendations for adapting the education of health professionals in the field of gerontology and geriatric practice were prepared.

KEYWORDS: aging, geriatric care, health professionals, educational needs, medical gerontology

PREPARING A CULTURALLY SENSITIVE HEALTHCARE WORKFORCE: OUTCOMES AND BENEFITS OF GERIATRIC COURSES

O. Catolico, A. Boyle, *School of Health & Natural Sciences Department of Nursing, Dominican University of California, San Rafael, California*

The World Health Organization predicts that persons aged 60 years and older will total 2 billion, an increase from 900 million in 2015 (WHO, 2015). In the U.S., there were 44.7 million persons who were 65 and older who accounted for 14.1% of the total population in 2013. (U.S. Census Bureau, Population Estimates, 2014). Also notable are demographic shifts related to migration. Over 1 billion people are migrants and this includes 244 million persons residing in a country other than their country of birth (2016, International Organization for Migration).

Given this information it is imperative that healthcare professionals are educationally prepared to provide effective and culturally sensitive care to older adults. Older adults nonetheless, continue to experience healthcare disparities including access to care and quality of care. Disparities in care continue to persist in Asian Pacific Islanders, Alaskan/Native Americans, African Americans, Hispanics, and LGBT populations (AHRQ, 2015). Social determinants of health, limited English proficiency and health literacy, inadequate healthcare provider knowledge and skills contribute to disparities in minority populations.

California is one of the most diverse states in the nation, yet few undergraduate programs have dedicated curriculum in geriatric nursing. A private independent university has required a foundational course in geriatric nursing for eight years. The objectives of this study are to: (1) identify the practice patterns of geriatric nursing competencies among its nursing program graduates (AACN, 2010), and (2) examine the impact of practice competencies on care outcomes of the older adult in respective healthcare settings through facility databases.

ASSOCIATION BETWEEN FRAILTY AND PAIN: A TIME BOMB

M. Gurgu¹, E.F. Bleotu², A. Zamfirescu³, H. Gurgu³, M. Gurgu⁴, M. Sporis², 1. *Emergency Hospital, Brasov, Romania*, 2. *Hospice Casa Sperantei, Brasov, Romania*, 3. *University of Medicine and Pharmacy "Carol Davila", Bucharest, Romania*, 4. *Emergency Pediatric Hospital, Cluj-Napoca, Romania*

Chronic pain is a common, frequently undervalued symptom in elderly patients. Frailty is a common geriatric syndrome in elderly, but frequently unquantified in medical practice. Pain and frailty are independent risk factors for high dependency in elderly and when associated they increase disability and lower the quality of life

Objectives: The aim of this paper was to study the association between persistent pain and frailty in two groups: robust and frail elderly and the impact on functional capacity.

Material and Methods: We conducted an observational study on 97 elderly patients selected from 678 patients, age

between 65 and 93 year. We excluded oncological patients, those dependent with advanced stages of somatic and psychiatric diseases. We split the patients in two groups: robust and frail. We used the Frailty Index to assess frailty, Brief Pain Inventory to assess pain and IADL and ADL scales to measure functional capacity.

Results: There was a high incidence of pain in the two groups (60%), highest being in the frail group (77.7%) and with a higher analgesic consumption (NSAID and Acetaminophen being most used). The association of pain and frailty increases the level of dependency, represented by ADL and IADL (mean score 4 compared to 6 for robust).

Conclusion: A thorough assessment of elderly patients that have persistent pain associated with frailty is a challenge, but with positive effects on quality of life. Frailty rises the difficulty of pain management which requires a complex approach: pharmacological and non-pharmacological, monitoring the side effects and drug interactions.

A 15-YEAR RETROSPECTIVE STUDY EXAMINING THE EXERCISE HABITS OF COMMUNITY-DWELLING OLDER ADULTS

B. Willis, M. Sims, E. Prost, S. Sayers, *Physical Therapy, University of Missouri-Columbia, Columbia, Missouri*

Routine exercise habits have been shown to reduce modifiable health risks associated with aging. Studies examining the exercise habits of older adults over a 15 year period are limited. The purpose of this study is to better understand the exercise habits of males (M) and females (F) in their 50's, 60's, 70's and those ≥ 80 years old(y/o). By examining mean age, sex, and number of lifetime visits(NLV), clinicians may improve targeted wellness education, reducing modifiable health risks associated with aging. The age, sex, and NLV of 1,988 community-dwelling older adults enrolled in a hospital-based wellness center from 9/1/2000 to 1/1/2016 were examined. Groups included: Grp1(50-59y/o; F;n=372,M;n=125), Grp2(60-69y/o; F;n=353, M;n=226), Grp3(70-79 y/o; F;n=258,M;n=192) and Grp4(80 y/o+; F;n=222,M;n=240). Statistical significance was accepted at $p < 0.05$. Overall mean age was 55.0 ± 2.8 (F= 55.1 ± 2.8 , M= 54.9 ± 2.7) for Grp1, 64.4 ± 2.9 (F= 63.9 ± 3.0 , M= 65.1 ± 2.8) for Grp2, 74.4 ± 2.9 (F= 74.5 ± 2.9 , M= 74.5 ± 2.9) for Grp3, and 86.9 ± 5.2 (F= 86.8 ± 5.3 , M= 86.9 ± 5.1) for Grp4. Overall mean NLV was 57.9 ± 123 (F= 52.5 ± 108 , M= 74.0 ± 160) for Grp1, 115 ± 262 (F= 115 ± 268 , M= 115 ± 253) for Grp2, 198 ± 427 (F= 173 ± 403 , M= 233 ± 455) for Grp3, and 323 ± 497 (F= 301 ± 501 , M= 343 ± 494) for Grp4. A significant main effect for age ($f=46$; $p < 0.001$) on NLV was observed. A strong trend for sex ($f=3.5$; $p=0.06$) on NLV was seen. No age by sex interaction ($f=0.68$; $p=0.57$) existed. Significant differences in NLV at each successive age group over age 60 were present. This study demonstrated that age had a significant impact on NLV. Also, a strong trend ($p=0.06$) suggests that men participated in more NLV than women. This reinforces that clinicians may benefit from considering a client's age and sex to improve targeted wellness education, increasing exercise participation and reducing modifiable age related health risks.

THE ASILA PROGRAM: IMPROVED CARE IN NURSING HOMES FOR FRAIL SENIORS

V. Boscart¹, G. Heckman², K. Huson¹, M. Heyer¹, J. Hirdes²,
1. School of Health & Life Sciences and Community Services, Conestoga College, Bright, Ontario, Canada, 2. University of Waterloo, Waterloo, Ontario, Canada

The Applied Simulated and Integrated Learning Approach (ASILA) aimed to advance targeted clinical outcomes for seniors through the use of evidence-informed case simulations of conditions among frail seniors with cognitive and physical challenges. The ASILA program is based on the use of the Minimum Data Set as a comprehensive geriatric assessment (CGA) and quality improvement framework to facilitate care planning.

A mixed method, repeated-measures design was used to assess changes in nursing assistants' (NA) knowledge and perceptions of CGAs and resident clinical outcomes.

Quantitative data indicated meaningful improvements in key knowledge areas. Qualitative data provided a description of the impact of the ASILA program on staff knowledge and role perceptions and how that translated to care practices.

The ASILA program successfully enhanced NAs' knowledge and perceptions of CGAs, and improved resident outcomes, while emphasizing quality of life and promoting best practices within a financial framework of accountability.

MASTER ON GERONTOLOGY: A PERSPECTIVE IN GERONTOLOGY EDUCATION IN MEXICO

E. Arias-Merino, N.M. Mendoza Ruvalcaba, I. Díaz-García, M. Flores Villavicencio, *Salud Pública, Universidad de Guadalajara, Zapopan, Jalisco, Mexico*

In order to prepare high-quality human resources in Gerontology able to face the challenges of our aging society, the University of Guadalajara (Mexico) had offered the Master of Gerontology degree since 1994. Based on this program, it has been developed a new program evaluated and accepted in 2016, in the National Quality Graduate Program of the National Council of Science and Technology (CONACYT).

For this Master degree, gerontology is understood as a field of the scientific knowledge inter-multi-transdisciplinary, dedicated to the study of the process of aging, the old stage and the older persons as individuals; from bio-psycho-social perspectives.

From a Public Health approach, and based in solid ethical values and attitudes, the gerontologist profile includes the knowledge to: 1) describe understand and explain the life-span from a bio-psycho-social perspective, 2) differentiate successful, active and healthy aging from pathological, 3) use methods and techniques for the generation of knowledge and intervention in the aging process, 4) understand the administrative process of institutions in gerontology, 5) analyze social policy and legislation, 6) analyze the importance of social perception of the older persons, 7) analyze the importance of the family and social network, as well as social support in gerontology interventions.

Is a competence-based program, and in a review, it was found that its approach applies the gerontology competencies for undergraduate and graduate education published by AGHE in November 2014.

HIGHER-LEVEL FUNCTIONAL CAPACITY AMONG THE COMMUNITY-DWELLING ELDERLY IN JAPAN

P. Zhang¹, H. Hayashi¹, H. Sato², T. Yamashita³, 1. Department of Nursing, Saitama Prefectural University, Koshigaya, Saitama Prefecture, Japan, 2. Takesato District Public Hall, Koshigaya, Saitama Prefecture, Japan, 3. Chuo Public Hall, Koshigaya, Saitama Prefecture, Japan

Objective: Japan is a rapidly aging society, and thus nursing approaches that enable the elderly to lead longer and more independent lives are needed. Therefore, the purpose of this study was to gain a better understanding of higher-level functional capacity among community-dwelling elderly.

Methods: A questionnaire survey was conducted at a Japanese community center for the elderly in October 2015. The questionnaire was designed to identify the characteristics of the elderly and assess higher-level functional capacity according to the following four aspects: "using a new instrument"; "collecting information"; "life management"; and "social involvement".

Results: A total of 135 elderly individuals (42 men, 93 women; mean age, 74.6 years; range, 65–90 years) completed the questionnaire. Fifty-nine (43.7%) respondents were living in a married household, 86 (63.7%) had a chronic disease, 111 (82.2%) were pursuing a hobby, and 67 (49.6%) frequently participated in activities. The mean (\pm standard deviation) higher-level functional capacity score was 10.5 ± 3.8 points out of a possible total of 16. The mean scores for "using a new instrument", "collecting information", "life management", and "social involvement" were 2.5 ± 1.3 , 3.1 ± 1.1 , 2.8 ± 1.1 , and 2.0 ± 1.6 , respectively.

Conclusions: According to a previous study, the mean higher-level functional capacity score for a nationally representative sample of community-dwelling elderly was 9.7 ± 4.2 ; that of this study was higher in comparison, indicating that the elderly individuals in this study had excellent functional capacity. In the future, nursing approaches that help rejuvenate the community by enabling the elderly to lead even longer and more independent lives are expected.

TRAINING AND MOTIVATION OF MEDICAL PROFESSIONALS FOR WORK WITH OLDER PEOPLE IN BULGARIA

S.M. Mladenova, E. Ivanov, P. Balkanska, A. Vodenicharova, A. Yanakieva, *Faculty of Public Health, Medical University - Sofia, Sofia, Bulgaria*

Introduction: In the recent decades, in Bulgaria and in Europe there is a steady trend of increase of the aging population and as a result of this raising of the proportion of older people.

One of the main tasks of our society is to provide appropriate conditions and satisfactory levels of care in order to achieve good quality of life for older people. It is especially important to take actions to provide a dignified aging of the elderly.

The training of nurses in Bulgaria in the curricula is included a course "Nursing care for elderly" which meets the increased needs for specialists ready to work with old people.

The aim of the study is to examine the need for specialized training, the readiness of medical specialists to work

with older people and to contribute for the motivation of these professionals to provide quality health care.

Methods applied: Conducted was an anonymous survey among 62 medical professionals trained in a part time form of training in the undergraduate program of the specialty “Management of health care”. The survey was conducted during the training internship of the students of third year who work in health institutions throughout the country.

The results show that the work with old people is not preferred by nurses. Working with the elderly is burdening them mentally and physically and sometimes this hampers the performance of professional activities. In order to motivate the medical professionals to work with older people they need more additional stimuli and specific knowledge and training to make them be able to contribute successfully for the better quality of life of the elderly.

SESSION 875 (POSTER)

HEALTH CARE

TRAJECTORIES OF MOTOR FUNCTION AND COGNITION IN RELATION TO HOSPITALIZATION

J. Hallgren¹, E.I. Fransson¹, D.G. Finkel², A.K. Dahl-Aslan¹,
1. *School of Health and Welfare Jonköping University, Jönköping, Sweden*, 2. *School of Social Sciences, Indiana University Southeast, New Albany, Indiana*

Background: Hospitalization among older people is common and associated with adverse outcomes. However, knowledge about long-term effects on motor functions and cognitive abilities in relation to hospitalization is scarce. In order to explore development of motor functions and cognition after hospitalization, a longitudinal study among middle-aged and older adults with up to 25 years of follow-up was conducted.

Methods: Overall, 828 participants from the Swedish Adoption/Twin Study of Ageing (SATSA) were linked to the Swedish National Inpatient Register, which contains information on participants’ hospital admissions. Up to 8 assessments of cognitive performance and 7 assessments of motor functions i.e. fine motor, balance/upper strength, and flexibility, from 1986 to 2010 were available. Latent growth curve modelling was used to assess the association between hospitalization and subsequent motor function and cognitive performance.

Results: A total of 735 (89 %) persons had at least one hospital admission during the follow-up. The mean age at first hospitalization was 70.2 (\pm 9.3) years. Persons who were hospitalized exhibited a lower mean level of cognitive performance in all domains and in motor functions compared with those who were not hospitalized. A significantly steeper decline was observed in motor function abilities as well as in processing speed, spatial/fluid, and general cognitive ability performance of hospitalized participants. These patterns remained even after comorbidities and dementia prevalence were controlled for.

Discussion: We are the first to show that hospitalization is associated with steeper decline in both motor function and

cognitive abilities across more than two decades of post-hospitalization follow-up.

IMPROVING PATIENT-PROVIDER PARTNERSHIPS ACROSS THE HEALTHCARE SYSTEM

P.T. Stolee¹, J. Elliott¹, G. Heckman¹, V. Boscart², S. Group¹,
1. *University of Waterloo, Waterloo, Ontario, Canada*, 2. *Conestoga College, Kitchener, Ontario, Canada*

Many older patients and their caregivers wish to be engaged in decisions around their care, but this is often not well accommodated in existing practice models. We synthesized available theories and evidence around engagement of older adults in healthcare decision-making into our previously developed “CHOICE” Patient Engagement Framework (Stolee et al., 2015; Elliott et al., 2016) and developed strategies to support meaningful partnerships of older patients and caregivers with their healthcare providers. In partnership with patients, caregivers and health care providers, this current project aimed to answer the following questions: 1) How do the CHOICE principles and strategies correspond with actual experiences of engagement? 2) What factors currently facilitate or hinder patient engagement? and 3) What resources, materials and implementation strategies are needed to support patient engagement in each health setting? We conducted observations and interviews in two healthcare settings (primary care and community care) with providers, patients, and families to understand current perspectives, practices, and facilitating/hindering factors related to patient engagement. Observation and interview data were analyzed using emergent coding as well as directed coding guided by the CHOICE framework. Using the information that emerged from the interviews and observations, resources and materials for patient/caregiver engagement have been co-created by patients, caregivers and healthcare providers, for use in multiple care settings.

ATTITUDES TOWARD AGING AND CHANGE IN PHYSICAL FUNCTION AMONG OLDER ADULTS IN TAIWAN

C. Sun¹, C. Yeh², H. Cheng¹, L. Lu¹, R. Shen³, C. Chiu¹,
1. *Division of Geriatrics and Gerontology, Department of Internal Medicine, National Cheng Kung University Hospital, Tainan, Taiwan*, 2. *Institute of Allied Health Sciences, National Cheng Kung University, Tainan, Taiwan*, 3. *Institute of Nursing, National Cheng Kung University, Tainan, Taiwan*

Attitudes are known to exert a powerful influence upon physical performance in later life, include ADL and IADL dependency, with variable impact. Aim of this study was to investigate the impact of attitudes toward one’s own aging on functional outcomes in a national-wide representative sample of community-dwelling older adults in Taiwan. Data on participants (N=3778) aged 65 and over who participated in the 2003 and 2007 Taiwan Longitudinal Study on Aging (TLSA) were analyzed. Physical disability, including mobility limitations, IADLs and ADLs were regressed on an individual’s attitude toward aging in 2003, with control of their physical function and other covariates in 2003. Results show that positive attitude toward aging was associated with higher levels of physical function four years later. Specifically, negative attitude on “Will you raise grandchildren in

retired-years” was associated with higher ADL limitations during follow-up (OR:1.75, 95% CI 1.26–2.42, $p<0.001$). Negative attitude on “Do you agree that government had provided welfare in accordance with demand” was associated with lower IADL limitations (OR:0.82, 95% CI 0.68–0.99, $p<0.05$). Besides, negative thought against actively instruction for intimate relationship maintenance was associated with higher limitations in mobility (OR:1.31, 95% CI 1.04–1.64, $p=0.02$) and ADLs (OR:1.40, 95% CI 1.01–1.94, $p<0.05$). Findings from this study suggest that having positive attitudes toward aging may contribute to better physical outcomes in older adults despite other well known risk. Helping older adults overcoming negative thought of aging at societal and individual level may help to achieve successful aging with positive physical outcomes.

GERIATRIC COLORECTAL SURGERY CO-MANAGEMENT PROGRAM: IMPACT ON PATIENT OUTCOMES

S. Cizginer¹, E. Prohl¹, J. Monteiro², S. Schechter¹, L. McNicoll¹, 1. *Brown University, Alpert Medical School, Providence, Rhode Island*, 2. *Brown Medical School, Rhode Island Hospital, Providence, Rhode Island*

In elderly surgical patients, multiple comorbidities and diminished reserve lead to increased post-operative complications and higher cost. We developed a Geriatric Surgery Co-management (GSC) program, as an innovative partnership between geriatrics and colorectal surgery, to improve patient care for elderly colorectal surgery patients in the post-operative setting. This retrospective study analyzed colorectal surgery patients aged 70 or older admitted to a community hospital before GSC program implementation. Historical control (HC) was compared to patients admitted after implementation of the GSC program. GSC patients received a post-operative comprehensive geriatric assessment, identification of risk factors for and prevention of geriatric syndromes, management of comorbidities and optimization of pain management. The data was collected via National Surgical Quality Improvement Program and chart review. The HC ($n=104$) and GSC ($n=44$) groups were comparable at baseline. The most common type of surgery was colectomy in both groups (59% of all cases). The mean length of stay (LOS) was 5% shorter (-0.6 days) in GSC (p -value=0.74); more pronounced in older and sicker patients: 15% shorter (-1.5 days) in patients ≥ 80 years old, 22% shorter (-1.7 days) in patients with Charlson comorbidity index ≥ 3 (p -values=0.47 and 0.25, respectively). Postoperative cardiac arrhythmia was markedly diminished from 12/104 (11%) in HC compared to 0/44 (0%) in GSC (p -value=0.02). The mean total hospital charge was \$9,500 (18%) less per patient in GSC (p -value=0.1). Our results suggest that a multidisciplinary approach to postoperative care for geriatric colorectal surgery could decrease LOS, improve patient outcomes while decreasing hospital costs.

AWARENESS AND BEHAVIOR ON THE PERIODIC HEALTH EXAMINATION IN KOREAN ELDERLY SUBJECTS

J. Shin¹, Y. Choi^{2,3}, 1. *Department of Family Medicine, Gangnam Severance Hospital, Yonsei University College of Medicine, Seoul, Korea (the Republic of)*, 2. *Center for*

Health Promotion, Samsung Medical Center, Seoul, Korea (the Republic of), 3. *Sungkyunkwan University School of Medicine, Seoul, Korea (the Republic of)*

To evaluate awareness and behavior on the periodic health examination (PHE) in Korean elderly person, we enrolled 899 subjects who visited the health promotion center of a university or the clinic for any kind of a health problem in the same hospital from February to May 2016. Thirty-two questionnaires about awareness, knowledge, and usefulness of early detection and behavior on PHE were administered. We compared the responses between elderly (≥ 65 years) and middle-aged (<65 years) group using Student's t -test or χ^2 test. The mean ages (standard deviation) of the two groups were 50.1(10.6) and 68.7(3.5) years ($P<0.001$). The elderly subjects perceived the awareness, knowledge and usefulness on PHE, similar with middle-aged subjects ($P>0.05$). Also, they wanted to take a PHE continuously without upper limit of age (52.4%) than middle-aged group (49.7%, $P=0.007$), despite a doctor's advice to stop PHE without further benefit. Although the elderly subjects started PHE later than the middle-aged group (≥ 50 years (66.4%), vs. 40–49 years (39.4%), $P<0.001$), they has been doing regularly (annual: 54.0% vs. 49.3%, $P=0.006$). Conclusively, Korean elderly subjects perceived the awareness of PHE and showed proactive behaviors. Therefore, it is needed to understand their awareness and behavior on PHE to prepare the individualized PHE.

ANALYSES OF HEALTH OUTCOMES FOR OLDER COPD PATIENTS WITH ICS USE IN TAIWAN

Y. Li, *Institute of Health Care Management, National Sun Yat-Sen University, Kaohsiung, Taiwan*

Inhaled corticosteroids (ICS) are commonly prescribed to patients with chronic obstructive pulmonary disease (COPD). Studies indicated that ICS use may lead to adverse effects for COPD patients. Nevertheless, the effects of increased risk of adverse events are inconclusive. What are the effects of related treatments for the COPD patients are critical research questions to be examined. However, limited study had explored such issues in Taiwan. This study aims to investigate the health care outcomes for older COPD patients under medication treatments. This study applied National Health Insurance database for analyses from year 2009 to 2012. COPD patients were grouped as case group or control group based on whether they use ICS or not. Meanwhile, this study conducted propensity score matching method to reduce potential sample selection bias. Health care outcomes include probability of having pneumonia, emergency department use, and hospital admission. There are 1237 cases and 3711 control observations in the final analyses. The mean age is 76 years old. Multivariate logistic regressions indicated that case group had significantly higher probability of getting pneumonia (OR=1.85, 95%CI=1.61, 2.13), higher probability of emergency department use (OR=1.57, 95%CI=1.35, 1.82), and higher probability of hospital admission due to pneumonia (OR=1.73, 95%CI=1.48, 2.01). The study results from nationally represented dataset provide empirical evidence that ICS use for older COPD patients in Taiwan may increase the probabilities of adverse events. Cautions of treatment influences on care processes for older COPD patients are in great needs in Taiwan.

CHRONIC KIDNEY FAILURE AND CONSERVATIVE (NON-DIALYSIS) CARE AMONG OLDER ADULTS

H. Tam-Tham, K. King-Shier, C. Thomas, R. Quinn, K. Fruetel, B. Hemmelgarn, *Community Health Sciences, University of Calgary, Calgary, Alberta, Canada*

Conservative (non-dialysis) management of adults with stage 5 chronic kidney disease (CKD, eGFR <15ml/min/1.73m²) is increasingly being provided in the primary care setting. We aimed to examine the prevalence of barriers and facilitators to conservative management of older adults by primary care physicians. We conducted a cross-sectional population-based survey of all primary care physicians in Alberta, Canada. Eligible participants had experience caring for adults aged ≥75 years with stage 5 CKD not planning on initiating dialysis. Questionnaire items were derived from a qualitative descriptive study, informed by the Behavior Change Wheel, and tested for face and content validity. Physicians were contacted via postal mail and/or fax, based on a modified Dillman method. Four hundred and nine eligible physicians completed the questionnaire (9.6% response rate). The majority of respondents were male (61.6%), aged 40 to 60 years (62.6%), and practiced in a large/medium population centre (68.0%). The most common barrier to providing conservative care in the primary care setting was the inability to access support to maintain patients in the home setting (39.1% of respondents). The second most common barrier was working with non-physician providers with limited kidney-specific clinical expertise (32.3% of respondents). Primary care physicians indicated that the two most common strategies that would enhance their ability to provide conservative management would be the ability to use the telephone to contact a nephrologist or clinical staff (86.9% and 85.6% of respondents respectively). Important areas were identified to inform clinical programs for supporting primary care physicians' provision of kidney conservative care.

SYSTEMIC INFLAMMATORY RESPONSE IN SENILE PATIENTS AFTER SINGLE-INCISION LAPAROSCOPIC CHOLECYSTECTOMY

A.V. Alekberzade, N. Krylov, J. Badalov, I. M. Sechenov *First Moscow State Medical University, Moscow, Russian Federation*

The aim of the study was to compare blood levels of tumor necrosis factor- α (TNF- α), interleukin-1 β (IL-1 β), α 1-antitrypsin and C-reactive protein (CRP) during acute phase of systemic inflammatory response in twenty-eight patients who suffered from chronic calculous cholecystitis and underwent single-incision laparoscopic cholecystectomy (SILC).

Patients were divided into two equal age groups. Youth group included patients aged up to forty-five years old and senile group included patients elder than seventy-eight years. Blood samples were taken from peripheral vein two hours before the surgery and six, twenty-four and forty-eight hours after the surgery.

It was found that the acute phase of systemic inflammatory response after SILS in senile group is differed from the youth group, as it had hyperactivity and delayed ending. TNF- α and IL-1 β increased after surgery if compared to the initial levels in both young and senile patients. The same

results were observed for α 1-antitrypsin and CRP. The study revealed the highest rates of pro-inflammatory cytokines in senile patients comparing to patients from the young group of control after surgery.

PREDICTING HEALTH LITERACY AMONG DISABLED ELDERLY IN KOREA: IMPLICATIONS FOR HEALTH JUSTICE

Y. Kim², H. Lee¹, B. Park³, K. Park¹, 1. *School of Social Work, University of Minnesota, St Paul, Minnesota*, 2. *Kyunghee University, Suwon, Korea (the Republic of)*, 3. *Pusan National University, Pusan, Korea (the Republic of)*

Background: Low health literacy is significantly linked to health disparity, and this link is particularly true for the disabled elderly. Despite 90% of the elderly population in Korea have chronic disease, there is limited research investigating health literacy in this population. This study aims to investigate (1) the level of health literacy and (2) factors associated with it among disabled elderly.

Methods: A convenience community dwelling sample of disabled elderly aged 60 and over (N=212) was recruited from Busan, Korea. Health literacy was measured by using 16 items from Chew et al.'s self-reported measure (2004) and Andersen's behavioral model theoretically guided this study (Andersen, 1995).

Results: The participants' average level of health literacy was 3.03 from 1 to 5 Likert scale. About 67% of the participants reported that they had difficulty to understand written health information, while about 71.2% were not confident when filling out medical forms. About 34.9% of the participants reported that they almost always (10.8%) and often (24.1%) had someone help them to read hospital materials. The participants' education, literacy, income, and health care cost were positively associated with health literacy.

Implications: Overall, disabled elderly in Korea reported a lower level of health literacy and this is lower than that of the elderly without disability (3.13) (Kim et al., 2014). Since our finding informed that health literacy is significantly linked to education and literacy, it is important to increase literacy education combined with community-based health literacy programs especially for the disabled elderly with low health literacy.

GERIATRIC HEALTHCARE IN DEVELOPING NATIONS: A REVIEW FROM INDIA

C. Felix, 1. *Geriatric Medicine, Welcare Hospital, Kochi, Kerala, India*, 2. *The George Institute for Global Health, Hyderabad, India*

In the highly populous India, the population above 60 were at 96 million in 2011 or 117 million in 2015, with a rapidly increasing trend. Alongside the demographic transition, there is also an epidemiological transition with increase in non-communicable diseases (NCDs) such as diabetes, hypertension, stroke and heart disease. Lower respiratory infections and diarrhoeal diseases decreased almost 80%, but ischaemic heart disease increased over 20%. For the large number of sick elderly though, geriatric healthcare, research, infrastructure, programs, policy and implementation present big gaps. Geriatrics as a medical specialty too is in its infancy, with only a handful of MD seats and very few geriatric departments across the nation.

Thus, common age-related medical conditions such as stroke and dementia are undiagnosed or underdiagnosed. There is no universal social security such as medicare for the elderly and very few are insured, that too only for acute or in-patient care. Elderly healthcare and its access thus is dismal, especially with disintegration of the traditional joint family system. For the non-working 60 plus, rationing of healthcare and finances has been the norm. This talk will address the lacunae in geriatric diagnoses, policy and implementing healthcare.

SESSION 880 (POSTER)

INNOVATIONS IN RESEARCH METHODS

INVOLVING OLDER ADULTS IN TECHNOLOGY RESEARCH AND DEVELOPMENT (OA-INVOLVE): AGE-WELL

Y. Ishigami-Doyle¹, I. Panek¹, L. Battersby², K. O'Doherty³, P. Kontos⁴, J. Sixsmith², S. Kirkland¹, 1. *Dalhousie University, Halifax, Nova Scotia, Canada*, 2. *Simon Fraser University, Burnaby, British Columbia, Canada*, 3. *University of Guelph, Guelph, Ontario, Canada*, 4. *Toronto Rehabilitation Institute - University Health Network, Toronto, Ontario, Canada*

Background: Maintaining and improving quality of life, safety, security, and independence for the growing older adult (OA) population requires innovative approaches and transdisciplinary collaboration. The development of novel technologies that address the needs and preferences of OAs can benefit from the active engagement of potential target users across the spectrum of technology research and development (R&D), from conceptualization, to formulating the research questions, to prototype testing to commercialization.

Objective: To explore and describe best practices for active OA involvement in technology R&D.

Methods: OA-INVOLVE is one of over 25 projects within the AGE-WELL Network, a National Centre of Excellence focusing on technology and aging. Working closely with an OA advisory group and partner organizations, OA-INVOLVE applies a unique participatory action research approach to document existing OA engagement practices within AGE-WELL and across the broader research community.

Results: Initial findings indicate that the majority of OAs are engaged in projects as study participants; few are involved as advisors or decision makers. We present a framework for OA engagement, including planning, recruitment, training and engagement strategies for OA participation as collaborators, consultants, and co-designers at every stage of technology R&D. We report on facilitators, barriers, lessons learned, and solutions to enhance meaningful engagement of OAs. Our multimedia knowledge dissemination strategy further mobilizes the larger technology R&D community as well as older adults to form effective partnerships.

Conclusions: This work enables us to establish evidence-based models for collaborative participatory work with OAs and describe potential impacts on the research process and associated outcomes.

LEVELS OF OLDER ADULTS' ENGAGEMENT IN TECHNOLOGY RESEARCH, DESIGN AND DEVELOPMENT: A SCOPING REVIEW

I. Panek¹, E.T. Crumley¹, Y. Ishigami-Doyle¹, J. Sixsmith², P. Kontos³, K. O'Doherty⁴, S. Kirkland¹, 1. *Community Health & Epidemiology, Dalhousie University, Halifax, Nova Scotia, Canada*, 2. *Simon Fraser University, Vancouver, British Columbia, Canada*, 3. *University Health Networks, Toronto, Ontario, Canada*, 4. *University of Guelph, Guelph, Ontario, Canada*

Background: Engaging older adults (OAs) in technology research, design and development is considered to be key in creating products that better fit their needs and preferences. However, engaging OAs, especially persons with mobility, physical or cognitive limitations, often requires employing individualized approaches and flexible ways of participating. Guidelines to support researchers and developers in creating meaningful working relationships with OAs are limited. In order to formulate guidelines facilitating effective OA engagement, we explored practices of conducting technology research and development. Our scoping review summarizes methods used for involving OAs and highlights different levels of their engagement.

Methods: We searched six databases and independently assessed articles for inclusion. A total of 54 articles met the inclusion criteria.

Results: The majority of studies involved OAs as participants in technology or prototype testing; fewer reported engagement in an advisory role or in true partnerships with shared decision-making. Making the research rewarding by catering to the interests and capabilities of the participants and providing adequate information about the technology and research process were essential to improved retention. A constant refinement of the activities and information materials, addressing the levels of the individuals' understanding was also critical. Furthermore, ensuring inclusive and non-exploitative relationships may involve re-consenting OAs at each step of the study or utilising process consent.

Conclusion: Involving OAs in research on a continuum, from conceptualization and technology development to user testing and knowledge translation, albeit time and human resource intensive, leads to social, research and technology development benefits.

DETECTING ASSOCIATIONS BETWEEN CHARACTERISTICS OF WALKING AND AGE USING RAW ACCELEROMETRY DATA

J. Harezlak¹, W. Fadel¹, J. Urbanek², N.W. Glynn³, 1. *Biostatistics, Indiana University Fairbanks School of Public Health, Indianapolis, Indiana*, 2. *Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland*, 3. *University of Pittsburgh Graduate School of Public Health, Pittsburgh, Pennsylvania*

Various subjective and objective methods have been proposed to measure physical activity. Subjective methods, such as ecological momentary assessment and surveys constitute relatively inexpensive ways of measuring one's physical activity; however, they are riddled with measurement error and bias due to self-report. Wearable accelerometers offer a non-invasive and an objective measure of study participants' physical activity and are widely used in observational studies.

Accelerometers record high frequency data and produce an unlabeled time series at the sub-second level. Since walking is often the only form of physical activity for older adults, it is important to properly identify its quantity (number of minutes per day) and quality (e.g. stability). Most methods use activity summaries which ignore nuances of walking data. Using in-the-lab data from the Developmental Epidemiologic Cohort Study (DECOS, N=49), we propose a statistical methodology to model age (scalar response variable) as a function of subject-specific walking acceleration power spectral density (PSD) estimated from the cadence-normalized domain utilizing functional linear models. Cadence-normalized PSDs provide representation of dynamic gait parameters that are robust to between- and within-subject variability caused by the cadence heterogeneity. We incorporate prior knowledge of walking mechanics as an additional information source in the statistical models proposed. We applied our methods to associate the characteristics of in-the-lab usual-paced 400-meter-walk DECOS data with age. We showed that older age is associated with a number of high harmonics indicating less stable and disrupted walking patterns. Our novel approach will be further applied to predict fall risks and mobility disability.

METHODOLOGY AND RECRUITMENT FOR DEVELOPMENT OF A PAIN MEASURE FOR PERSONS WITH DEMENTIA (PIMD)

M.M. Hilgeman^{1,2,3}, P. Nash¹, P. Block^{2,1}, A.N. Collins¹, M.L. McDarby^{4,5,6}, M. Ersek^{5,6}, T. PIMD Investigator Team^{7,8,9}, 1. *Tuscaloosa VA Medical Center, Tuscaloosa, Alabama*, 2. *The University of Alabama, Tuscaloosa, Alabama*, 3. *University of Alabama at Birmingham (UAB), Birmingham, Alabama*, 4. *Washington University in St. Louis, St. Louis, Missouri*, 5. *University of Pennsylvania School of Nursing, Philadelphia, Pennsylvania*, 6. *Corporal Michael J. Crescenz VA Medical Center, Philadelphia, Pennsylvania*, 7. *Northwestern University, Evanston, Illinois*, 8. *University of Iowa, Iowa City, Iowa*, 9. *The Mountain-Whisper-Light Statistics, Seattle, Washington*

This paper describes the recruitment strategy and sampling plan for a study to develop a multidimensional pain intensity measure for individuals with moderate to severe dementia. Almost 590 nursing home residents from 16 facilities across four states screened eligible (Brief Interview for Mental Status, BIMS < 10) and consent was obtained for N = 208. Participants were 45.8% women, 31% Black/African American with a mean age of 83.9 (range = 50–107) and BIMS = 3.42 (SD = 3.14, range = 0–9). Sampling to observe a range of pain levels – necessary for scale development – was difficult. Pain was generally well-controlled in the recruited sample. Amendments to study methods during data collection were made to increase the number of participants with high pain intensity (e.g., expanded/targeted recruitment; observations at movement; increased frequency of observations). Expert clinicians estimated current pain intensity on a scale from 0–10; indicating a mean of 3.17 (SD = 6.36), mode = 0, median = 1, and range = 0–9. Current pain intensity of 3 or greater was observed in 16% (n = 33) of the final sample. Four facilities with higher rates of current pain (range = 22–25% of participants) were examined for commonalities. Though sample sizes in this four-facility

sub-group are small, thematic observations about researcher access to residents in distress are described (e.g., higher Centers for Medicare/Medicaid Services quality ratings; “outsider” vs. “insider” perceptions of the research team). Strategic approaches are necessary to ensure that recruited study samples reflect clinical populations in long term care settings.

THE USEFULNESS OF LOWER-LIMB MUSCLE ULTRASONOGRAPHY AS A DIAGNOSTIC METHOD OF SARCOPENIA

K. Sugimoto, M. Isaka, T. Fujimoto, H. Akasaka, K. Yamamoto, H. Rakugi, *Osaka University Graduate School of Medicine, Suita, Osaka, Japan*

The problem in the diagnosis of sarcopenia is that calculated values of muscle mass are dependent on measuring instruments and enough space and time is needed to measure walking speed accurately, and that standard way of measuring muscle mass cannot detect decline of fast-twitch fibers, which is accentuated in age-related sarcopenia. Thus, the method making it possible to diagnose sarcopenia more accurately and conveniently should be required. The goal of this study is to examine the usefulness of lower-limb muscle ultrasonography in the diagnosis of sarcopenia.

The subjects of this study were outpatients or inpatients in our department of Osaka University Hospital who were over 65 years old. Muscle mass, muscle strengths and physical functions including walking speed and balancing ability were measured, and the relationships between these indexes and muscle thickness or echo intensity of lower-limb muscles (TA; anterior tibialis, GM; gastrocnemius, SOL; soleus) using ultrasonography were examined.

102 subjects were recruited in this study and the average of age was 75.6 ± 6.1. There were positive correlations between muscle thicknesses of TA, GM and SOL and knee extensor muscle strength, grip strength and walking speed. Muscle echo intensities of TA and GM were negatively correlated with knee extensor muscle strength and grip strength, however muscle echo intensity of SOL was not correlated with muscle strengths or physical functions.

The measurements of muscle thickness and echo intensity of lower-limb muscles using ultrasonography were useful as a convenient diagnostic method of sarcopenia.

AAA-2016 CONFERENCE IDENTIFIES RAPALOG MILESTONE; NOMINATES EXEMPLARY HEALTHSPAN RESEARCH PROTOCOLS

R.J. Martin¹, R. Ziman³, W. Ashford⁴, A. Wetherell⁵, G.M. Martin², 1. *Blueberry Health Study / MMT Corp, Sherman, Connecticut*, 2. *University of Washington, Seattle, Washington*, 3. *Genentech, South San Francisco, California*, 4. *Stanford / Veterans Affairs Aging Research Ctr, Palo Alto, California*, 5. *Department of Defence, United Kingdom, United Kingdom*

Background: Research conferences generally cluster scientists by discipline and limit cross-disciplinary communication. Rushed presentations frequently truncate messages. Travel costs prevent most scientists from ever meeting one another. And delays prior to publication and [sometimes] year-long web-posting embargoes impede the progress we all desire. In some research areas preclinical and clinical trials

have replication problems so severe that the US-National Institutes of Health funded a replication program which then failed to replicate 15 of 16 key studies [see PMIDs: 18838063,22078760,22134153,22177997]. Because the plenary discussion of the first large-scale healthspan/longevity trial, the TAME trial (Targeting/Taming Aging with METformin), was cut short by time constraints, a communication group formed to continue the healthspan-trial-design discussion after the American Aging Association conference (AAA-2016), thereby improving/speeding communication between conferees and with IAGG-2017 and other healthspan-related conferences.

Methods: A brief 6-question survey (Healthspanstudy.com/Survey) invited trial-design recommendations, exemplary protocols, comments on memorable conference moments and research “milestones”.

Results: TAME and rapalog milestones were supported by convincing (>3-to-1) majorities; blueberry-milestone by 1-to-1; exemplary trial protocols included the CALERIE Protocol [www.calerie.duke.edu/files/phase2_protocol.pdf specifically citing research samples now available], the US/NIH Toolbox[NIHToolbox.org], European AGARD STRES battery[www.ncbi.nlm.nih.gov/pubmed/9182033]; high-precision Memtrax.com-memory and Blueberry Study hearing websites.

Main Conclusion: These results represent a rapalog-research milestone “[L]ife expectancy [increased] by more than 50%”[Kaeberlein]; “[R]apamycin can rejuvenate cardiac function, the cardiac proteome, metabolome and energetics”[Rabinovitch group]; RAD001 enhanced human immune-function and reduced impaired T-lymphocyte accumulation with age [Mannick]; “Rapamycin reverses metabolic deficits in Lamin A/C-deficient mice”[Liao & Kennedy]; and reduces Aβ accumulation and restores AD-like-memory deficits [Hussong & Galvan].

SESSION 885 (POSTER)

LGBT AGING AND GENDER

HOME CARE EXPERIENCES OF OLDER LESBIANS: A NATIONAL QUALITATIVE STUDY

S.S. Butler, *University of Maine, Orono, Maine*

Research has found that lesbian, gay, bisexual and transgender (LGBT) older adults fear what they might experience in accessing long term services and supports (LTSS) and that these fears are often grounded in reported incidents of discrimination. This paper reports on a national study isolating the experiences of older lesbians who have used LTSS (thus women receiving care predominantly from women—often older themselves), to determine if such experiences might be less fraught. Telephone interviews, comprised of open-ended questions, were completed with 20 lesbian women, 65 years of age and older ($m = 71.9$), who had received home care in the previous ten years. Additionally, six informal caregiving partners and five of the study participants’ home care workers were interviewed. Themes emerging from constant comparative qualitative data analysis underscore diverse experiences.

Most study participants did not discuss their sexuality with their workers ($n = 12$), with some considering the information irrelevant to the relationship and others feeling a need to protect themselves from discrimination; a few disclosed their sexuality up front ($n = 4$). A minority experienced homophobic behavior from a home care aide ($n = 6$), while most described their care as non-homophobic ($n = 13$). While many study participants ($n = 16$) had had home care workers with whom they were dissatisfied, ultimately, all but two had also experienced very good care. Study implications outline how the experiences of older lesbians may be unique within the overall LGBT category. Understanding such distinctions is critical in providing culturally competent care.

SOCIAL REPRESENTATIONS OF LGBT AGING: STUDY AMONG LAW, PEDAGOGY, AND PSYCHOLOGY BRAZILIAN STUDENTS

L.F. Araujo, F. Negreiros, K. Pessoa Teixeira Carlos, *Psychology, Universidade Federal Do Piauí, Parnaíba, Piauí, Brazil*

This study aimed to evaluate and compare the social representations of Brazilians university students (Law, Education and Psychology) on LGBT aging of a private higher education institution in the city of Teresina-PI, Brazil. It also sought to identify the participated and elaborate knowledge of the students about homosexuality in old age and check and compare the social representations about homosexuality. It took part 300 university students (100 of each course), of both genders, with a mean age of 28 years old. It used Free Words Association Test (TALP) Socio-demographic questionnaire and semi-structured interviews, conducted collectively within the educational institution. Data were analyzed with the support of Iramutec software (Camargo & Justo, 2013) through the Analytic Hierarchy Descending, which allows an analysis of lexical roots, considering the word as unit also offers its contextualization in the corpus. The data obtained emerged representations into two antagonistic poles: on the other hand, the right that every individual has to make their independent sexual choices apart of the stage of life they are in, and other, the prejudice suffered by homosexuals, worsening when they are elderly. It was verified that there were social representations of old age LGBT in a negative connotation, and commonly associated with shame, loneliness, suffering and oppression. It emphasizes the need for further study of gender and generation, psychosocial interventions that focus on improving the quality of life of LGBT elderly, and public policies that protect the elderly and especially the LGBT public.

METHODOLOGICAL ASPECTS OF GENDER ON CAREGIVING BURDEN: EVIDENCE FROM 2015 U.S. CAREGIVING DATA

H. Kim^{1,2}, S. Hong¹, B. Woo¹, M. Lee³, S. Kwon¹, 1. *College of Nursing, Yonsei University, Seoul, Korea (the Republic of)*, 2. *Mo-Im Kim Nursing Research Institute, Seoul, Korea (the Republic of)*, 3. *School of Nursing University of Virginia, Charlottesville, Virginia*

Although extensive research has investigated gender to predict caregiving burden, methodological challenges

resulting from univariate comparison between men and women need to be overcome. This study adopted a dyadic approach to differentiate gender status and discrepancy to explain the caregiving burden.

Using 2015 National Alliance for Caregiving data (N=1391), we compared caregiving burden models using: (1) a traditional approach that includes separate gender variables of caregivers and care-recipients; and (2) an alternative approach that includes a variable of gender discrepancy, in which caregivers and care-recipients differ. Covariates include caregivers' age and years spent caregiving. Descriptive, univariate, and a series of multivariate linear regression analyses were completed for general caregivers and sub-groups.

Based on adjusted R-squared change, Akaike, and Bayesian information criteria, both models could be considered for general caregivers and non-Hispanic African American caregivers of older care-recipients (aged > 65). The alternative model of gender discrepancy was more appropriate than the traditional model for non-Hispanic Caucasian caregivers of care-recipients with cognitive or emotional problems. Both models aggravated the model fit in non-Hispanic Asian caregivers with younger care-recipients (aged < 65) with behavioral problems. Gender discrepancy had a predictive value for the caregiving burden with a regression coefficient ranging from .278 to .388 ($p < .001$), but separate gender variables did not.

Overall, the model of gender discrepancy is more suggestive to predict the caregiving burden. However, we suggest researchers to consider both the traditional and the alternative model for specific types of caregivers. Primary data collection and in-depth interview are required to confirm our findings.

RELEVANCE OF INTERSECTIONAL APPROACH TO UNDERSTAND AGING AMONG ELDERLY IMMIGRANT WOMEN

M. Charpentier, 1. *Social Work, UQAM-University of Quebec in Montreal, Montreal, Quebec, Canada*, 2. *Research Chair on Aging and Citizen Diversity, Montréal, Quebec, Canada*

This poster will present some of the results of a qualitative research aimed to analyze the experiences of aging among older immigrant women in Montreal, Quebec (Canada).

The sample included 83 women aged 65 years and older with diverse variables such as: age, ethno-cultural background (Arab, African, Haitian, Japanese, Romanian, etc.); timing of migration (during youth, adulthood or retirement) and immigration status. Each focus group consisted of 3–6 women sharing the same ethno-cultural background and speaking the same language, but having varied characteristics in terms of marital status, education, income and migration patterns.

Results show that immigration brings changes to women. These women demonstrate resiliency and great capacity for adaptation. For them, aging is not conceptualised and lived in terms of losses, far from it; they speak about it more in terms of gains in regards to identity and liberty. Migration has allowed them to age in a safer environment but also for the majority to feel freer as a woman, free to be themselves, to dress as they wish, to go out alone. Migration has opened opportunities for personal development and self-affirmation.

Aging is also accompanied by significant challenges for women arising from a triple discrimination; ageism, sexism and racism whose socio-economic conditions are particularly present in women of an advanced age especially when they migrated at an older age. The findings presented demonstrate the relevance of the intersectional approach in understanding the complexity and social conditionings of women's life courses.

A TIME SERIES ANALYSIS OF THE CORRELATION BETWEEN WIDOWHOOD AND THE ECONOMIC STATUS OF ELDERLY WOMEN

H. Oh, *Seoul National University, Seoul, Korea (the Republic of)*

Millar (1996) has mentioned that there are 'gender dimension of poverty' so that it leads the economic dependence of the wife on her husband. Older women without a spouse are more likely than men to face threats to their economic security. This study used data from Korea Welfare Panels (KOWEPs). KOWEPs is the largest panel study in Korea that allows long-term samples from 2006 to the present. In this study, descriptive analysis have been performed for 297 elderly women who were married from the ten waves (2006–2015) of the KOWEPs. Hierarchical Linear Model (HLM) and Hierarchical Generalized Linear Model (HGLM) were conducted for the adjusted household income and the poverty status. Women over 60 year-old and married in 2006 were included. The dependent variable is income, consumption, poverty status. The independent variable is marital state (married=0, spouse loss=1), age, education, living area, health condition, employment statement, child co-residence, employment status. *The changes in the marital status do not have significant effects on household income changes of elderly women nor increase the risks of living in poverty for elderly women in Korea.* These results, which are contrary to those of existed foreign studies reporting negative impacts of widowhood on the economic status of elderly women, would be due to strong dependence on private transfers from their children and comparatively greater impact on co-residence with children on the economic status of elderly women. In the future, there's need of enhancing and redesigning public income security policy focusing on women in Korean context.

MENTAL HEALTH RESILIENCE IN OLDER CHINESE WOMEN

H. Chen², A.T. Hagedorn¹, X. Peng², 1. *Gerontology, University of Southern California, Monterey Park, California*, 2. *Fudan University, Shanghai, China*

Nearly all older women across China are dependent on family support due to limited income to support for their retirement years. Declines in family size and migration strains that family dependence. Older women offer a unique perspective as they generally played a key role in their families lifelong and generally depend on social support from their family and close friends in older age to cope with any limitations they face as a result of age-related changes in their health and functional ability. We examine the research question which factors predict mental health resilience in older women using the Third wave of the 2010 Female Social Status Survey conducted by the

Women's Federation (n=3,527). Regression models exploring predisposing, supportive and health need variables were tested using SPSS version 22 exploring an 8 question mental health scale. Results showed that living with a spouse was not a significant predictor of mental health for women, while it was for men ($b=-1.2$, $p<.01$), income was significant only for women ($b=-.71$, $p<.01$), ownership of property only for men ($b=-.96$, $p<.05$), whereas women's mental health is more strongly predicted by current exercise ($b=-.89$, $p<.01$) and participation in leisure activities ($b=-.69$, $p<.001$). Policy making and implementation should do more than assess gender differences, but also mitigate the negative impacts on both genders with the help of the policy lever. Even under the current situation, it should play some role in protecting older women to compensate for the impacts of cumulative disadvantage on their later life.

SESSION 890 (POSTER)

ORAL HEALTH

ASSOCIATION BETWEEN SATISFACTION WITH ORAL HEALTH AND DEMOGRAPHIC CONDITIONS IN MEXICAN ELDERLY

I. Daz, E. Arias-Merino, R. Pelayo-Ramírez, D. Hernández-Santos, *University of Guadalajara, Guadalajara, Jalisco, Mexico*

Objective: To determine association between satisfaction with oral health and demographic conditions in Mexican elderly. **Methods:** A randomized cross-sectional study was conducted with data from the Survey of Health, Welfare and Aging. Project coordinated by the Pan-American Health Organization. This study included 1547 participants, men and women cognitively healthy 60 years and over living in the metropolitan area of Guadalajara City. Data were collected by examiners trained and calibrated at participants' homes and included an interviewer-administered structured questionnaire with items on socioeconomic variables, etc. To measure satisfaction with oral health, the Geriatric Oral Health Assessment Index [GOHAI] validated and translated in Spanish language was applied. This questionnaire is a Likert scale of 12 items, is scored: Always, often, sometimes; rarely and never. The total score ranges from 12 to 60 points. A score below 57 is considered as an indicator of dissatisfaction with oral health. The GOHAI values Oral health-related quality of life in the context of older people. Descriptive statistics and Chi square test was applied to analyze data for sex, age and GOHAI. Two age groups of 60–74 and 75–102 years were created. **Results:** 983 women (63.6%) and 564 men (36.4%). (Mean age 72.5 ± 8.4 years). The sample had an average value of GOHAI (53.32 ± 7.3) which means a moderate satisfaction with oral health. No significant differences were observed in relation to sex and GOHAI $p > 0.05$, but if for age, showing less satisfaction with their oral health the group of 60–74 years old; $p = 0.0001$ with 95% confidence. **Conclusions:** The participants perceive a moderate dissatisfaction of their oral health. The youngest group (60–74 years old) had less oral health satisfaction.

PREDICTORS OF CHEWING DIFFICULTIES AMONG COMMUNITY-DWELLING OLDER ADULTS IN KOREA

S. Moon, G. Hong, *Nursing, Hanyang university, Hwaseong-si, Kyeong-gi do, Korea (the Republic of)*

Chewing difficulties in older people associated with not only poor health status but also risk of mortality. The purpose of this study was to identify the prevalence and the predictors of chewing difficulties among community-dwelling older adults. This study used the sixth Korea National Health and Nutrition Examination Survey (KNHANES) conducted in 2014. Of the total 7,550 participants in the sixth KNHANES, data from 1,340 older adults aged over 65 years olds were used for analysis. Chewing difficulties was assessed by the self-report for having chewing problems. Mean age of the participants was 72.70 ± 5.60 and a total of 62.7% of the older adults reported having chewing difficulties. 78.4% and 31.9% were reported having perceived poor oral health and having oral pain, respectively. In logistic regression, education level (OR=1.51, 95% CI= 1.02–2.24), perceived oral health (OR=3.18, 95% CI=2.12–4.76) and oral pain (OR=2.03, 95% CI=1.47–2.81) were the significant predictors of chewing difficulties among community-dwelling older people. In conclusion, the prevalence in chewing difficulties was fairly high in Korean older adults, and education level, perceived oral health, oral pain were associated with chewing difficulties. To improve chewing ability, strategical oral health program is needed in this population.

RELATIONSHIP BETWEEN SARCOPENIA AND CHEWING ABILITY IN JAPANESE COMMUNITY-DWELLING ELDERLY

H. Hirano², Y. Watanabe¹, M. Murakami¹, A. Eda¹, K. Motokawa¹, M. Shirobe¹, J. Yasuda¹, *1. Tokyo Metropolitan Institute of Gerontology, Tokyo, Japan, 2. Tokyo Metropolitan Geriatric Hospital and Institute of Gerontology, Itabashiku, Tokyo, Japan*

Purpose: In old age, one of the most important factors to maintain chewing ability is the number of remaining teeth. Although in recent years elderly people increasingly tend to have greater remaining teeth, chewing ability decreases with age. Therefore, this study investigated the relationship between sarcopenia and chewing ability in addition to determining chewing ability related factors. **Methods:** A total of 1097 participants (445 men and 652 women, aged 74.8 ± 6.1 years) who attended the comprehensive survey for early detection and treatment of geriatric syndrome were selected in this study. We defined sarcopenia according to EWGSOP, and adopted the cut-off value according to AWGS. The logistic regression analysis was performed to determine the association of the occlusal force with each factor for sarcopenia. **Results:** Of the participants, 13.6 % were classified as sarcopenia. As a result of the logistic regression analysis, the decrease in the occlusal force was associated with the number of remaining teeth (OR: 0.86, CI = 0.85–0.88), the presence of sarcopenia (OR: 2.04, CI = 1.26–3.32), and the presence of medication (OR: 1.48, CI = 1.09–2.02). **Conclusion:** This study suggests that sarcopenia is related to chewing ability, even after controlling for known chewing ability related factors. As a background of this result, there might be a possibility that sarcopenia influences masticatory muscles. The present results suggested that sarcopenia, and

not only number of teeth, is an important factor in maintaining chewing ability among community-dwelling elderly people.

THE RELATIONSHIP BETWEEN ALZHEIMER'S DISEASE AND ORAL HEALTH: A SCOPING REVIEW

G. Mathur², K. Mehndiratta², T. Yasmina¹, N. Bhela³, R.M. Mirza¹, 1. *University of Toronto, Toronto, Ontario, Canada*, 2. *Poznan University of Medical Sciences, Poznan, Poland*, 3. *York University, Toronto, Ontario, Canada*

A growing number of elderly will be diagnosed with Alzheimer's disease (AD), and although AD is recognized as a debilitating illness with no cure, limited attention has been paid to the implications of poor oral health for those with cognitive impairments such as AD. Oral health care is often not appropriately assessed by carers for those with AD and as such those with AD are at greater risk for oral diseases. A scoping review was conducted to synthesize the available literature on AD and oral health. With the assistance of a professional librarian, an exhaustive database search using keyword strings yielded 6000+ articles. Abstracts were manually curated and 110 studies which fulfilled inclusion criteria were fully analyzed. Studies of AD and oral health identified outcome and quality-of-life differences between community dwelling patients versus those in long-term care (N=34), implications of tooth-loss (n=13), influence of medications (n=11), assessment strategies (n=22), and mortality risk (n=30). Findings indicate that those in institutional settings have poor oral health; that the severity of AD may lead to deterioration of oral health and that the reverse association may also exist; that individuals with the fewest teeth had the highest risk of AD; and that women with AD had better oral health than men. The findings from this scoping review highlight that poor oral health for AD sufferers may have far-reaching implications and that greater research and practice focus on assessment in institutional settings will be needed in this area.

POOR ORAL CONDITIONS ARE RELATED TO THE DECLINE OF ORAL DIADOCHOKINETIC RATE AMONG JAPANESE ELDERLY

S. Hara¹, H. Miura², K. Yamasaki¹, 1. *Kyushu Univ. of Health and Welfare, Nobeoka, Miyazaki, Japan*, 2. *National Institute of Public Health, Wako, Saitama, Japan*

Purpose: There are few studies that have reported the prospective change of Oral diadochokinetic (ODK) rate. We studied the association between the 1-year change of ODK and dental status among the elderly living in rural Japan.

Subjects and Methods: A total of 268 Japanese residents aged >65 years (mean age = 74.5) participated in this study. ODK was measured by having subjects repeat the phonetic sounds /pa/, /ta/, /ka/, and /pataka/ for 5 s each. The tooth and periodontal status as well as intraoral cleaning habits were assessed. We analyzed the change in ODK rate over 1 year and compared tooth and periodontal status and intraoral cleaning habits between subjects that had declining ODK and those that had maintained their ODK rates.

Results: The number of subjects that showed decreased ODK by 5 points in score was 58 (21.6%) in /pa/, 49 (18.3%) in /ta/, and 46 (17.2%) in /ka/. In total, 64 subjects (23.9%) had decreased ODK by 2 points of /pataka/

over 1 year. Subjects in the declining /pataka/ group had a significantly higher number of untreated teeth than those in the maintained /pataka/ group ($p < 0.05$). The decline of /pa/ was significantly associated with the presence of periodontal diseases and low awareness in oral cleaning habits ($p < 0.05$).

Conclusion: Decreasing ODK for 1 year was found in approximately 20% of Japanese elderly residents. Furthermore, the results suggest that poor oral conditions and cleaning habits have been closely related to the decline of ODK.

EFFICACY OF PROPOLIS ON DENTURE STOMATITIS IN OLDER ADULTS: A MULTICENTRIC RANDOMIZED TRIAL

G. Pina^{1,4}, E.N. Lia⁴, A.A. Berreta³, A.P. Nascimento³, E.C. Torres³, A.M. Buszinski³, E.B. Coelho², V.d. Martins⁴, 1. *UniEvangélica University Center, Anapolis, Brazil*, 2. *University of Sao Paulo, Ribeirao Preto, Brazil*, 3. *Apis Flora Indl. Coml. Ltda., Ribeirao Preto, Brazil*, 4. *University of Brasilia, Brasilia, Brazil*

Our hypothesis tested the efficacy and safety of standard formulation of Brazilian propolis extract gel compared to miconazole oral gel for the treatment of denture stomatitis due *Candida spp* infection in older adults. A total of 40 older patients were randomly allocated in a non-inferiority clinical trial (NCT02818803) into two groups. The control group (MIC) received 20mg/g miconazole oral gel and the study group (PROP) received mucoadhesive formulation containing standardized extract of 2% propolis (EPP-AF®) during 14 days. Patients were examined by a dentist on days 1, 7 and 14. The Newton's score was used to assess the denture stomatitis. The colony forming unity count (CFU/mL) was quantified and compared before and after the treatment (days 1 and 14). Age, gender, duration of complete denture's use, baseline Newton's score, and baseline CFU/mL did not differ between groups. Both treatments reduced the Newton's score ($P < 0.0001$). Miconazole, but not propolis, reduced the CFU (6.2×10^3 vs. 10 CFU/mL, D1 vs. D14; $P < 0.001$). The candidiasis cure rate, defined as both absence of oral lesions and a negative culture for *Candida*, was only 30% for miconazole and 20% for EPP-AF® group. Both treatments resulted in improvement of the clinical symptoms of candidiasis, showing a clinical cure rate of 0.60 for miconazole and 0.50 for propolis. No serious adverse events were observed in neither group. The EPP-AF® appears to be non-inferior to miconazole considering the clinical cure rate and could be recommended as an alternative treatment for oral candidiasis in older patients. Financial support: FINEP(Brazil)/CNPq

SALIVATION DISORDERS IN ELDERLY PATIENTS

N. Denewet, *Geriatric Department, CHU Charleroi, Brussels, Belgium*

Saliva possesses many important functions including antimicrobial activity, pH balance, lubrication, remineralization and mechanical cleansing of the oral mucosa. Xerostomia results from reduced or absent saliva flow. Its prevalence increases with age and is approximately 30% in patients over 65 years. Numerous medications include xerostomia as side effect. Dry mouth has multiple oral health consequences and affects quality of life. Oral candidiasis is one of the most common oral infections seen in association with xerostomia.

Methods: We recorded systematic anamnesis about swallowing difficulties, taste modification, dry mouth sensation, and results of oral dysphagia and mouth clinical examination.

Results: Forty-one patients were admitted consecutively in an acute geriatric unit. Median age was 86 (range: 76–99), and 80% of the patients were female. The median number of drugs lines was 8 (range 1–17). Thirty-one patients (76%) complained of xerostomia, 19 (46%) for more than 3 months, 27 (66%) need liquids to swallow dry foods, 16 (39%) feel swallowing difficulties, while 11 (37%) had a real dysphagia screened by a speech therapist. Oropharyngeal candidiasis was found in 14 patients (34%). Patients with MNA-confirmed risk of malnutrition complained more of xerostomia. Only red depapillation had significant statistical association with candidiasis. Antibiotics, opioids and diuretics showed an increased trend to xerostomia.

Conclusion: Xerostomia and oropharyngeal candidiasis can be frequently symptomatic in the elderly, who are particularly frail and challenged by polypharmacy and multiple comorbid conditions. Physicians should be aware of oral health and drug related salivation disorder.

IDENTIFYING ORAL FUNCTION AS AN INDEXING PARAMETER FOR DETECTION OF MILD COGNITIVE IMPAIRMENT

Y. Watanabe¹, H. Arai², H. Hirano¹, Y. Ohara³, A. Eda¹, H. Shimada³, T. Kikutani⁴, T. Suzuki², 1. *Tokyo Metropolitan Institute of Gerontology, Tokyo, Japan*, 2. *National Center for Geriatrics and Gerontology, Obu, Japan*, 3. *Department of Oral Health Education, Graduate School of Medical and Dental Science, Tokyo Medical and Dental University, Tokyo, Japan*, 4. *Division of Clinical Oral Rehabilitation, Graduate School of Life Dentistry, Nippon Dental University, Tokyo, Japan*

Objectives: We examined the association between MCI and oral cavity conditions (e.g., oral hygiene and compromised oral function). In addition, we developed a screening index to identify MCI, focusing on oral assessment.

Methods: A total of 5,104 elderly people living in a community in Japan were classified into 930 people with MCI and 2,669 without MCI, and analyzed for relevant factors.

Results: Both the men and women with MCI showed significantly lower levels of the following: the number of the functional teeth; number of the remaining teeth; oral diadochokinesis (ODK) /Pa/Ka/; palpation of masseter muscle tone ($p < 0.01$). As a result of discriminant analysis between two groups of MCI, MCI and non-MCI groups a significant association was observed in age, sex, educational background, grip strength, Geriatric Depression Scale, Mini-Mental State Examination, history of cardiac disease, albumin level, and ODK /pa/ as assessment of the oral function. Although the proper diagnosis rate of our screening index for MCI was not as high at 0.63, it was in the acceptable range as a screening index because it is possible to increase sensitivity.

Conclusion: The results of our study showed a possibility that lip movement might have been impaired in patients with MCI. Impairment of movement of the lips may occur before oral hygiene worsens or chewing ability is impaired. This index may support early detection of MCI, and be one of the keys to prevent dementia. Also it may provide information which is useful to establish effective prevention strategy.

ADMINISTRATIVE PERSPECTIVES ON INTERPROFESSIONAL ORAL HEALTH EDUCATION IN LONG-TERM CARE SETTINGS

J. Crittenden¹, L.W. Kaye¹, L. Nelligan², C. Mackenzie², D. O'Connell², 1. *UMaine Center on Aging, Bangor, Maine*, 2. *Lunder-Dineen Health Education Alliance of Maine, Bangor, Maine*

The WHO has recognized the importance of older adult oral health as a global health issue of concern. Responding to the global call-to-action to improve older adult oral health, Lunder-Dineen Health Education Alliance of Maine and an advisory team have established MOTIVATE: Maine's Oral Team-Based Initiative: Vital Access To Education project; an interprofessional, evidence-based, and sustainable educational model to enhance oral health care in long term care (LTC). MOTIVATE training curriculum was formulated based on a needs assessment study administered at six LTC pilot sites. Administrative staff (N=51) were surveyed to assess oral health practices, training priorities, and their relationship to organizational mission. Respondents indicated oral health training fits with their organizational mission as it relates to: 1) providing high quality care (98%); 2) advancing resident and family satisfaction (94%); and 3) embodying resident and family-centered care (90%). Barriers to the provision of preventive oral care included resident behavior (85%), lack of staff training (70%), and lack of access to an oral health provider (62%). Varying levels of knowledge of interprofessional care roles were reported with 26% disagreeing that every healthcare team member has a clear role in oral care provision. Staff do not generally receive oral health training at the start of their employment (57%) or follow-up trainings (68%) leaving room for additional oral health training in LTC settings. Recommendations include framing oral health in terms of its fit with organizational mission, the need to increase understanding of oral health interprofessional roles, and increase opportunities for LTC staff training.

EFFECT OF ORAL HEALTH CARE ON HYPERSENSITIVITY SYNDROME AMONG THE ELDERLY IN LONG-TERM CARE

M. Shirobe¹, R. Nakayama², Y. Ohara², K. Endo², Y. Watanabe¹, H. Hirano¹, C. Hakuta², 1. *Tokyo Metropolitan Institute of Gerontology, Tokyo, Japan*, 2. *Graduate School of Medical and Dental Sciences, Tokyo Medical and Dental University, Tokyo, Japan*

Background: There are some elderly people with hypersensitivity syndrome (HS) showing symptoms, such as thrashing one's arms and legs, and frowning up one's faces. In addition, HS is difficult for care-givers to implement oral health care for elderly people. The purpose of this study was to examine the effect of hypersensitive removal care on HS, that is one of the professional oral health care. **Methods:** From 80 residents of nursing home in Tokyo, we selected 14 residents (1 men and 13 women; mean age: 90.6 ± 4.5 y) who had HS. The participants were randomly divided into two groups: intervention ($n = 7$) and control groups ($n = 7$). The intervention group was with usual care by the facility staff and hypersensitive removal care by dental hygienists twice a week for 3 months. The control group was with only usual care by the facility staff. We counted places of HS on the face and in the mouth before and after the

intervention (0 - 9). **Results:** There were no differences in the participant characteristics between two groups at baseline. In the intervention group, the HS numbers significantly improved after the intervention (1.7 ± 2.1) as compared to the baseline (3.6 ± 1.5). In the control group, there was no significant change in the HS numbers. **Conclusions:** The present study suggested that hypersensitive removal care was effective for elderly people in long-term care. Therefore, this technique can contribute to not only easing their discomfort but also reducing the burden of care-givers.

SATISFACTION WITH DIETARY LIFE AFFECTS SUBJECTIVE WELL-BEING IN VERY ELDERLY PEOPLE
T. Iinuma¹, Y. Fukui¹, Y. Shioda¹, J. Lee¹, M. Fukumoto¹, N. Gionhaku¹, Y. Arai², M. Takayama², 1. *Nihon University School of Dentistry, Tokyo, Japan*, 2. *Keio University School of Medicine, Tokyo, Japan*

Age-related deterioration in physical condition and oral health in very elderly people are important problems that decrease healthy life expectancy. We investigated the effects of satisfaction with dietary life (SDL) in everyday life on subjective well-being in very old individuals. We evaluated 426 elderly individuals aged 85 years or older. All participants completed a questionnaire and oral, physical, and mental health examinations. The comprehensive oral health assessment consisted of a face-to-face interview, including a questionnaire about SDL and subjective well-being.

The relationship between the results of the questionnaire about SDL and subjective well-being were confirmed using a multiple logistic regression analysis. In the multivariate model adjusted for age, gender, drinking status, BMI, cognitive function, disability, physical performance, and comorbidity, participants who answered “enjoyable” with regard to SDL had a significantly lower risk for getting the lowest scores on the PGC and WHO-5 (OR = 0.589, 95% CI = 0.348–0.996; OR = 0.452, 95% CI = 0.263–0.775, respectively). After further adjustment for number of teeth present, the association was generally maintained. SDL was significantly associated with subjective well-being, even after adjusting for potential confounders, such as age, drinking habits, cognitive function, physical fitness, presence of disease, and loss of teeth. Based on these results, dental professionals must contribute to the lives of very elderly individuals in order to maintain oral function.

SOCIOECONOMIC DIFFERENCES IN RECENT USE OF DENTAL HEALTH SERVICES AMONG ELDERLY INDIVIDUALS

F. Bof de Andrade¹, F. Barroso², 1. *Oswaldo Cruz Foundation - FIOCRUZ, Belo Horizonte, MG, Brazil*, 2. *Dental School, PUC Minas, Belo Horizonte, MG, Brazil*

Objective: Assess the prevalence of recent use of dental services and its association with sociodemographic factors among community-dwelling elderly individuals from Brazil. **Methods:** This was a cross-sectional study with data from the last Oral Health Survey conducted in the State of Minas Gerais, Brazil. The sample was representative of people aged 65–74 years living in Minas Gerais. The dependent variable was “recent use of dental services” (last dental visit \leq 2 years). Independent variables included: sociodemographic factors (age, gender, education, household income, skin color); clinical measures of oral health (number of teeth, need for dental

treatment, prosthetic use, need for prostheses). The independent association between the use of the dental services and sociodemographic variables was assessed by multiple logistic regression. **Results:** The prevalence of recent dental appointment was 36.7%. According to the adjusted analysis recent use of dental services was independently associated with schooling. There was a positive gradient showing increasing chances of recent use with increasing number of schooling years. Higher chance of recent use was also observed among elderly individuals in need for dental treatment, whereas individuals in need for dental prosthesis had lower chance of recent dental appointment. **Conclusion:** Recent use of dental services among these elderly individuals is low and is related to socioeconomic inequalities.

THE MOUTH MATTERS: CHARACTERIZATION OF ORAL MICROBIOTA IN NURSING HOME RESIDENTS

T. Ogawa¹, M. Honda², K. Ikebe¹, M. Kibi¹, S. Kawabata², Y. Maeda¹, 1. *Department of Prosthodontics, Gerodontology and Oral Rehabilitation, Osaka University Graduate School of Dentistry, Suita Osaka, Japan*, 2. *Department of Oral and Molecular Microbiology, Osaka University Graduate School of Dentistry, Suita Osaka, Japan*

Oral health in aging is recognized as an increasingly important area of research endeavor. Over 700 bacterial species have been detected in the mouth. However, the relationship between oral commensal bacterial community (microbiota), aging, and health still remain unclear. A microbiota is the ecological community of commensal, symbiotic and pathogenic microorganisms that literally share our body space that controls the human body in health and disease. The link between intestinal microbiota and health is well studied using the new technology of microbiome analysis.

To elucidate potential associations between oral microbiota, aging, and health, we conducted microbiota analyses using salivary samples from 16 independently living older adults (aged 83 to 93 years old), 15 nursing home residents (aged 68 to 101 years old), and 17 young, healthy controls (aged 25 to 53 years old). Genomic DNA was extracted from each salivary sample for bacterial identification.

We found that microbial composition among three groups was significantly different at the phylum, which has potential implications for human health and aging. The change of bacterial composition itself is not important, however, the reduced microbiota diversity is possibly the result of increased frailty, that indicated by numerous previous reports. For example, loss of gut microbiota diversity is known to associate with aging or frailty.

Besides, saliva may be preferable for assessment of microbiota in older individuals due to its ease of sampling. It was previously reported that both gut and oral microbiota showed universal dynamics, potentially indicating similar mechanisms for imbalance of bacterial composition.

ORAL HEALTH INTEGRATION IN LONG-TERM CARE SETTINGS: LESSONS FROM A VIRGINIA PILOT PROGRAM

L.D. Slashcheva, *Geriatric & Special Needs Dentistry, Dental Public Health, University of Iowa College of Dentistry, Iowa City, Iowa*

Meeting oral health needs of older adults in Long-Term Care (LTC) settings means addressing unique challenges and disparities for this population. The Virginia Dental Association (VDA) LTC Access to Care Work Group facilitated a one-year pilot program integrating oral healthcare professionals into two public LTC facilities to demonstrate cost-effectiveness and benefits of ensuring preventive and referral oral health services into the LTC setting. A Registered Dental Hygienist and a Dental Assistant staffed the pilot program, providing training to direct support staff on oral disease/hygiene and recording oral health status, treatment indicated and rendered, and oral health-associated hospitalizations throughout the pilot program in order to raise the value placed on oral health in LTC settings, improve oral health of LTC residents, and demonstrate reduced morbidity and cost of oral health-related ailments/hospitalizations. To qualitatively assess the pilot program and inform the broader discussion on best practices for integrating oral health programs into LTC settings, VDA LTC Access to Care Work Group members and pilot program staff were interviewed. Key challenges and opportunities for integrating oral health services into LTC settings exist both on the direct care provision and administrative level. The novel Community Dental Health Coordinator (CDHC) may be a suitable catalyst to address recommendations emerging from pilot program. Continued collaboration between oral healthcare and LTC professionals as exhibited in this pilot program will strengthen and improve the LTC infrastructure in valuing and improving oral health for older adults.

SESSION 895 (POSTER)

PHYSICAL ACTIVITY AND EXERCISE II

FOUR-YEAR TRAJECTORIES OF PHYSICAL HEALTH IN CANADIAN SENIORS

S. Figueiredo^{1,2}, J.A. Morais^{3,4}, N.E. Mayo^{5,1,4}, 1. *School of Physical and Occupational Therapy, McGill University, Montreal, Quebec, Canada*, 2. *Center for Outcomes Research and Evaluation, Research Institute, McGill University Health Centre, Montreal, Quebec, Canada*, 3. *Faculty of Medicine, McGill University, Montreal, Quebec, Canada*, 4. *Department of Geriatrics, McGill University Health Center, Montreal, Quebec, Canada*, 5. *Division of Clinical Epidemiology, McGill University, Montreal, Quebec, Canada*

Seniors are living longer and many experience what is called Healthy Aging, an aging process without significant impairment. However, the vast majority of older adults will have some degree of limitations. In order to develop successful healthcare strategies it's necessary to understand the dynamics of aging. The global aim of this study was to describe trajectories of physical health over a 4-year period among a Canadian senior population and to identify factors associated with deteriorating health.

Between 2004 and 2009, the Quebec Longitudinal Study on Nutrition and Successful Aging (NuAge) recruited 1793 seniors. Participants were assessed annually, for up to 4 years, including socio-demographic characteristics, comorbidities,

medication, physical function, cognition, health behaviors, social environment, and health status. Physical health was assessed using the SF-36 Physical Component Summary (PCS). Group-based trajectory modelling (GBTM) was used to create group individuals with similar physical health trajectories. Logistic regression was used to identify predictors of physical health deterioration among those with excellent or very good physical health.

From the sample of 1793 seniors (853 men, 940 women; mean age 74 ± 4 years), 6 unique trajectories of physical health were identified. Three groups started at values well below Canadian norms but this poor physical health remained stable over time. Three groups ($n=869$) had values above the norm and 1 showed persistent excellent health (PCS intercept = 55); 2 groups started with very good physical health (PCS intercept = 52) but 1 showed a drastic deterioration. Among those with starting out with excellent or very good health, three factors predicted membership in the deteriorating group: (i) heavier body weight (OR = 1.31 per 30kg. difference; 95%CI 1.12–1.78);(ii) more depressive symptoms (OR per symptom = 1.08; 95%CI 1.03–1.15); whereas (iii) higher physical activity (PA) protected against deterioration (OR = 0.69 per 30% more PA; 95%CI: 0.48–0.97). In conclusion, inactive, seniors with excess weight and depressive symptoms do not age well. These should be targets of preventive health strategies.

ASSOCIATION OF MULTISITE CHRONIC MUSCULOSKELETAL PAIN WITH PHYSICAL ACTIVITY IN ELDERLY

S. Murata¹, R. Sawa², T. Isa¹, Y. Tsuboi¹, K. Torizawa¹, A. Fukuta¹, S. Misu^{1,3}, R. Ono¹, 1. *Department of Community Health Sciences, Kobe University, Graduate School of Health Sciences, Kobe, Hyogo, Japan*, 2. *Department of Physical Therapy, School of Health Sciences at Narita, International University of Health and Welfare, Narita, Chiba, Japan*, 3. *Kobe City Hospital Organization, Kobe City Medical Center, West Hospital, Kobe, Hyogo, Japan*

To our knowledge, no study focus on number and severity of pain about the association between pain and physical activity. The purpose of this study is to investigate the association of the number of chronic musculoskeletal pain and pain severity with objectively measured physical activity in community-dwelling older adults. In this cross-sectional study, 231 community-dwelling older adults in Japan (mean age: 74.9 years, women: 71.0%) were recruited. Exclusion criteria included a score of <18 in the mini-mental state examination (MMSE), broken or lost accelerometer, not meeting criteria to wear accelerometer and not having completed all clinical examinations. Participants were asked to wear uniaxial accelerometer (Kenz Lifecorder EX; Suzuken Co, Ltd, Nagoya, Japan) for one week in order to assess steps, light intensity (1.5–2.9 METs) and moderate intensity (3.0–5.9 METs) of physical activity. The number of chronic musculoskeletal pain was assessed by counting the number of chronic musculoskeletal pain locations, and was categorized into three groups (no pain, one site and multisite). Pain severity was assessed using subscale of Brief Pain Inventory and was categorized into tertile. Linear regression models showed that significant association of multisite chronic

musculoskeletal pain with low steps and low moderate intensity of physical activity even after adjustment with age, gender, education, obesity, smoking status, alcohol consumption, MMSE, depressive symptoms and analgesic medication use [steps: beta = -1209.53, $p < 0.05$; moderate intensity: beta = -8.72, $p < 0.05$ (reference: no pain)]. Multisite chronic musculoskeletal pain may effect on physical activity.

STEP COUNT ACCURACY AND RELIABILITY FROM ACTIVITY MONITORS WORN BY MOBILITY-INTACT OLDER ADULTS

S.A. Maganja¹, M.G. Donaldson², D.C. Mackey^{1,2}, 1. *Simon Fraser University, Burnaby, British Columbia, Canada*, 2. *University of British Columbia, Vancouver, British Columbia, Canada*

Accurate and reliable measurement of physical activity is necessary to assess adherence to and effects of physical activity interventions within a growing population of physically inactive older adults. The STRIDES Study was designed to determine accuracy (criterion=tally counter) and reliability (test-retest) of step counting in mobility-intact older adults from six wearable activity monitors (Fitbit Charge, Fitbit One, Garmin Vivofit2, Jawbone UP2, Misfit Shine, and New-Lifestyles 1000 pedometer). Participants (n=10, 69–80 years) completed a continuous 400-meter walk (average speed 1.3m/s), a non-continuous 400-meter walk (1.1m/s) designed to mimic daily walking patterns incorporating small disturbances, and two 100-step reliability walks. For the continuous walk, five monitors had small mean errors less than +/-5% (One -0.3%, 95%CI=-0.4to-0.2%; Vivofit2 -0.6%, CI=-1.4to0.2%; UP2 -3.2%, CI=-5.7to-0.6%; Shine 0.5%, CI=-6.3to7.4%; New-Lifestyles -0.7%, CI=-1.1to-0.3%) while error for the Charge was larger (-7.7%; CI=-17.1to1.6%). Step counts from the One, Vivofit2 and New-Lifestyles were strongly correlated with criterion ($r \geq 0.95$). For the non-continuous walk, the One, Vivofit2, and Shine had small errors less than +/-5% (-4.4%, CI=-5.4to-3.5%; -4.2%, CI=-8.1to-0.2%; -1.4%, CI=-5.6to2.8%), while errors for the Charge, UP2 and New-Lifestyles were larger (-8.1%, CI=-15.5to-0.6%; -6.3%, CI=-10.6to-2.1%; -6.2%, CI=-11.4to-0.9%). Only step counts from the One were strongly correlated with criterion ($r=0.95$). The Charge, One, Vivofit2, and New-Lifestyles were reliable with no significant differences in step counts between trials, while the Shine and UP2 were unreliable (mean differences between trials of 25.6 and 14.6%, $p < 0.05$). In summary, we found that most activity monitors were reliable and accurate for step counting in older adults during continuous walking, while accuracy of some monitors was compromised during non-continuous walking.

REACH FOR AN ACTIVE LIFESTYLE: PROGRAM FEASIBILITY AND PARTICIPANT PERCEPTIONS

N. Cherneski², L. Burnett², L. Fleig⁴, K. Milne⁵, L. Giangregorio⁶, L. Clemson⁷, M.C. Ashe^{1,2,3}, 1. *Family Practice, The University of British Columbia, Vancouver, British Columbia, Canada*, 2. *Centre for Hip Health and Mobility, Vancouver, British Columbia, Canada*, 3. *The University of Adelaide, Adelaide, South Australia, Australia*, 4. *Freie Universität Berlin, Berlin, Germany*, 5. *Cardea Health Consulting, Vancouver, British Columbia, Canada*,

6. *University of Waterloo, Waterloo, Ontario, Canada*, 7. *University of Sydney, Sydney, New South Wales, Australia*

Return to Everyday Activities in the Community and Home (REACH) is an active living model targeting adults around retirement age. The gradual progression of the REACH program and its evidence-based foundation support the main principles of the model: sit less, move more and be strong. Our overall aim is to scale up the program; in this feasibility study we included women 55 years+ who attended a 6-week community-based group program (2-hours/session) to test key implementation factors and selected health outcomes. Participants provided feedback after each session, and additional information via semi-structured interviews at baseline, 3 and 6 weeks. They also completed questionnaires on habit formation, and exercise identity and confidence. We report all values as median (IQR). There were 10 women who completed the program, aged 64.1 (8.3) y, BMI 24.8 (4.7) and 9714 (4111) baseline steps/day. Participants attended 5(1)/6 sessions; they rated sessions as 5.94 (0.59)/7 and presentation/group facilitation as 6.19 (0.51)/7. For habit formation (pre-post: 7 point scale) they had an increase of 0.75 (2.35) point for breaking up prolonged sitting, 0.97 (1.26) point for physical activity and 1.03 (1.54) point for balance and strength activities. At final assessment, participants reported a very high level of confidence in their ability to use what they learned in daily life routines.

GAIT ADAPTATIONS AND DORSIFLEXION STRENGTH OF OLDER CARIBBEAN AMERICANS AFTER AN EXERCISE PROGRAM

E.R. Vieira¹, R.M. Tappen², M.M. Severi¹, G. Engstrom², S. Gropper², 1. *Physical Therapy and Neuroscience, Florida International University, Miami, Florida*, 2. *Florida Atlantic University, Boca Raton, Florida*

Older Caribbeans are migrating to the US in increasing numbers. They have difficulty integrating and often become isolated and deconditioned. The objective of this pilot study was to evaluate the feasibility and effects of an exercise program on walking during street crossing situations and on the dorsiflexion strength of older Caribbean Americans. Ten older Caribbean Americans completed a 30 to 40 minutes long group exercise program twice a week for 6 months with assessments at baseline, 3 and 6 months including measures of walking velocity, cadence, step length, base support, swing and stance time, single and double support time, knee flexion, and dorsiflexion strength. Participants walked 3 times at preferred speed (reference to normalize the street crossing simulations), and at simulated street crossing with regular time and with reduced time. There were no significant differences between street crossing conditions at baseline, but there were significant differences between conditions at 3 and 6 months for velocity ($P < 0.005$) and peak knee flexion ($P < 0.013$), and at 6 months for cadence ($P = 0.009$), step length ($P = 0.012$), swing time ($P = 0.045$), single ($P = 0.036$) and double support time ($P = 0.013$). Dorsiflexion strength at 6 months was significantly higher than during baseline ($p < 0.001$) and 3 months ($P = 0.004$). The program was feasible, acceptable, and showed some positive effects on walking and knee flexion during street crossing situations, and on the dorsiflexion strength.

BALANCE AND MOBILITY PRE-AND POST-TREATMENT WITH VIRTUAL REALITY OF OLDER LIVING AT NURSING HOMES

M. Scheicher, L. Faber, L. Moreira, *Department of Physiotherapy and Occupational Therapy, Marília, São Paulo, Brazil*

Falls are common among older people needing health care and are a serious public health problem in this population. Studies indicate that about 50–66% of people over 65 years who live in the nursing homes fall annually. Often, institutionalized older have fewer opportunities to participate in activities and tasks of daily living, having a higher deleterious effects in the physiological losses from aging, compromising gait and balance. Postural balance training involving new technologies can promote challenging situations for the older, increasing patient motivation and adherence to the program. The aim of this study was to evaluate the effects of virtual reality training on the static balance and mobility of older living at nursing homes. Five institutionalized older participated in the study and were submitted to 12 weeks of virtual reality training (Nintendo Wii® Balance Board). The static balance was assessed using a force platform (eyes open and closed base). Were used the total path length (cm), the mean velocity (cm/s) and the 95% of the ellipse area to measure the subject's stability. The mobility was assessed by TUG test. The results showed a decrease of TUG values pre and post-treatment (17.3 ± 4.3 and 14.7 ± 4.7 , $p=0.19$). The static balance showed decrease pre and post-treatment in total path length (61.3 ± 18.7 and 59.8 ± 16.3 , $p=0.86$) and mean velocity (2.08 ± 0.62 and 1.99 ± 0.54 , $p=0.75$), but not in the 95% of the ellipse area (5.5 ± 2.96 and 5.7 ± 1.7 , $p=0.87$). The results showed that the treatment with virtual reality can increase the balance and mobility of institutionalized older patients.

THE DISTRIBUTION OF SEDENTARY BEHAVIOR AMONG OLDER U.S. ADULTS BY AGE AND GENDER: IDENTIFYING RISK

M. Huisingh-Scheetz¹, E. Chang¹, M. Kocherginsky², P. Schumm¹, S. Birch¹, W. Dale¹, L.J. Waite¹, *1. University of Chicago Medicine, Chicago, Illinois, 2. Northwestern University, Chicago, Illinois*

Background. Sedentary behavior is a risk factor for and marker of poor health, independent of activity participation. Older adults spend the majority of time sedentary making this behavior a critical target for successful aging. The purpose of this study is to provide older adult normative data for sedentary behavior by age and gender, identifying the least and most sedentary patterns for each group as a reference to gauge risk.

Methods. We used hip accelerometry data from the nationally representative National Health and Nutrition Examination Survey (NHANES) sample from 2003–2006 to examine the distribution of average daily minutes of sedentary behavior among older U.S. adults. Sedentary behavior was defined as fewer than 100 counts per minute. The average number of minutes spent sedentary per day were calculated for the most sedentary quartile, the least sedentary quartile, and the middle quartiles for each age category (65–69, 70–74, 75–79, 80–85) by gender.

Results. Sedentary behavior increased with age and was higher among men than women. The most sedentary quartiles for each age group (youngest-oldest) spent an average of 659–709 minutes and 620–694 minutes per day sedentary for men and women, respectively. The least sedentary quartiles for each age group (youngest to oldest) spent an average of 376–419 minutes and 326–396 minutes per day sedentary for men and women, respectively.

Conclusions. Approximately 2–2.5 hours of sedentary time per day differentiated the most and least sedentary quartiles from the middle quartiles in each age/gender group. This reference can help identify individual risk relative to peers.

CHANGES IN COGNITIVE FUNCTION AFTER EXERCISE INTERVENTION AMONG COMMUNITY DWELLING OLDER ADULTS

M. Chang Gudjonsson^{1,2}, A. Ramel³, O. Geirsdottir³, I. Thorsdottir³, P.V. Jonsson^{1,3}, *1. The Icelandic Gerontological Research Center, Landspítali University Hospital, Reykjavik, Iceland, 2. Reykjavik University, Reykjavik, Iceland, 3. University of Iceland, Reykjavik, Iceland*

Background: Low cognitive function is a risk factor for mobility disability and low physical activity. The purpose of the study was to investigate the changes of cognitive function after 12 weeks of resistance training among healthy community dwelling older adults in Iceland. **Methods:** Subjects ($N=236$, 73.7 ± 5.7 years, 58.2% female) participated in a 12-week resistance exercise program (3 times/week; 3 sets, 6–8 repetitions at 75–80% of the 1-repetition maximum), designed to increase strength and muscle mass of major muscle groups. Body composition, physical activity status, cardiovascular risk factors, 6 minute walk for distance (6MWD), and Mini Mental State Examination (MMSE) were measured at baseline and endpoint. **Results:** The mean MMSE at baseline was 27.5 ± 2.1 , and the MMSE score significantly increased (change of score, 0.53) after the exercise intervention. However, at the individual level, half of the study subjects improved their cognitive function while the other half had the same or lower levels of cognitive function after the intervention. According to linear models, post intervention MMSE score was significantly associated with baseline grip strength.

Conclusion: After 12-week resistance training, improvement in cognitive function was significantly associated with baseline grip strength.

DETERMINANTS OF FUNCTIONAL MOBILITY IN OLDER ADULTS

S. Gore, J. Blackwood, *Physical Therapy, University of Michigan - Flint, Bad Axe, Michigan*

Background and Purpose: Physiological changes with aging are associated with muscle strength and physical activity (PA) declines in older adults. The purpose of this study was to assess if changes in muscle strength and time spent in PA could predict gait speed (GS) in older adults.

Methods: The study population was identified from the NHANES 1999 - 2000 data set. All adults over the age of 64 years were included in the study. GS was assessed using a 20-foot timed walk. Quadriceps muscle strength was assessed using the Kim Kom dynamometer and recorded as

the peak force in newtons (N). Time spent in PA was assessed by a questionnaire.

Results: Data from 198 older adults were included in the study. Muscle strength was significantly associated with timed walk ($r = -0.217$, $p < 0.05$). Using the enter method, our regression model with muscle strength, PA, BMI, age and gender as predictors explained 18.1% of the variance in GS ($F(5,191) = 8.451$, $R^2 = .181$, $p < 0.001$).

Discussion: Muscle strength, age and BMI were found to be significant predictors of GS in older adults. The walk time decreased by 0.13 seconds for every 1 N unit increases in strength. On the other hand, the walk time increased by 0.01 and 0.145 seconds respectively for every 1 unit increase in age and BMI.

Conclusion: Based on the standardized coefficients, strength appears to have the biggest impact on GS. Gender and physical activity duration did not significantly predict gait speed performance in older adults

RELATIONSHIP BETWEEN THE 8-FOOT UP-AND-GO AND POWER IN OLDER ADULTS

L. Boyd, M. Powers, M. Curtis, A. Kiser, M. Smith, S. Wickham, C. Patrick, T. Bodman, *Kinesiology and Health Studies, University of Central Oklahoma, Edmond, Oklahoma*

As people age, muscular power tends to decline to a greater extent than muscular strength. This may have a detrimental impact on balance and functionality. However, the relationship between vertical power and dynamic balance and agility are not completely understood. The purpose of this study was to determine whether power production during a chair stand is related to 8 Foot Up-and-Go (UPGO) time. **METHODS:** Participants included residents of an independent living retirement community ($N=31$, $M=81 \pm 6.81$ years). The UPGO required participants to stand and walk around a cone 8 feet away and return to a seated position as quickly as possible. Muscular power was assessed using a Tendo Power Analyzer™ during a maximum velocity chair stand conducted five times. A one minute rest period was given between each trial. **RESULTS:** After removal of an outlier, no relationship existed between the UPGO and average ($r = .04$, $p = .85$) and peak ($r = -.11$, $p = .57$) power. **CONCLUSION:** The lack of a relationship between power production and the UPGO may indicate other factors are more influential in dynamic balance and agility performance. Differing movement angles of the tests may have also played a role in the results. Future research should evaluate the influence other factors, such as muscular strength or reaction time, might have on UPGO performance, as well as account for angular differences.

THE FEASIBILITY AND EFFICACY OF AN EXERGAMING PROGRAM IN UNDERSERVED URBAN COMMUNITIES

Y. Chao, R. Musanti, *Rutgers, the State University of New Jersey, New Brunswick, New Jersey*

Purpose: Low levels of regular leisure-time physical activity were noted among African Americans. The study tested the feasibility and efficacy of an exergaming program in this underserved communities. **Methods:** The study was a single-group with pre-and-post test design. Twelve

older African-American (64.17 ± 6.74 years old) engaged in a Wii Fit U exergaming program once or twice a week for 24 sessions over 14 weeks. Community health workers (CHWs) implemented the program through coaching and supporting mechanism to motivate participants to exercise in the two public housing health centers. Outcomes included functional mobility (muscular strength, flexibility, dynamic balance), depressive symptoms, and quality of life. Descriptive statistics and Wilcoxon signed-rank test were used. Semi-structural individual interviews were also conducted. **Results:** After the program, participants showed statistically significant improvements in lower-body flexibility ($p = .012$), and physical domain of health-related quality of life ($p = .005$). Participants had comparable outcomes of upper-body strength and flexibility, lower-body strength, dynamic balance, depressive symptoms, and mental domain of health-related quality of life before and after the program. Four themes were identified related to the benefits of the CHW-led exergaming program: (1) improving health; (2) feeling enjoyment; (3) getting connected; and (4) knowing you. **Conclusion:** CHWs played a significant role in influencing and improving health outcomes in the underprivileged communities. The CHW-delivered exergaming program provided an easy-to-implement and potentially effective intervention that could be used in the community-directed center to improve health and well-being in the underserved population.

CHINESE IMMIGRANTS' VIEWS ON EXERCISE AND USING TECHNOLOGY TO ENHANCE PHYSICAL ACTIVITY

C. Katigbak¹, S. Zuo¹, P. Chan², *1. Connell School of Nursing, Boston College, Chestnut Hill, Massachusetts, 2. Chinese Consolidated Benevolent Association of New England, Boston, Massachusetts*

Older Asian Americans have lower rates of physical activity (PA) compared to their White counterparts and other minority groups. Little is known about PA among older Asian American *immigrants* and few studies disaggregate this data to highlight the variations in PA profile among Asian ethnic groups. To address this knowledge gap, we employed a community based participatory research approach to conduct focus groups aimed at understanding older Chinese immigrants' culturally bound attitudes, behaviors, and beliefs about PA. A secondary aim sought to elicit perspectives on the acceptability of, and barriers and facilitators to engaging with PA-promoting technology such as wearable physical activity trackers and exergaming devices (e.g. Nintendo Wii™, and Microsoft Kinect™) – technologies not typically available to at-risk vulnerable groups such as immigrant elders.

A bilingual (Cantonese/English) facilitator led focus groups using an interview guide based on constructs from Ajzen's (1991), Theory of Planned Behavior. Data were translated, transcribed, and analyzed following methods for qualitative thematic analysis.

We will present the main findings from 6 focus group interviews with community-dwelling elders in Boston, Chinatown; sharing salient themes relating to culturally bound normative attitudes and beliefs on PA, and perceived barriers and facilitators to engaging in leisure time physical

activity. Furthermore, we will present participants' perspectives on using PA-promoting technology, and offer their views on how these tools may be integrated into the larger context of their daily lives. This study has broad applicability to gerontological professionals seeking to develop interventions that improve PA for minority older adults.

HAND GRIP STRENGTH, PHYSICAL FUNCTION, AND MORTALITY AMONG MEXICAN AMERICANS 75 YEARS AND OLDER

D. Sampson³, J. Graham¹, A. Kumar², K.S. Markides¹, K.J. Ottenbacher¹, S. Al Snih¹, 1. *University of Texas Medical Branch at Galveston, Galveston, Texas*, 2. *Center for Gerontology and Healthcare Research, Providence, Massachusetts*, 3. *Genesis in Myrtle Beach, SC, Charleston, South Carolina*

The objective of this study was to investigate the associations between handgrip strength and both physical function and mortality in older Mexican Americans. Data are from a ten-year prospective cohort study of 1,368 Mexican-Americans aged 75 and older from the Hispanic Established Population for the Epidemiologic Study of the Elderly. Measures included socio-demographic variables, hand grip strength, the Short Physical Performance Battery (SPPB), medical conditions, cognitive function, depression, body mass index, and mortality. Baseline hand grip strength means for women and men were 17.6 Kg (4.8) and 27.9 Kg (7.2), respectively. Means for the SPPB were 6.7 (2.9) for women and 7.5 (2.9) for men. At follow-up, 584 participants were confirmed dead. Using general linear mixed models, we found that women in the second and third lowest handgrip strength quartiles had greater SPPB declines over time ($b = -0.13$; standard error=0.06, $p=0.02$ and $b = -0.14$, standard error=0.05, $p=0.01$, respectively) compared to participants in the highest quartile. This association remained statistically significant after controlling for all covariates. No significant association was found between hand grip strength quartiles and changes in SPPB scores in men. In women and men in the lowest hand grip strength quartile, the hazard ratio of death controlling for all covariates was 1.66 (95% CI = 1.17–2.37) and 2.09 (95% CI = 1.42–3.07), respectively, compared with those in the highest hand strength quartile. Hand grip strength is a strong predictor of long-term decline in physical function and mortality in older Mexican Americans, after controlling for other relevant risk factors.

FATIGABILITY AS A MEASURE OF PHYSICAL RESILIENCE IN OLDER ADULTS

S.L. Murphy^{1,2}, S.L. Schepens³, A.L. Kratz¹, 1. *Physical Medicine and Rehabilitation, University of Michigan, Ann Arbor, Michigan*, 2. *Ann Arbor VA Health Care System, GRECC, Ann Arbor, Michigan*, 3. *University of Southern California, Los Angeles, California*

A better understanding of physical resilience, ability to recover or optimize function when confronted with stressors such as age-related losses or disease, is needed to develop effective successful aging strategies. Few measures of physical resilience exist; one method is to use measurable aging phenotypes, such as fatigability. Fatigability can

be captured by assessing older adults' capacity to perform strenuous physical tasks. The purpose of our study was to examine fatigability as an indicator of physical resilience in older adults by exploring its associations with recently proposed contributors to physical resilience (Whitson, 2016). This was a secondary data analysis of 163 older adults with clinically-relevant fatigue and lower extremity osteoarthritis. Participants completed questionnaires, 7-days of at-home physical activity monitoring, and functional assessments, including a test of fatigability measured via change in self-reported fatigue pre- to post-Six-Minute Walk Test (SMWT) divided by distance walked. A binary logistic regression was performed to identify relevant psychosocial and physiological contributors to high versus low fatigability (determined by median split). Low fatigability was associated with fewer chronic conditions, faster scores on the timed up and go test, and lower BMI compared to high fatigability. Fatigability was not associated with peak V02, depression, pain, or percent immobile time during home monitoring. While lab-based fatigability assessments may reflect some aspects of physical resilience, such as physical functioning, obesity, and comorbidities. Other facets of physical resilience, such as physiologic reserve, mood, symptom burden, and sedentarieness, may not be captured by lab-based fatigability tests.

EFFECTS OF TRAMPOLINE TRAINING ON COGNITIVE FUNCTIONS IN OLDER ADULTS: A PRELIMINARY STUDY.

G. Zurek^{1,2}, A. Zurek³, T. Halski², 1. *Wroclaw Sports University, Wroclaw, Poland*, 2. *Public Medical School, Opole, Poland*, 3. *University of Wroclaw, Wroclaw, Poland*

Intellectual ability gains a lot of importance in the era of aging of societies and in the face of the impact of variable diseases violating its level. This is confirmed by the results of research, indicating that along with the aging the importance of physical health decreases, while the role of mental health remains unchanged. Other research show the strategic role of the balance for the independent life of seniors. The purpose of the presented research was evaluation of the efficiency of regular physical exercises, performed on a mini trampoline, for selected cognitive functions among variously aged seniors.

32 people (aged 60,5 - 81,7) took part in the research. According to WHO classification they were divided into two subgroups: younger (below 70yo) and older (over 70yo).

Participants took part for ten weeks in a trampoline balancing program. Classes were always held in the morning, twice a week. Seniors were examined twice: before and after the cycle of classes. The CTT-test (Color-Trails-Test composed of CTT-1 and CTT-2) was used to access the efficiency of the processes of attention and executive functions. Analysis of variance revealed differences between the results obtained before and after the study. As a result of the applied intervention the duration of completing the tasks significantly reduces in CTT-2 in the older group (Duncan-test). The CTT-1 confirmed there are no differences in the duration of completing tasks in the first and second group. The mini trampoline program showed a significant effect in intelligent functioning in the older group.

SESSION 900 (POSTER)

PREVENTION, HEALTH RISK, AND HEALTH CARE

USING OLDER ADULTS' GOALS OF CARE TO DRIVE PERFORMANCE MEASUREMENT

M. Henry, E. Giovannetti, E. Anderson, P. Lighter, S.H. Scholle, J.B. French, *NCQA, Washington, District of Columbia*

Care for older adults with complex needs should be aligned with their goals, values, and preferences. To create alignment, providers must elicit and document goals. Efforts are underway to make goal-directed care a reality. This qualitative descriptive study was conducted to build a taxonomy of older adults' goals to be used for goals-based performance measurement. Community-dwelling older adults with one or more functional limitations participated in focus groups or semi-structured interviews at six sites in three regions. Researchers coded transcripts in a template modeled on a pre-existing taxonomy with the following domains: Accessing Services and Supports; Choice and Control; Advanced Illness; Medical Care; Physical Quality of Life; Social, Emotional and Cognitive Quality of Life; and Caregiver Support. New goals were added as needed. [JBF1] Among the 65 goal codes across domains, a plurality of goals articulated by participants were clustered in the Medical Care domain. While many of these goals were outcomes (e.g. lose weight, manage pain), the goals most often articulated were care processes, including "receive needed care," "coordinated care," and "providers who work with/listen to/hear me." Goals were influenced by past and current health care experiences and were context-specific. More research is needed to address the complexity and heterogeneity of older adults' care goals for care planning, goal-based care and performance measurement. These results will support future research efforts to align care goals with care provided and to identify outcome measures (e.g. patient-reported outcome measures) that are important to and driven by older adults.

ALCOHOL USE AND OUTPATIENT SERVICE UTILIZATION AMONG OLDER ADULTS IN CHINA

Y. Zhang¹, A.C. Mui¹, H. Chen², N. Jiang¹, Y. Li³, 1. *School of Social Work, Columbia University, New York, New York*, 2. *Washington University in St. Louis, St. Louis, Missouri*, 3. *Tsinghua University, Beijing, China*

This secondary research is based on the WAVE I (2010) of the WHO Study on Global AGEing and Adult Health (SAGE). This study used the China sample to examine the role of alcohol use and other factors in predicting outpatient service utilization among older alcohol drinkers (self-identified) in China [n = 2,497; age 55 and older; 82% male; mean age=65.23; SD=7.88]. Outpatient services included consultation to doctors, Chinese traditional healers, and pharmacy use in the last 12 months Alcohol consumption was measured from "no days per week" to "5 or more days per week" in the last 12 months. Results showed that 60.1% of the sample had received at least one outpatient service in the last 12 months (mean= 6.14; SD = 9.7). Based on the Andersen and Newman Behavioral Model of Health Services Utilization, factors of

predisposing, enabling and need were used in the logistic regression. Other things being equal, alcohol consumption is a disabling factor to outpatient service use. Results suggest heavy drinkers were less likely to use outpatient services. Among the predisposing factors, rural residency was associated with outpatient service use. In China context, rural elders may have easy access to traditional healers in their villages. Other significant enabling factors predicting service use were elders who had more financial resources, had a higher level of social participation, and reported a better quality of life. As expected, poor health was a need factor for outpatient service utilization. Implications of the findings for health care professionals will be discussed.

THE EFFECT OF AGE AND CLINICAL COMPLEXITY ON PRIMARY CARE CLINICIANS' GLYCEMIC MANAGEMENT DECISIONS

E. McCreedy, R.L. Kane, *University of Minnesota, Minneapolis, Minnesota*

To reduce the risk of severe iatrogenic hypoglycemia, existing guidelines recommend less stringent glycated hemoglobin (HbA1c) targets for medically complex type 2 diabetics with limited life expectancy. The current study considers the effects of patient age, cognitive impairment, and history of myocardial infarction on primary care clinicians' decisions to intensify antihyperglycemic medication therapy at two HbA1c levels within the acceptable range for more complex patients: 7.5% and 8.5%.

We employed a vignette study design that asked primary care clinicians to make antihyperglycemic medication decisions for hypothetical patients with diabetes. For each vignette, clinicians recommended continuing with first-line treatment, Metformin, or intensifying the current medication by adding one of five second-line treatments. We administered vignettes to 376 primary care clinicians in 11 states.

At a HbA1c of 8.5%, 74% of clinicians intensified treatment for an 80-year old woman with longstanding diabetes, cognitive impairment, and heart disease; 36% of clinicians intensified treatment for the same patient with a HbA1c of 7.5%. Further, 29% of clinicians who viewed the 80-year-old patient with cognitive impairment intensified with insulin or a sulfonylurea, agents known to increase the risk of hypoglycemia in these populations. Compared to family practice physicians, internal medicine physicians and nurse practitioners had a higher predicted probability of treatment intensification.

Our findings conservatively suggest clinicians may inappropriately recommend an additional medication for complex older patients over a third of the time. Family practice physicians' lower enthusiasm for intensifying treatment for medically complex patients suggests they may be more familiar with existing guidelines.

FORECASTING HOSPITAL UTILIZATION AND COST OF FUTURE ELDERLY IN SINGAPORE.

C. Chen^{1,2}, S. Sidharta², W. Koh³, J. Yuan⁴, S. Ma⁵, D. Heng⁵, K. Tan⁵, J. Yoong^{1,2}, 1. *University of Southern California, Los Angeles, California*, 2. *National University of Singapore, Singapore, Singapore* 3. *Duke NUS, Singapore, Singapore*, 4. *University of Pittsburgh,*

Pittsburgh, Pennsylvania, 5. Ministry of Health, Singapore, Singapore

Singapore is one of the fastest-aging populations in the world. Predictions show that the percentage of citizens aged 65 and above will increase from 12.4% in 2014 to 24.0% in 2030. In addition, obesity and the burden of chronic diseases are both increasing as lifestyles change. Future health expenditures are determined by multiple factors: age, sex, health status, obesity and smoking. Resource allocation and cost-containment pose growing challenges to policy makers. The goal of this paper is to model future healthcare expenditures based on current trends and evaluate the impact of alternative interventions that aim to reduce smoking prevalence and obesity.

To project the health and functional status of future cohorts of the elderly and to understand their cost implications, we have developed a version of the Future Elderly Model (FEM) adapted to the context of Singapore. FEM-Singapore is a dynamic Markov micro-simulation model that allows individual health states to evolve over time and accounts for trends in background drivers such as aging, obesity, diseases and disability. Our main source of population data is the Singapore Chinese Health Study (SCHS), a cohort study of over 63,000 respondents followed in three waves from 1993–2010. The SCHS is linked with a detailed cost database from the Ministry of Health, Singapore that captures all hospitalization episodes for the same period. Our simulation model projects inpatient healthcare costs into 2050.

UN AGENDA 2030: ADULT VACCINATIONS AS A PUBLIC HEALTH INTEREST FOR HEALTHY AGEING

C. Stuen¹, J. Barratt¹, K. Bluestone³, E. Dhar², 1. *United Nations, International Federation on Ageing, New York, New York*, 2. *AARP International Office, New York, New York*, 3. *Age International, London, England, United Kingdom*

The United Nations adopted a 15 year Sustainable Development Agenda for 2016–2030 (Agenda 2030). The prior agenda, known as the Millennium Development Goals, made no reference to older persons, however a Stakeholder Group on Ageing advocated so that Agenda 2030 has an overarching principle of “leaving no one behind.” There are 17 Goals and 169 Targets and accompanying indicators that contain specific and implied references to older persons. Specific attention will be given to Goal 3 of Agenda 2030—“to ensure healthy lives and promote wellbeing for all at all ages.” The implementation of one of its targets such as “Achieve universal health coverage...access to safe, effective, quality, and affordable, essential medicines and vaccines for all” provides a global opportunity to develop and seek ways to promote healthy ageing including adult vaccinations. Research has shown that adult immunizations can drive healthy ageing initiatives however obstacles still remain to successful implementation. This poster presents the opportunities and strategies to convince policymakers to adopt a lifecourse approach to healthy ageing including adult immunizations. The Stakeholder Group on Ageing members from across the globe will identify programmes to influence policies on ways to promote healthy ageing and reablement in this poster.

SOCIAL VALUE OF PREVENTING ELDERLY DEPRESSION WITH COLLABORATIVE STEPPED CARE AND PRODUCTIVE AGEING

T. Lum, A.C. Cheung, J. Tang, P.W. Wong, V. Lou, W. Chan, S. Ng, G. Wong, *The University of Hong Kong, Hong Kong, Hong Kong*

Approximately 10% of older adults living in the community has clinically significant depression in Hong Kong. The associated societal costs (e.g., years of life lost, direct healthcare and long-term care costs, disease complications) are huge. Previous analysis of Medicare and Medicaid claims data has suggested an additional direct healthcare costs for late-life depression ranging from US\$5,771 to up to US\$17,607 per person per year depending on care setting.

Indicated prevention (targeting older persons with high risk factors) and selective prevention (targeting those with high risk factors and mild symptoms) can reduce suffering and societal costs. Funded by the Hong Kong Jockey Club Charities Trust, this study aims to test a best practice model for effective outreach, engagement, and prevention of late-life depression in 3,840 community-dwelling older adults. The 3-year project has three components: (1) collaborative stepped care between elderly and mental health services; (2) productive ageing for active outreach and engagement; and (3) community empowerment for mental health literacy.

The overall social value of the model will be assessed using social return on investment (SROI) method, a type of cost-benefit analysis, to provide evidence for further service rollout. Following standard SROI study method, focus groups and interviews will be conducted to identify areas of changes and map outcomes/financial proxies with stakeholders, and quantitative data will be collected for evidencing, establishing impact and calculating SROI. We report here the service model, preliminary findings from focus groups and interviews, and the forecast SROI of the model.

U.S. RESOURCES FOR DELIVERING CHRONIC DISEASE-SELF-MANAGEMENT EDUCATION: THE NATIONAL RESOURCE CENTER

C. Plass¹, M. Altpeter², K. Kulinski³, 1. *National Chronic Disease Self-Management Resource Center, National Council on Aging, Arlington, Virginia*, 2. *University of North Carolina, Chapel Hill, North Carolina*, 3. *Administration for Community Living/AoA, Washington, District of Columbia*

Effective interventions, such as chronic disease self-management education (CDSME) programs, are necessary to address the growing epidemic of chronic diseases in the US and abroad. Funded by the US Administration for Community Living (ACL), the National Council on Aging (NCOA) serves as the National Resource Center to support the expansion and sustainability of evidence-based CDSME programs countrywide. This poster is designed for professionals interested in exploring CDSME program delivery resources that are accessible at the Center. It will showcase the ways NCOA provides training and technical assistance to a nationwide network of state and community-based organizations that offer CDSME programs. It will describe and explain how to access the range of webinars that cover a variety of topics on CDSME programming, including outreach to underserved populations, health care integration,

strategies for sustainability, and more. The poster will also feature the Center's national clearinghouse of resources and best practices for CDSME programs. This includes the "Best Practices Toolkit, a compilation of over 150 resources, grounded in "real world contexts" from partners across the country implementing CDSME programs. It will also feature the Center's multi-level online "Community Integrated Health Care Toolkit," designed to help community-based organizations build partnerships with health care systems and receive payment for the CDSME programs that they offer. The clearinghouse resources are organized for ease of access and can help professionals strategize their efforts in building leadership and partnerships, enhancing capacity, creating centralized and coordinated processes, designing business plans, and conducting quality assurance and evaluation activities.

EXPANDING THE SCOPE OF PATIENT-CENTERED PRACTICE TO INCLUDE NON-MEDICAL RESOURCES

J. Ilardo, D. Contreras, *College of Human Medicine, Michigan State University, East Lansing, Michigan*

Using resource mobilization aspects of social movement theory, we conceptualize the melding of patient self-management education led by community organizations, such as area agencies on aging and senior centers, into medical management of chronic conditions as an element of a social movement. According to the partial theory defined in the seminal work by McCarthy and Zald, resource mobilization 'examines the variety of resources that must be mobilized, the linkages of social movements to other groups, and dependence of movements upon external supports for success and the tactics used by authorities to control or incorporate movements.' In our frame, we identify community-based patient education and coaching as resources that can be mobilized to enhance patient outcomes and quality of life. We will describe the methods we used to create an interdisciplinary team that includes physicians, social workers, nurses, health educators, program designers, dietitians, outpatient practice administrators, and reimbursement specialists to design innovative models that incorporate patient engagement, activation, self-management education, and coaching. We will present two models that emerged from this process.

ADHERENCE TO GLYCEMIC CONTROL GUIDELINES AND 8-YEAR MORTALITY RISK AMONG U.S. ADULTS WITH DIABETES

E. Handing¹, H. Meng², W. Monaco², M. Ji², M. Li², P. Foulis², S. Buslovich³, 1. *Wake Forest School of Medicine, Winston-Salem, North Carolina*, 2. *University of South Florida, Tampa, Florida*, 3. *University of Buffalo, Buffalo, New York*

The objective of this study was to examine whether life expectancy adjusted adherence to glycemic control guidelines is associated with 8-year mortality risk among U.S. older adults with diabetes. We used data from the Health and Retirement Study to identify a cohort of adults who had glycated hemoglobin A1c (HbA1c) tested in 2006. The study sample consisted of 1,300 adults aged 50 and older with diabetes. Glycemic control was defined as: (1) having an HbA1c of under 7% (the old guideline); or (2) having an HbA1c of under 7.5%, 8.0%, or 8.5% based on an individual's life

expectancy (the new guideline). The primary outcome measure is time until death or censoring as of 2014. Independent variables included socio-demographics, diabetes treatment regimen, health status, comorbidities, and lifestyle variables. We used Cox Proportional Hazards model to estimate the effect of guideline adherence on survival, controlling for covariates. The mean age of the sample was 69.2 years and 59.5% were female. We found that individuals who met the new guideline had similar survival as compared to those who met the old guideline (HR=1.02, 95% CI=0.77-1.36, p=0.881), whereas those who met neither guideline had a 38% increase in risk of death (HR=1.38, 95% CI=1.05-1.81, p=0.020). The findings suggest that diabetes patients who are reclassified as achieving glycemic control under the new guidelines are not at greater mortality risk. Further research is warranted on how to balance the needs for glycemic control and the management of other comorbidities that contribute to mortality for diabetes patients.

FILLING THE GAP: SOCIAL SUPPORT FOR OLDER ADULTS LIVING WITH HIV/AIDS

V.A. Charles^{1,2}, J. Gradillas¹, K.H. Marr¹, 1. *Youth Learning Institute, Clemson University, Pickens, South Carolina*, 2. *University of South Carolina, Columbia, South Carolina*

Social support is a critical resource for older adults living with HIV/AIDS to help meet both emotional and functional needs. Social isolation and loneliness have been linked to decreased quality of life and poorer health, especially for populations marginalized by social stigma. Recent literature has identified a gap in knowledge about training and service provision to reduce HIV-related stigma and loneliness (Beaulaurier et al., 2009; Roger, Mignone, & Kirkland, 2013). This descriptive study aims to provide information on sources of social support in middle and older adulthood generating knowledge for tailoring training and service provision.

The study sample (n=181) consisted of people in SC on an HCBS HIV/AIDS Medicaid waiver. Most were men (68%) with a mean age of 56 years. When asked to identify people providing social support, family members and case managers were selected as providing the most social support (64%). **One in 5 reported no support from family or friends. A subgroup of participants (n=39) had home health workers, whom they identified as providing more social support than any other group (67%).**

These findings underscore the importance of the role of the formal support system to meeting critical social support needs. Given the world wide growing HIV/AIDS aging population and the reality that resources are limited everywhere, it is imperative to meet the need now. Home health workers are already providing these supports. Therefore organizations, large and small, can structure training around culturally and ethically appropriate methods of social engagement to build working relationships with older adults.

IMPACT OF ORAL CARE BY DENTAL PROFESSIONALS AMONG ELDERLY PATIENTS IN A REHABILITATION FACILITY

S. Ono¹, M. Ishimaru¹, Y. Ono², H. Matsui¹, H. Yasunaga¹, 1. *The University of Tokyo, Tokyo, Japan*, 2. *National Defense Medical College, Saitama, Japan*

Evidence has suggested that oral health may be linked with general health, and oral care potentially decrease pneumonia in frail elderly. However, it remains uncertain whether oral care by dental professionals is superior to that by non-professionals in terms of improvement in general health in elderly patients. In 2009, Japanese long-term care insurance system introduced additional reimbursement for oral care by dental professionals in geriatric rehabilitation facilities. This system innovation prompted us to conduct a quasi-experimental study using a nationwide database of long-term care to analyze the impact of oral care by dental professionals on the outcomes (incidence of critical illness, hospitalization, or mortality; discharge to home; and costs) among elderly patients in geriatric rehabilitation facilities. We identified in 294,541 patients in 1168 facilities that provided oral care by dental professionals, and 329,678 patients in 1523 facilities that did not provide oral care by dental professionals from 2008 to 2012. In difference-in-difference analyses, no significant difference was shown in the incidence of critical illness, hospitalization, mortality, or costs between patients with and without oral care by dental professionals. Significant increases in the proportions of discharge to home were observed in patients with oral care by dental professionals, being 0.16% (95% confidence interval, 0.02% to 0.30%) at 1 year, 0.26% (0.05% to 0.48%) at 2 years and 0.37% (0.10% to 0.65%) at 3 years. The results suggest that oral care by dental professionals may improve general condition of elderly patients in geriatric rehabilitation facilities and promote their discharge to home.

HOW ELDERLY MIGRANTS ACCESS HEALTHCARE? A QUALITATIVE ANALYSIS

W. Wang¹, Y. Wang¹, Z. Li², Z. Wang³, F. Yan¹, 1. *Fudan University, Shanghai, Shanghai, China*, 2. *Health Bureau of Jing-An District, Shanghai, China*, 3. *Gong He Xin Community Health Center of Jing-An District, Shanghai, China*

The number of elderly migrants (≥ 60) in China reached 10.6 million in 2014. There have quite a few studies on social adaptation of these old people, but limited focus on their utilization of healthcare. This study aims to understand the health services utilization of elderly migrants and identify its impact factors.

In-depth individual interviews were employed. 4 administrators from the district-level government departments, 2 health workers from a community health center and 30 elderly migrants from 3 communities in Shanghai were interviewed in 2015.

The results showed that majority of elderly migrants didn't see doctor when they got sick, except in an emergency or serious illness. They might buy drugs from pharmacies nearby or take the reserved drugs from hometown, and some of them would go back to their hometown to see doctor, especially for hospitalization. The factors including familiarity of living environment, family members accompanying, benefit package of health insurance and income played more important role in the pattern of accessing health care for the elderly migrants, compared to the local elders. Especially, almost all of the interviewees mentioned the problem of cross-region benefit of health insurance. When the elderly migrants see the doctor in Shanghai, they need go back to hometown to

get the reimbursement, the reimbursement procedure is complicated and the rate is much lower, and most outpatient services are not covered.

It requires particular attention on improving cross-region settlement system of health insurance, and strengthening the role of social organization and family supports.

EVIDENCETOPROGRAMS.COM: TOOL KIT FOR IDENTIFYING, SELECTING, AND IMPLEMENTING EVIDENCE-BASED PROGRAMS

A.B. Stevens¹, M.G. Ory², R. McGhee³, 1. *Center for Applied Health Research, Baylor Scott & White Health, Temple, Texas*, 2. *School of Public Health, Texas A&M Health Science Center, College Station, Texas*, 3. *Central Texas Council of Governments, Belton, Texas*

Community organizations are an excellent delivery channel for evidence-based programs (EBPs), and organizations providing EBPs frequently receive preference in accessing program funding. However, it is often challenging for them to access and implement EBPs that match their clients' needs. In response, we developed a web-based interactive toolkit, EvidenceToPrograms.com, to serve as a user-friendly guide to select, implement, and evaluate EBPs.

Divided into two sections, (1) selecting a suitable EBP and (2) implementing EBPs with fidelity, the Toolkit provides a comprehensive overview of EBPs that can benefit community organizations, healthcare professionals, and students alike. The Toolkit also guides the user through a series of steps to facilitate an organization's understanding of their ability to deliver evidence-based programming with model fidelity. Some of the Toolkit's unique features include rich content with supporting diagrams and tables, links to external sites for additional information and resources, and even interactive Readiness Questions that help foster organizational readiness to implement an EBP. The Toolkit also offers strategies that can help organizations increase the sustainability of their implemented program. Other features of the Toolkit include expert videos and an FAQ section where users can submit their questions regarding EBPs.

Whether new or experienced with EBPs, all organizations will find useful materials within the Toolkit.

MERELY A RHETORIC PROMISE? OLDER USERS' CHOICE AND CONTROL IN SWEDISH HOME CARE SERVICES

A. Dunr, P. Bjalkebring, B. Johansson, *University of Gothenburg, Gothenburg, Sweden*

Swedish eldercare is a publicly funded, municipal responsibility and older people are encouraged to remain in their own homes for as long as possible, supported by home care services. The policy goals have traditionally emphasized universalism [same services were directed toward and used by all socio-economic groups]. But in recent years, a policy shift towards individualized eldercare, with an emphasis on consumer-choice, has taken place. The policy intention is to give older people more choice and control and more customized services, regardless of what service or form of support they receive, and however it is provided. The aim of the paper is to analyze older people's views and experiences of available choice and control in the home care services. Empirical data consist of a survey ($n=2676$) and qualitative interviews ($n=$

25) with older people in three Swedish municipalities with different social care models that we label a *consumer-choice model*, a *service-choice model* and a *traditional model*. The theoretical frame for the analysis comprise Tronto's concepts care logic vs market logic and Hirschman's concepts voice, exit and loyalty. Preliminary results show that the respondents had trouble acting as consumers according to market logics. Instead, they emphasized the importance of a mutually respectful caring relationship and wanted to have 'voice'.

A DEMONSTRATION STUDY ON THE ELDERLY'S DEMANDS FOR NURSING CARE SERVICES IN BEIJING, CHINA

Q. Yuan, H. Ruan, G. Chen, *Peking University, Beijing, China*

Based on the data from the fourth survey of the living condition of Chinese elderly in 2015, this paper studied the factors of the elderly's demands for nursing care services from the perspective of gender. Binary Logistic model was used in this paper to analyze the effect of each variable on the elderly's demands for nursing care services. The results showed that the economic status and health status were the most important factors that affect the elderly's demands for nursing care services. That means those who are in better economic condition are in a higher demand for nursing care services and the healthier the elderly people are, the lower their demand is. Besides, a Good social participation can reduce the elderly's demands for nursing care services. In addition, male elderly have a higher demand for nursing care services than female elderly, and their demand is quite different in the type of aging service projects. So integrating the perspective of gender into the construction of aging service system and the improvement of aging service projects is urgently needed in Beijing, China.

NEW COLLABORATIVE PRACTICES IN PRIMARY CARE: PROVIDING COMPREHENSIVE SERVICES TO PATIENTS AT RISK

R. Mahrer Imhof^{1,2}, L. Imhof¹, *1. Institute of Nursing, Zurich University of Applied Sciences, Winterthur, ZH, Switzerland, 2. University of Southern Denmark, Odense, Denmark*

One of the major challenges is to provide effective, efficient and better care to older people in primary care. A RCT study that tested a prospective care intervention provided by Advanced Practice Nurses to home dwelling people over the age of 80 years (n=461) in an urban area of Switzerland showed significant effects on reducing acute events (NNT 4.3; p=.001), falls (NNT 7.1; p=.003), and hospitalization (NNT 10.0; p=.03). Following this positive trial, a new model of care highlighting collaborative practices amongst health care professionals in primary care has been proposed. Subsequently, a program for home dwelling frail patients has been developed by a group of health care professionals in primary care and researchers using participatory action research methodology. The program focuses on patient-directed goal setting, involvement of family members, in-home care provision and coordination of services amongst health care providers especially advanced practice nurses and family physicians in an urban area. Despite many challenges

such as different professional languages and cultures, resistance of health care professionals toward new models of care and lack of reimbursement systems that allow embracing new collaborative practices, the program has been implemented and testing is under way. Primary results of the acceptance and satisfaction of patients and families, as well as collaborative practices amongst health care professionals will be presented.

COMPARING AGE PATTERNS OF CARDIOVASCULAR DISEASE AND ITS RISK FACTORS IN THE USA AND RURAL GHANA

M. Hafkamp¹, J. Koopman², R. Westendorp³, J. Slaets¹, D. Van Bodegom¹, *1. Research, Leyden Academy on Vitality and Ageing, Leiden, Netherlands, 2. Leiden University Medical Center, Leiden, Netherlands, 3. University of Copenhagen, Copenhagen, Denmark*

Despite increasing efforts of prevention, western populations face a persistently high prevalence of age-related diseases, most notably cardiovascular diseases and diabetes. Since these diseases are largely driven by a modern affluent lifestyle, they are scarce in developing populations without such a lifestyle.

Here, we compare population distributions of cardiovascular disease and risk factors amongst older people in the United States (NHANES) with our own field data from older people in a rural area in northern Ghana. We compared the mean levels and distributions of body mass index (BMI), glucose and cholesterol.

We observed that the mean levels of these risk factors were markedly lower in Ghana than in the United States. Interestingly, however, the entire distributions of these risk factors were shifted while retaining a similar dispersion around the mean. When studying the prevalence of cardiovascular disease, we observed a shift of disease onset towards later ages.

The observed shift of the distributions of lifestyle-related risk factors of cardiovascular diseases suggests that the high prevalence of these diseases in developed nations is due to factors that increase cardiovascular disease risk in all individuals, rather than a subset of individuals. In the terminology popularized by the epidemiologist Geoffrey Rose, developed nations have sick populations, and they still have much to gain from combatting the determinants of disease that act on entire populations. Though lifestyle change may be brought about through an individual-based approach, interventions aimed at disrupting population-level determinants of unhealthy lifestyle will likely be more successful in reducing disease prevalence.

USING EDUCATIONAL INTERVENTIONS TO AFFECT PROVIDER PRACTICES IN IMMUNIZATIONS

D. Hawks, *ACOG, Washington, District of Columbia*

Infectious diseases and vaccine-preventable diseases pose great health burdens to the older population. The older population suffers a significantly higher proportion of disease burden than other populations in vaccine-preventable diseases such as influenza, pneumonia and shingles. Obstetrician-gynecologists provide a high proportion of primary care to women. The American College of Obstetricians

and Gynecologists developed several educational resources and toolkits for providers and patients to increase the uptake of immunizations by adult women. A national survey was conducted prior to and following the educational intervention to assess the impact on providers' knowledge, attitudes and practices regarding education, recommendation, and implementation of immunizations into their standard practice with their adult female patients. A randomized pre- and post-intervention survey was sent to 1500 ob-gyns in 2012 and 2105. In the postintervention survey significantly more ob-gyns reported that they had received the educational toolkit (84.5% vs 67.0%, $p < .001$) and that they offered or planned to offer influenza and other vaccines to their adult patients (76.8% vs 59.3%, $p < .001$). A statistically significant difference was found in providers following these educational interventions documenting the efficacy on increasing immunization uptake in adult health care.

HEALTH INEQUALITY AND ITS DECOMPOSITION AMONG THE OLDER ADULTS IN XIAMEN, CHINA

Y. Fang^{1,2}, K. Elder³, S. Hao^{1,2}, Z. Qian³, Z. Zhou^{1,2}, 1. *State Key Laboratory of Molecular Vaccinology and Molecular Diagnostics, Xiamen, China*, 2. *Key Laboratory of Health Technology Assessment of Fujian Province University, Xiamen, China*, 3. *Department of Health Management & Policy, Saint Louis University College for Public Health & Social Justice, Saint Louis, Missouri*, 4. *Department of Epidemiology, Saint Louis University College for Public Health & Social Justice, Saint Louis, Missouri*

Purpose of the Study: To examine socioeconomic status (SES) inequality in comprehensive health (CH) among the Chinese elderly and to evaluate the contributions of the key factors to the inequalities.

Design and Methods: Data were utilized from a survey of 14,292 Chinese adults aged 60 years and older in Xiamen, China. The health included six domains, and each had five three-point or five-point items. First, domain score was calculated as the sum of each item score within the domain and then was normalized into the scale of 0 to 100. Second, CH and SES scores were derived by factor analyses. Third, concentration indices (CIs) were used to quantify the CH inequality. Finally, linear decomposition analysis was performed to estimate the contributions of key factors to CH inequalities across five SES groups.

Results: The means of the CH scores for SES from I to V were 61.10, 64.36, 68.43, 74.30 and 79.04, respectively. The CIs for overall CH was 0.053 (95%CI: 0.050, 0.055). 76.54% of the CH inequality was contributed by economic condition and education, other notable contributors were children's economic status (16.92%) and Medical Insurance for Urban Residents (-10.01%). Living in an urban area (9.77%), having Medical Insurance for Urban Employees (7.03%) and exercising (7.99%) also had significant contributions to the CH inequality.

Implications: Inequality in health among the elderly in Xiamen of China was largely determined by economic conditions, educational level, medical insurance, residence, and exercise. Comprehensive social policies should be considered to address CH inequalities for older adults.

FILLING THE GAP IN ORAL HEALTH FOR OLDER ADULTS: A COMMUNITY GUIDE TO PROGRAM IMPLEMENTATION

C.A. Gruman¹, M. Worstell², P. Sprowls³, 1. *The Lewin Group, Rehoboth Beach, Delaware*, 2. *Office of Women's Health, Washington, District of Columbia*, 3. *Administration for Community Living, Washington, District of Columbia*

The realization that oral health is strongly connected to overall health is growing. Beyond the health of teeth and gums, a visit to a dental professional can detect signs of poor nutrition, disease, infection, immune disorders, and some cancers, leading health experts to regard the mouth as "a mirror of health and disease."

The Administration for Community Living and the Office on Women's Health funded The Lewin Group to develop and disseminate the Community Guide to Adult Oral Health Program Implementation - a web-driven, online database of promising oral health programs for older adults, and a how-to-guide for communities interested in starting such oral health programs.

The team identified and researched over 200 community-based oral health programs through a systematic review. Performance criteria were developed with the help of a Subject Matter Expert Working Group, and five reviewers used the criteria to independently evaluate these programs.

These programs serve a broad cross-section of the older adult population and they range from mobile dentistry to hygienist administered prevention programs. The community-based oral health programs will be catalogued in a searchable online database organized by key program features such as location, services, and funding sources. The website will also include a Community Guide to Adult Oral Health Program Implementation providing resources addressing the following components of program development: conducting a needs assessment, developing a mission and goals, establishing partnerships, designing a program, financing the program, implementing the program, evaluation, and program sustainability.

REGISTERED NURSES DELEGATES THE ADMINISTRATION OF MEDICINE TO UNLICENSED PERSONNEL IN NURSING HOMES

M. Westerbotn^{1,2}, Å. Gransjön Craftman¹, 1. *Sophiahemmet University, Stockholm, Sweden*, 2. *Department of Clinical Science and Education, Södersjukhuset, Karolinska Institutet, Stockholm, Sweden*

Aims and objective: The administration of medicine is frequently delegated by registered nurses to unlicensed assisting personnel when caring for older people in residential care. Our aim was to describe registered nurses' experience in the context of delegating the administration of medication to unlicensed personnel in residential care homes.

Background: The residents in residential care homes have a need for extensive care and nursing and large amounts of medicines are common practice. Registered nurses' workload and difficulties in fulfilling their duties, such as administration of medicines, have led to frequent delegation of this task between the registered nurses and unlicensed assisting personnel. It is of course a great responsibility to ensure that the

care of the elderly remains safe while maintaining quality in the prevailing situation.

Design: A qualitative inductive descriptive study.

Methods: Data were collected using audio-recorded semi-structured interviews with a purposive sample of 18 registered nurses and interpreted using manifest content analysis. The study was approved by the Ethical Research Committee.

Results: The study showed that registered nurses delegate the administration of medicine to unlicensed personnel with a wide-ranging variety of experiences in the care of the elderly and knowledge of medicine, administration and side-effects. Good communication and follow-up of the delegated administration of medicines to unlicensed personnel were considered to be two important factors in patient safety.

Conclusions: Delegating the administration of medicine as a registered nurse to unlicensed assisting personnel in residential care homes entails a challenging responsibility.

SESSION 905 (POSTER)

TECHNOLOGY

PARKINSON'S DISEASE CAN LIMIT THE EFFECTS OF MOTOR-COGNITIVE TRAINING IN VIRTUAL REALITY ENVIRONMENT

J.R. Bacha, T.B. Freitas, K.G. Silva, G. Gomes, L. Viveiro, C. Torriani-Pasin, J. Greve, J. Pompeu, *Department of Physical Therapy, Speech Therapy and Occupational Therapy, School of Medicine, University of Sao Paulo, São Paulo, São Paulo, Brazil*

Objective: To evaluate if patients with Parkinson's disease and elderly people can improve on their postural control (PC) and cognition after virtual reality training.

Methods: Sample size was composed by ten subjects, 5 idiopathic PD (PDG) [68.2±6.01 years; Hoehn & Yahr scale = 1:2 subject; 1.5:2 subject and 3:1 subject], and 5 elders subjects (ESG) [68.2±6.3 years]. Fourteen sessions of Kinect Adventures games were carried out [1 hour, 2x/week for 7 weeks, during *on* period of dopaminergic replacement]. PC and cognition were assessed by Mini-Balance Evaluation Systems Test (MBT) and Montreal Cognitive Assessment (MoCA). Assessments were performed before, after and 1 month after the end of training (follow-up). Descriptive analysis was performed (mean, standard deviation and confidence interval of 95%). **Results:** Regarding PC, MBT scores in PDG were at baseline: 26.0±3.6 [21.52 – 30.47]; after training: 26.2±3.42 [21.95 – 30.44] and follow-up: 27.6±2.6 [24.36 – 30.83]. MBT scores in ESG were at baseline: 27.4±2.7 [24.04 – 30.75], after training: 29.2±2.77 [25.75 – 32.64] and follow-up: 28.4±1.81 [26.14 – 30.65]. MoCA scores in PDG were 24.0±1.87 [21.67 – 26.32] at baseline 23.6±3.2 [19.61 – 27.58] after training and 23.6±2.7 [20.24 – 26.95] at follow up. MoCA scores in ESG were 21.0±3.08 [17.17 – 24.82] at baseline, 27.2±2.16 [24.50 – 29.89] after training and 26.2±2.48 [23.10 – 29.29] at follow up. **Conclusion:** Scores of groups in both scales at baseline indicated that patients were next to ceiling of scales. Nevertheless, CG showed improvement on PC and cognition

after training. However, future studies with larger sample are needed in order to generalize the results.

EFFECT OF KINECT GAMES ON COGNITION AND QUALITY OF LIFE OF ELDERLY: RANDOMIZED CLINICAL TRIAL

J.R. Bacha, K.G. Silva, T.B. Freitas, G. Gomes, E.M. Varise, L. Viveiro, C. Torriani-Pasin, J. Pompeu, *Department of Physical Therapy, Speech Therapy and Occupational Therapy, School of Medicine, University of Sao Paulo, São Paulo, São Paulo, Brazil*

Objective: To analyze the effect of Kinect Adventures games on cognition and quality of life of community dwelling elderly people. **Method:** This is randomized clinical trial. 36 elderly were selected with mean age 69.68 (5.60) were randomized into control group (CG) and experimental group (GE), 18 in each group. The subjects underwent 14 training sessions of one hour, twice a week. The sessions of the CG were composed by warming up, balance training, aerobic exercises, muscular strengthening and cool-down. EG played four Kinect Adventures games. Participants were assessed before, after and 30 days after the training (follow up). Cognition was assessed by the Montreal Cognitive Assessment (MoCA) and the quality of life by the World Health Organization Quality of Life-Older Adults (WHOQOL-OLD). The Study was registered in the Brazilian Registry of Clinical Trials (RBR-4z4f48). Statistical analysis was performed using ANOVA of repeated measures and the post hoc test of Tukey, adopting alpha of 0.05. **Results:** CG showed improvement on MoCA after training (the mean difference between before and after training was 3.5; 95% Confidence Interval 1.11 to 5.99; P<0.01). GE showed improvement on MoCA on follow up (the mean difference between before and follow up was 3.66; 95% Confidence Interval 1.18 to 6.14; P<0.01). There was no difference between the groups. Regarding Quality of Life, both groups showed no improvements. **Conclusion:** Both training improved cognition and did not interfere on quality of life of community dwelling elderly people. This result is attributed to the short intervention time and small sample.

SMART-PHONE APPLICATION EVALUATION FOR OLDER ADULTS PRESCRIBED PHYSICAL THERAPY FOR FALL PREVENTION

L. Kneale¹, S. Chaudhuri¹, D. Rosenberg², G. Demiris¹, E.A. Phelan^{3,1}, 1. *University of Washington, Seattle, Washington*, 2. *Group Health Research Institute, Seattle, Washington*, 3. *Harborview Medical Center, Seattle, Washington*

Strength and balance exercise reduces fall risk in older adults (OAs), but low adherence is a key barrier to realizing the benefits of an exercise routine. We partnered with a smart-phone application manufacturer to test the feasibility and effectiveness of Wellpepper, an application designed to improve adherence to physical therapy-based (PT) exercise, with OAs at high fall risk. Wellpepper provides users access to personalized videos taken during PT sessions that show the OA or physical therapist performing exercises. Wellpepper also generates reminders, allows communication between the OA and physical therapist, and facilitates tracking exercise completion, pain and/or other difficulty with the

exercises. Study participants are community-dwelling OAs aged 65+ who are undergoing PT for fall risk reduction, their physical therapists, and their caregivers. Data collection consists of interviews to assess user perceptions and a survey to assess physical activity level, fear of falling, and confidence to perform at-home exercise. Data collection is ongoing. Findings to date (N=4 physical therapists, 2 OAs) suggest that physical therapists are eager to use these tools in their practice and believe that the tools will help the OA adhere to their home exercise program. OAs are willing and able to use smart-phone applications as part of their exercise routine following instruction in use of the application. Effectiveness data indicate that the OA participants have a strong commitment to their at-home routines and low fear of falling at the close of the intervention period. Data from the entire study sample will be presented at the meeting.

CHALLENGES AND BENEFITS OF TECHNOLOGY-ENABLED REHABILITATION TO PROMOTE PHYSICAL FUNCTIONING

L. Letts, J.A. Richardson, D. Chan, H. Siu, S. Sinclair, S. Sanford, L. Thabane, *School of Rehabilitation Science, McMaster University, Hamilton, Ontario, Canada*

Rehabilitation has potential to exploit information technology (IT) to address changes in physical functioning associated with chronic diseases and aging. This presentation will explore technology-specific aspects of a cohort study designed to determine feasibility of using an electronic patient health record to prevent physical functional decline in persons ≥ 44 years. Participants in the study (97 persons with chronic diseases/conditions (CD) and 50 persons without chronic conditions (NCD); mean age 64 years) interacted with occupational and physical therapists primarily through on-line assessments within a patient health record, and subsequently used secure messaging to receive and communicate about suggested rehabilitation strategies. Although most participants described themselves as being familiar users of IT (86% of CD group; 92% of NCD), some participants were either non-users or beginners. Seven in-depth interviews were conducted to explore participants' experiences and satisfaction with the technology and intervention at the study's completion. Initial content analyses suggest many participants experienced technological challenges; people who reported high levels of computer literacy professed greater engagement with the process. Benefits of technology included flexibility with on-line communications, and ongoing awareness of targets in relation to physical function from self-monitoring. However, participants requested more direct integration between their providers and the technology, including opportunities to discuss findings, and to better understand the purpose of advice received electronically. Findings suggest a range of experiences in using IT-enabled rehabilitation; such rehabilitation strategies can be developed to promote physical function, but may need to be implemented in a blended model with in-person interactions.

LUDO: AN INTERVENTION SYSTEM TO DETERMINE PERSONS WITH MILD DEMENTIA FROM INACTIVITY AND RESTLESSNESS

S. Khan¹, N. Neubauer², J. Jeremic³, T. Jose¹, V.F. Cervantes², M. Lussier⁴, 1. *Department of Occupational Science and*

Occupational Therapy, Toronto Rehab Institute, Toronto, Ontario, Canada, 2. University of Alberta, Edmonton, Alberta, Canada, 3. Simon Fraser University, Vancouver, British Columbia, Canada, 4. Universite Du Quebec Montreal, Montreal, Quebec, Canada

The prevalence of dementia is on the rise worldwide. As symptoms of dementia progress, many will experience increased bouts of physical inactivity and restlessness, which will inevitably impair their ability to remain independent in their homes. Existing interventions have incorporated home-based monitoring and/or stimulating activities, however standalone they remain insufficient. In this work, we present 'LuDo', which integrates home-based monitoring and stimulating activities in a single working system. LuDo is equipped with two components: (i) A wearable device, and (ii) An interactive stimulating suite. Using advanced machine learning algorithms, LuDo senses an extended period of inactivity or restlessness in persons with dementia (PWD), which triggers the computer to play a familiar sound. Users respond by approaching the periphery of the Kinect camera, activating the TV screen. The screen provides a voice/touch interface for PWD to interact with LuDo. Options include interactive activities and music. LuDo is capable of learning the habits of PWD over time which will recommend content based on user preference, and provides alerts to the carer if the PWD does/ doesn't respond or engage with the auditory cue. LuDo operates automatically, without user or carer intervention, works passively, activates only when necessary and can be deactivated at any time. An Initial prototype of LuDo is tested on healthy adults and was found to be able to reroute them from their inactive state and engage them in mentally stimulating activities. In future, we plan to conduct similar experiments with PWD and test their level of interaction with LuDo.

IPAD TRAINING INCREASES FRIENDS AND REDUCES LONELINESS IN OLDER ADULTS

J.T. Giger¹, S. Smallfield², J. Austin², 1. *University of Kentucky College of Social Work, Lexington, Kentucky, 2. Oregon Health and Science University, Portland, Oregon, 3. Washington University in St. Louis, St. Louis, Missouri*

Information and communication technologies such as the iPad are important instruments for reducing loneliness and improving social connectedness. The present study examined change in loneliness following an iPad training program. A sample of 46 women and 9 men, aged 63 to 95, was drawn from community-dwelling older adults. Loneliness and key variables were assessed at baseline, 6 months, and 12 months. A 6-month iPad training was delivered following baseline measurement. We hypothesized that iPad training would reduce loneliness, and that increases in the reported number of close friends would be negatively associated with loneliness. We performed a tobit-mixed-effects model including age, socioeconomic status, meal habits, baseline number of friends, change in number of friends from baseline, and time. Data revealed both baseline number of friends and increases in the number of friends were negatively associated with loneliness. Eating meals alone was associated with more loneliness and increased age was associated with decreased loneliness. Loneliness did not change over time. Because this contradicted our initial hypothesis, we performed a follow-up

analysis to test whether ‘change in number of friends’ was accounting for the effect of time. We removed this variable from the model and re-ran the analysis. In this model, loneliness was significantly lower in the follow-up period than either baseline or end of the intervention. Findings suggest that iPads can be used as a suitable intervention for loneliness in older adults by helping improve relationships with family and friends. Implications of the findings are discussed for practitioners, researchers, and policy-makers.

MOBILE TECHNOLOGY IN MEDICATION MANAGEMENT FOR OLDER ADULTS: FEASIBLE AND EFFECTIVE

M. Tse, *School of Nursing, The Hong Kong Polytechnic University, Hong Kong*

This study aims to encourage community older adults to use technology for medication management. Ten community-dwelling older adults joined our study. Each participant attended a one-on-one teaching session which lasted for around 40 to 60 minutes. Each session included (1) teaching on the use of smartphone apps and QR code; (2) return demonstration; (3) immediate evaluation. A disc consisting of educational video and leaflet were given after the teaching session.

Medication incidents such as delayed dose (70%) and missing dose (40%) were common. In spite of these problems, nearly all of the participants (90%) did not adopt any methods to remind them taking the medications. After the intervention, participants used the reminder apps (80%) and QR code (70%) for medication management. An increased medication adherence was demonstrated by self-reported survey. This pilot study shows that mobile technology has potential to increase the compliance and knowledge of medication among older population.

RELIABILITY OF A SENSOR TO DETECT FLUID SWALLOWS IN COMMUNITY-DWELLING OLDER ADULTS

J.C. Mentès¹, H. Kalantarian², M. Sarrafzadeh², *1. Nursing, UCLA, Los Angeles, California, 2. UCLA Computer Science, Los Angeles, California*

Dehydration continues to be a costly, underappreciated precipitating or co-morbid condition leading to excess hospitalizations for older adults. There is no “gold standard” measure of hydration status, however many methods to assess this have been used, such as biologic specimens from blood, urine and saliva as well as clinical signs and symptoms. In this study we pilot tested a piezoelectric sensor (“WearSens”) worn as a necklace, as a novel method to detect swallows of various fluids in real time. The purpose of this project was to determine the ability of the device to reliably distinguish fluid swallows. We recruited 14 participants, mean age 68.7 years, 10 females, 4 males. Participants drank pre-determined amounts of fluid in 4 randomized situations (cold, hot, room temperature and with a straw) while wearing the Wearsens device. Percent agreement (n=13, one was not included because the sensor was loose) was 67%, with agreement highest for cold fluids (75%), with room temperature at 70%, fluids by straw at 61.5% and hot fluids at 50%. Cold ($r=.632, p=.02$) and room temperature ($r=.711, p=.004$) actual and predicted values were significantly correlated. Hot values had the most errors in prediction. When these outliers were removed the

correlation was significant ($r=.788, p=.007$). We concluded that the lower reliabilities were related to a less than optimal fit of the sensor. An improved design is being used in current study, which is focusing on distinguishing between solid and fluid swallows under normal living conditions.

VALIDATION OF A SCREENING TOOL FOR ED TO IDENTIFY OLDER AUSTRALIANS IN NEED OF SPECIALIST ASSESSMENT

M. Martin-Khan¹, Y.C. Hornby-Turner¹, A.P. Costa², L.C. Gray¹, *1. Centre for Research in Geriatric Medicine, The University of Queensland, Brisbane, Queensland, Australia, 2. McMaster University, Hamilton, Ontario, Canada*

EDs are inefficient at diagnosing and treating elderly people with geriatric complexity. To meet the needs of older adults in ED, high risk screening for those most in need of targeted assessments, risk reduction interventions, as well as those who would benefit from community based care/services is warranted. The aim of this study is to validate the interRAI ED Screener to categorize high risk older adults at triage.

364 patients (50% female) aged 70+ years, presenting to ED were assessed with the interRAI ED screener. The interRAI ED screener scores were compared with hospital identified frail elderly persons whose needs are sufficiently complex to warrant further assessment, as well as those most in need of specialist support services after leaving ED. Secondly, we tested for an association between the interRAI ED screener score and hospital admission (N=364), ED representations (N=102), referrals for specialist services (N=364), and prolonged length of hospital stay (N=262).

Implementing the interRAI ED screener instrument into EDs may help identify those in need of further comprehensive geriatric assessment. An implementation case study will be described as one site has adopted the screener as part of standard clinical practice.

FEASIBILITY OF VIRTUAL REALITY EXPERIENCE OF NATURE AS A NURSING INTERVENTION

T. Song, S. Moon, B. Park, J. Lung, E. Song, H. Kim, G. Hong, *Hanyang University, Seoul, Korea (the Republic of)*

Older adults in nursing homes have a limited visual experience due to their moving abilities. This study aimed to investigate the feasibility and effects of Virtual Reality Experience of Nature (VREN) using head mounted device (HMD) in older adults residing in nursing homes in Korea. A one-group pre-posttest design was used to assess the positive (PEE) and negative emotional expression (NEE) using the Observable Display of Affect Scale. One time VREN intervention was done for 2 minute. Two trained research assistants rated the PEE (facial, verbal, and posture) and NEE (facial, verbal, and posture) at pre, during, and post intervention for 2 minute. Data were analyzed with the repeated ANOVA to examine the changes of PEE and NEE. Means age and level of education of total 61 participants were 82.36 ± 8.34 and 6.61 ± 5.14 , respectively. Majorities were female (70.5%), diagnosed with dementia (65.6%), and partially dependent on mobility (63.9%). A total score of PEE ($F=31.68, p<.001$) was significant, but total NEE

($F=1.06$, $p=.354$) was not significant among pre, during, and post intervention. Verbal ($F=43.36$, $p<.001$) and posture PEE ($F=12.01$, $p<.001$) were significantly high during the intervention. Facial NEE ($F=6.34$, $p=.003$) was significantly high at pre-test, but verbal NEE ($F=6.77$, $p=.002$) was significant during the intervention. There were no significant differences in emotions during the intervention period by cognitive impairment and mobility. The results demonstrate that the VREN promotes PEE during and post the intervention for a short period of time. Replication study of VREN should be investigated using the randomized clinical trials with a larger sample.

THE CAREGIVER PERSPECTIVE ON USING THE MOBILE SYSTEM FOR ELDERLY MONITORING (SMAI)

L.B. da Motta, A. Sztanjberg, A. Brites, C. Caldas, *Rio de Janeiro State University, Rio de Janeiro, Rio de Janeiro, Brazil*

The Mobile System for Elderly Monitoring (SMAI) uses Android mobile applications as the infrastructure to monitor elderly patients with chronic degenerative disease and functional loss. The system development involves the Computer Science Laboratory (CSL) and the Geriatric Service (NAI) from the Rio de Janeiro State University (UERJ). Applications are designed based on strict requirements proposed by the health team, which assists over 300 elder patient and their caregivers. SMAI is being assessed in a randomized clinical trial with 60 patients (30 intervention and 30 control group), focusing the caregiver perspective on using the system. Pre-configured smartphones were delivered with minimal training, and the system was used for six months. The evaluation was based on the amount and frequency of sent information and through an interview with the caregivers. A Focus Group Interview (FGI) was then conducted with a sub-set of seven caregivers, which shared their opinions on using the SMAI to transmit information regarding the patient and to interact with the NAI professionals. Applying the thematic-categorical content analysis method, four categories were designed: caregiver overall experience; communication; management and administration of medicines to the patient; and the perceived impact/burden using the system. One of the caregiver reported: "I feel more confident taking care of my mother. Whenever I need, I get help..." The data collected will be mined correlating system use, caregiver stress and system resoluteness to confirm the expected outcomes: quality of life improvement for the caregivers and an effective tool for the health team.

SESSION LB910 (POSTER)

LATE BREAKER POSTER SESSION 2

SOCIAL SUPPORT AS FACILITATORS OF DENTAL CARE UTILIZATION AMONG LOW-INCOME OLDER CHINESE IMMIGRANTS

S. Ge¹, X. Dong³, B. Wu², 1. *School of Nursing, Duke University, Durham, North Carolina*, 2. *NYU Rory Meyers College of Nursing, New York, New York*, 3. *Rush University Medical Center, Chicago, Illinois*

Background: Few studies have been conducted that examined dental care utilization among low-income older Chinese immigrants in the United States (US). The purposes of this study are to (1) understand dental care utilization behaviors; and (2) understand the perceived sources and types of social support as facilitators of accessing dental care among low-income community-dwelling older Chinese immigrants in the US.

Method: Data was collected in the Greater Chicago area from July 1st to July 28th, 2016. Eighteen participants with income below the state-level poverty threshold completed an in-depth interview. Content analyses were conducted.

Results: The results show that all the participants interviewed had some oral health problems (e.g., toothache, bleeding, dentures, missing teeth, and edentulism). However, treatment to any dental issues were delayed until the symptoms became so severe that affect their work or daily activities. Most older immigrants preferred going back to China to see a dentist rather than seeking care locally given their perceived high cost of dental care in the US.

Children were the major source of informational and instrumental (financial) support, while spouses were the major source of emotional support for the participants. Meanwhile, participants were skeptical to seek any support from friends due to that they did not perceive friends as being able to help. Children's financial support was the most efficient facilitator towards seeking any dental care in the US.

Conclusion: Low-income older Chinese immigrants have unmet dental care needs. Children's financial support played the most significant role in promoting dental care utilization among low-income community-dwelling older Chinese immigrants in the US.

AN IMPLEMENTATION EVALUATION OF A PEER-LED HEALTH PROMOTION PROGRAM FOR SENIORS WITH FEAR OF FALLING

A. Lorthios-Guillemot^{1,2,3}, J. Filiatrault^{4,2}, L. Richard^{5,3}, 1. *School of Public Health, Université de Montréal, Montreal, Quebec, Canada*, 2. *Research Center, Institut Universitaire de Gériatrie de Montréal, Montreal, Quebec, Canada*, 3. *Institut de Recherche en Santé Publique de l'Université de Montréal (IRSPUM), Montreal, Quebec, Canada*, 4. *School of Rehabilitation, Faculty of Medicine, Université de Montréal, Montreal, Quebec, Canada*, 5. *Faculty of Nursing Sciences, Université de Montréal, Montreal, Quebec, Canada*

The use of seniors as peer educators is gaining in popularity for promoting seniors' health. However, the conditions under which peer-led health promotion programs (HPP) can be optimally implemented are not well understood. Based on an extensive literature review, we developed a theoretical framework to identify factors related to programs, participants, peer educators and the organizational/environmental context, which could impact implementation outcomes of peer-led HPP. Our study aimed to test this framework using implementation data collected in a pragmatic effectiveness study of a peer-led HPP targeting seniors who are afraid of falling. Peers delivered the program to groups of 12 participants in 6 retirement homes. Program fidelity (peers' adherence to program principles and guidelines) and participants' responsiveness to the program were monitored using peers' logbooks,

observation grids, attendance sheets and satisfaction questionnaires completed at program termination. Implementation factors were documented through individual interviews conducted among a subgroup of program participants ($n=24$), peer leaders ($n=6$) and program managers in each retirement home ($n=6$). Participants' response to the program was excellent, as reflected by their high satisfaction level with the program and a 91% attendance rate. Peers closely followed the program principles and guidelines. Coherent with our framework, individual-related factors (e.g. participants' health condition, peers' experience) and program-related factors (e.g. quality of materials) emerged as important implementation factors during preliminary qualitative data analysis. Results from this study can help program practitioners and managers design effective strategies to achieve successful implementation of peer-led HPP for seniors.

OLDER ADULTS AND READINESS TO CEASE DRIVING

D. Kandasamy^{1,2}, D.B. Carr³, T.M. Meuser⁴, A. Harmon³, M. Betz², 1. *University of Michigan-Flint, Flint, Michigan*, 2. *University of Colorado-Denver, Denver, Colorado*, 3. *Washington University in St. Louis, St. Louis, Missouri*, 4. *University of Missouri-Saint Louis, St. Louis, Missouri*

Examining older driver readiness for driving cessation may facilitate successful mobility transitions that decrease adverse outcomes like depression and social isolation. The purpose of this study was to examine associations between older driver characteristics and driving cessation readiness using the Assessment of Readiness for Mobility Transition (ARMT), a measure that evaluates attitudinal and emotional readiness for prospective mobility loss or change. The study recruited community-dwelling, English-speaking adults aged ≥ 65 years from three internal medicine clinics affiliated with a tertiary-care academic center; all were active drivers lacking significant cognitive impairment. Participants completed the ARMT short-form questionnaire: ARMT scores ≥ 29 points suggest unreadiness for driving cessation while scores < 29 suggest readiness. Descriptive statistics were generated for each ARMT group, with chi-squared tests utilized to consider associations. Among 301 participants, 89% were white, 5% were Hispanic and 29% lived alone; 53% were male and median age was 72 (range: 65–93). Median ARMT score was 25 (SD=5.60); 25% had scores ≥ 29 . Only 13% had discussions about mobility transition. Older adults unready to relinquish driving were Hispanic (10% vs 3%, $P=0.02$) and not college graduates (43% vs 29%, $P=0.04$). ARMT score was not significantly associated with other demographic characteristics. Results confirm positive associations between driving cessation unreadiness and Hispanic ethnicity and education level. They also indicate that while most participants were ready to cease driving, few had discussed mobility transitions with anyone. Introducing the ARMT measure to clinical and private settings may assist in beginning the dialogue for eventual driving cessation in older adults.

PREDICTORS OF FEAR OF FALLING AMONG COMMUNITY-DWELLING OLDER ADULTS IN KOREA

E. Song, G. Hong, *Hanyang University, Seoul, Korea (the Republic of)*

Fear of falling is a common and syndrome with potentially serious health problems in older adults. Fear of falling

can lead to the avoidance of activities, loss of independence, depression, and decreased quality of life; however, predictors of fear of falling among community-dwelling older adults are not well-explored. The purpose of this study was to explore the predictors of fear of falling in community-dwelling older adults based on Health Belief Model. Data collection was done from August 2016 to September 2016. A total of 143 older adults over 65 years old were recruited from Seoul and Kyung-gi areas, Korea. Data analysis included descriptive statistics, independent t-test, one-way ANOVA, and hierarchical multiple linear regression. The mean age of the participants was 75.9 ± 6.2 years. A total of 88.8% of participants reported a fear of falling. Fear of falling by characteristics of participants were significantly associated with living with spouse, number of chronic diseases, perceived chronic pain in last 6 months, falling experience in last 1 year, exercise, and self-efficacy for exercise. Exercise was the strongest predictor for fear of falling ($\beta = -.31$, $p < .001$). Perceived chronic pain in last 6 months ($\beta = .20$, $p = .026$), falling experience in last 1 year ($\beta = .15$, $p = .056$), and living arrangement ($\beta = -.15$, $p = .056$) were also significant predictors. These variables explained 25.8% of the variance in fear of falling ($F = 5.11$, $p < .001$). The prevention and management on fear of falling should be developed considering the factors of exercise, perceived chronic pain, falling experience, and living arrangement in this population.

WALKING FOR OUR HEALTH: MARRIED PARTNERS' COLLABORATION AND PHYSICAL ACTIVITY

M. Marshall¹, M.M. Franks¹, E. Richards¹, M. McDonough², S. Christ¹, 1. *Human Development & Family Studies, Purdue University, West Lafayette, Indiana*, 2. *University of Calgary, Calgary, Alberta, Canada*

Despite the known benefits of regular physical activity (PA), less than 5% of older adults meet PA recommendations, and maintaining PA is even more challenging. Several couple-focused interventions have been tested to promote PA, and findings have been mixed. The purpose of this study was to examine whether collaborative strategies to promote PA may be facilitated when partners are working toward similar PA goals.

The Walking for Our Health intervention study included older adult couples ($n = 32$), and partners were randomized together into two goal-setting conditions. In the collaborative goal-setting condition, partners set a combined goal and tracked cumulative steps taken by both members of the couple. Partners in the concurrent individual goal-setting condition set goals and tracked their steps independently. Partners' use of collaborative strategies to increase PA (e.g., worked together) was assessed pre and post intervention. Moderate to vigorous PA was measured objectively using accelerometers pre and post intervention. During the 8-week intervention, participants tracked daily steps using pedometers, and participated in weekly goal-setting phone consultations.

Following the goal-setting intervention, partner's reports of collaborating with one another to be more active increased ($p < 0.001$) in both intervention conditions. Additionally, weekly minutes of moderate to vigorous physical activity increased ($p < 0.001$), and BMI decreased ($p < 0.01$), on average. There was no difference in changes across intervention conditions. Future research should examine whether

collaborative strategies are effective in facilitating health behavior change and maintenance in the context of married partners.

VARIOUS INTENSITIES OF PHYSICAL ACTIVITY IN CHINESE OLDER ADULTS WITH CHRONIC KIDNEY DISEASE

E. Chen¹, V. Lou¹, E.J. Nicklett², Y. He³, 1. *Department of Social Work and Social Administration, The University of Hong Kong, Hong Kong, China*, 2. *School of Social Work, University of Michigan, Ann Arbor, Michigan*, 3. *School of Public Health, Shanghai Jiaotong University, Shanghai, China*

The increasing prevalence of chronic kidney disease (CKD) become a health problem in China and worldwide. Physical activity can improve physical functioning and slow the decline in kidney function. However, less is known on correlates of physical activity among early stages of CKD. The current study used the data from China Health and Retirement Longitudinal Study to examine physical activity with different intensities and its correlates among Chinese middle-aged to older adults with chronic kidney disease. Based on eGFR less than 60 mL/min per 1.73 m², 1089 adults older than 40 years old and completed the measure of physical activity were identified. Overall, 28.7% of adults with CKD participated in vigorous-intensity activities, and 50.1% and 78.7% participated in moderate- and light-intensity activities in a week, respectively. Multivariate logistic regression analysis indicated that older age (>80 years old), being female, living in city, receiving higher education (high school or more), being single/widowed/divorced, no employment, perceiving higher financial burden, having functional limitation in at least one aspect, having diabetes and heart disease contributed to lower participation in vigorous-intensity activities. Living in city, no employment, and having functional limitation in at least one aspect significantly predicted the lower engagement in moderate-intensity activities. However, socio-demographics and comorbidity exerted little effect on engagement in light-intensity activities. Since effect of physical activities on health can vary with the intensity of activities, it is recommended to consider the correlates of physical activity with different intensity in promoting the engagement in physical activity among older adults with CKD.

IMPACT OF EDUCATION AND INCOME ON COGNITIVE FUNCTIONING IN LOW- AND MIDDLE-INCOME COUNTRIES

F.S. Then^{1,2}, S.G. Riedel-Heller², T. Luck², S. Chatterji³, 1. *USC Edward R Roybal Institute on Aging, Los Angeles, California*, 2. *University of Leipzig, Leipzig, Germany*, 3. *World Health Organization (WHO), Geneva, Switzerland*

Previous studies have shown that higher education, in sense of a cognitive reserve, promotes a good cognitive health. Poverty, on the other hand, represents a threat to health. We therefore investigated whether a cognitive reserve (higher education) would still enhance cognitive functioning under the constraints of poverty (low income). Our analyses were based on a sample of 45,000 individuals from low- and middle-income countries who participated in the World Health Organization's multi-country Study on global AGEing and adult health (WHO SAGE). Multivariate regression analyses

and structural equation modelling (adjusted for childhood socioeconomic conditions, health state, age, gender, and country) revealed that higher education as well as higher income was significantly associated with a better cognitive functioning – with similar effects in middle-aged and old-aged individuals. Our results suggest that a cognitive reserve of only six years of education could substantially enhance the cognitive health of individuals living in poverty. Therefore, expanding efforts to achieve universal education are essential for offsetting adverse effects of poverty and early life disadvantages and for promoting a good cognitive functioning over the entire life-span.

DOES DIAGNOSIS TYPE MATTER? GAPS IN END OF LIFE PLANNING

M. Hendricksen, N.V. Shellito, C. Lee, *University of Massachusetts Boston, Boston, Massachusetts*

End of life planning can be a useful tool to help people cope with a complex period of the life course. Individuals who plan in advance for their end of life care are less likely to experience pain and depression. As more of the United States population enters old age, research continues to explore if an association between disease burden and end of life care decisions exists. The objective is to investigate the impact of disease diagnosis on end of life planning. This study uses data from the Health and Retirement Study to examine participants who died between 2012 and 2014, merged with core data from 2010. 2,065 participants are included and variables analyzed include individual disease diagnoses and completion of written end of life instructions. Findings show that participants who have been diagnosed with cancer (OR=1.59, p<.001) and heart problems (OR=1.25, p<.05) are more likely to have end of life care instructions than those who have never been diagnosed. Additionally, demographic factors show that increases in age (OR=1.04, p<.001), education (OR=2.60, p<.001), and household net worth (OR=1.86, p<.001) all have greater odds of completing end of life plans. These findings suggest that depending on diagnosis type, patients may not receive exposure to end of life planning opportunities. Fatal diagnoses, such as lung disease and stroke, did not show significant associations with end of life planning. These results demonstrate a potential gap in patient care and provide possible opportunities for improvement in physician and patient communication.

INVESTIGATION OF PERSONALITY USING DIFFERENT TIME MATRICES, CONTROL VARIABLES, AND INCLUSION GROUPS

T. Yoneda¹, E. Graham², A. Berg³, B. Johansson³, M. Katz⁵, N.L. Pedersen⁴, A.M. Piccinin¹, 1. *University of Victoria, Victoria, British Columbia, Canada*, 2. *University of Northwestern, Evanston, Illinois*, 3. *University of Gothenburg, Gothenburg, Sweden*, 4. *Karolinska Institutet, Solna, Sweden*, 5. *Einstein Aging Study, Bronx, New York*

Two studies suggest that personality change may be an early indicator of dementia (Balsis et al, 2005; Smith-Gamble et al, 2001); however, these studies did not assess personality trait change. Although Yoneda et al (2015) prospectively examined personality traits, the nature of the analyses did not allow comparison between trajectories in normal and abnormal aging. The current study includes comparison

of trajectories of extraversion and neuroticism personality traits in individuals who did and did not receive a dementia diagnosis.

This study used data from the OCTO-Twin Study, Longitudinal Aging Study Amsterdam, Swedish Adoption Twin Study of Aging, and Einstein Aging Study. For each dataset, a series of latent growth curve models were run examining each personality trait, first including a subsample of individuals eventually diagnosed with dementia and time-to-dementia metric, and second including the entire dataset, dementia diagnosis as a variable, and time-in-study metric.

Controlling for sex, age, education, depressive symptoms, and the interaction between age and education, the first series of analyses revealed a consistent pattern of personality change preceding dementia diagnosis across datasets, specifically linear increases in neuroticism and stability in extraversion. The second series of analyses revealed a less stable pattern of results: dementia diagnosis was only a significant predictor of neuroticism trajectories in some datasets. These findings will be discussed.

Identification of early indicators of dementia, specifically how personality changes differ for healthy individuals compared to individuals eventually diagnosed with dementia, may aid in early care strategies and facilitate development of screening assessments.

PERSONALITY TRAITS PREDICT DIETARY HABITS IN MIDDLE-TO-OLDER ADULTS

S. Weston^{1,2}, G. Edmonds³, S. Hampson³, P. Hill¹, 1. *Psychology, Washington University in St. Louis, Evanston, Illinois*, 2. *Northwestern University, Evanston, Illinois*, 3. *Oregon Research Institute, Eugene, Oregon*

Personality traits predict dietary habits in middle-to-older adults.

Personality traits are consistently associated with health behaviors, but little research has examined the role of traits on eating habits among middle-to-older adults. Importantly, food choices are constrained by financial resources or availability of healthy options, suggesting the need to test differential associations across SES. We examined the associations between traits and dietary habits, whether healthy eating predicted health at age 60, and if SES moderated these relationships. We used a sample of 665 middle-to-older adults from the Hawaii Personality and Health Cohort. Participants completed personality and eating questionnaires at age 44 and reported health at age 60. Dietary items were consolidated using factor analysis, which resulted in two factors: healthy and unhealthy foods. Eating healthy foods was associated with higher levels of agreeableness ($r = .11$), conscientiousness (.14), emotional stability (.14) and openness (.19) and predicted better self-rated health (.21) and lower BMI (-.19). Eating unhealthy foods was associated with lower levels of agreeableness ($r = -.11$), conscientiousness (-.12), emotional stability (-.09) and openness (-.14) and predicted lower self-rated health (-.13). Unhealthy food consumption did not predict BMI. Surprisingly, these results were not moderated by SES. Overall, we conclude that personality traits have a consistent relationship with dietary habits across levels of SES, and thus the use of traits to predict and understand eating choices can be applied consistently across patients, regardless of financial resources. Moreover, these associations between

traits and eating choices may consequences for older-adult health.

STRESS, PHYSICAL ACTIVITY, AND AGING: COORDINATED ANALYSES OF TWO LONGITUDINAL DATA SETS

R. Vendittelli, *Psychology, University of Victoria, Saanich, British Columbia, Canada*

Although modest declines in cognition are considered normative, it is becoming increasingly evident that severe decline and dementia are not inevitable outcomes caused by age. Person-specific variables such as physical activity (PA) and stress are two modifiable lifestyle factors that have been demonstrated to be associated with poorer cognitive outcomes. To date, there are no studies examining both the between-person (BP; or person-mean levels) and within person (WP; or occasion specific fluctuation relative to one's expected trajectory) effects of PA and stress on cognitive abilities. Data from two longitudinal data sets were analyzed in a coordinated manner. Specifically, utilizing comparable variables, data were fit to the same models with processing speed, memory and MMSE as separate outcome variables. Higher average PA was associated with less decline in processing speed, working memory and MMSE scores in one of the two data sets. Interestingly, the WP effects of PA were associated with better cognitive outcomes in all models except memory performance in one of the studies. Unexpectedly, the WP effects of stress were associated with higher processing speed and working memory performance in one of the studies, while the BP effects were non-significant across both studies and outcome variables. Findings indicate that higher average PA, as well as individual specific fluctuations in activity can positively influence cognition. Moreover, proximal stress seems to enhance cognition. These findings corroborate literature implicating activity in cognitive functioning, and are nuanced in demonstrating that more proximal indicators of activity level and stress are associated with cognitive performance.

THE IMPORTANCE OF SUFFICIENT CHALLENGES TO POSITIVE EMOTIONS AMONG OLDER ADULTS

D. Tse, J. Nakamura, M. Csikszentmihalyi, *Quality of Life Research Center, Claremont Graduate University, Claremont, California*

Flow theory postulates that people enjoy the optimal experience when challenge level of an activity matches their skill level. However, little research has extended the theory to examine the effect of challenge-skill balance on older adults' emotional experiences. This recently completed study investigated whether older adults experienced more frequent high arousal positive(HAP) and low arousal positive(LAP) emotions in challenge-skill balanced activities. 104 younger(Mage=25.8, SD=2.76) and 93 older adults(Mage=65.0, SD=4.78) identified underchallenging(challenge-lower-than-skill), challenge-skill balanced, and overchallenging(challenge-higher-than-skill) activities that they had chosen to do in the past, and reported their typical emotions in each activity. Results were analyzed by repeated measures ANOVA and paired comparison t-tests. Consistent with flow theory, both younger and older adults reported more frequent HAP and LAP emotions

in challenge-skill balanced activities than in underchallenging or overchallenging activities, $F(2,392)=133.42$, $p<.001$, partial eta-squared=.405 for HAP emotions; and $F(2,392)=139.92$, $p<.001$, partial eta-squared=.417 for LAP emotions. In addition, although older adults experienced less frequent HAP emotions than younger adults in underchallenging and overchallenging activities, such affective difference was not observed in balanced activities. These findings are consistent with flow theory that challenge-skill balance is associated with high frequencies of HAP and LAP emotions among both older and younger adults. More important, engagement in sufficient but not overwhelming challenges can offset the differences in HAP emotions between younger and older adults. The study provides insight to older adults and those who serve this population on the importance of older adults maintaining sufficiently challenging activities to maximize their positive emotional experience.

SUICIDE AMONG THE ELDERLY IN KOREA: A META-ANALYSIS

J. Lee, J. Yang, J. Lyu, *Hallym University, Chuncheon, Gangwon-do, Korea (the Republic of)*

Elderly suicide is a major public health issue in South Korea. The aim of this study was to systematically examine the current knowledge about suicidal ideation among Korean older adults with specific focus on risk and preventive factors. In order to achieve this aim, a meta-analysis was conducted using Korean academic peer-reviewed journals published since 2001. A total of 97 articles were selected that met the research criteria (e.g., original study findings and key words of suicidal ideation, suicidal thought, and suicide). Three domains were identified and used for further analysis: individual, family, and society. Results showed that among individual factors, depression and burden or stress increased the risk of suicidal ideation, while better mental health reduced the risk of suicidal ideation. Among family factors, living alone was a risk factor for suicidal ideation, while family cohesion was a preventive factor for suicidal ideation. Among social factors, elderly discrimination, social isolation, and negative relationships were significant risk factors, while social support, social environment, and social activities were significant preventive factors affecting suicidal ideation. The results suggest several practical implications for developing suicide prevention programs and counseling approaches to address suicidal ideation. For example, depression and stress can be reduced by MBSR (Mindfulness-Based Stress Reduction) program where meditation is used as a coping strategy. In addition, counseling programs specifically focused on improving family and social relations should be implemented. Government should continuously support for these programs to prevent suicide among older Koreans.

DAILY SOCIAL INTERACTION RELATES TO SUBJECTIVE COGNITIVE FUNCTION

J. Kang, J. Hyun, M. Sliwinski, J.A. Mogle, *Human Development and Family Studies, The Pennsylvania State University, State College, Pennsylvania*

Self-reports of cognitive problems are required for the clinical diagnosis of mild cognitive impairment (MCI). Identifying factors affecting subjective evaluations of cognition is essential to the early recognition of cognitive

impairment. One such factor is social engagement, which is an established protective factor for long-term cognitive health. However, little is known about how recent social interactions relate to reports of subjective cognitive function in everyday life. Therefore, we examined whether the frequency and quality of daily social interactions predicted day-to-day variability in reports of subjective cognition.

A systematic probability sample of 251 racially diverse adults (age=25–65) completed a 14-day ecological momentary assessment protocol that measured social interactions, mood and fatigue at 5 random times throughout each day. At the end of each day, participants provided subjective reports of their memory, speed, and attention, as well as their overall appraisal of the quality of their social interactions on that day.

Using multilevel modeling we found on days during which they had more frequent social interactions, participants reported better cognitive function (Estimate=1.56, $p<.0001$). Moreover, on days they reported more pleasant interactions, participants reported higher levels of subjective cognitive function (Estimate=0.16, $p<.0001$). Both effects remained significant after controlling for daytime affect and fatigue. The effects of both daily social interaction and end-of-day appraisal on subjective cognition were invariant across age.

This study illustrates that the frequency and quality of social interactions has a proximal (same day) relationship to subjective cognition. These results have implications both for assessing subjective cognition and for interventions.

THE ROLE OF GRANDMOTHERS IN KOREAN WOMEN'S WORK-LIFE BALANCE

S. Jeon, M. Gilligan, *Iowa State University, Ames, Iowa*

Although many Korean women want to pursue both successful careers and families, Korean culture limits women's ability to maintain work-family balance. Constrained by their ability to both work and care for their children, working Korean women tend to call on their aging mothers for assistance. The purpose of this study was to better understand the important role of grandmothers in working Korean women's work-family balance. We conducted in-depth interviews with 22 married, working women living in Korea ($M=35.9$ years) who have at least one young child (infant / preschooler) and who rely on their mothers ($M=62.5$ years) for child care. Several themes emerged from these newly available data. Women who had good relationships with their mothers tended to be more appreciative of their mother's help. Several women expressed feelings of guilt that their mothers took care of grandchildren because several of the grandmothers were experiencing health concerns of their own. However, despite these feelings of guilt, the women indicated that they hoped that their mothers would take care of their children until their children enter elementary school. Also, the women expressed the Korean government's childcare policy is unrealistic and they indicated that it would be beneficial if the Korean government provided support to grandmothers caring for grandchildren. Overall, our findings suggested that work-family balance is an important concern of many working Korean women. Often these women rely on support from their mothers in an attempt to obtain work-family balance. However, many of these grandmothers experience their own health concerns.

CARDIORESPIRATORY FITNESS BENEFITS VERBAL MEMORY IN OLDER BUT NOT YOUNGER BREAST CANCER PATIENTS

H. Derry, W.B. Malarkey, J. Kiecolt-Glaser, *Institute for Behavioral Medicine Research, The Ohio State University Wexner Medical Center, Columbus, Ohio*

Breast cancer survivors often experience cognitive problems following surgery and prior to further treatment. Cardiorespiratory fitness (CRF) benefits cognitive function in healthy older adults. However, few studies address CRF's effects among breast cancer survivors or consider how this pattern may vary by age. As part of a larger study, 110 female post-surgical breast cancer survivors (ages 26 to 75, stages I-IIIa) completed a graded cycle ergometry test to measure peak oxygen consumption prior to chemotherapy or radiation treatment. Neuropsychological tasks assessed verbal memory (Hopkins Verbal Learning Test), verbal fluency (F-A-S), executive function (Trail Making Test, n-back task), and sustained attention (Continuous Performance Test). Regression models revealed that the relationship between CRF and immediate verbal recall scores varied significantly by age, above and beyond education, comorbidities, cancer stage, and time since surgery ($b = .013$, $SE = .006$, $p = .032$). Among women ages 62 and older, those with better fitness had better immediate verbal recall compared to those with poorer fitness, using the Johnson-Neyman method. The age by CRF interaction did not significantly predict performance on other cognitive tasks in adjusted models. Accordingly, older participants who were more fit had better immediate verbal recall than those who were less fit, while younger women's CRF was not significantly related to their verbal memory performance. The fitness-cognitive function link may be particularly relevant for older cancer survivors compared to their younger counterparts. Longitudinal studies would help discern if physical fitness prevents accelerated cognitive aging among cancer survivors, and prompt relevant interventions.

FACTORS SHAPING GRANDPARENTS RESPONSIBILITY FOR GRANDCHILDREN IN THREE-GENERATION HOUSEHOLDS

N. Velasco, J.E. Mutchler, *Gerontology, University of Massachusetts Boston, Boston, Massachusetts*

The number of grandparents identified as primary responsible for grandchildren is on the upswing. Data from the American Community Survey (ACS) suggest that the percent of coresident grandparents responsible for grandchildren increased from 11% in 2010 to 15% in 2015. Additionally, estimations indicate that among the nearly 2.7 million U.S. grandparents who claimed responsibility for their minor grandchildren in 2015, two-thirds lived in a three-generation household, including minor grandchildren, one or both of their parents, and one or more grandparents. However, most of the literature on grandparent caregivers has focused on the grandparent's role in skipped-generation households, and little is known about the grandparent's role in three-generation households. The purpose of this study is to explore the factors that lead grandparents to be identified as primarily responsible for grandchildren living with them in three-generation households. The analysis was conducted using the 2015 ACS 5-year estimates dataset. Household

income and income balance between the grandparent and parent generations are determinants of whether the grandparent is classified as being primarily responsible; specifically, grandparents who provide a high share of household income are more likely to be classified as primarily responsible for the grandchild. As well, race and ethnicity are related to the grandparent's identification as primary caregiver, with African American grandparents being more likely to be classified as primarily responsible for grandchildren. Together, these findings suggest that a grandparent's responsibilities in the three-generation household are defined in part by economic responsibility, but in part by cultural norms relating to the grandparent role.

MANIPULATION OF EFFICACY AND FUNCTIONAL MOTOR PERFORMANCE IN OLDER WOMEN

N. Roncesvalles¹, M. Bregendahl², *1. Texas Tech University, Kinesiology and Sport Management, Lubbock, Texas, 2. Stanford University School of Medicine, Division of Primary Care, Palo Alto, California*

Fall prevention remains a worthy goal for the aging population (Ungar, et al., 2013). This study contributes by testing the malleability of motivation and behavior of older women beginning to exhibit the fear of falling. Will manipulation of efficacy significantly affect both perceived fear (falls efficacy) and behavior (i.e. gait, balance)?

Forty-two older women ($N=42$), between 55 to 75 years were administered with the Falls Efficacy Scale-International (FES-I) and the Short Physical Performance Battery (SPPB) on two occasions: 1) Initial screening (baseline), and, 2) Post-manipulation. Baseline assessment included documentation of health, mental state, heart rate, activity levels and other demographic data. Those with low to moderate concern for falling (FES-I) were included in the participant pool and randomly assigned to three groups: enhanced efficacy (EE), reduced efficacy (RE), and control (C). A rhythmic weight shifting task (SMART Balance Master®) was undertaken to manipulate perception (efficacy). Fabricated verbal feedback were tailored according to group: regardless of actual performance, positive for EE, and negative for RE. Participants in the C group were provided none. Comparison (Friedman's Test) of the pre- and post-manipulation scores revealed that provision of manufactured verbal feedback did not influence FES-I or SPPB in any group examined ($p \geq 0.05$). In addition, no significant relationship was found between the variables before and after manipulation.

The non-significant results were likely attributable to the short intervention protocol. Perhaps a longer and consistent protocol, with specific focus on populations already experiencing a significant level of fear will produce alternative results.

DEPRESSIVE SYMPTOMS IN CHILD CAREGIVERS OF VERY OLD MEXICAN AMERICANS

D.V. Flores¹, S. Rote², J.L. Angel³, N. Chen¹, B. Downer¹, K.S. Markides¹, *1. University of Texas Medical Branch, Galveston, Texas, 2. University of Louisville, Kent School of Social Work, Louisville, Kentucky, 3. University of Texas, Austin, Texas*

Objective: To study the effects of disability, cognitive impairment, and neuropsychiatric disturbance among older

Mexican Americans on depressive symptoms in their children caregivers.

Methods: This study utilizes data from Wave 7 (2010–11) of the Hispanic Established Populations for the Epidemiologic Study of the Elderly to assess caregivers that provided direct personal care with activities of daily living (ADL) and who were children of the care recipient. Two hundred adult caregivers provided direct personal care (e.g., bathing, toileting, dressing, etc.) to their older parents (average age = 87). We analyzed the influence of ADL disability, cognition (MMSE), and neuropsychiatric symptoms (NPI) on depressive symptoms of the adult child caregiver. A cross-sectional multivariable linear regression analysis was conducted to examine the effect of neuropsychiatric disturbance on caregiver depressive symptoms.

Results: ADL disability of the care recipient, cognitive functioning of the care recipient, and caregiver health status alone did not have a significant effect on depressive symptoms of the caregiver but NPI of the care-recipient did. Not being married, high perceived social stress, and caregiver-assessed NPI of the care recipient had a significant effect on caregiver depressive symptoms.

Conclusions: In a Mexican American familistic culture, disability and cognitive impairment might be better tolerated by families but neuropsychiatric behavioral symptoms related to dementia may take an increased toll on family member caregivers. The need to provide respite services, mental health resources and community services for caregivers of care recipients with neuropsychiatric dysfunction is of paramount importance to alleviate depressive symptoms and burden among caregivers.

THE STRENGTH OF SOCIAL TIES: HOW COUPLES FACE AD TOGETHER OR ALONE

R.L. Beard¹, R. Daley², M. O'Connor², S. Shirk², 1. *Sociology and Anthropology, College of the Holy Cross, Worcester, Massachusetts*, 2. *Edith Nourse Rogers Memorial Bedford VAMC, Bedford, Massachusetts*

Social and behavioral research on Alzheimer's disease (AD) has largely neglected the potential positive appraisals of AD experiences relative to the so-called stress and burden assumed to accompany the condition. The very word caregiving implies a unidirectional and exclusively negative experience for everyone involved. Spouses provide the majority of care for individuals with AD yet few prior studies have examined the association between positive caregiving appraisals and quality of marital relationship. The qualitative literature suggests that these couples adopt either a *We/Us* approach where they describe experiences as a composite whole or an *I/Me* approach where they describe themselves as experiencing the impact of AD separately. Little is known about how these perspectives relate to the individual characteristics of either party. Eleven spousal dyads were divided into *I/Me* ($n = 5$) and *We/Us* ($n = 6$) groupings based on qualitative analyses. Diagnosed individuals were given measures of cognitive and functional ability and caregivers completed anxiety, depression, burden, relationship satisfaction, and positive aspects of caregiving measures. We found no significant differences between groups on patient cognitive or functional ability, or caregiver anxiety, depression, burden, or relationship satisfaction. However, *We/Us* caregivers

expressed more positive aspects of caring than *I/Me* couples. These findings suggest the *I/Me* approach is not associated with differences in cognitive status or functional ability or carer emotional health, perceived burden, or relationship satisfaction. Those taking a *We/Us* approach, however, were able to identify more positive aspects of caring. This may be related to mutual compassion and could be protective.

PASSIVE SUICIDAL IDEATION AMONG OLDER ADULT INSOMNIA CLINIC PATIENTS WITH INSOMNIA DISORDER

R. Cui, D. Richter, A. Fiske, *Psychology, West Virginia University, Morgantown, West Virginia*

Up to 29% of older adults suffer from insomnia symptoms (Ancoli Israel & Cooke, 2005; Schubert et al., 2002). Symptoms of insomnia have been found to be associated with suicidal ideation among older adults (Nadorff, Fiske, Sperry, Petts & Gregg, 2013). The present study seeks to investigate factors associated with suicidal ideation within a sample of 51 older adults diagnosed with Insomnia Disorder seeking treatment at an Insomnia Clinic. The sample was primarily female (70.6%) and Caucasian (96.1%). Participants completed self-report measures of insomnia symptoms (Insomnia Severity Index, ISI), daytime sleepiness (Epworth Sleepiness Scale, ESS), anxiety symptoms (Beck Anxiety Inventory, BAI), depression symptoms (Center for Epidemiologic Studies Depression Scale Revised, CESD-R), emotion regulation strategies (Emotion Regulation Questionnaire reappraisal and suppression scales, ERQ reappraisal and ERQ suppression), and social support (Interpersonal Support Evaluation List, ISEL). Passive suicidal ideation was assessed with items 14, "I wished I were dead" and 15, "I wanted to hurt myself", from the CESD-R and coded as a dichotomous variable. Passive suicidal ideation was endorsed by 9.8% of the sample. Older adults with passive suicidal ideation had more anxiety symptoms ($F_{1,48} = 17.59$, $p < .01$), more depression symptoms ($F_{1,49} = 21.39$, $p < .01$), greater use of suppression strategies to regulate negative emotions ($F_{1,36} = 7.24$, $p = .011$), and less social support ($F_{1,31} = 6.37$, $p = .017$). These findings indicate the need to screen for suicidal ideation among older adults seeking treatment for insomnia who present with elevated depression or anxiety symptoms.

MINDFULNESS-BASED PROGRAM ENHANCES THE QUALITY OF LIFE FOR COMMUNITY-DWELLING OLDER ADULTS IN TAIWAN

H. Hsu¹, S. Cheng¹, Y. Hsu¹, C. Chiu¹, C. Kuo², 1. *Yangsheng Foundation, Taipei, Taiwan*, 2. *National Pingtung University, Pingtung, Taiwan*

Aim: This study aimed to evaluate the impact of an eight weeks mindfulness-based program on the quality of life for older adults from community population.

Methods: The benefits of mindfulness research on human well-being have accumulated much empirical evidences. Several studies have also indicated that mindfulness training enhances cognitive functions. However, it is unknown whether the positive effect can be generalized to older adults. An eight-weeks mindfulness-based program which was modified from Mindfulness-based Cognitive Therapy (MBCT) that involve understanding mindfulness, the benefits of mindfulness to increase self-awareness,

accept yourself and cultivate compassion minds through the practice of body stretch, sitting meditation, body scan, and breathing. In addition, role play, clam jar and ten-finger appreciation activities were also included to enrich the social element of the program. It is noteworthy that this program is easy-to-implement for older adults. Eighty-nine older adults recruited from a community center volunteered for the present study. All participants were over 60 years old, and the mean age was 71.88 years old ($SD = 5.92$). Before and after the program, the quality of life, depression, cognitive states was measured by visual analogue scale, Taiwanese Geriatric Depression Scale-5, and modified Chinese Mindfulness Awareness Attention Scale (mCMAAS), respectively.

Results: The results showed that the quality of life was enhanced after the program, $t(88) = 3.15, p < .01$. Both the depression state and cognitive state were remained the same ($p = .841$ for depression, $p = .633$ for cognitive state).

Conclusions: It is an exciting finding that the quality of life was significant improved after the Mindfulness-Based Program for community-dwelling older adults. It is likely that the mood and cognitive measures reached the ceiling so that they were insensitive to changes. The impact of a long-term training program and more sensitive measures on mood and cognitive ability should be further examined.

RESULTS OF A MINDFULNESS INTERVENTION FEASIBILITY STUDY AMONG ELDER AFRICAN AMERICAN WOMEN

J. Proulx, M. Hebert, R. Croff, B. Oken, *Oregon Health & Science University, Portland, Oregon*

This study used mixed methods to examine the feasibility of implementing a 4-week mindfulness class with 10 elder African American women (aged 50 – 69). We measured changes in PSS, PANAS, LSI, Perseverative Cognition Scale, and the Multidimensional Inventory of Black Identity before and after the intervention. We also used these measures as a means to assess the salience of these scales to this population. Focus groups provided information on motivation, effective strategies, preferences, and perceived benefits of the mindfulness class. There was a significant change in numbers of participants who reported a meditation practice (1 person at time 1; 8 people at time 2, $\chi^2(1) = 5.84, p < .05$). There were marginally significant improvements in PSS, $t(18) = 1.99, p = .06$, and PANAS positive affect, $t(18) = -1.99, p = .06$. Stressors that motivated participation in the mindfulness class included family obligations and daily race-based microaggressions. Effective strategies to address stressors salient to our participants included taking time for self-care, quiet prayer, removing oneself from stressful people, remembering one's core self in the face of discrimination (i.e., centering), and having a positive mindset. Preferences included integration of faith-based language, using a facility recognized as a community center for the classes (e.g., church), and African American class instructors. Participants noted perceived benefits such as mindfulness as calming and centering, better body and pain awareness, an increased sense that one can better tune out chaos, and that the mindfulness group can provide a forum for race and diversity.

COULD POSITIVE EFFECTS OF LIFE REVIEW ON COGNITION LAST? THE FOLLOW-UP STUDY ON LIFE REVIEW IN TOME

A. Hosokawa, *National Center for Geriatrics and Gerontology, Obu, Aichi, Japan*

Life review could be defined as an evidence-based intervention for secondary aging. A part of the life review study in Tome found that regular participation in group life review session has positive effects on cognitive abilities in later life. Can these positive effects of group life review be maintained? The purpose of the current study was to follow the study in Tome up to see effects of group life review on memory, cognition, and QOL one year after intensive intervention. After having completed 10-week intensive group life review session, the life review group kept on participating in intermittent group life review session. All the participants took tests including Logical Memory and Verbal Paired Associates from WMS-R, MMSE, and SF-36 before, after, and one year after the intensive life review intervention. The life review group improved their scores on immediate recall of propositions in the short stories for Logical Memory subtest from WMS-R immediately after the intensive intervention ($M = 29.92, SD = 6.69$) and even maintained their performance one year after the intervention ($M = 30.08, SD = 7.24$). They also associated more pairs in delayed recall immediately after the intensive intervention ($M = 7.62, SD = .77$) and still improved their performance one year after the intervention ($M = 7.69, SD = .63$). There were no any significant differences in QOL, however. The results suggested that the intermittent intervention by life review contributed to maintaining improved performance on memory test while the intensive intervention could draw drastic improvement.

SELF-TALK ON HEALTH BY ASSISTED LIVING RESIDENTS: NEW IMPLICATIONS FOR PROVIDERS

J.G. Schumacher¹, R. Millar¹, E. Stephenson¹, H. Kim²,
1. *University of Maryland, Baltimore County (UMBC), Baltimore, Maryland*, 2. *University of Maryland, Baltimore (UMB), Baltimore, Maryland*

Assisted living (AL) settings serve as a significant congregate living environment for older adults worldwide and continue to increase in scope. This research examines how AL residents talk about their health issues in the context of two newly integrated, large qualitative data sets from two federally funded (NIA) ethnographic studies of ALs across a total of 10 AL settings spanning a consecutive 10 year period. Ethnographic interviews were collected and team coded by an interdisciplinary group of researchers using Atlas.ti software. Thematic analysis and interpretation of the "self-talk on health" code was consensus driven and guided by Levy's stereotype embodiment theory. Analysis suggests dominant self-talk on health themes that include: falls/fear of falling, medications, function/mobility, memory, symptoms, and pain. Notably, themes on health were almost completely negative in tone with only isolated references to positive self-talk on health by the AL residents. Stereotype embodiment theory suggests the strongly negative self-talk on health can gain salience in the lives of older adults and contribute to lack of self-fulfillment and may accelerate overall physical and mental health decline. Acknowledging the prevalence of negative self-talk on health in ALs can provide insight to

AL providers for new strategies in creating health-oriented programs to address positive coping and appraisal strategies including accommodation and adaptation. Providers proactively addressing negative self-talk on health can contribute to improving AL residents' self-perception on their health and well-being which can contribute to lengthening AL residents aging in place.

WHEN YOU LIMIT YOUR DRIVING: ASSOCIATION WITH COGNITION AND FUNCTIONAL ABILITIES IN OLDER AMERICANS

B.A. Fausto, D.J. Dobbs, H. Lee, *University of South Florida, Tampa, Florida*

Driving is a complex functional task that allows participation in routine, community, and social activities. Driving limitations in later life are associated with negative biopsychosocial consequences including increased depression, health declines, loss of independence, and social isolation. Employing the Multifactorial Model of Driving Safety, we hypothesized that older drivers who limited their driving were more impaired than older drivers who drove long trips. In addition, we examined changes in driving patterns. We used data from the 2008 and 2012 Health and Retirement Study. The sample included older drivers ($M=73.6$ years of age, 53% women, 86.5% white) at baseline ($n=7,992$). Descriptive statistics, MANOVA, and multinomial logistic regression were conducted. At baseline, approximately 38% limited their driving to nearby places. MANOVA results indicated that, compared to those who drove long distances, older drivers who limited their driving to nearby places had significantly poorer cognition scores, poorer self-rated hearing and eyesight, greater difficulties with activities of daily living, poorer self-rated health and tended to be older, female, and non-white, $\lambda=.79$, $F(11, 7980)=189.40$, $p<.001$, partial $\eta^2=.21$. About 27% of older drivers who limited driving at baseline stopped driving at four-year follow-up. Those who stopped driving at follow-up also showed poorer cognitive, sensory, and physical health status than those who did not. Results suggest that older drivers with cognitive, sensory and/or physical difficulties may regulate their driving behavior. Such driving patterns can inform the driving capacity, potential for rehabilitation, and risk of driving cessation of the aging population.

THE DECISION TO WORK PAST STATE PENSION AGE AND HOW IT AFFECTS QUALITY OF LIFE: EVIDENCE FROM ENGLAND

G. Di Gessa¹, K. Glaser², L. Corna², D. Price³, 1. *Department of Social Policy, The London School of Economics and Political Science, London, United Kingdom*, 2. *King's College London, London, United Kingdom*, 3. *University of Manchester, Manchester, United Kingdom*

Introduction: Increasing numbers of older people in the UK and other industrialised countries are now working beyond state pension age (SPA). However, to date, little is known about the motives beyond continued work at older ages and whether the reasons for extending working lives are associated with quality of life (QoL).

Aim: Our study examined whether, and to what extent, reasons given for being in paid work beyond SPA are associated, both cross-sectionally and longitudinally, with QoL.

Data and Methods: We employed data from Waves 4 and 7 of the English Longitudinal Study of Ageing. Using linear regression models we assessed both cross-sectional and longitudinal associations between reasons for being in paid work beyond SPA and QoL among men aged 65–74 and women aged 60–69 ($N=2,306$). Our cross-sectional analyses controlled for baseline health and socio-economic characteristics, as well as for social participation and the quality of social relationships. In our longitudinal analyses we also controlled for changes over time.

Results: Almost 23% of the sample is in paid work beyond SPA. Of these, almost two thirds reported that they were in paid work because they 'enjoy working' or to 'keep active and fit', whereas the other third reported financial issues as the main reason for working beyond SPA. Reasons which reflect a lack of control over the decision to work after SPA (i.e. financial reasons) are associated with lower QoL. In contrast, those reasons which capture a degree of control (enjoyment of the job or wanting to remain active) are associated with higher QoL both cross-sectionally and over time.

CHILDHOOD DEPRIVATION AND LATER-LIFE COGNITIVE HEALTH IN A SOUTH AFRICAN COHORT STUDY OF AGING

L.C. Kobayashi¹, M. Glymour², K. Kahn^{3,5}, R. Wagner^{3,5}, F. Mateen⁴, S. Tollman^{3,5}, L.F. Berkman¹, 1. *Center for Population and Development Studies, Harvard University, Cambridge, Massachusetts*, 2. *University of California, San Francisco, San Francisco, California*, 3. *University of the Witwatersrand, Johannesburg, South Africa*, 4. *Harvard Medical School, Boston, Massachusetts*, 5. *MRC/Wits Rural Public Health and Health Transitions Research Unit, Agincourt, South Africa*

Although the populations of low-to-middle income countries are rapidly aging, very little research has evaluated the drivers of cognitive aging in these settings. We aimed to investigate the relationship between father's occupation during childhood (a marker of childhood socioeconomic deprivation) and later-life cognitive function, and whether educational attainment may explain this relationship among older, rural South Africans. Data were from baseline assessments in "Health and Aging in Africa: A Longitudinal Study of an INDEPTH Community in Rural South Africa" (HAALSI), a population-based cohort in Agincourt, South Africa. The cohort included 5059 men and women aged ≥ 40 years in 2015. A formal mediation analysis was conducted using linear models adjusted for age cohort, sex, country of birth, and self-rated childhood health. Nearly half of the sample had no education (45%) or were illiterate (40%). The total effect of father's occupation during childhood on z-standardized latent cognitive function score was 0.134 (95% CI: 0.074–0.187 for skilled vs. unskilled labor) and the controlled direct effect not explained by education was 0.104 (95% CI: 0.048–0.157). The indirect effect mediated by education was 0.030 (95% CI: 0.010–0.054), representing 22% of the total effect. These results indicate that older South African adults whose father worked in unskilled labor had, on average, worse cognitive outcomes than those with a father in skilled work, partly because they received very little, if any formal education. In this post-Apartheid context of aging in rural South Africa, socioeconomic inequalities in cognitive

outcomes appear consistent with patterns observed in high-income countries.

DUCHENNE SMILING AND STIGMA IN OLDER ADULTS WITH PARKINSON'S DISEASE

S. Gunnery, L. Tickle-Degnen, *Tufts University, Medford, Massachusetts*

Older adults with Parkinson's disease (PD) often have limited positive expressivity due to diminished ability to activate facial muscles. People with this deficit appear more depressed and withdrawn, which can lead to stigmatization. The Duchenne smile, which includes crinkling around the eyes, is the most potent way to express happiness. Older adults with PD maintain some deliberate control of their faces and could learn to compensate for loss of spontaneous expression by deliberately posing the Duchenne smile. We measured the ability to spontaneously and deliberately produce Duchenne smiles, and tested the relationship between smiling and enacted stigma (experiencing unfavorable attitudes from others) and felt stigma (internalizing negative stereotypes about one's disease). Fifty-four participants with PD (Mage=65) were videotaped posing four happiness scenarios in which they were instructed to smile and say a phrase (deliberate task), and while telling an interviewer about an enjoyable activity (spontaneous task). The most expressive clip from the spontaneous task and the four role-plays were coded for Duchenne and non-Duchenne smiles. Forty participants produced at least one Duchenne smile during their spontaneous narrative (range: 1–2) and 36 produced at least one Duchenne smile in the deliberate task (range: 1–4). Deliberate Duchenne smiling correlated with experiencing less felt stigma, $r(52)=-.27$, $p=.05$, while spontaneous Duchenne smiling correlated with experiencing less enacted stigma, $r(52)=-.28$, $p<.05$. These data indicate two possible means by which older adults could reduce the stigmatization of reduced facial activation—deliberately to reduce feeling normatively inadequate and spontaneously to reduce experiencing the negative evaluations of others.

IMPROVING TECHNOLOGY-BASED BEHAVIOUR CHANGE INTERVENTIONS: LEARNINGS FROM THE GRAY MATTERS STUDY

I. Cleland¹, C. Nugent¹, S. McClean¹, M.C. Norton², *1. Ulster University, Newtownabbey, United Kingdom, 2. Utah State University, Logan, Utah*

The potential of mobile and wearable technology to encourage individuals to adopt and sustain healthy lifestyle behaviours is receiving much attention. Indeed, if successful, these technologies could have a major impact on reducing risk factors and offering prevention strategies for a wide range of age related health conditions such as Alzheimer's Disease (AD). This session presents findings from the Gray Matters Study, a 6-month multi-domain lifestyle intervention for middle-aged persons (40–64 years). The RCT recruited 146 participants (treatment $n=104$; control $n=42$) and tracked lifestyle behaviours across six domains: physical activity, food, social, cognitive stimulation, sleep quality and stress. Users tracked their physical activity using a wearable activity monitor and self-reported lifestyle behaviours through a smartphone app. The app aimed to increase knowledge about AD prevention through daily recommendations of

how lifestyle behaviours could be modified. Study findings included increases in intrinsic motivation and actual changes in healthy behaviours. Usage of the app impacted positively on clinical measures (serum glucose ($p=0.015$), Insulin ($p=0.011$), HDL cholesterol ($p=0.037$) and BMI ($p=0.048$)). On conclusion of the study, however, none of the participants continued to use the app. This finding is in line with recent research highlighting that, whilst the popularity of health apps is increasing and their use is associated with improved health outcomes, achieving sustained engagement with the technology over time is more challenging. This session will discuss findings and best practices from Gray Matters including what technological improvements can be made in order to better sustain these healthy improvements over time.

USING INTERVALS OF NEED TO BETTER MEASURE FUNCTIONAL STATUS, SERVICE REQUIREMENTS, AND DISPARITIES

J.N. Laditka¹, S.B. Laditka¹, C. Jagger², *1. University of North Carolina, Charlotte, North Carolina, 2. Newcastle University, Tyne, United Kingdom*

Older adults' service needs are often assessed by counting dependence in activities of daily living (ADLs) and instrumental ADLs (IADLs). That approach lacks precision and does not adequately consider service need levels. We addressed those limitations with an approach adopted by the World Health Organization, using cognitive status and specific ADL/IADL combinations and impairment levels to identify time intervals when help was needed (e.g. weekly, daily, constant). Using Health and Retirement Study data ($n=29,933$, 146,324 status transitions, 306,997 person-years), we estimated seven-state multinomial logistic Markov models predicting need intervals and death by age, sex, race/ethnicity, and education. We then simulated populations, each individual in one of 6 need intervals each year, age 50 through death. Interval I1 was independence; I2, periodic standby help; I3, weekly IADL help, e.g., shopping; I4, regular guidance for cognitive impairment without ADL help; I5, scheduled help daily; I6, nursing home or equivalent care. Among women with high school education at age 80 African Americans averaged 13.5%, 9.5%, 2.9%, 18.2%, and 22.6% of remaining life in I2–I6, respectively; Hispanics: 10.4%, 7.7%, 4.4%, 19.2%, and 26.9%; whites: 11.7%, 8.6%, 2.6%, 17.6%, and 17.5% (all $p<0.01$). Remaining life in I6 for the same groups at age 90 was 37.4%, 44.0%, and 30.1%, with 22.3%, 27.2%, and 16.7% of those at this age in I6, respectively. Thus, at older ages more Hispanics required the highest care level, for longer periods of life. Measuring need intervals improves estimates of functional impairment, needs for formal and informal care, and health disparities.

CAN FAVOURABLE WORKING CONDITIONS HELP CHRONICALLY ILL WORKERS TO EXTEND THEIR WORKING LIVES?

M. Fleischmann, J. Head, *Epidemiology & Public Health, University College London, London, United Kingdom*

As a result to the increase of retirement ages, more workers with a chronic illness have to extend their working lives. We study the relevance of favourable psychosocial working conditions for workers with a chronic illness to extend their

working lives. Men and women (30%) aged 35–55, working, and having no chronic illness in phase 1 of the Whitehall II study on civil servants in the United Kingdom were selected ($n=7,957$). In the following 9 phases, spanning more than 20 years, we observe participants' exit from work through health-related retirement ($n=538$), other retirement (i.e. not health-related; $n=3,905$), and other exit (i.e. unemployment, inactivity; $n=500$). We investigate the impact of favourable psychosocial working conditions, chronic illness, and their interaction, for work exit. Competing risk models using the subdistribution hazard function revealed that favourable working conditions related to work exit. More occasions with high job control or work social support in midlife were related to a lower risk of health-related retirement. More work social support also decreased the risk of exit through unemployment or inactivity. Having a chronic illness increased the risk of any type of work exit, but only for health-related retirement this association was significant. The effect of chronic illness on work exit was only partially moderated by favourable psychosocial working conditions. Good working conditions in midlife can contribute to extended working lives, especially among those who exit young, e.g. due to health-related reasons.

GOAL-ORIENTED COGNITIVE REHABILITATION IN EARLY-STAGE DEMENTIA: RESULTS FROM THE GREAT TRIAL

A. Kudlicka¹, A. Bayer³, R. Jones², M. Kopelman⁴, I. Leroi⁵, J.R. Oyebode⁶, B. Woods⁷, L. Clare¹, 1. *Psychology, University of Exeter, Exeter, United Kingdom*, 2. *Research Institute for the Care of Older People, Bath, United Kingdom*, 3. *Cardiff University, Cardiff, United Kingdom*, 4. *Kings College London, London, United Kingdom*, 5. *University of Manchester, Manchester, United Kingdom*, 6. *University of Bradford, Bradford, United Kingdom*, 7. *Bangor University, Bangor, United Kingdom*

Cognitive rehabilitation (CR) is an individualised intervention for people with early-stage dementia. CR aims to improve management of everyday activities and reduce functional disability through identifying personal goals, applying a problem-solving approach and implementing evidence-based rehabilitative strategies.

We tested this approach in the multi-centre GREAT trial. Participants had early stage Alzheimer's, vascular or mixed dementia (ICD-10 criteria, MMSE score ≥ 18) and a family carer willing to contribute. All participants identified goals before being randomised to receive either treatment as usual (TAU) or home-delivered CR (10 therapy sessions over 3 months followed by 4 maintenance sessions over 6 months). Participants were followed up 3 and 9 months post-randomisation, with assessments conducted by a researcher blind to group allocation. The primary outcome was self-reported and carer-reported goal attainment at 3 months. Secondary outcomes were participant quality of life, mood, self-efficacy and cognition, and carer stress, health status and quality of life.

We randomised 475 participants, of whom 427 completed the trial (CR=209, TAU=218). There were statistically-significant large positive effects at 3-month follow-up for participant-rated goal attainment ($d=.97$, 95%CI .75-1.19), corroborated by carers ($d=1.11$, 95%CI .89-1.34). These

effects were maintained at 9-month follow-up for both participant ($d=.94$, 95%CI .71-1.17) and carer ratings ($d=.96$, 95%CI .73-1.2). There were no significant differences in secondary outcomes.

This major randomised controlled trial demonstrates that CR is effective in supporting functional ability in early-stage Alzheimer's, vascular or mixed dementia. CR offers a means of enabling people with early-stage dementia to maintain independence and engagement in everyday activities.

RELATIONSHIP BETWEEN SOCIAL SUPPORT AND MORTALITY RISK IN OLDER BLACK ADULTS

A. Gamaldo¹, R.J. Thorpe², A.T. Aiken Morgan³, J. Allaire⁴, K. Whitfield⁵, 1. *Penn State University, State College, Pennsylvania*, 2. *Johns Hopkins University, Baltimore, Maryland*, 3. *NC A&T State, Greensboro, North Carolina*, 4. *North Carolina State University, Raleigh, North Carolina*, 5. *Wayne State University, Detroit, Michigan*

The current study examined the relationship between social support and mortality risk utilizing data from the Baltimore Study of Black Aging (BSBA; $n = 602$; Mean age = 69.12). Participants were administered a battery of demographic (e.g., age, sex, income, education), social (e.g., social support), and health surveys (e.g., perceived stress, depressive symptoms, and diagnosed health conditions). Participants were also administered a global mental status test (Mini-Mental State Examination). Approximately 9 years after data collection, 52 participants were deceased. A logistic regression tested whether reports of social support given/received at BSBA wave 1 data collection predicted mortality risk (living or deceased) following the wave 1 visit. High levels of social support given was associated with lower odds of mortality (OR=.89; 95% CI 0.81–0.99) even after adjusting for demographic and health covariates (i.e., age, sex, education, income, stress, depression, number of health conditions, and global mental status). No significant association was observed between social support received and lower odds of mortality (OR=1.02; 95% CI 0.93–1.12). These results suggest the ability to provide (and not necessarily to give) social support is an indicator for mortality risk in older Black adults.

COPD CACHEXIA IN A MURINE MODEL

T. Graber, B. Rawls, B. Tian, W. Durham, A. Brasier, B. Rasmussen, C. Fry, *University of Texas Medical Branch, Galveston, Texas*

Chronic Obstructive Pulmonary Disease (COPD) has a 6.3% prevalence in the USA (hundreds of millions worldwide), has an age-associated onset, features progressively declining lung function, and is currently incurable. Cachexia of varying severity is indicated in up to 40% of COPD patients, leading to significant loss of muscle, strength, and function--perhaps contributing to sarcopenia or frailty development. Our poly(I:C)-induced mouse model (male C57BL/6; 5 months old) was representative of inflammatory/fibrotic COPD. We hypothesized that some treated mice would present with cachexia. We tested a subset (two groups, $n=4$, one treated with Poly I:C and one a PBS sham) for function, contractile physiology and cellular morphology. The treated group showed significant (two-tailed t-test, $p<0.05$) reductions compared to the sham in function (grip test -50%,

treadmill -36%), body mass (-25%), muscle wet-weight (gastrocnemius -26%, soleus -33%), and in vitro soleus isometric contraction (-35%). Furthermore, with treatment, we found evidence of muscle remodeling, such as cellular cross-sectional area loss (-26% gastrocnemius, -29% soleus), fiber-type shift (diaphragm increased oxidative fibers, IIx to IIa + 22%), increased mitochondrial density/oxidative capacity and mitochondrial biogenesis (succinate dehydrogenase activity, PGC1- α protein content). In conclusion, 75% of the treated mice showed at least some overt signs of COPD cachexia, with one very similar to a frail elderly mouse. This model will serve as the basis for future investigation into mechanisms and treatments for COPD-related cachexia, with the hope to eventually discover strategies to mitigate progression and improve the quality of life for older adults living with this disease.

ADVANCED GLYCATION END PRODUCTS IN HEMATOPOIETIC DEVELOPMENT

N. Huber, K.L. Rudolph, *Stem Cell Aging, Fritz Lipmann Institute - Leibniz Institute on Aging, Jena, Germany*

Advanced glycation end products (AGEs) are posttranslational protein modifications that emerge from glycation, a non-enzymatic reaction between the protein and a sugar. AGEs are reported to have negative effects on proteins, cells, tissues and organisms and are linked to several age-related diseases such as Alzheimer's disease, diabetes, inflammation signaling and cardiovascular diseases, among others. AGEs are also linked to nutrition, as research indicates that AGE-high diets could have negative effects on the body. We investigate AGEs in the hematopoietic system, a tissue strongly relying on stem cell function and differentiation, which is compromised in older individuals. We find that throughout hematopoietic development, populations show different AGE levels, depending on their lineage (myeloid or lymphoid) and differentiation stage (early progenitor or fully matured). In T cell development, these population-dependent levels are unchanged upon old age and caloric restriction, which indicates them to be conserved and potentially inevitable during differentiation. The differences in AGE levels point towards a possible relationship between glycation and differentiation within the hematopoietic system. This begs the question if differentiation drives glycation or if AGEs could actually contribute to differentiation. This would argue for an important role of AGEs and could help to rethink the dogma that renders AGEs simply harmful. Though focused on aging, the field of glycation research neither concentrates on stem cells nor the hematopoietic system, thereby neglecting their importance. Our studies serve to gain a better understanding of the biological role of glycation during aging and in stem cells, starting with the hematopoietic system.

ASSOCIATIONS BETWEEN METABOLITES AND PHYSICAL FUNCTION IN OLDER BLACK MEN

R.A. Murphy¹, S.C. Moore⁴, M. Playdon⁴, S.B. Kritchevsky⁵, A. Newman², H. Ayonayon⁶, C. Clish⁷, T.B. Harris³, 1. *School of Population and Public Health, University of British Columbia, Vancouver, British Columbia, Canada*, 2. *University of Pittsburgh, Pittsburgh, Pennsylvania*, 3. *National Institute on Aging, Bethesda, Maryland*, 4. *National Cancer Institute, Rockville, Maryland*, 5. *Wake*

Forest School of Medicine, Winston-Salem, North Carolina, 6. *University of California, San Francisco, California*, 7. *Broad Institute of MIT, Cambridge, Massachusetts*

Functional decline is a common condition among older adults but mechanisms that give rise to functional decline and disability are incompletely understood. To identify metabolic perturbations that may impact functional decline, non-targeted metabolomics was used to measure 350 metabolites in baseline plasma from 313 black men in the Health, Aging and Body Composition Study (median age 74 years, median BMI 26.7). Usual gait speed was measured over 20 meters. Cross-sectional relationships between gait speed and metabolites were explored with Pearson partial correlations adjusted for age, study site and smoking status. Risk of incident mobility disability (2 consecutive reports of inability to walk ¼ mile or climb 10 stairs) over 13 years of follow-up was additionally explored with cox regression models among 307 men who were initially free of mobility disability. Significance was determined at $p \leq 0.01$ and $q \leq 0.30$. Ten metabolites were correlated with gait speed. The most strongly correlated were hydroxyglutarate ($r = -0.18$), gluconurate ($r = -0.18$), homogentisate ($r = -0.16$), salicylurate ($r = -0.19$), and tryptophan ($r = 0.15$). Sixteen metabolites; all unique from gait speed-correlated metabolites, were associated with incident mobility disability. The top metabolites were creatine (HR 5.21, 95% CI 1.85–14.7); symmetric dimethylarginine, a biomarker of kidney function (HR=3.30, 95% CI=1.46–7.48); inositol (HR 2.73, 95% CI 1.48–5.02) and quinolate; a metabolite of tryptophan degradation (HR 2.54, 95% CI 1.64–3.93). This hypothesis generating study identified 26 involved in biological mechanisms including tryptophan metabolism, prospectively associated with functional decline in older men. The novel function-related metabolites identified here may help target future investigation of perturbed metabolic pathways.

SYSTEMIC OVEREXPRESSION OF AT-1/SLC33A1 CAUSES A PROGERIA-LIKE PHENOTYPE

Y. Peng, S. Shapiro, K. Hewitt, G. Kong, E. Bresnick, J. Zhang, L. Puglielli, *University of Wisconsin- Madison, Madison, Wisconsin*

The import of acetyl-CoA into the lumen of the endoplasmic reticulum (ER) by AT-1/SLC33A1 regulates N ϵ -lysine acetylation of ER-resident and -transiting proteins. Mutations or increased expression of AT-1/SLC33A1 have been associated with diseases such as familial spastic paraplegia, developmental delay with premature death, and autism spectrum disorder with intellectual disability and dysmorphic features. Additionally, increased gene dosage and protein levels have been reported in patients with late-onset Alzheimer's disease. Our lab has demonstrated that the imbalance of acetyl-CoA influx into the ER lumen affects the induction of autophagy and mitochondrial adaptation (J Neurosci 2014; 34: 6772 and J Exp Med 2016; 213: 1267). In this study, we generated a systemic AT-1 Tg mouse model that ubiquitously overexpresses human AT-1. The animals demonstrate a progeria-like phenotype that mimics an accelerated form of aging. The phenotype includes short lifespan, osteoporosis, skin changes, anal prolapse, reduced stemness of stem cells, and reduced proliferation potential of mitotically competent cells. At the mechanistic level, the phenotype is caused by

defective proteostasis and reduced cell proliferation potential, which appears to be linked to aberrant mitochondria metabolic adaptation. Funding: NIH.

PRODUCTION OF TNF EX VIVO IS PREDICTIVE OF AN IMMUNE RESPONSE TO FLU VACCINATION IN ELDERLY SUBJECTS

F. Bloch¹, B. Charmeteau³, M. Tovey⁴, J. Meritet^{2,5}, C. Desaint^{2,6}, O. Launay^{2,5,6}, P. Lebon³, 1. *CHU Amiens-Picardie, Amiens, Hauts de France, France*, 2. *Hôpitaux Universitaires Paris Centre (APHP), Paris, France*, 3. *INSERM institute, Paris, France*, 4. *Biomonitor SAS, Villejuif, France*, 5. *Université Paris Descartes, Sorbonne Paris Cité, Paris, France*, 6. *INSERM, CIC 1417, F-CRIN, I-REIVAC, Paris, France*

Objective: To investigate the relationship between the response to influenza vaccination and the ability to produce proinflammatory cytokines in elderly subjects.

Methods: Peripheral blood mononuclear cells (PBMC) of 25 elderly subjects collected before flu vaccination were stimulated with the influenza vaccine in order to evaluate the secretion of five specific cytokines: TNF α , IFN α , IFN γ , IL2 and IL10. The results were correlated with the increased HAI antibody titres three weeks after vaccination.

Results: Only 30% of elderly individuals seroconverted after flu vaccination. Although 50 to 70% of the cohort did not produce TNF α , IFN α , IFN γ , IL2 or IL10, All the individuals who seroconverted were able to produce TNF α . Furthermore production of IFN gamma, with or without production of IFN α /b, was not associated with a better response to the vaccine.

Conclusion: Production of TNF α appears to be primordial for an efficient vaccine response and may provide a predictive marker for the humoral response to vaccination. It may also provide the basis for evaluating agents designed to rescue TNF α producing cells. This study emphasizes the necessity and the timing to rescue the function the TNF producing cells.

VITAMIN C DEFICIENCY LEADS TO SKELETAL MUSCLE ATROPHY AND MUSCLE FIBER TRANSFORMATION

Y. Kondo¹, S. Takisawa¹, Y. Noda¹, S. Machida², T. Aigaki³, A. Ishigami¹, 1. *Molecular Regulation of Aging, Tokyo Metropolitan Institute of Gerontology, Tokyo, Japan*, 2. *Juntendo University, Chiba, Japan*, 3. *Tokyo Metropolitan University, Tokyo, Japan*

Recently, we have reported that plasma L-ascorbic acid (AA, reduced form of vitamin C) concentrations in community-dwelling elderly women were related well to their muscle strength and physical performance (Saito, K. et al., 2012, *J. Gerontol. A Biol. Sci. Med. Sci.*). To clarify the physiological functions of AA in skeletal muscle, we investigated the effect of AA deficiency in skeletal muscle using senescence marker protein-30 (SMP30)/gluconolactonase (GNL)-knockout (KO) mice that lacks AA biosynthesis ability just like a human being.

SMP30/GNL-KO female mice at age of 8 weeks were divided into two groups: AA-deficient group (AA-) given tap water and AA-sufficient group (AA+) given 1.5 g/L AA water. At 16-week of experimental period (age of 24 weeks), AA

was not detected at all in skeletal muscles of AA-deficient mice. The gastrocnemius, soleus, plantaris, and tibialis anterior muscle weight of AA-deficient mice were significantly lower than those of AA-sufficient mice, but EDL muscle weight showed no difference. In soleus muscle, the area of muscle fibers and the percentage of type I fiber (slow-twitch fiber) were decreased in AA-deficient mice when compared to AA-sufficient mice. In contrast, the percentage of type IIa fiber (fast-twitch fiber) was increased in AA-deficient mice.

These results strongly suggested that vitamin C deficiency in skeletal muscle leads to muscle atrophy and switches muscle fiber types from slow to fast.

FRAILTY EFFECTS ON COGNITIVE CHANGES IN AGING ARE MODERATED BY DOMAIN, GENETIC RISK, AND SEX

S. Thibeau², K. McDermott², G. McFall², S. Wiebe², K. Rockwood¹, R.A. Dixon², 1. *Dalhousie, Halifax, Nova Scotia, Canada*, 2. *University of Alberta, Edmonton, Alberta, Canada*

Introduction: Age-related frailty reflects cumulative multisystem physiological and health decline. Frailty increases risk of adverse brain and cognitive outcomes, including differential decline and dementia. In a longitudinal sample of non-demented older adults, we examine whether (a) frailty predicts trajectories across three cognitive domains (memory, executive function (EF), and speed) and (b) prediction patterns are modified by Alzheimer's genetic risk (Apolipoprotein E (APOE)) or sex.

Methods: Participants (n = 655; M age = 70.7, range 53–95; 3 waves) were from the Victoria Longitudinal Study. After computing a frailty index, we used latent growth modeling and path analysis to test frailty effects on level and change in three latent cognitive variables. We tested two potential moderators by stratifying by APOE risk (e4+, e4-) and sex.

Results: First, frailty levels predicted speed and EF performance levels, and differential memory change slopes. Second, change in frailty predicted rate of decline for both speed and EF. Third, genetic moderation analyses showed that APOE risk (e4+) carriers were selectively sensitive to frailty effects on memory change. Fourth, sex moderation analyses showed that females were selectively sensitive to (a) frailty effects on memory change and (b) frailty change effects on speed change. In contrast, the frailty effects on EF change were stronger in males.

Conclusion: In non-demented older adults, increasing frailty is associated with differential decline in cognitive trajectories. These effects vary by cognitive domain and are moderated by both genetic risk and sex.

AMYLOID- β RISK FACTOR FOR AGE-RELATED MACULAR DEGENERATION

A.P. Bobrov, V.V. Ermilov, A. Smirnov, *Forensic medicine and Pathology, Volgograd State Medical University, Russia, Volgograd, Russian Federation*

Age-related macular degeneration (AMD) is the leading cause of severe visual impairment in the elderly. The appearance of amyloid- β in eye tissues makes it possible to see in a new light the problem of eye amyloidosis. Amyloidosis and aging is fundamental biological problem. The appearance

of amyloid- β in eye tissues is related with development of some gerontophthalmological diseases. Histological, immunohistochemical, and electron microscopic studies of the 137 eyes with AMD revealed amyloid- β in the drusen, Bruch's membrane, and between the basal membrane of the retinal pigment epithelium (RPE) and internal collagen layer of Bruch's membrane. Comparative analysis of morphological changes in tissues of the macular and paramacular areas and the incidence of amyloid- β incorporations in them permit us to propose that accumulation of local senile amyloid- β is conducive to development and aggravation of AMD. Ultrastructural studies of Bruch's membrane in the macular region have shown that amyloid- β fibrils are localized in inner collagenous zones of Bruch's membrane with fragments of degrading RPE cells closely attached to them. By reason not clear yet, a portion of the damaged photoreceptor membrane material resists the enzymatic digestion. The fact results in partial degradation, autophagy and accumulating in the cytoplasm of RPE cells of some material except lipids out of which amyloid- β fibrils may be formed. The authors put forward a hypothesis of the pathogenesis of AMD, in which the principal role in the formation and deposition of abnormal protein-amyloid- β , is played by degenerative cells of RPE.

REPEATED ELECTROMAGNETIC FIELD STIMULATION LOWERS A β PROTEIN LEVELS IN HUMAN NEURONAL CULTURES

F. Perez¹, J.P. Bandeira¹, J. Bailey², J. Morisaki³, D. Lahiri², N. Chopra², 1. *Department of Medicine, Division of General Internal Medicine and Geriatrics, Indiana University School of Medicine, Indianapolis, Indiana*, 2. *Department of Psychiatry, Institute of Psychiatric Research, Neuroscience Research Center, Indiana University School of Medicine, Indianapolis, Indiana*, 3. *Department of Bioengineering, University of Illinois at Chicago, Chicago, Illinois*

Former studies in AD mouse model demonstrated that Repeated Electromagnetic Field Stimulation (REMFS) reversed cognitive impairment by decreasing A β levels (1). However, extrapolation of data that would allow safe utilization in humans has been limited by the increased potential risk of thermal injury. Previously, we determined that frequencies of 50 to 70 MHz were more appropriate for human exposure (2). The present work presents the effects of REMFS on A β levels in primary human fetal brain (HFB) cultures, and determines the minimal energy to induce this biological effects (MEBE) without secondary toxicity. The results obtained suggest a new therapeutic strategy to decrease A β in humans.

Methods: Primary human fetal brain (HFB) cultures were treated with REMFS at different frequencies, powers, specific absorption rates (SAR), and times. Exposures were performed using a TEM cell chamber. Levels of A β 1–40 and 1–42 levels were measured using ELISA.

Results: Compared to untreated cultures, exposure of HFB cultures to REMFS resulted in a 58.35 percent reduction ($P=0.001$) in A β 1–40 levels when treated with a frequency of 64 MHz at a SAR of 0.6W/Kg for 1 hour/day during 21 days. Lower energy (SAR 0.4W/Kg) exposure at 64 and 100 MHz for 1 and 2 hours/day during 14 days also resulted in significant reduction of A β levels. Further data

demonstrated that REMFS exposure at 64 MHz with a SAR of 0.4 and 0.9W/Kg at 4, 8 and 14 days did not cause a significant change in A β Precursor Protein secretion, but rather increased A β degradation. Notably, all results were achieved with no signs of cellular toxicity in treated cultures, as would be suggested by differences in LDH levels, cell number, cell morphology, cell attachment, or neurite extension.

Conclusion: This study confirms that REMFS reduces A β levels in human neurons. Our results suggest that REMFS at 64 MHz/SAR of 0.4W/Kg for one hour during 14 days may be the MEBE required to induce degradation of A β peptides, this effect likely occurring via up-regulation of the main controller of proteostasis, Heat Shock Factor1(1). These findings are encouraging, given the EMF frequency and power used in our experiments make REMFS both suitable and safe for human trials.

VITAMIN E BOOSTS NEUTROPHIL ELASTASE ACTIVITY AND THEIR ABILITY TO KILL STREPTOCOCCUS PNEUMONIAE

E. Bou Ghanem, J.N. Lee, S. Meydani, J.M. Leong, A. Panda, *Molecular Biology and Microbiology, Tufts University, Boston, Massachusetts*

Streptococcus pneumoniae (pneumococcus) remain a leading cause of life-threatening infections such as pneumonia, bacteremia and meningitis in the elderly. Neutrophils are innate immune cells that are key determinants of disease following infection as their presence is initially required to control bacterial numbers, but their persistence in the lungs can lead to tissue destruction and bacterial spread. We previously found that vitamin E (VE) supplementation reverses the age-associated increase in susceptibility to *S. pneumoniae* in mice by modulating pulmonary recruitment of neutrophils. The objective of this study was to test the effect of VE on the ability of neutrophils isolated from young (22–35 years) or elderly (65–69 years) volunteers to migrate across lung epithelial cell in response to *S. pneumoniae* and to kill complement-opsonized bacteria *in vitro*. We found no distinguishable differences in neutrophil migration from young and elderly donors and that VE diminished transepithelial migration across all ages. Surprisingly, unlike previous studies showing defective killing of antibody opsonized bacteria with aging, we found that when compared to young donors, neutrophils of older donors were better at killing complement opsonized pneumococci *ex vivo*. This increased antibacterial response in neutrophils from elderly individuals correlated with elevated activity of the antimicrobial serine protease neutrophil elastase. Exposure of neutrophils to VE elevated enzymatic activity of neutrophil elastase in young donors and increased pneumococcal killing by these cells. These findings demonstrate that VE is an effective modulator of innate immune cell function with potential to fight bacterial pneumonia.

INFLUENZA-INDUCED MUSCLE DEGRADATION: A PATHWAY TO AGE-ASSOCIATED DISABILITY

J. Bartley, S.R. Keilich, G. Kuchel, L. Haynes, *UConn Health Center, Farmington, Connecticut*

Influenza (flu) is problematic for the elderly with increased severity of infection and greater risk for hospitalization and death. Flu infection is limited to pulmonary epithelial cells; yet myalgias are a common symptom and elderly are at increased risk for disability post-flu. Recent studies from our laboratory were the first to demonstrate a molecular link for this interaction by characterizing the impact of flu infection on muscle health. We demonstrated declines in mobility and altered gait kinetics in both young and aged mice during infection with more prolonged deficits with aging. Gastrocnemius gene expression of inflammatory cytokines (IL-6, IL-6R, TNF, CXCL10) was upregulated with flu with more dramatic and prolonged alterations in the aged mice. Similarly, genes involved in muscle degradation and proteolysis (Atrogin1, MuRF-1, Ubiquitin B, Ubiquitin C) were upregulated with infection and remained elevated for longer in the aged mice. In contrast, positive regulators of muscle mass and myogenesis (IGF-1, Pax7, MyoD) were downregulated during infection and to a greater extent in aged mice. This may indicate that flu infection is a previously unrecognized contributor to sarcopenia and frailty in the elderly. Recent studies just completed in our laboratory have shown that vaccination with recombinant flu nucleoprotein can partially protect mice from functional decrements and muscle gene alterations. Thus, despite decreased vaccine efficacy with aging, vaccination may be a potential strategy to prevent flu-induced disability with aging. Mechanisms are currently being investigated; however, these initial findings provide preliminary highly translational advancements to protect the aging population.

RISK FACTORS FOR OLFACTORY DYSFUNCTION IN MIDDLE-AGED AND OLDER U.S. ADULTS

G. Bello¹, G. Dumancas², 1. *Icahn School of Medicine at Mount Sinai, New York, New York*, 2. *Louisiana State University Alexandria, Alexandria, Louisiana*

Olfaction is a key sensory mechanism in humans, playing important roles in multiple facets of daily life. Deficits in this chemosensory function have wide-ranging impacts on overall health, wellbeing and quality of life. In the United States, olfactory dysfunction is considered a significant public health issue. More than 2 million Americans suffer from smell disorders. Various risk factors for olfactory dysfunction have been identified, with age being the primary one. Impairments in chemosensory perception (both smell and taste) are a hallmark of aging, and begin to manifest around middle age. This study examines the role of environmental, biological and lifestyle factors as determinants of olfactory dysfunction among middle aged and older adults in a large, randomly selected national sample. We examine the association of environmental exposures (phthalates, volatile organic compounds, phenols, heavy metals and polycyclic aromatic hydrocarbons [PAHs]), measures of physiological function and various lifestyle/behavioral characteristics on olfactory function. Evaluation of olfactory function was carried out using a short 8-item test, and was limited to basic scent-identification tasks. Penalized ordinal regression models were used to test for associations between the explanatory variables and olfactory assessment scores, adjusting for potentially confounding covariates. Our results identified metabolic parameters with significant association with

olfactory deficits, suggesting their putative roles as risk factors for this condition. Further, increased urinary levels of environmental phenols were found to be associated with olfactory impairment.

INCREASED PLASMA PROLINE CONCENTRATION IS ASSOCIATED WITH SARCOPENIA OF ELDERLY PEOPLE

K. Toyoshima¹, M. Nakamura¹, T. Hakamada¹, Y. Adachi², A. Imaizumi², Y. Abe¹, E. Kaneko¹, K. Shimokado¹, 1. *Tokyo Medical and Dental University, Tokyo, Japan*, 2. *Institute for Innovation, Ajinomoto Co., Inc., Kawasaki, Japan*

Background and purpose: Metabolome analyses have shown that plasma amino acid profiles reflect various pathological conditions, such as cancer and diabetes mellitus. It is not known, however, whether the plasma amino acid profile changes in patients with sarcopenia. This study aimed to investigate whether sarcopenia-specific changes occur in the plasma amino acid profile.

Methods: A total of 153 community-dwelling elderly individuals and 7 institutionalized elderly individuals (male, n=56; female, n=104 women; age, 77.7 ± 7.0 years old) were recruited for this cross-sectional analysis. We performed a comprehensive geriatric assessment, which included an evaluation of the subjects' hand grip strength, gait speed, muscle mass and blood chemistry, including the concentration of 18 amino acids.

Results: Twenty-eight of the 160 participants met the criteria for sarcopenia established by the Asian Working Group on Sarcopenia in Older People. A univariate analysis showed that lower plasma concentrations of glutamine, histidine and tryptophan, and a higher concentration of proline were associated with sarcopenia. A multivariable analysis revealed that a higher concentration of proline was the only variable to be independently associated with sarcopenia.

Conclusions: The plasma concentration of proline may therefore be useful for understanding the underlying pathophysiology of sarcopenia.

PARADOXICAL ADVERSE ASSOCIATION BETWEEN HIGH VITAMIN D LEVEL AND MUSCLE STRENGTH

T. Auyeung, J. Lee, J. Leung, N. Tang, R. Yu, T. Kwok, J. Woo, *The Chinese University of Hong Kong, Hong Kong, China*

Introduction: High vitamin D level is believed to be advantageous for muscle. However, much of the studies were cross-sectional and its effect on cardiovascular outcomes was opposite. We therefore examined the cross-sectional and longitudinal association between vitamin D level and muscle mass and strength.

Methods: 2815 community-dwelling older adults ≥65 years of age had baseline 25(OH) vitamin D level measured by liquid chromatography and mass spectrometry. In addition, baseline and 2-year muscle mass and strength were measured by DXA and handgrip strength (dynamometer) respectively. The baseline appendicular muscle mass and strength and their changes in 2 years were compared with respective to 3 vitamin D levels, namely <50, 50–69.9 and ≥70nmol/L, adjusted for age and physical activity level (PASE).

Results: At baseline, women with higher vitamin D level had a stronger grip strength (p-for-trend=0.017), which remained significant after adjustment for age and physical activity (PASE). After 2 years, in women, a higher vitamin D level was associated with a faster decline in handgrip strength (p-for-trend<0.0001), which remained significant after adjustment for age and physical activity (p-for-trend<0.0001). No association was observed in men.

Conclusion: There exists a paradoxical adverse association between vitamin D and muscle strength in women. High vitamin D level is not always advantageous for health.

REGULATION OF LIPOLYTIC CONTROL BY NEUROPEPTIDE Y PROMOTES SURVIVAL IN CALORIE-RESTRICTED MICE

S. Park, T. Komatsu, S. Kim, H. Hayashi, R. Mori, I. Shimokawa, *Nagasaki University, Nagasaki, Japan*

Neuropeptide Y (NPY) is an orexigenic peptide that plays an essential role in caloric restriction (CR)-mediated lifespan extension. However, the mechanisms underlying the NPY-mediated effects in CR are poorly defined. Here, we report that NPY deficiency in mice during CR increases mortality in association with lipodystrophy. NPY^{-/-} mice displayed a rapid decrease in body weight and fat mass as well as increased lipolysis during CR. These alterations in fat regulation were inhibited by the lipolysis inhibitor, acipimox (ACM), a treatment associated with reduced mortality. The lipolytic signaling pathway, β 3-adrenergic receptor/hormone sensitive lipase was markedly activated in white adipose tissue of NPY^{-/-} mice compared with that of NPY^{+/+} mice, and NPY administration reduced thermogenesis in fasted NPY^{-/-} mice. These results demonstrate the critical role of NPY in the regulation of lipid metabolic homeostasis and survival via control of lipolysis and thermogenesis in a state of negative energy balance.

ROLES FOR FOXO1 AND FOXO3 IN REGULATION OF CANCER AND LIFESPAN IN DIETARY-RESTRICTED MICE

I. Shimokawa, T. Komatsu, *Nagasaki University, Nagasaki, Japan*

Forkhead box O (Foxo) transcription factors may be involved in the salutary effect of dietary restriction (DR). We investigated roles for Foxo1 and Foxo3 in regulation of cancer and lifespan in mice. The preventive effect of DR on cancer was diminished in Foxo1-knockout heterozygotic (+/-) mice, although the life-extending effect of DR remained in Foxo1 (+/-) mice. By contrast, the life-extending effect of DR was abrogated in Foxo3 (+/-) mice; the incidence of cancer was diminished by DR in Foxo3 (+/-) mice. These findings indicate differential roles for Foxo1 and Foxo3 in regulation of cancer and lifespan in the DR condition. To elucidate a mechanism by which Foxo3 affects the life-extending effect of DR, we analyzed a metabolome in liver tissues and bioenergetics of mitochondria isolated from 24-month-old mouse liver. The metabolome revealed that some metabolites in the glycolysis/ gluconeogenesis were lower; and that the ratio of lactate: pyruvates and the ratio of NADH: NAD⁺ were greater in Foxo3^{+/-} DR mice, compared to WT DR mice. The findings suggest a pseudohypoxic condition in

Foxo3^{+/-} DR mouse tissues. The mitochondrial membrane potential was greater in Foxo3^{+/-} DR mice than in WT-DR mice. These findings suggest that Foxo3 is required for metabolic adaptation to DR, and that the impairment diminishes the life-prolonging effect of DR.

THE ASSOCIATION OF FRAILTY WITH RECOVERY FROM DISABILITY AMONG NEWLY DISABLED OLDER ADULTS

C. Wu¹, D. Kim^{2,3}, D. Lee^{4,1}, M. Odden¹, 1. *Oregon State University, Corvallis, Oregon*, 2. *Beth Israel Deaconess Medical Center, Boston, Massachusetts*, 3. *Institute for Aging Research, Hebrew SeniorLife, Boston, Massachusetts*, 4. *Oregon Health and Science University, Portland, Oregon*

Research has demonstrated that disability is a dynamic rather than an irreversible process and transitions among different disability states are common. However, little is known about factors that affect recovery from disability. We analyzed data from the Health and Retirement Study to test the hypothesis that frailty, a physiologic state of decreased resilience to stressors, was associated with lower recovery from disability in the newly disabled adults (≥ 65 years). Disability was defined as having difficulty in any of the six activities of daily living (ADLs; dressing, eating, toileting, bathing, transferring, walking across a room). Frailty was assessed using five criteria measured two years before disability: weakness, slowness, exhaustion, inactivity, and shrinking. We classified individuals as “robust” (0 criteria; n=355), “prefrail” (1–2 criteria; n=650), and “frail” (3–5 criteria; n=161). Recovery was defined as regaining independence in all ADLs within two years of disability. Of the 1166 participants with incident disability, 43.9% of the robust, 35.7% of the prefrail, and 16.8% of the frail recovered from disability. After adjusting for socio-demographics, lifestyle, chronic conditions, self-rated health, cognitive function, and severity of disability, frail individuals were less likely to recover compared with the robust (risk ratio [RR]=0.57, 95%CI: 0.39–0.83). We found no difference between the robust and the prefrail (adjusted RR=0.99). In summary, frailty is an independent predictor of poor recovery of ADL disability among newly disabled elders. These findings validate frailty as a marker of decreased resilience, and may offer new opportunities for individualized interventions and geriatric care based on frailty assessment.

THE RELATIONSHIP AMONG TYPES OF DAILY LIVING ASSISTANCE AND LONG HOURS OF INFORMAL CARE

H. Ueshima¹, N. Tamiya¹, H. Noguchi³, F. Sandoval Garrido^{3,1}, H. Takahashi², 1. *University of Tsukuba, Tsukuba, Ibaraki, Japan*, 2. *Fukushima Medical University, Fukushima, Japan*, 3. *Waseda University, Tokyo, Japan*

Long hours of informal care cause adverse events among family caregivers. However, it is not certain what type of daily living assistance prolong time of informal care. The aim of this study is to determine the types of daily living assistance related to extensive time of informal care. We used the Comprehensive Survey of Living Conditions from 2007, 2010, 2013. It is a cross-sectional survey by the Ministry of Health, Labor and Welfare, Japan. The subjects were care

recipients over 65 years and their main family-caregiver, for a total of 6094 dyads included. Among them, there were 1638 care recipients with stroke and 1245 care receivers with dementia. We used ordered logistic regression analysis stratified by stroke patients and dementia patients to examine the relationship between the hours of informal care (lending a hand when needed, 2 to 3 hours or around half a day, and almost all day) and each daily living assistance adjusted for the characteristics of caregivers and care recipients. Our finding was that the daily living assistances associated with extensive time of informal care were: wiping the body, changing position, and taking medicine in stroke patients, while oral health, taking bath, and changing clothes in dementia patients. Toileting and feeding in both kind of patients. In conclusion, the types of assistance associated with long hours of informal care were different between stroke patients and dementia patients. It seems better to make separate plans to support family caregivers of stroke patients and dementia patients.

COGNITIVE DEFICITS IN CHRONIC STROKE PATIENTS: NEUROPSYCHOLOGICAL ASSESSMENT AND SELF-REPORTS

A. Nakling^{1,2}, E. Wehling^{2,4}, D. Aarsland^{1,3}, H. Naess^{2,4}, 1. SESAM, University Hospital of Stavanger, Bergen, Norway, 2. University of Bergen, Bergen, Norway, 3. King's College, London, United Kingdom, 4. Haukeland University Hospital Bergen, Bergen, Norway

The aim of this study was to assess cognitive functioning 12 months after stroke, using screening instruments and comprehensive neuropsychological assessment, and to compare self-reported problems with neuropsychological testing.

106 stroke patients (62 males, 44 females, 75 (71%) were aged 60 and older) performed cognitive testing 12 months following stroke. The self-reporting Stroke Impairment Scale (SIS2), MMSE, HADS (Hospital Anxiety and Depression Scale) were administered, as well as neuropsychological tests of visual memory, executive function, verbal skills and processing speed. A score of 1.5 SD below age-, gender- and educational level adjusted scores was regarded as cognitive impairment.

59 (56 %) of these stroke patients had cognitive impairment in at least one domain, mostly visual memory and executive function. The proportion of impairment was significantly higher in those aged >60 years. 32 patients (36 %) reported "no cognitive problems" on the SIS2-scale. Of these, 23 (72 %) showed cognitive impairment on neuropsychological testing, 18 males, 5 females. 19 patients (21 %) reported of cognitive problems on the SIS2, but showed no cognitive impairment on neuropsychological testing, thus over-reporting; 10 males, 9 females. Among these, only 3 (16 %) had depression, compared to 13 (17 %) of participants over 60 years. HADS scores were not correlated with cognitive test scores.

Cognitive impairment 12 months after stroke is common, and is mainly affecting executive function, visuospatial memory, and processing speed. More men than women self-reported "no problems", though having measurable cognitive impairment.

LONGITUDINAL EFFECTS OF SOCIAL NETWORK DIVERSITY ON MORTALITY AND DISABILITY AMONG ELDERLY

T. Ali¹, C. Nilsson², J. Weuve³, K.B. Rajan⁴, C.F. Mendes de Leon¹, 1. University of Michigan, Ann Arbor, Michigan, 2. University of Copenhagen, Copenhagen, Denmark, 3. Boston University, Boston, Massachusetts, 4. Rush University, Chicago, Illinois

Having a larger social network has beneficial effects on health and survival in adults, but few studies have evaluated the role of network diversity, in addition to network size. We aim to determine whether social network diversity is associated with mortality, physical function, and disability in a population of older black and white adults. We used data from the Chicago Health and Aging Project, a longitudinal, population-based study of adults aged 65 years and older. We estimated hazard ratios (HRs) of mortality using Cox proportional hazards models (N=6,595), mean difference (b) in physical function using generalized estimating equations (N=4,304), odds ratios (ORs) of disability onset using logistic regression (N=5,318), and relative risk (RR) of disability progression using Poisson regression (N=5,318), associated with network diversity. Models were adjusted for age, gender, race, education, marital status, and health-related variables. In adjusted models, elderly with more diverse social networks had a lower risk of mortality (HR=0.76; 95% CI = 0.62–0.92) and higher physical function at baseline (b=0.85; p<.001) compared to elderly with less diverse networks. Increased diversity in social networks was also associated with lower odds of disability onset (OR=0.58; 95% CI = 0.36–0.91) but not with progression of disability. Social networks are particularly important for older adults as they face the greatest threats to their health, and depend on their network relationships, more than younger individuals, to meet their needs. Increasing diversity, and not just increasing size, of social networks may be essential for improving health and survival among the elderly.

SEX DIFFERENCES IN THE CIRCUMSTANCES OF FALLS AMONG OLDER ADULTS IN LONG-TERM CARE

Y. Yang^{1,2,3}, K.S. van Schooten^{3,2}, J. Sims-Gould^{1,2}, H.A. McKay^{1,2}, F. Feldman^{4,3,2}, S.N. Robinovitch^{3,2}, 1. Family Practice, University of British Columbia, Vancouver, British Columbia, Canada, 2. Centre for Hip Health and Mobility, Vancouver, British Columbia, Canada, 3. Simon Fraser University, Burnaby, British Columbia, Canada, 4. Fraser Health Authority, Surrey, British Columbia, Canada

Introduction: Falls are a major health concern for both older men and women. However, few studies have examined sex differences in the circumstances of falls. We analyzed real-life falls captured on video to compare scenarios leading to falls between men and women in two long-term care (LTC) facilities.

Methods: Between 2008 and 2016, we video-captured 1738 falls experienced by 231 men and 298 women (mean age=83±9 years). We focused our analysis on the biomechanical causes of imbalance and the activities at time of falling, and compared these to sex and health status.

Results: Men were more likely than women to fall from loss of support with an external object (odds ratio 1.37; 95%

CI 1.08–1.73) and less likely to fall from tripping (0.72; 0.54–0.96). Men were more likely to fall while seated (1.42; 1.07–1.87) or while rising from sitting (1.49; 1.11–1.99), and less likely to fall while walking (0.61; 0.50–0.75). Falls in men were more likely to involve wheelchairs (1.50; 1.16–1.93), and less likely to involve walkers (0.57; 0.43–0.76). Falls from loss of support were more common among individuals who were less independent in performing activities of daily living (ADL), who used multiple medications, and who used mobility aids. Individuals with independent ADL and intact cognition were more likely to fall while walking, but less likely to fall while seated or while rising.

Conclusion: Our results elucidate differences between older men and women in the scenarios that lead to falls, to inform strategies to prevent falls in the LTC setting.

OPTIMIZING MEDICATION USE AMONG OLDER PEOPLE RESIDING IN AGED CARE FACILITIES

K. Thiruchelvam¹, S. Hasan¹, P. Wong¹, T. Kairuz², 1. *International Medical University, Kuala Lumpur, Wilayah Persekutuan Kuala Lumpur, Malaysia*, 2. *The University of Newcastle, Newcastle, New South Wales, Australia*

Medication reviews are essential in the optimization of pharmacotherapy among the older population. This study developed a comprehensive approach to medication management among older people in aged care facilities. The framework is centered on medication appropriateness and comprises a five-step medication review algorithm that is supplemented with a 10-component tool, the Medication Appropriateness Index-Geriatric version (MAI-G). This version incorporates geriatric components and detects changes in medication use. The MAI-G supplements the algorithm and quantifies the appropriateness of medications, determining improvements and permitting measurable outcomes. The components in the MAI-G closely correspond to components in the algorithm to allow for quick and unequivocal extrapolation. The algorithm and MAI-G were implemented in a 6-month prospective study among 202 residents aged 60 years and above across 17 aged care facilities in Malaysia. The proportion of residents with inappropriate medications detected by the MAI-G were 55.0% at baseline, 50.5% at 3-months and 46.5% at 6-months. The number of inappropriate medications detected by the MAI-G also decreased from 0.83 ± 0.93 at baseline, to 0.76 ± 0.92 at 6-months. The MAI-G average scores decreased from 1.19 ± 1.03 , at baseline, to 1.16 ± 0.98 , at 6-months (MAI-G scores range from 0–21). This study supports the need for a comprehensive medication review process that is supplemented by quantification of medication appropriateness which identifies changes in medication use. This study also provides an overview of the medication appropriateness among older people residing in aged care facilities in Malaysia.

ASSESSING THE MEALTIME ENVIRONMENT IN CANADIAN LONG-TERM CARE HOMES USING THE MEALTIME SCAN

S. Iuglio¹, H.H. Keller^{1,2}, H. Chaudhury³, J.M. Morrison¹, S.E. Slaughter⁴, C. Lengyel⁵, N. Carrier⁶, V. Boscart^{7,2}, 1. *Kinesiology, University of Waterloo, Schomberg, Ontario, Canada*, 2. *Research Institute for Aging, Waterloo, Ontario, Canada*, 3. *Simon Fraser University, Burnaby, British*

Columbia, Canada, 4. *University of Alberta, Edmonton, Alberta, Canada*, 5. *University of Manitoba, Winnipeg, Manitoba, Canada*, 6. *University of Moncton, Moncton, New Brunswick, Canada*, 7. *Conestoga College, Waterloo, Ontario, Canada*

The mealtime environment in long term care (LTC) may influence food intake of residents, and could improve food intake. Making the Most of Mealtimes (M3) is a cross-sectional, multi-site study with data collected from 82 dining rooms in 32 LTC homes in 4 Canadian provinces. The Mealtime Scan (MTS) was developed to quantify the overall dining atmosphere and includes items that assess the physical and social environments and person-centred care practices. MTS was completed 4–6 times in each dining room and average values used for analysis. Protein and energy intake of residents (n=639) was collected with non-consecutive weighed 3-day records. Units were stratified based on whether or not they specialised in dementia care. Regression analyses were used to identify MTS items adjusted for age, gender and cognitive status that predicted individual energy and protein intake ($p < 0.05$).

In dementia care units, number of residents eating alone was positively associated with energy intake; while meal length, number of residents eating alone, and person-directed care practices were negatively associated with protein intake in designated dementia units. In general units, none of the mealtime environment characteristics, as measured by the MTS, were associated with energy intake; protein intake was positively associated with number of persons in the dining room and negatively associated with person-directed care practices towards residents that required eating assistance. This analysis suggests that environmental features of designated dementia and general units differ in their association with residents' food intake. Strategies to support food intake should be tailored to the target population.

ASSOCIATION OF PSYCHOSOCIAL WORK STRESS WITH COGNITIVE DECLINE AND BRAIN STRUCTURE DIFFERENCES

K. Pan, W. Xu, G. Kalpouzos, L. Bäckman, F. Mangialasche, L. Fratiglioni, H. Wang, NVS, *Karolinska Institutet, Solna, Sweden*

Evidence on the influence of psychosocial work stress on cognitive function and brain structure is limited. This study examined whether work-related stress is associated with structural brain changes and cognitive decline in old age. In a population-based prospective cohort study, 2876 dementia-free participants aged ≥ 60 years were followed-up for up to 9 years. A subsample (n=436) underwent brain magnetic resonance imaging (MRI) at baseline. Global cognitive function was measured by the Mini-Mental State Examination at baseline and all follow-ups. Levels of job control and demands in the longest held job over the whole working life were assessed by a validated matrix. Data were analyzed using mixed-effects linear regression. People with low levels of job control and demands exhibited greater cognitive decline (β : -0.13, 95% CI: -0.19 to -0.07; β : -0.10, 95% CI: -0.16 to -0.04), compared to those with high levels. Relative to persons who had active job strain, faster cognitive decline was found in those who had high job strain (β : -0.11, 95% CI: -0.18 to -0.05,) and passive job strain (β : -0.16, 95%

CI: -0.23 to -0.09). MRI data showed that low levels of job demands and passive job strain were both related to smaller total hippocampal volume (β : -0.23, 95% CI: -0.39 to -0.08; β : -0.19, 95% CI: -0.37 to -0.01). Work-related psychosocial stress is associated with smaller hippocampal volume and may accelerate cognitive decline even in the eight decade of life, suggesting that neural alterations play a role in the work stress-cognitive decline link.

NEIGHBORING GREEN SPACE AND TRANSITIONS BETWEEN FRAILTY STATES AMONG CHINESE ELDERLY IN HONG KONG

D. WANG^{1,2}, K. Lau^{4,5}, R. Yu³, S. Wong², T. Kwok³, J. Woo^{1,3}, 1. *CUHK Jockey Club Institute of Ageing, The Chinese University of Hong Kong, Shatin, Hong Kong*, 2. *Jockey Club School of Public Health and Primary Care, Shatin, Hong Kong*, 3. *Department of Medicine & Therapeutics, The Chinese University of Hong Kong, Shatin, Hong Kong*, 4. *Institute of Future Cities, The Chinese University of Hong Kong, Shatin, Hong Kong*, 5. *Institute of Environment, Energy and Sustainability, The Chinese University of Hong Kong, Shatin, Hong Kong*

Frailty is a clinically recognizable and prevalent geriatric syndrome predicting adverse health outcomes for the elderly. Green space has been identified as a health-benefiting factor via multiple pathways. We explored the effects of green space on transitions in frailty states.

Three frailty phenotypes (robust, pre-frail, frail) for 3,355 community-based Chinese elderly (≥ 65 years) were identified at baseline (2001–2003) and at subsequent two-year follow-up (2003–2005), adopting the 5-item Fried Criteria (weight loss, exhaustion, low physical activity, muscle weakness, and slow walking speed). Two-year transitions in frailty states were determined as improved, stable, or deteriorated. With the Normalized Difference Vegetation Index assigned to pixels (15×15 m) within 600m buffered around each validated address, the percentage of green space was calculated as a continuous independent variable. Ordinal logistic regression models were used to estimate the effects of green space on transitions in frailty states, controlling for demographics, lifestyle, housing type, proximity to major roads, living height, and PM2.5 concentration.

During the two-year period, frailty status was identified as improved for 273 (8.1%) and deteriorated for 856 (25.5%) subjects. Mean coverage of green space within 600m buffer was 26.8%, with every 10% increase in green space, there was a significant decrease in the odds of deteriorated frailty state (OR 0.95, 95%CI 0.91–0.99; p -value=0.038), regardless of demographics, lifestyle, and other environmental characteristics.

Increasing coverage of neighboring green space could be an applicable approach in developing age-friendly environment in high density urbanized cities, therefore protecting the elderly from becoming frail and improving their individual independence and wellness.

THE BERG BALANCE SCALE AS A SCREENING TEST TO PREDICT FALLS IN OLDER ADULTS: A SYSTEMATIC REVIEW

C.A. Lima, M. Perracini, E. Nogueira, N. Ricci, *Universidade Cidade de São Paulo, São Paulo, Brazil*

Although the Berg Balance Scale (BBS) is widely used in daily practice, there is no consensus about its value to predict

falls. This systematic review aims to verify the BBS ability to predict fall risk in older adults through the analysis of prospective studies. Manual and electronic searches (Medline, EMBASE, CINAHL, Ageline, Lilacs, Web of Science, Cochrane and PEDro) were conducted without language restriction and with publication date after 1989 (BBS development year). We included prognostic studies with older people sample that evaluated the BBS (predictive factor) and the fall event in the last 6 or 12 months (outcome measurement). The studies methodological quality was assessed using the Quality In Prognosis Studies tool. We found 509 studies. This review included 8 studies from ten articles and they presented moderate to low risk of bias. Five studies had a 6 months follow-up period and 3 had a 12 months. The BBS average score for non-fallers was 49.4 and 52.5 points; and for fallers 44.5 and 51 points in 6 and 12 months, respectively. The BBS cut-off ranged from 45 to 51 points. Only in three studies the BBS score was able to discriminate fallers and non-fallers. It was not possible to define a BBS cut-off score due to studies lack of homogeneity, adequate sample size and absence of subgroup analysis. Evidence is insufficient to determine an adequate BBS cut-off score to predict falls in older adults. Ultimately, BBS should not be used as a prediction tool for falls in clinical practice.

PREVENTION OF ADVERSE DRUG REACTIONS IN HOSPITALIZED OLDER PATIENTS: PHYSICIAN VERSUS PHARMACIST

K. Dalton¹, D. O'Sullivan¹, M.N. O'Connor¹, S. Byrne¹, D. O'Mahony^{1,2}, 1. *University College Cork, Cork, Ireland*, 2. *Cork University Hospital, Cork, Ireland*

Potentially inappropriate prescribing (PIP) in the multimorbid elderly is a major healthcare problem. Explicit criteria such as Screening Tool of Older Persons' Prescriptions (STOPP) and Screening Tool to Alert to Right Treatment (START) are well recognized for identifying PIP instances, and the application of STOPP/START criteria has been shown to reduce adverse drug reactions (ADRs) in older people. Two randomized controlled trials were conducted in the same hospital whereby a pharmacist and physician individually applied the STOPP/START criteria to older patients' medication lists at hospital admission and made recommendations to the attending teams. All of the physician's recommendations were delivered in both oral and written forms. All of the pharmacist's recommendations were delivered in written form, and approximately one third communicated orally. Attending teams accepted 37.8% of the pharmacist's STOPP/START recommendations compared to 83.4% of the physician's STOPP/START recommendations. Whilst the physician's intervention focused solely on STOPP/START recommendations, the pharmacist's intervention was multifaceted - other than the pharmacist's STOPP/START recommendations, the remainder addressed medicines reconciliation, renal dose adjustment, and other prescribing criteria issues. With the same control cohort ($n=372$), the physician's intervention resulted in a significantly greater absolute risk reduction in ADRs than the pharmacist's (9.3% vs 6.8%) in comparable intervention cohorts (360 patients vs 361 patients). The greater acceptance rate for the physician's recommendations was attributed to having a narrower intervention focus, communicating the recommendations

in both oral and written form, and the physician having an already recognized prescribing role within the hospital.

SEASONAL CHANGES IN BLOOD PRESSURE AND SERUM ELECTROLYTES FOR OLDER PATIENTS WITH HOME MEDICAL CARE

E. Koujiya¹, M. Kabayama¹, K. Sakanoue¹, Y. Huang¹, M. Akiyama¹, M. Yamamoto¹, H. Rakugi², K. Kamide¹,
1. *Osaka University Graduate School of Medicine, Suita, Osaka, Japan*, 2. *Department of Geriatric Medicine and Nephrology, Osaka University Graduate School of Medicine, Suita, Osaka, Japan*

We investigated seasonal variations of blood pressure (BP) and serum electrolytes in order to obtain suggestions about future effective treatments or nursing care in old patients with home medical care. Study subjects were 78 patients age 65 years or older receiving home medical care participating in Osaka home medical care registry (OHCARE), a prospective cohort study. Two seasons data were collected in summer (1st June-31st August) and winter (1st December-28th February). The mean age of the subjects was 84.4(±8.6) and male was 37%. About 60% subjects in present study were very frailty or bedridden. Mean Systolic BP (SBP) and diastolic BP (DBP) was higher in winter than in summer (122.4±17/65.4±10 vs. 124.5±20/68.4±10mmHg) and there was statistically significant difference in DBP (p=0.007). Especially, high SBP group (SBP≥130mmHg) had greater changes both in SBP and DBP than low SBP group (SBP<130mmHg). About changes of serum electrolytes, sodium level was lower and potassium level was higher in summer than in winter. Patients who showed changed potassium level were 'Older' and had 'Lower renal function' than patients with unchanged potassium level. The present study revealed the seasonal changes in BP and serum electrolytes in old patients receiving home medical care. Doctors and visiting nurses should pay attention for these variabilities in patients with home medical cares.

ASSOCIATION OF VISITING NURSES' RESPONSE WITH CANCER PATIENTS' GOOD DEATH BY AWARENESS OF DYING TYPE

M. Akiyama^{1,2}, M. Kabayama¹, K. Kuyama², K. Kamide¹,
1. *Osaka University Graduate School of Medicine, Suita, Osaka, Japan*, 2. *School of Nursing, Mukogawa Women's University, Nishinomiya, Hyogo, Japan*

The Awareness of Dying (AOD) theory has been investigated worldwide; however, there are few studies investigate the association of good death (GD) with visiting nurses' response (VNR) based on the types of AOD. AOD is composed of closed-awareness (CA), suspected-awareness (SA), mutual-pretense-awareness (MPA), and open-awareness (OA). The aim of this study was to determine the association of VNR with GD in four types of AOD for end-stage home cancer patients.

We sent self-administered questionnaire to visiting nurses in order to assess their response with end-stage cancer patients and statistically analyzed with one-way ANOVA and t-test.

Participants' average age (N=386) was 46.8±7.6 years. The proportions of AOD type were OA (67.1%), CA (10.6%), SA (8.8%), and MPA (7.3%).

The GD score of OA was higher than SA (p=.01) and the CA was higher than the SA (p=.01). In dealing with information related to patient's death, the VNR score was higher for OA than for SA (p=.01). The higher VNR score was significantly associated with the higher GD scores.

The study findings suggest that the most frequent AOD is OA in Japanese home cancer care. For OA and CA, visiting nurses had more desirable responses and actively handled information on death compared to SA. When visiting nurses regard the patient's death as good, they took more desirable responses. This suggests that VNR may be involved in the association between AOD and GD. This is the first report on the association between AOD, VNR, and GD in end-stage cancer patients with home care.

SUPERNORMALS' OVER-TIME BRAIN MAP LINKS TO ALZHEIMER'S PATHOLOGY: A MULTIVARIATE PATTERN ANALYSIS

X. Wang², T. Baran¹, P. Ren¹, R.D. Raizada², F.V. Lin¹, 1. *University of Rochester Medical Center, Rochester, New York*, 2. *University of Rochester, Rochester, New York*

We recently investigated a cross-sectional relationship between the function of a selected set of brain regions and cognition in older adults with excellent memory capacity (a.k.a., Supernormals), and revealed that a unique brain map covering anterior and posterior regions in Supernormals protected their cognition from Alzheimer's disease (AD) pathology (Lin et al., 2017, Cortex). In the present study, we continued the validation of the longitudinal relationship between the brain map and cognition and AD pathology in Supernormals. We hypothesized that an over-time stable brain map involving anterior and posterior regions would differentiate Supernormals from their cognitively normal or abnormal counterparts, and such a brain map would link to AD pathology. Here, we identified 22 Supernormals, 25 with normal cognition (NC), 70 with amnesic mild cognitive impairment (MCI) and 28 with AD. Multivariate pattern based searchlight analysis of resting-state functional MRI data was applied to identify brain regions with constantly high discriminative powers between Supernormals and NC over 2 years. The regions included right cerebellum, left middle temporal gyrus, right middle frontal gyrus, right precuneus, right precentral gyrus. The brain map composed by these regions predicted multiple cognitive assessments and their longitudinal changes with 51% to 82% accuracy, discriminated NC, MCI and AD at 62% to 78%, and predicted beta-amyloid/pTau at 71%. Our findings suggest that applying searchlight analysis with longitudinal resting-state imaging data from Supernormals construct a brain map that sheds lights on understanding Alzheimer's disease associated neurodegeneration.

EFFECTS OF REALLOCATING TIME IN SEDENTARY BEHAVIOR WITH PHYSICAL ACTIVITIES ON SLEEP IN ELDERLY

J. Seol¹, Y. Fujii¹, T. Abe^{1,2}, K. Joho¹, T. Okura¹, 1. *Comprehensive Human Sciences, University of Tsukuba, Tsukuba, Ibaraki, Japan*, 2. *Japan Society for the promotion of Science, Tokyo, Japan*

Previous studies showed that sedentary behavior (SB) and physical activity (PA) are linked to sleep. Recent research

suggested that an isotemporal substitution (IS) model enables an estimate of the effect of displacing one activity by an equivalent amount of time in another activity. However, it is unclear how the reallocation of time from one activity to another affects sleep outcomes.

This study aimed to examine the effects of reallocating time to SB and various intensities of PA on objective sleep parameters in older adults. The participants were seventy-six community-dwelling older Japanese adults (70.9 ± 4.5 yrs). We measured SB, intensity of PA (light-intensity PA (LPA), moderate-to-vigorous PA (MVPA)), and objective sleep parameters using ActiGraph accelerometry for a week. In this study, SB, LPA, and MVPA were 316.2 ± 175.3 , 517.9 ± 78.7 , and 23.3 ± 12.0 min, respectively. After adjusting confounding factors, the IS models showed that replacing one hour of SB with LPA was favorably associated with sleep efficiency ($\beta = 1.155$; 95% confidence interval (CI), 0.234, 2.075) and wake after sleep onset ($\beta = -0.114$; 95% CI, -0.187, -0.040). Replacing one hour of MVPA with LPA was favorably associated with sleep efficiency ($\beta = -7.405$; 95% CI, -13.417, -1.394) and wake after sleep onset ($\beta = 0.488$; 95% CI, 0.006, 0.970).

Substituting time spent in SB and MVPA with LPA may be beneficial to sleep in older people.

PHYSICAL RESTRAINT REDUCTION IN LONG-TERM CARE: IMPLEMENTATION OF A GUIDELINE-BASED PROGRAM

A. Rahn¹, A. Buhl², A. Behncke³, S. Koepke³, 1. *University of Hamburg, Unit of Health Sciences and Education, Hamburg, Hamburg, Germany*, 2. *Workers Welfare Association, Kiel, Schleswig-Holstein, Germany*, 3. *University of Lübeck, Institute of Social Medicine and Epidemiology, Nursing Research Unit, Lübeck, Schleswig-Holstein, Germany*

Despite evidence on unintended consequences, physical restraints continue to be part of standard care. We implemented a successfully tested guideline-based multicomponent program on physical restraints reduction into routine long-term care.

We performed a before-after study in home care services and nursing homes of one health care provider in northern Germany. The intervention, originally developed for nursing homes, was adapted for use in home care.

Four one-day nurse training courses were conducted. Participating facilities received the evidence-based guideline, associated materials and structured telephone counselling. Prior to the first training and after one year, the percentage of care recipients with at least one physical restraint was assessed by direct observation.

Nine home care facilities and 15 nursing homes with 1,490 care recipients took part in the study and 34 nurses were trained. In nursing homes, the number of residents with physical restraints was reduced from 11.1% to 5.7% (reduction 5.4%, 95%CI: 2.1–8.6, $p=0.001$).

In home care, the number was reduced from 6.1% to 3.8% (reduction 2.3%, 95%CI: 0.4–4.3, $p=0.021$).

In conclusion, the guideline-based program was successfully adapted and implemented for the needs of home care services and nursing homes of one large care provider in Germany. However, not all services could be equally reached

by the intervention. Regular training and updates are necessary for permanent implementation.

BRIDGING BARRIERS: CHINESE AMERICAN SENIORS' END-OF-LIFE DECISION-MAKING

T. Dzou, A.A. Guzman, S. Balcha, J.C. Menten, H. Pieters, *University of California, Los Angeles, Los Angeles, California*

In the United States (US), the underutilization of hospice resources by Asian Americans is evident in the low rates of hospice enrollment, 2.4%, where they comprise 5.6% of the US population. The low utilization of end-of-life (EOL) services has been associated with increased deaths in hospitals and increased costs to Medicare, revealing a significant health disparity within the Asian American community.

Chinese Americans represent the largest subgroup of Asian Americans with a population of 4.5 million in the US. Seminal studies on Chinese American Seniors EOL have accentuated the taboo nature of the topic, and recommended health care professionals to prevaricate EOL discussions to promote cultural sensitivity. In contrast, recent findings in literature suggests Chinese American Seniors' lack of knowledge as a main contributor to the underutilization of EOL resources. A pilot study using semi-structured interviews was conducted to understand the preferences and EOL decision-making processes of Chinese American Seniors. Using Constructivist Grounded Theory methodology, data from the interviews was analyzed in an iterative process to reveal the emergent themes of trust / distrust towards health care professionals and health care systems, the role of religion in decision-making, and protecting the family. Synthesis of the findings reveal the role of health care professionals in bridging barriers to EOL decision-making among Chinese American Seniors.

A QUALITATIVE SYSTEMATIC REVIEW EXPLORING ROLES, RISKS, AND SOCIAL PATTERNS OF DRINKING IN LATER LIFE

B.K. Bareham, E. Kaner, L.P. Spencer, B. Hanratty, *Institute of Health and Society, Newcastle University, Newcastle upon Tyne, United Kingdom*

Older adults may be at risk from even moderate levels of drinking, due to conditions and medications that are problematic when combined with alcohol. Current cohorts of older adults may have consumed alcohol regularly through most of their adult life. This represents additional risk of chronic disease linked to their drinking. Alcohol policy and practice has therefore turned to focus on this older group. However, in combatting alcohol use amongst older adults, we must first consider the roles of alcohol in their lives. This recently completed systematic review synthesises qualitative research evidence on older adults' perceptions of non-dependent drinking in later life. Medline, PsychINFO, Scopus, ASSIA and CINAHL databases were systematically searched for relevant articles. The principles of thematic analysis were applied to synthesise findings. Twenty-four studies were identified from ten different countries, including the USA, Canada and the UK. Four key themes were: i) Routines and Rituals, ii) Self-image as a Responsible Drinker, iii) Alcohol and the Ageing Body, iv) Access to Alcohol. Differences in roles and patterns of drinking between genders

and age groups, across cultures and socioeconomic status, are explored. Drinking creates social and leisure opportunities, which may have depleted due to retirement and other factors in later life. Health concerns and issues surrounding purchasing alcohol or getting to drinking settings are important considerations for older drinkers. These roles and practicalities are contrasted against those identified for younger age groups in other qualitative studies. Recommendations for alcohol-related policy and practice are presented given these findings.

COMBINED LOW MUSCLE MASS AND STRENGTH AFFECT MOBILITY LIMITATION IN THE ELDERLY: A 4-YEAR FOLLOW-UP

M. Kim¹, T. Abe¹, T. Jindo², S. Shen¹, A. Sato¹, K. Fujii¹, T. Okura¹, 1. *University of Tsukuba, Tsukuba, Ibaraki, Japan*, 2. *Physical Fitness Research Institute, Meiji Yasuda Life Foundation of Health and Welfare, Tokyo, Tokyo, Japan*

The study aimed to investigate which combined muscle mass and strength among four different combinations might be a risk factor for mobility limitation and falls in older adults. A total of 284 older adults participated in this study from baseline until the 4-year follow-up. We assessed the appendicular skeletal muscle mass index (AMI) using bioelectric impedance analysis. Additionally, the appendicular strength Z-score (ASZ) based on the hand-grip strength for the upper extremity and peak reaction force during sit-to-stand movement for the lower extremity were measured at baseline. The participants were classified into 4-group according to their AMI and ASZ score: Low AMI and Low ASZ; Low AMI; Low ASZ; and Normal. Mobility limitation and falls were assessed by a self-reported questionnaire at baseline and during follow-up. We used a Cox regression analysis with an adjustment for sex, age, body mass index, knee pain, and back pain. Among participants with no mobility limitation at baseline, the hazard ratio of any new mobility limitation was 5.54 (95% CI 2.24–13.69) in Low AMI and Low ASZ compared with Normal. As for participants with no falls at baseline, the hazard ratio of any new incident falls was 4.01 (95% CI 1.83–8.82) in Low AMI and Low ASZ, 2.05 (95% CI 1.11–3.77) in Low ASZ compared with Normal. These results suggest that the type of combined low muscle mass and low strength is an important risk factor for mobility limitation and falls. Moreover, low strength alone may independently predict incident falls in older adults.

ASSESSMENT OF HEALTH-PROMOTING BEHAVIORS BEFORE AND AFTER AN ALZHEIMER'S PREVENTION PROGRAM

A. Laffer¹, R. Sandoval², E. Blocker², E. Vidoni², A. Watts¹, J. Burns², D.K. Sullivan², 1. *University of Kansas, Lawrence, Kansas*, 2. *University of Kansas Medical Center, Fairway, Kansas*

With the rapidly aging population and associated increased risk of Alzheimer's disease (AD), interventions aimed at preventing AD are crucial. We investigated whether older adults would benefit from empirically supported psychoeducation targeting strategies to prevent or delay AD. Twenty-seven older adults (Mean age (SD) = 81.93(5.68)),

completed a six-month group psychoeducation program created by the University of Kansas Alzheimer's Disease Center. Twelve sessions occurred twice monthly in a local retirement community, led by an interprofessional team with expertise in AD prevention. Sessions focused on modifiable risk factors for AD (i.e., physical activity, nutrition, sleep, stress). We used paired t-tests to measure changes in Health Promoting Lifestyle Profile subscale scores (nutrition, physical activity, spiritual growth, and stress management) from pre-intervention to post-intervention. There was statistically significant improvement in stress management ($p = .004$). There were no differences on nutrition or physical activity subscales. There was a trend toward significance for spiritual growth ($p = .059$), though our study was underpowered due to small sample size. Average physical activity scores were lowest across the subscales. Our group-based psychoeducation program targeting promotion of healthy lifestyle behaviors resulted in improved self-reported stress management. This is an important outcome for an older adult population seeking to be proactive about their brain health. Future research will explore how this stress reduction may occur (e.g., reduced helplessness, internal locus of control). The average lower scores on physical activity compared with other subscale scores suggest that strategies aimed at increasing physical activity show the greatest room for improvement.

A MEDIATIONAL MODEL OF STRESS IN HIPPOCAMPAL NETWORKS IN MILD COGNITIVE IMPAIRMENT

K. McDermott, F.V. Lin, P. Ren, *School of Nursing, University of Rochester, Rochester, New York*

The hippocampus regulates learning and memory formation and storage, while also playing a significant role in regulating the Hypothalamic-Pituitary-Adrenal axis and stress responses. AD-associated neurodegeneration is known to affect all of these aspects. However, it's still unclear how different types of stress (chronic vs. acute) mediate the hippocampal regulation of learning and memory, especially in AD associated neurodegeneration. The present study combined neuropsychological testing, resting state functional MRI, structural MRI, acute stress tests, and self-report chronic stress questionnaires to compare MCI subjects ($n = 18$) to their age-, sex-, and education-matched healthy controls (HC, $n = 21$). The MCI group had significantly smaller right hippocampal grey matter volumes ($t = 2.50$, $df = 30$, $p = .018$) than the HC group. The connectivity between the right hippocampus and the inferior frontal gyrus (Rhipp-IFG) was significantly positively related to both acute and chronic stress for the entire sample. After testing our mediation model for the two groups separately, we found that acute and chronic stress showed significant mediating effects in the association between Rhipp-IFG and learning (before adding mediators: $t = -2.56$, $p = .022$; when including mediators: $t = 0.21$, $p = .84$) in the HC group, but not in the MCI group. This suggests that chronic and acute stress act as mediators for the right hippocampus-involved neural network for learning and memory, and this mediating effect may be disrupted in the AD-associated neurodegeneration process.

COGNITIVE STATUS, CO-MORBID CONDITIONS, AND UNPLANNED READMISSIONS IN OLDER SURGICAL PATIENTS

M. Gehring¹, E.A. Burns¹, G. Telford¹, J. Whittle¹, L. Copeland³, M. Morris⁴, M. Hawn², 1. *Medical College of Wisconsin, Milwaukee, Wisconsin*, 2. *Stanford University School of Medicine, Stanford, California*, 3. *VA Central Western Massachusetts Healthcare System, Leeds, Massachusetts*, 4. *University of Alabama at Birmingham School of Medicine, Birmingham, Alabama*

Unplanned hospital readmissions are associated with poor patient outcomes and incur increased resource utilization and costs. Cognitive impairment, greater burden of comorbidity, and increased age are associated with unplanned hospital readmissions of medicine patients, but are not well-studied among surgical patients. To-date a cohort of 331 patients undergoing elective gastrointestinal, thoracic or vascular surgery, have been enrolled in a prospective longitudinal study at three VA Medical Centers. Patients were interviewed on day of discharge, and administered the Short Blessed Test to screen for cognitive dysfunction. Length of stay and 30-day readmissions were determined via chart review, and a Charlson Comorbidity Index (CCI) score calculated for 62 patients. 146 underwent abdominal/colorectal or hernia repair, 123 vascular, 62 thoracic procedures. Mean age was 65.8 + 9.9 years, and length of stay (LOS) 6.3 + 4.4 days; neither was significantly different by surgery ($F=3.20$, $p=0.15$). Age was positively associated with CCI (i.e. higher risk of mortality; $r=-0.68$, $p<.0001$), with worse SBT and LOS ($z=15.77$, $p<.0001$). There were 52 unplanned readmissions (15.7%), with readmitted patients being older (66.4 vs. 65.6 years, $p<.0001$), having worse scores on the SBT ($F=6.16$, $p<.003$), and higher CCI ($F=4.27$, $p<.02$) after controlling for type of surgery. In older adults, greater comorbid burden and cognitive impairment may confer a risk for unplanned surgical readmission similar to that seen for medical readmissions.

VALIDATION OF A SCREENING TOOL (GERIATRIC-CHECK) FOR GERIATRIC PATIENTS

M.A. Hobert^{1,2}, F.P. Bernhard², J. Sartor², K. Bettecken², W. Maetzler^{2,1}, M. Jamour³, 1. *Department of Neurology, Christian-Albrechts-University of Kiel, Kiel, Germany*, 2. *Center for Neurology and Hertie Institute for Clinical Brain Research, Department of Neurodegeneration, University of Tuebingen, Tuebingen, Germany*, 3. *Geriatric Rehabilitation Clinic of Ehingen (Krankenhaus GmbH Alb-Donau district), Ehingen, Germany*

Introduction: The Geriatric-Check is a short screening tool to identify geriatric patients. According to recent recommendations from the Baden-Württemberg Hospital Association, the test should be performed in all patients aged 70 and older who are referred to a hospital. It consists of two parts. If part A is positive, the patient is identified as a probable geriatric patient. Part A assesses age, care level, presence of dementia and whether the person is living in a nursing residency. Part B is performed in case part A is negative. Part B covers the domains mobility, autonomy, cognition, depression, and hospital stays during the last year. Although regularly used in German hospitals, this test has to our best knowledge not yet been validated.

Methods: We included 107 inpatients of the Neurological Department of the University of Tuebingen, aged 70 and older in a cross-sectional study. We performed part A and B of the test in all patients and compared the results with a comprehensive geriatric assessment.

Results: Twenty-three patients (22%) showed a positive part A. Twenty of these patients (87%) also showed a positive part B. Compared with the patients without positive results, patients with positive results in both parts of the Geriatric-Check were older, had lower gait speed and grip force, and had greater fear of falling.

Conclusion: This analysis shows that the results of the Geriatric-Check are in concordance with the results of the comprehensive geriatric assessment. It can thus be considered as a useful screening tool for the identification of geriatric patients.

EFFECTIVENESS OF MOTOR SKILL OF WALKING GROUP EXERCISE IN OLDER ADULTS: A CLUSTER RANDOMIZED TRIAL

J. Brach¹, S. Perera¹, J.M. Van Swearingen¹, S. Gilmore², N. Nadkarni¹, E. Ricci¹, D. Brodine², 1. *University of Pittsburgh, Pittsburgh, Pennsylvania*, 2. *University of Pittsburgh Medical Center, Pittsburgh, Pennsylvania*

Many standard group exercise programs emphasize muscle strengthening, flexibility and general conditioning because of the association of such impairments with walking difficulties, but do not emphasize the ability to walk or the timing and coordination of movement that is critical to walking. We developed a group exercise program that includes timing and coordination exercises for walking called On the Move (OTM). In a single blind cluster-randomized trial, we evaluated the effectiveness of OTM and standard group programs to improve mobility, function and disability in 32 independent living facilities, community centers and senior apartment buildings. Programs were 1 hour, twice weekly for 12 weeks and ≤ 10 participants per class. OTM consisted of warm-up, timing and coordination (stepping and walking patterns), strengthening and stretching exercises. The standard program consisted of warm-up, aerobic, strengthening and stretching exercises. 298 participants (mean age 80.0 ± 8.1 years) were randomized, and groups were not significantly different at baseline. Despite a lower rate of attending 80+% of classes (50% vs 65%; $p=0.0324$), OTM elicited greater gains than the standard program in gait speed (0.05 m/s; $p=0.0022$) and 6-minute walk distance (16.7 m; $p=0.0344$), but not in function and disability (Late Life Function/Disability Index). Exploratory subgroup analyses suggest those with better mobility at baseline (gait speed > 0.8 m/s and 6-minute distance farther than 300m) may elicit greater benefits from OTM than the standard program. A group exercise program that addresses the motor skill of walking is more effective than a standard strength and conditioning program in improving mobility.

ASSOCIATIONS OF QUADRICEPS TORQUE PROPERTIES WITH MUSCLE SIZE AND ADIPOSITY IN OLDER ADULTS

A. Frank-Wilson^{2,1}, D. Chalhoub^{2,1}, P. Figueiredo^{2,1}, P.V. Jonsson³, V. Gudnason⁴, L.J. Launer^{2,1}, T. Harris^{2,1}, 1. *National Institutes of Health - National Institute on Aging*,

Bethesda, Maryland, 2. Laboratory for Epidemiology and Population Sciences, Bethesda, Maryland, 3. University of Iceland, Reykjavik, Iceland, 4. Icelandic Heart Association Research Institute, Reykjavik, Iceland

Atrophy and fatty infiltration of muscle with aging is associated with fractures and fall-related health outcomes. This study examined the association between CT-derived quadriceps muscle measures and function in a population-based cohort of older adults. It was hypothesized that participants with lower muscle attenuation (HU), area, and greater intra-muscular adipose tissue (%IMAT) will exhibit both slower rates of torque development (RTD) and lower peak knee torques. Participants (N=4863 [2060:2803 male:female]) from the Age Gene/Environment Susceptibility Reykjavik Study with a mean age of 76 ± 0.1 y had complete imaging and isometric torque knee testing. Linear regression models were adjusted for 16 covariates related to muscle size and function, health, behavior & comorbidities. After adjustment for covariates, the knee RTD was independently associated with HU (men $\beta=0.06$, 95% CI [0.01, 0.11]; and women $\beta=0.06$, 95% CI [0.02, 0.10]); as well as muscle area (men $\beta=0.14$, 95% CI [0.08, 0.20]; women $\beta=0.1$, 95% CI [0.06, 0.15]). Additionally, peak torque was independently associated with HU (men $\beta=0.11$, 95% CI [0.07, 0.15]; and women $\beta=0.12$, 95% CI [0.09, 0.16]); as well as muscle area (men $\beta=0.38$, 95% CI [0.34, 0.43]; women $\beta=0.33$, 95% CI [0.29, 0.37]). With the exception of RTD in women ($\beta=-0.06$, 95% CI [-0.10, -0.02]), and peak torque in men ($\beta=-0.05$, 95% CI [-0.09, -0.01]), %IMAT was not associated with function after adjusting for muscle HU and area. These novel results suggest that muscle HU is associated with the RTD independent of muscle area, further elucidating a potential pathway underpinning previously described relationships of muscle HU with falls, fractures, and poor balance.

MULTI-LEVEL DETERMINANTS OF LONG-TERM CARE RESIDENT ENERGY INTAKE: MAKING THE MOST OF MEALTIMES

H.H. Keller^{1,2}, S. Slaughter³, N. Carrier⁴, C.O. Lengyel⁵, J.M. Morrison¹, L. Duizer⁶, C. Steele^{7,8}, 1. *Kinesiology, University of Waterloo, Waterloo, Ontario, Canada*, 2. *Schlegel-University of Waterloo Research Institute for Aging, Waterloo, Ontario, Canada*, 3. *University of Alberta, Edmonton, Alberta, Canada*, 4. *Universite de Moncton, Moncton, New Brunswick, Canada*, 5. *University of Manitoba, Winnipeg, Manitoba, Canada*, 6. *University of Guelph, Guelph, Ontario, Canada*, 7. *University Health Network, Toronto, Ontario, Canada*, 8. *University of Toronto, Toronto, Ontario, Canada*

The Making the Most of Mealtimes (M3) prevalence study collected data from a representative Canadian sample of residents (n=639), staff (n=461), dining rooms (n=82), and homes (n=32). Three non-consecutive days of weighed and estimated food intake was used to determine energy intake. Mealtime and dining room observations, home management and staff questionnaires, health records, and physical assessments were collected by research staff. Mini-Nutritional Assessment-SF was used to determine nutritional risk. The Edinburgh-Feeding Questionnaire (Ed-FED) was used to identify eating challenges and eating independence. Dining environments were assessed for physical features using the

Dining Environment Audit Protocol and a derived homelikeness summary score. The Mealtime Scan was used to record mealtime experience and ambiance, and three summative scores were derived on physical, social and person-centered practices. Hierarchical multivariate regression determined predictors of energy intake. Mean age of participants was 86.6 ± 7.8 years and 31% were male. Mean energy intake was 1571.9 ± 411.9 kcal. Age, more eating challenges, requiring some eating assistance, and homelikeness scores were negatively associated ($p < 0.05$) with energy intake. Male gender, MNA-SF, often requiring eating assistance, being on a dementia unit and a more person-centred meal environment were positively ($p < 0.05$) associated with energy intake. There was also a significant interaction ($p < 0.05$) between being prescribed a pureed/liquidized diet and requiring eating assistance. These findings indicate that interventions focused on pureed food, restorative dining, eating assistance and person-centered care practices may improve food intake and should be targets for further research. (Funded by Canadian Institutes of Health Research)

EFFECT OF AGING AND GLUCAGON-LIKE PEPTIDE 2 ON INTESTINAL MICROBIOTA IN SD RATS

J. Wu, *Department of Geriatrics, Zhongshan Hospital, Fudan University, Shanghai, China*

Objective: To study the influence of aging and GLP-2 on intestinal microbiota in rats. Methods: Twelve 3 months old male SD rats were randomly divided into two groups: group C and group G. Twelve 26 months old male SD rats were randomly divided into two groups: group L and group T. GLP-2 was intraperitoneally injected into rats from group G and group T for 14 days. The fecal bacterial compositions were investigated by Miseq high-throughput sequencing. Results: Diversity of intestinal microbiota in group L was lower than that in group C. There was no obvious difference about the diversity of intestinal microbiota between group C and group G, group L and group T. At the phylum level, the relative abundance of Bacteroidetes, Firmicutes and Proteobacteria were higher in all rats. There was no obvious difference about the relative abundance at the phylum level except Spirochaetae. At the genus level, the relative abundance of Allobaculum and Bifidobacterium in group L was lower. The relative abundance of Anaerovibrio, Thalassospira, Streptococcus and Treponema in group L was higher. The relative abundance of Desulfovibrio, Intestinimonas and Oscillibacter in group G was higher. The relative abundance of Parasutterella, Prevotella and Psychrobacter in group G was lower. Conclusions: Aging significantly decreases the diversity of intestinal microbiota in SD rats, while GLP-2 has no significant effect. Aging reduces the probiotic bacteria, increases pathogenic bacteria of rats. GLP-2 increases parts of probiotic bacteria, reduces parts of pathogenic bacteria in young rats.

FUNCTIONAL ABILITIES AND GOALS IN POST-ACUTE CARE: AN EARLY LOOK AT STANDARDIZED ASSESSMENT DATA

L.A. Palmer¹, A. Deutsch¹, T. McMullen², A. Levitt², S. Mandl², T. Le¹, M. Toth¹, T. Mota², 1. *RTI International, Raleigh, North Carolina*, 2. *Centers for Medicare & Medicaid Services, Baltimore, Maryland*

Functional status is tied to important health outcomes, yet the collection of functional status data has not been standardized across post-acute care (PAC). The IMPACT Act of 2014 required the submission of standardized assessment data by PAC providers, including data related to function. Previously, functional assessment data collected in skilled nursing facilities (SNFs), inpatient rehabilitation facilities (IRFs), and long-term care hospitals (LTCHs) consisted of different assessment instruments, scales, and items. Standardization of functional data across PAC settings has the potential to improve care coordination. We present a preliminary review of recently implemented standardized self-care and mobility data by examining the cross-setting quality measure, Application of Percent of Long-Term Care Hospital (LTCH) Patients with an Admission and Discharge Functional Assessment and a Care Plan That Addresses Function.

We analyzed the first quarter of assessment data available for all three PAC settings (October – December, 2016). Data sources with these standardized data elements include the Minimum Data Set, IRF-PAI, and LTCH CARE Data Set. We examined the reporting of patient and resident functional abilities and goals across PAC settings. For example, among 404 LTCH facilities, the average hospital completed an admission and discharge functional assessment and assigned at least one discharge goal for 95.5% of patients. Results were slightly higher for the average IRF facility (98.7%, $n=1,105$). Analysis of the SNF setting data as well as within setting variability by geographic regions, urbanicity, ownership, and number of discharges will also be presented. Policy implications of these findings will be discussed.

ASSOCIATION BETWEEN PERCEIVED SOCIAL SUPPORT AND DEPRESSIVE SYMPTOMS AMONG OLDER CHINESE AMERICANS

Y. Chao¹, N. Zhang², X. Dong³, 1. *Rutgers, the State University of New Jersey, Somerset, New Jersey*, 2. *Seton Hall University, Newark, New Jersey*, 3. *Rush Institute for Healthy Aging, Rush University Medical Center, Chicago, Illinois*

Purpose: Depressive symptoms are common among older immigrants. Social support is an important factor that can relieve the stress due to the process of acculturation. This study was to examine the association between social support and depressive symptoms among U.S. Chinese older adults.

Methods: Data were from the Population Study of Chinese Elderly in Chicago (PINE) study. Independent variables were positive social support and negative social support. Dependent variable was depressive symptoms. Logistic regression analyses were performed.

Results: A total of participants were 3,157 Chinese older adults with the mean age of 72.8 years (range 60–105). After controlling for age, gender, income, marital status, the number of children, and the number of medical comorbidities, higher positive social support was associated with fewer depressive symptoms (mild vs. minimum odds ratio [OR] = 0.88, 95% confidence interval [CI]: 0.85–0.92; moderate-severe vs minimum OR = 0.82, 95% CI: 0.79–0.86). In contrast, higher negative social support was associated with more depressive symptoms (mild vs. minimum OR = 1.34, 95% CI: 1.24–1.46; moderate-severe vs minimum OR = 1.38, 95% CI: 1.26–1.52).

IAAG 2017 World Congress

Conclusion: Future prevention and intervention programs should incorporate valuable cultural insight to improve mental health among older Chinese immigrants. In addition to enhancing family and spousal support, the negative interactions (e.g. abuse, demands, and criticism) should be avoided to alleviate the severity of depressive symptoms.

GLYCEMIC CONTROL AND CLINICAL OUTCOMES IN INSTITUTIONALIZED DIABETIC OLDER ADULTS

C. Shum, K. Leung, Y. Kwan, C. Mok, *Department of Medicine and Geriatrics, Tuen Mun Hospital, Hong Kong, Hong Kong*

In institutionalized diabetic older adults, the harms of intensive glycemic control may outweigh the benefits. However, evidence-based data are lacking.

A retrospective cohort of older adults (age ≥ 65 years) with diabetes mellitus living in nursing homes with HbA1c measurements were identified. They were divided into groups according to their HbA1c: $<7.0\%$, $7.0\text{--}8.4\%$, $8.5\text{--}9.9\%$ and $\geq 10.0\%$. Baseline characteristics included demographics, clinical, functional and laboratory parameters and study outcomes (mortality and hospitalizations) were evaluated.

376 institutionalized diabetic older adults (mean age 81.6 ± 6.7 years) were included. The majority had multiple comorbidities (Charlson Comorbidity Index 4.7 ± 2.1) and functional limitations (70.8% with impaired mobility). The lowest 1-year mortality and hospitalization rate were found in the group with HbA1c $8.5\text{--}9.9\%$. Multivariate analyses showed that there were J-shaped associations between HbA1c and hazard ratio for mortality and between HbA1c and odds ratio of recurrent hospitalization with best outcomes in those with HbA1c $8.5\text{--}9.9\%$. Advanced age, presence of stage 5 chronic kidney disease and peripheral vascular disease, impaired mobility, polypharmacy and lower albumin level were independent predictors of mortality. Among those with intensive glycemic control (HbA1c $<7.0\%$), 55.9% received glucose-lowering therapy with high hypoglycemia risk (sulfonylurea and/or insulin).

Institutionalized diabetic older adults with HbA1c $8.5\text{--}9.9\%$ had the lowest 1-year mortality and hospitalization rate. This may provide a reference for the recommended HbA1c in this population. Comprehensive geriatric assessment can prognosticate clinical outcomes in this population. Our findings suggested that a substantial proportion of this population was potentially over-treated and de-intensification of drug treatment should be considered.

CAN PROTEIN AND VITAMIN D ENHANCE THE COGNITIVE BENEFITS OF RESISTANCE TRAINING IN TYPE 2 DIABETICS?

H. Macpherson¹, E.G. Miller¹, D.W. Dunstan², C. Nowson¹, D. Kerr³, D. Menzies⁴, R.M. Daly¹, 1. *Deakin University, Melbourne, Victoria, Australia*, 2. *Baker IDI, Melbourne, Victoria, Australia*, 3. *Curtin University, Perth, Western Australia, Australia*, 4. *South Eastern Melbourne Primary Health Network, Melbourne, Victoria, Australia*

Type 2 Diabetes (T2DM) is associated with an increased risk of cognitive impairment. Exercise and nutrition are the cornerstone of T2DM management and can improve cognition, but whether they produce additive benefits remains unknown. This 24-week RCT examined whether protein-vitamin D supplementation could enhance the effects of

progressive resistance training (RT) on cognition in adults aged 50–75 with T2DM. All participants (n=198) were prescribed RT and randomized to receive a whey-protein drink (20 g/d before breakfast plus 20 g/d after RT) plus vitamin D (2000 IU/d) (RT+ProD, n=98), or no additional powder/supplements (RT, n=100). Cognition was assessed at baseline, 12 and 24 weeks using three composite z-score measures [global cognitive function; working memory/learning (WML), attention/psychomotor function] from the Cogstate computerised battery. All results were adjusted for age, gender, education and diabetes duration. Overall 177 (89%) and 168 (85%) completed the 12- and 24-week assessment. Exercise compliance was 68% in RT+ProD and 58% in RT (P<0.05). Mean compliance with the whey-protein and vitamin D supplements was 79% and 92%, respectively. For global cognitive function, both groups experienced similar significant improvements after 24-weeks (0.17–0.19 SD, P<0.001). For WML, there was a 0.19 SD greater improvement in RT+ProD versus RT after 12-weeks (P<0.05), but by week 24 both groups displayed a similar significant improvement (0.22–0.24 SD, P<0.01). Attention/psychomotor scores did not change in either group. In conclusion, protein-vitamin D supplementation initially enhanced the effects of exercise on working memory/learning in older people with T2DM, but does not appear to provide additional long-term benefits.

BMI, INFLAMMATION, AND PHYSICAL FATIGABILITY IN OLD AGE: SHARED OR INDEPENDENT PATHWAYS?

R. Cooper¹, M. Popham¹, A.J. Santanasto², N.W. Glynn², D. Kuh¹, 1. *MRC Unit for Lifelong Health and Ageing at UCL, London, United Kingdom*, 2. *University of Pittsburgh, Pittsburgh, Pennsylvania*

Physical fatigability, the level of fatigue experienced while undertaking specified physical tasks, increases with age. These age-related changes, which reflect reductions in energy availability, precipitate declines in function and activity participation. Cross-sectional analyses suggest that obesity and inflammation may be modifiable risk factors for fatigability which require further investigation in longitudinal studies. Using data on 2095 participants from the MRC National Survey of Health and Development, a nationally representative British birth cohort, we aimed to assess whether body mass index (BMI) and inflammatory markers were associated with physical fatigability and, if so, whether these act on shared pathways. Linear regression models were used to relate BMI from age 36 and inflammatory markers (C-reactive protein (CRP) and interleukin-6 (IL-6)) at age 60–64 to physical fatigability scores on the Pittsburgh Fatigability Scale (PFS) at age 68. Women had higher mean PFS scores than men (16.0 (SD=9.3) vs 13.4 (SD=9.0), p<0.01), with higher scores indicating greater perceived physical fatigability. In sex-adjusted analyses, higher BMI across adulthood and higher levels of CRP and IL-6 were associated with higher PFS scores. For example, participants with BMI ≥30 kg/m² at age 36 had a sex-adjusted mean PFS score 6.1 (95% CI: 3.9–8.2) points higher than those with BMI 20–24.9 kg/m². When these associations were mutually adjusted, BMI and IL6 remained associated with PFS scores, whereas associations with CRP were fully attenuated. These findings highlight that BMI and inflammatory markers earlier in adulthood are associated

with physical fatigability in old age and act on both shared and independent pathways.

THE EFFICACY OF A FALLS CLINIC FOR ELDERLY AND THE ADDED ROLE OF THE TILT TABLE TEST

A. Rabinovich^{1,2}, N. Vislapu¹, I. Rasooly^{1,3}, Y. Lerman^{1,2}, 1. *Geriatrics, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel*, 2. *Tel Aviv University, Tel Aviv, Israel*, 3. *Israel Ministry of Health, Geriatric Division., Jerusalem, Israel*

Background: Many geriatric centers include special fall clinics for evaluating elderly patients who fall in an attempt to prevent such events that pose a threat to patients' independence. Few studies have assessed the added value of the Head-Up Tilt Table (HUTT) test in the elderly.

Objective: In a fall clinic we evaluated the impact of HUTT test and the efficacy of structured instructions to patients.

Methods: This descriptive comparative study included 150 consecutive patients presenting with falls due to dizziness or suspected syncope. All participants underwent a comprehensive evaluation and were referred to HUTT test. Seventy-five underwent the test and the other 75 who did not comprised the comparison group. Each participant received personal guidance to prevent falls. Clinical data, including HUTT results, were collected retrospectively from patients' files. A follow-up telephone interview was conducted 6 months later.

Results: The two groups were similar in gender, number of falls, medical history, motor FIM score and number of medications. Those in the HUTT test group were 6 years younger (average). The response rate to the follow-up telephone survey was 87.3%, and 75.6% of responders were the patients themselves. There was good adherence to the fall clinic's recommendations and a significant decrease in dizziness. Syncope, fall rates and hospitalizations due to falls. These findings did not differ between the study groups nor according to HUTT results.

Conclusion: Our study demonstrates the impact of comprehensive evaluation and structured instructions in a specialized fall clinic for elderly patients, beyond a single diagnostic test.

FACTORS ASSOCIATED WITH FUNCTIONAL DECLINE AMONG ADULTS AGE 50 YEARS OR OLDER: A 4-YEAR FOLLOW-UP

M.A. Cabrera¹, M.U. Vieira^{1,2}, A.R. Silva¹, M.A. Bortolletto¹, A.A. Lopes¹, 1. *Universidade Estadual de Londrina, Londrina, Paraná, Brazil*, 2. *UNOESTE, Guarapuava, Paraná, Brazil*

This is a prospective 4-year follow-up study (2011–2015) in a population-based sample of 713 adults aged 50 years or older residing in a medium-sized city in Southern Brazil. In this analysis, only 412 individuals, who were considered independent for instrumental activities of daily living (IADL), were included in the baseline assessment. The outcome was the functional decline (FD), defined as the functional loss of at least two IADL after 4 years of follow-up. The independent variables associated with FD were sociodemographic, lifestyle, and comorbidities. The results showed that 78 of the 412 subjects (18.9%) were considered dependent for

IADL after 4 years of follow-up. When adjusted for sex, age, economic class, and schooling, the following variables were identified as having significant associations with high FD: absence of spouses, relative risk (RR) = 1.75 [95% confidence interval (CI): 1.08–2.95]; low consumption of vegetables and fruits, RR = 1.85 (95% CI: 1.11–3.07); diabetes, RR = 1.69 (95% CI: 1.13–3.28); hearing impairment, RR = 2.06 (95% CI: 0.24–3.43); and falls, RR = 1.61 (95% CI: 1.01–2.57). In conclusion, we observed an overall worsening of functional status in a population aged 50 years or older within a short period of 4 years, especially in groups at higher risk such as those without spouses, those having diabetics, those with low consumption of fruits/vegetables, and those having hearing impairment. Therefore, it is important to adopt measures to maintain the functional capacity in these specific populations.

VALIDITY OF FRUIT AND VEGETABLE INTAKE ASSESSED BY A FOOD FREQUENCY QUESTIONNAIRE IN OLDER ADULTS

C. Neville, M.C. McKinley, F. Kee, I. Young, C. Cardwell, J. Woodside, *UK CRC Centre of Excellence for Public Health, Queen's University Belfast, Belfast, United Kingdom*

Accurately assessing dietary intake in older populations is vital to determine the potential role of diet in healthy ageing. Based on the uncertainty over the utility of a food frequency questionnaire (FFQ) to determine dietary intake in older people, the objective of this study was to validate fruit and vegetable (FV) intake from a FFQ, using a food diary (FD). A sub-sample of 50 participants (aged >50y) from the Northern Ireland Cohort for the Longitudinal Study of Aging completed a FFQ and 4-day FD (reference method) at two time-points (Month 0 and Month 6). Estimates of FV intake were compared between methods using Spearman's correlation coefficients, cross-classification, weighted kappa and Bland-Altman plots. At both time-points, median fruit, vegetable and total FV intake were higher (all $p < 0.001$) in the FFQ than the FD. Positive correlations (all $p < 0.05$) were observed between the FFQ and FD estimates at both time-points (Mo 0, $r = 0.44$, 0.52 and 0.46 for fruit, vegetables, total FV, respectively; Mo 6 $r = 0.49$, 0.44 and 0.44 , respectively) while weighted kappa showed fair-moderate agreement between methods for FV intake. Cross-classification indicated that 79% of participants were classified into the same or adjacent quartile. Bland-Altman plots revealed a widening in limits of agreements, between the FFQ and FD, with higher FV intakes. While over-reporting is evident with the FFQ compared to the FD, the results show good comparability in ranking older adults according to their FV intake. Analysis of FV biomarkers within this sample will provide a more objective assessment of FV intake.

A CASE FOR DEVELOPING AN EXERCISE-BASED PREVENTIVE SWALLOW HEALTH MAINTENANCE PROGRAM IN THE ELDERLY

D. Agrawal, M. Kern, A. Wilson, S. Gao, F. Edeani, G. Balasubramanian, P. Sanvanson, R. Shaker, *Gastroenterology and Hepatology, Medical College of Wisconsin, Milwaukee, Wisconsin*

Oropharyngeal dysphagia (OPD) associated with frailty is an important national healthcare concern with

serious consequences, enormous cost and limited therapeutic options. Despite positive health outcomes with strength training exercises for locomotive health maintenance in the elderly, to date there has been no systematic approach for an exercise-based swallow function maintenance program. Aim: To determine the effect of a swallow exercise program on the oropharyngeal deglutitive biomechanics in healthy elderly and dysphagic patients using a novel technique of Swallowing Against Laryngeal Restriction (SALR). Methods: We studied 24 healthy elderly (76+/-7yrs, 10M) by videofluoroscopy before and after six-weeks of real exercise. 12 of these volunteers also underwent pre and post-exercise high-resolution pharyngeal manometry. 10 elderly (81+/-6yrs, 1M) were studied by videofluoroscopy before and after six-week of sham exercise. We also studied a heterogenous group of 21 OPD patients (64+/-10yrs, 10F) with videofluoroscopy before and after a minimum of six-weeks of real exercise. Real exercise consisted of 30 swallows at 15 second intervals TID using a device hindering deglutitive laryngeal excursion. Results: In healthy elderly, real exercise, but not sham exercise, significantly improved upper esophageal sphincter (UES) opening, posterior pharyngeal-wall thickness, anterosuperior laryngeal excursion and pharyngeal contractile integral. In patients, UES opening, anterior laryngeal excursion and symptom-specific outcome EAT-10 improved significantly post-exercise. Conclusions: Strength training facilitated by SALR technique safely improves deglutitive biomechanics, function, and reverses pharyngeal sarcopenia. In addition to developing similar program for deglutitive rehabilitation of OPD, the findings of this study provide the basis for developing an exercise-based preventive swallow health maintenance program for the elderly.

RESPIRATORY MUSCLE STRENGTH IS ASSOCIATED TO PARITY AMONG LOW-INCOME WOMEN FROM NORTHEAST BRAZIL

S. Cmara¹, I.G. Azevedo¹, C. Pirkle², N.T. Rosendaal^{2,3}, A. Maciel¹, E.d. Viana¹, *1. Universidade Federal do Rio Grande do Norte, Natal, Brazil, 2. University of Hawaii, Honolulu, Hawaii, 3. Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland*

High parity is common in low-income settings and it is related to chronic conditions among women. This study investigated associations between parity and respiratory muscle strength in low-income women (Northeast Brazil). In a cross-sectional study, 204 community-dwelling women (40–80 years-old) were evaluated regarding the number of lifetime childbirths and ability of generating maximal inspiratory (MIP) and expiratory (MEP) pressures with a digital manometer. We performed multiple linear regression analyses to model the effect of multiple births on MIP and MEP, adjusting for covariates (current age, age at first birth, income, education, smoking, BMI, time seated during a day and walking per week). Forty four percent of the sample had ≤ 3 births, 30.4% had 4 to 6 births and 25.5% had 7 births or more. There is a clear gradient in relation to MEP and parity groups; those with a higher number of births had lower MEP values. In the fully adjusted model, women with ≥ 7 births and women with 4–6 births presented lower mean MEP ($\beta = -17.79$ cmH₂O; $p = 0.01$ and $\beta = -12.46$ cmH₂O; $p = 0.02$, respectively) than women with ≤ 3 births. No relation was

observed between parity and MIP. We hypothesized that multiparity may affect the abdominal strength due to impairment in the muscles biomechanics. Diastasis recti is common after multiple pregnancies and may cause disadvantage in strength generation, reducing expiratory pressures. Lower expiratory pressures are related to higher incidence of lung diseases including atelectasis and recurrent pneumonia, which are important debilitating conditions for elderly.

IMPROVING AIR QUALITY AND CARDIOVASCULAR HEALTH FOR LOW-INCOME ELDERLY IN DETROIT, MICHIGAN

R.A. Ziemba¹, R.D. Brook², R.L. Bard², C. Spino³, S. Adar³, M. Morishita⁴, 1. *Independent Researcher, Ann Arbor, Michigan*, 2. *Division of Cardiovascular Medicine, University of Michigan, Ann Arbor, Michigan*, 3. *School of Public Health, University of Michigan, Ann Arbor, Michigan*, 4. *Department of Family Medicine, East Lansing, Michigan*

Ambient fine particulate matter (PM_{2.5}) compromises cardiovascular health (CV) by stimulating inflammatory reactions in blood vessels. We tested the effectiveness of indoor air filtration to reduce PM_{2.5} exposure and improve CV health in seniors living in a government-subsidized low-income apartment building. This facility is located in downtown Detroit, Michigan, where documented average indoor PM_{2.5} concentrations are more than twice the current annual US National Ambient Air Quality Standard. This facility is in an area where we have previously demonstrated that exposure to both ambient and personal PM_{2.5} is significantly associated with elevated blood pressure within 1–3 days after exposure. For the current study, we conducted a randomized crossover intervention study with repeat health and exposure measurements from 39 seniors exposed to unfiltered, low-efficient (LE) filtered, and high-efficiency (HE) filtered air. Preliminary results indicate that both LE and HE indoor filtration effectively reduce indoor and personal PM_{2.5} concentrations by 35–51%. Effects on cardiovascular outcomes and inflammation markers are pending. If shown to be effective, in-room air filtration offers a relatively inexpensive intervention to improve air quality and CV health in seniors living in areas of high air pollution.

A SHORT SURVEY TO ASSESS HEALTH STATUS AMONG OLDER ADULTS

T. Wells¹, G.R. Bhattarai¹, K. Hawkins¹, S. Musich¹, S. Kraemer², Y. Cheng¹, D. Armstrong³, 1. *OptumInsight, Ann Arbor, Michigan*, 2. *Healthcare Transformation, UnitedHealthcare, Minnetonka, Minnesota*, 3. *AARP Services, Inc., Washington, District of Columbia*

The purpose of this study was to test the feasibility of fielding a short survey to a large older population to learn about their self-rated health, compliance with annual flu vaccinations, and willingness to participate in population health programs. 675,772 older adults were contacted to participate in the survey. Responses were linked to eligibility, medical claims, and pharmaceutical data to identify: 1) those who responded to the survey; 2) those whose self-rated health was different than their Hierarchical Condition Category (HCC) risk score measured with claims data and; 3) those that reported not having a flu vaccination. The survey response

rate was 14%, and 32% of respondents reported no flu vaccination. Among those rating their health as poor-fair, 1/3 had an HCC score indicating they were healthy (HCC<1.0). Among those rating their health as good-excellent, 4% had HCC score indicating they were sick (HCC>2.8). This telephonic short survey outreach to a large population successfully gathered important population health metrics not available in claims data. First, the flu vaccination information can be used to effectively target an intervention for those not vaccinated. Second, using self-rated health to prioritize those being considered for a population health intervention may be more effective than using claims data. Finally, individuals who complete a survey have demonstrated that they are more likely to join a population health program when offered, and therefore given a high priority when determining whom to target for these programs.

EFFECTS OF A SIX-WEEK STRENGTH TRAINING PROGRAM ON FUNCTIONAL FITNESS LEVELS AMONG OLDER ADULTS

K. Caillouet², A. Nelson¹, M.E. Livingston², 1. *University of West Florida, Pensacola, Florida*, 2. *Georgia Gwinnett College, Lawrenceville, Georgia*

Introduction: Muscular strength, flexibility, aerobic endurance, and balance are well-known contributors to health and quality of life among older adults. Prior research has indicated older adult participation in resistance training provides foundational strength for performance of activities of daily living. Purpose: To investigate the effects of a six-week progressive resistance training program on strength, flexibility, aerobic endurance, and dynamic balance and agility among community-dwelling older adults. Methods: From 2010–2015, ten separate sessions of a six-week progressive resistance training program were implemented and resulted in a total of 95 community-dwelling older adult participants (37 male, 58 female; M=73.5 + 7.2). The resistance-training program included bi-weekly, 1-hour sessions targeting all muscle groups. Assessments included 30-second arm curl, 30-second chair stand, back scratch, chair sit-n-reach, 2-minute step test, and 8-foot up-and-go. Statistical Analysis: The Wilcoxon Signed-Rank Test was performed to evaluate group differences between baseline and post-program for upper- and lower-body strength, upper- and lower-body flexibility, aerobic endurance, dynamic balance and agility. Results: Significant differences between pre- and post-assessments were found for upper- and lower-body strength ($z = 6.81, p < .001$; $z = 6.46, p < .001$, respectively); upper- and lower-body flexibility ($z = 3.81, p < .001$; $z = 4.85, p < .001$, respectively), aerobic endurance ($z = 6.04, p < .001$), and dynamic balance and agility ($z = 5.52, p < .001$). Conclusion: The six-week progressive resistance-training program targeting all muscle groups resulted in significant improvements in strength, flexibility, aerobic endurance, balance, and agility among community-dwelling older adult participants.

IMPACT ON CARDIORESPIRATORY OUTCOMES OF HIGH VS. STANDARD DOSE INFLUENZA VACCINE IN U.S. NURSING HOMES

S. Gravenstein^{1,2}, J. Ogarek², M. Taljaard⁴, L. Han³, H. Davidson³, P. Gozalo², V. Mor², 1. *Case Western Reserve University, Cleveland, Ohio*, 2. *Brown University,*

Providence, Rhode Island, 3. *Insight Therapeutics, Norfolk, Virginia*, 4. *University of Ottawa, Ottawa, Ontario, Canada*

Age and multiple morbidities increase susceptibility to influenza whilst responsiveness to vaccination declines. However, Fluzone® High-Dose, Influenza Vaccine (HD) reduces clinical influenza more than Fluzone vaccine standard dose (SD) among outpatient elderly. In 2013–2014 we randomized 823 nursing homes (NHs) to either SD or HD as their care standard. HD significantly reduced hospitalizations. We now report on diagnoses for hospitalization, using Medicare Fee-For-Service (FFS) discharge data. We compared primary and secondary discharge diagnoses for index hospitalizations for cardiac and respiratory illnesses using ICD-9 codes (acute myocardial infarction: 410.xx, 411.xx; heart failure: 428.x, 429.0, 429.1, 419.7; atrial fibrillation: 427.x; stroke: 433.xx–436.xx; and respiratory illness: 460–466, 480–488, 490–496, 500–518). We used marginal Poisson regression, accounting for clustering of NH residents and for pre-specified resident and facility baseline covariates: age and average age of NH residents, ADL and average ADL of NH residents, cognitive function, hospitalizations in prior year, and patients' chronic heart failure. On 11/1/2013, of 38,256 FFS NH residents living in their NH >3 months, and ≥ 65 years old, 19,126 were offered HD and 19,129 were offered SD. From November through April, 7,297 FFS residents were hospitalized (3509 HD, 3788 SD, $p=0.0110$). The difference in all-cause hospitalization was accounted for largely by hospitalization for the combination of cardio-respiratory outcomes (unadjusted RR=0.918, 0.861–0.980 95% CI, $p=0.0098$; adjusted RR=0.908, 0.858–0.961 95% CI, $p=0.0009$). In our prospective cluster-RCT, HD provided better protection than SD against both respiratory and certain cardiac conditions that lead to hospitalization.

EARLY FRAILTY TRANSITION PREDICTS 17 YEARS OF MORTALITY AMONG NON-DISABLED OLDER MEXICAN AMERICANS

C. Li, S. Al Snih, K.J. Ottenbacher, *Rehabilitation Sciences, University of Texas Medical Branch, Galveston, Texas*

Understanding frailty transitions over time and its impact on mortality is crucial for early prevention and long-term care for any individual who is going through aging process. We used 1995/96 to 2012/13 data from the Hispanic Established Populations for the Epidemiological Study of the Elderly (EPESE) survey to investigate the effect of early frailty status transition on 17-year mortality. This study included 1688 Mexican Americans aged 67 years and older and were non-disabled at baseline. Frailty was defined as meeting two or more following criteria: unintentional weight loss > 10 pounds, weakness, self-reported exhaustion, and slow walking speed. According to the frailty transition between 1995/96 and 1998/99, participants were divided into 9 transition groups: non-frail-non-frail, non-frail-pre-frail, non-frail-frail; pre-frail-non-frail, pre-frail-pre-frail, pre-frail-frail; frail-non-frail, frail-pre-frail and frail-frail. Using Cox proportional hazards regression, we estimated mortality as a function of early frailty transitions controlling for socio-demographics, comorbidities, and cognitive impairment. Participants who transitioned from pre-frail to non-frail status had 20% lower mortality risk [Hazard

Ratio (HR) = 0.80, 95%CI=0.64–0.99] compared to those who remained non-frail. Non-significant reduction in risk of mortality was seen among those who transitioned from frail to non-frail (HR=0.67, 95%CI=0.38–1.19). Non-significant high risk of mortality was found among those who transitioned from pre-frail to frail, frail to pre-frail and remained frail. This study demonstrated that non-disabled older Mexican Americans who transitioned from pre-frail to non-frail had significant lower risk of mortality over 17-years of follow-up. Intervention targeting older Mexican Americans in pre-frail status could potentially decrease mortality in a long run.

A CHOICE-BASED PHYSICAL ACTIVITY AND ACTIVE TRAVEL INTERVENTION FOR OLDER MEN

D.C. Mackey^{1,2}, A. Perkins², K. Hong Tai², J. Sims-Gould², H.A. McKay², 1. *Biomedical Physiology and Kinesiology, Simon Fraser University, Burnaby, British Columbia, Canada*, 2. *University of British Columbia, Vancouver, British Columbia, Canada*

Low levels of physical activity contribute to loss of mobility and independence in older men. We conducted a 12-week randomized controlled feasibility trial of choice-based physical activity (PA) and active travel. Participants were community-dwelling 'low active' men aged 60+ ($n=29$ intervention (INT), $n=29$ waitlist control). Trained activity coaches delivered: 1) one-on-one participant consultations to develop personal action plans for PA and active travel; 2) monthly group-based motivational meetings; 3) weekly telephone support; 4) complimentary recreation and transit passes; and 5) pedometers and diaries for self-monitoring. INT chose a wide range of group-based and individual PAs (e.g., group exercise classes, walking, cycling) and destinations (e.g., parks, cities, shops/restaurants) for their personal action plans. At 12 weeks, INT achieved 9.0 more minutes/day of moderate-to-vigorous PA ($p=0.06$) and 1140 more steps/day ($p=0.04$), engaged in 5.2 more moderate intensity PAs/week ($p<0.01$), and expended 1493 more kcal of energy/week from moderate PAs ($p=0.02$). INT was 4.2 times more likely to take at least one transit trip/week (95%CI:1.2–18.0) and 3.3 times more likely to meet national guidelines of ≥150 minutes/week of moderate-to-vigorous PA in bouts of ≥10 minutes (95%CI:0.75–16.3). At 24 weeks follow-up (12 weeks after intervention end), INT benefits relative to baseline were sustained for minutes/day of moderate-to-vigorous PA, number of moderate intensity PAs/week, and kcal of energy/week from moderate PAs. In conclusion, a choice-based model of PA paired with active travel may be an effective approach to promote PA among older men.

NUTRIENT INTAKE OF FEMALE RESIDENTS CONSUMING A PUREED DIET IN CANADIAN LONG-TERM CARE (LTC) HOMES

V. Vucea¹, H.H. Keller^{1,3}, J.M. Morrison¹, A.M. Duncan², L. Duizer², 1. *Kinesiology, University of Waterloo, Waterloo, Ontario, Canada*, 2. *University of Guelph, Guelph, Ontario, Canada*, 3. *Schlegel-UW Research Institute for Aging, Waterloo, Ontario, Canada*

Older adults residing in long-term care (LTC) face increased risk of malnutrition because of many factors, including decreased appetite, difficulty eating, and cognitive

impairment. Issues associated with pureed texture diets (e.g., dysphagia, poor dentition, lack of appeal, and extra menu planning) further contribute to this risk. The current study examined the adequacy of nutrient intake among female LTC residents prescribed a pureed texture diet. Making the Most of Mealtimes (M3) is a cross-sectional study of 639 residents from 32 LTC facilities across four Canadian provinces (AB, MB, NB, ON). Of these, 67 residents (10.5%) were prescribed a pureed texture diet, 51 of which were female (88 ± 8 years old). Weighed food intake was measured on three non-consecutive days and analyzed using ESHA Food Processor software. Intake of energy and 25 nutrients were adjusted for intra-individual variability and compared to their corresponding Estimated Average Requirement (EAR) or Adequate Intake (AI) value. Mean energy intake among female consumers of pureed diets was 1487 ± 376 kcal/day. Estimated inadequacies were found for vitamins D, E and folate (>95% of individuals below EAR); and vitamin B6, calcium and magnesium (>50% but <90% below EAR). For nutrients with an AI, median intakes of dietary fibre, potassium and vitamin K were below their AI. These findings indicate that female residents prescribed a pureed texture diet in Canadian LTC homes have low intake of several micronutrients. Careful menu planning and nutrient-dense options for pureed texture diets in LTC are recommended. (Funded by Canadian Institutes of Health Research).

SKILLED NURSING FACILITY TO HOME CARE TRANSITIONS: OUTCOMES OF EARLY OUTPATIENT FOLLOW-UP

J. Carnahan, J. Slaven, C.M. Callahan, W. Tu, A. Torke, *Indiana University, Indianapolis, Indiana*

As hospital lengths of stay have decreased, more older adults have discharged to skilled nursing facilities (SNFs) prior to returning home. Patient characteristics and factors that prevent post-discharge adverse outcomes, such as hospital readmissions, are poorly understood. This study utilized a database comprised of data from one health system's Electronic Medical Record, matched to Medicare, Medicaid and the Minimum Data Set. Among patients who transitioned from hospital to SNF to home, we used survival analysis to examine whether a home health visit or outpatient visit within one week of SNF discharge was associated with reduced hospital admission. Out of 8,754 community dwelling, hospitalized older adults with a hospital stay of 3 or more days, 4,577 were discharged home (52.3%; hospital to home group) and 3,025 (34.6%) were discharged to a SNF, of whom 1,543 (51.0%) returned home (SNF to home group). Patients discharged after SNF stay were older (median age 77.82 years v. 73.75, $p < 0.0001$), had more comorbidities (median 6 v. 5, $p < 0.0001$) and a longer hospital length of stay (median 7 v. 4 days, $p < 0.0001$). After SNF discharge, a home health visit within a week was associated with reduced hazard of 30-day hospital readmission (adjusted hazard ratio (aHR) 0.61, $p < 0.0001$) but outpatient physician visits were not (aHR=0.67, $p = .8214$). Patients discharged to a SNF prior to returning home are a high risk group. The finding that a home health visit within a week of discharge is associated with reduced hazard of 30-day hospital readmissions suggests a potential avenue for intervention.

AGING IN CONTEXT: A MIXED METHODS INVESTIGATION OF PERSON-PLACE INFLUENCES ON WELL-BEING

J. Finlay¹, L.C. Kobayashi², *1. University of Minnesota, Minneapolis, Minnesota, 2. Harvard University, Cambridge, Massachusetts*

Aging occurs in context; yet, too often environmental characteristics are ignored. Seated and mobile interviews with community-dwelling older adults (n=124, mean age 71 years), combined with environmental audits, explored the everyday contexts of older adults living in three distinct areas of the Minneapolis (USA) metropolitan area. Convergent parallel analyses examined four constructs of wellbeing: (1) self-rated health, (2) isolation and loneliness, (3) sense of safety, and (4) happiness. Logistic regression models adjusted for age, gender, past occupation, race/ethnicity, living alone, street type, residential location, and building density were used to predict the wellbeing constructs. Qualitative thematic analyses probed individual perspectives and personal experiences. The sociodemographic qualitative findings generally converged with the quantitative results. For instance, the most consistent predictor of wellbeing in the quantitative models was living alone, which was negatively associated with all four aspects of wellbeing (e.g. odds ratio [OR] for moderate/poor/very poor vs. good/very good self-rated health = 3.08; 90% confidence interval [CI]: 1.31–7.20). This estimate paralleled the qualitative findings, in which numerous participants living alone voiced struggles with vulnerability, isolation, and poor health. However, individualized qualitative perspectives on environmental contexts problematized the quantitative results. Linear trends generated by regression modelling, which indicated that wellbeing steadily decreased when moving outwards from the city center toward suburban zones, diverged from nuanced qualitative data that captured significant variation in wellbeing within each residential context. Findings advance scholarship on health-place interconnections, and elucidate how interacting personal variables and environmental contexts 'get under our skin' to shape the experience of aging.

PNEUMONIA READMISSION IN OLDER ADULTS WITH DEMENTIA

S. Knox, *1. Physical Therapy, MGH Institute of Health Professions, Charlestown, Massachusetts, 2. Nova Southeastern University, Ft. Lauderdale, Florida*

Pneumonia readmissions have significant quality of care and policy implications for patients and health care providers. Research suggests that initiatives to decrease readmissions should target high-risk subgroups. Older adults with dementia are known to be at an increased risk of contracting pneumonia and have higher hospitalization rates due to pneumonia, suggesting that older adults with dementia may be at high-risk of pneumonia readmissions. There is a lack of research addressing the relationship between dementia and pneumonia readmissions. The purpose of this retrospective study was to investigate pneumonia readmission rates and predictive factors of older adults with and without dementia. A nationally representative sample of 389,198 discharge records was extracted from the 2013 Nationwide Readmission Database. Significant differences were found ($p < .001$) when comparing patient characteristics of older

adults with and without dementia who were readmitted within 30 days of discharge. Older adults with dementia had a readmission rate of 23.5% and were 2.9 times more likely to be readmitted (OR; 95% CI, 1.93,4.40) than older adults without dementia. Predictive factors were calculated using a generalized linear model with dementia included as an interactive effect. Dementia significantly modified ($p < .05$) the relationship between pneumonia readmissions and four factors; (a) discharge disposition, (b) chronic conditions, (c) risk of mortality, and (d) median household income. Classifying older adults with dementia as a high-risk sub-group for pneumonia readmissions is supported by the findings of this study. Development of strategies to reduce pneumonia readmissions that are tailored to individuals with dementia should be considered.

HEALTH EQUITY PREDICTORS AMONG AGING PARENTAL CAREGIVERS OF ADULTS WHO HAVE AUTISM

H. Church¹, C. Marsack², 1. *Western University, London, Ontario, Canada*, 2. *Eastern Michigan University, Troy, Michigan*

The principles guiding initiatives related to aging among individuals with intellectual disabilities (i.e., independence, participation, care, self-fulfilment and dignity) are based on the principles adopted in the United Nations Principles for Older Persons (resolution 46/91) (United Nations, 1991). This resolution must implicitly include their aging parental caregivers. Aging parental caregivers of adults with Autism Spectrum Disorder (ASD), may be particularly vulnerable as they balance their own needs that change as they age and care for their adult child. Policies and funding decisions directed at meeting the needs of people with ASD have tended to focus on the individual with the developmental disorder, yet implementation relies heavily on family caregivers, primarily parents. Little is known about the health impacts, both positive and negative, among aging parents caring for an adult with ASD.

It is necessary to consider the health of the parents of adults with ASD, as they are aging themselves. The province of Ontario has developed the Health Equity Impact Assessment (HEIA), a five-step model designed to identify the unintended health impacts, both positive and negative, of policies. The purpose of this research is to use the HEIA as a framework to identify the health impacts of community-based policy on aging caregivers of adults who have ASD.

Participants (N= 320), completed the World Health Organization Quality of Life – Brief, Caregiver Burden Inventory, ENRICH Social Support Instrument, Caregiver Reaction Assessment, and demographic questionnaires were analyzed using multiple regressions. Interviews were also conducted among parents (N= 50), age 50 years old and older, of adults diagnosed with to explore how the services and supports provided influenced the social determinants of health (SDOH).

Results: The findings demonstrated a negative correlation between burden experienced by the parents and various aspects of social determinants of health. Caregiver burden was a predictor of QOL. Subthemes, identified using line-by-line analysis of transcribed interviews used a grounded theory perspective, included: stress, fatigue, physical assaults,

worsening of chronic conditions, fear and helplessness experienced by these parents. This study highlights impediments to SDOH experienced by aging parental caregivers of adults who have ASD, which can be mitigated by service providers.

CHARACTERISTICS OF RESIDENTS IN NEED AND FAMILY PERCEPTIONS OF FAMILY CARE CONFERENCES IN LTC

P.M. Durepos¹, S. Tamara², S. Kaasalainen¹, J. Ploeg¹, D. Parker³, G. Thompson⁴, 1. *School of Nursing, McMaster University, Hamilton, Ontario, Canada*, 2. *McGill University, Montreal, Quebec, Canada*, 3. *University of Technology Sydney, Sydney, Western Australia, Australia*, 4. *University of Manitoba, Winnipeg, Manitoba, Canada*

Few long-term care (LTC) homes follow a systematic process for communicating with families of residents near end of life (EOL). Barriers to communicate may include limited resources and difficulty prognosticating. A new program called 'Strengthening a Palliative Approach to Care' (SPA-LTC) examined Family Care Conferences (FCC) for residents who were nearing EOL as a way to increase communication between staff and families. The purpose of this study was to explore: 1) characteristics of residents who had FCCs compared to those who did not, and 2) family perceptions of FCCs through a mixed methods approach.

At study end, there were 39 families enrolled and 28% (n=11) of residents had died, all in the LTC setting. FCCs were held for 24 families and three additional residents died before an FCC occurred. Descriptive statistics showed residents who had an FCC tended to have dementia, higher Charlson Comorbidity Index, and were hospitalized more often during the last year. Eight families attending FCCs agreed to be interviewed. Participants reported feeling well-supported during FCCs, found conferences beneficial and all had identified EOL preferences. One interviewed participant recommended holding FCCs earlier in the course of illness.

Findings suggest that families of residents with specific characteristics (e.g., dementia diagnosis) may have increased need for communication or acceptance of FCCs at EOL. Overall, family members perceived FCCs as beneficial supporting the value of this intervention and participant suggestions can contribute to tailoring FCCs. Analysis of resident characteristics in particular should be repeated in additional studies to confirm findings.

THE EFFECT OF HEALTH ON THE TIMING OF RECEIVING RETIREMENT BENEFITS

F. Huang, *University of Florida, Gainesville, Florida*

Health is one of major factors that cause people to retire. However, referring to the gender gap in pensions, empirical studies mostly focus on the influence of working years, occupation and education on the gap, instead of gendered health disparity. This study aims to understand how the effect of health on the timing of receiving retirement benefits are conditioned by gender, cohort and the institution.

This study will use the 1992–1998 and 2004–2014 waves of Health and Retirement Study (HRS) data and the 1989–1999 and 1996–2011 waves of the Taiwan Longitudinal Study in Aging (TLISA) to examine the effects of gender disparity in late adulthood health on the timing of SSB and pension receipts. Discrete-time event history analysis by logistic

regression models are adopted to investigate the hazard rate of receiving retirement benefits across individuals and cohorts.

Based on cumulative disadvantage or advantage approach in life course perspective, this study suggests the mechanisms “work incapacity”, “wage depressing”, “the limitation of job opportunity” and “anticipation of shorter life expectancy” could lead gender and cohorts to have dissimilar patterns of retirement income receipt timing. Additionally, the social policies and the institutions such as cash benefits and health insurance system could be pathways to change the opportunities structure and incentive structure in the timing of retirement benefit receipt. This study not only enriches life course perspective but also provides the implication of the policy “delaying retirement ages for full SSB” for the U.S. and the East Asia countries like Taiwan.

INSTITUTIONAL LTC FOR ELDERS IN ASIA AND AFRICA: OWNERSHIP, RESIDENT CHARACTERISTICS, AND STAFFING

S. Balaswamy¹, M.E. Adamek², 1. *Ohio State University, College of Social Work, Columbus, Ohio*, 2. *Indiana University, School of Social Work, Indianapolis, Indiana*

The population aging is occurring at a faster pace in developing countries than in developed countries. By 2030, 80% of the world's elders will be living in developing countries. The demand for congregate long term care (LTC) in developing countries will accelerate due to the growing number of frail elders, limited financial security, and lack family support. Currently, little is known about the policies, programs, and characteristics of institutional LTC (ILTC) for elders in developing countries as defined by the UNO. To fill this gap, a systematic review was conducted using 9 databases and other non-peer review data sources with various combinations of the keywords elder care homes, old age homes, nursing homes and residential facilities to identify research published since 2000. Data was analyzed from 83 empirical sources on ILTC for elders in developing countries to assess the resident characteristics, funding source, and staffing. Findings confirm great diversity in provision of ILT among developing countries. Asian countries far excel in ILTC policies and program (e.g. Hong Kong, Singapore, Taiwan) than other countries in Asian (e.g. Bangladesh, Pakistan, India, Philippines) and Africa. However, the characteristics of ILTC elderly residents (women, poor, chronic illnesses, disabled, very old, dementia diagnosis, developmental disabilities, mental illness), limited skilled staff (nurses, physicians), funding sources (government, NGO & Private) are common in most countries. Based on this review, recommendations are made for future research, policy, practice and educational training to improve LTC. Collaborative international partnerships are needed to develop solutions to the global gap in LTC.

COMMUNITY-ENGAGED SERVICE LEARNING HELPS RECENT REFUGEE ELDERS RECONSTRUCT IDENTITY AND WORTH

L.M. Holley, M. Patton, M. Marx, *Gerontology, University of Nebraska Omaha, Omaha, Nebraska*

During Fall 2016 the University of Nebraska at Omaha partnered with a local non-profit branch of a worldwide faith-based refugee relief organization to design and test

a project to facilitate recent refugee elders' adjustments to America and to speed and deepen student understanding of human geography and the refugee experience. Student project participants were an honors cohort of freshmen enrolled in a gerontology course that was linked with an English composition course and a world human geography course. Elder refugee participants were from Afghanistan, Bhutan, Burma, and Sudan – four different regions of the world. The theoretical foundation of the project was Butler's basic work in the therapeutic value of life review. The goal of the project was for each student team (with an interpreter and a faculty member) to conduct lifespan review interviews of their elder that explained how and why the elder came to America, and to develop the elder's story into a brief but expandable book. Results of the first phase of project evaluation indicate that outcomes of the project include strengthening the elders' feelings of worth and agency, and deepening student understandings of both their home culture and that of the elder. This poster describes the model sufficiently to support consideration of its replication by other educational institutions in other communities. Given the domestic and global impact of recent developments in US immigration policies and practices, dissemination of this useful model seems imperative.

RESIDENTS' STRENGTHS AND INFLUENCING FEATURES IN A SUPER-AGED SOCIAL HOUSING COMMUNITY

Y. Matsuoka⁴, M. Saito², R. Wada³, M. Akiyama¹, 1. *Health Consultation Center 'KURASHI NO HOKENSHITU', Tokyo, Japan*, 2. *Tokyo kasei University, Department of Nursing, Tokyo, Japan*, 3. *Tokyo Kasei University, Department of Home Economics, Tokyo, Japan*, 4. *Tokyo Kasei University, Department of Humanities and Science, Tokyo, Japan*

Purpose: This study aims to clarify the perceived difficulties and strengths of residents for aging in place in a super-aged social housing community and to explore the features influencing those difficulties and strengths. The Social housing community studied has been owned by the Tokyo Metropolitan Government since 1960, and its residents have a greater than 50% aging rate.

Data Collection: Using a mixed method approach, we conducted five focus group interviews with 44 residents and examined this result with a quantitative questionnaire survey given to all 3,150 households.

Methods and Results: The response rate was 33.9%, 1,069 respondents. Through factor analysis with varimax rotation, we found four valid factors: desire to age in place, mutual aid spirit, difficulties due to super aged society, and ambiguous anxiety, which were composed from 24 concepts derived from the interviews. All Cronbach's alpha were over 0.6. We also found five features of the residents: long term residence, many old single households, good social contact, little use of public facilities, and low income. After multi-variable step-wise regression analysis between each factor's score (dependent variable) and the five features (independent variables), the long term residence showed a significant influence on the aging in place factor ($\beta=.214, p<.01$), and good social contact showed a significant influence on the mutual aid factor ($\beta=.174, p<.01$).

Implications: Many researchers investigate super-aged societies without focusing on the residents' strengths, which we can empower efficiently for aging in place by promoting good social contacts among long-term residents.

INVESTIGATING COMMUNITY PSYCHOSOCIAL CARE FOR RURAL ELDERS WITH EARLY-STAGE DEMENTIA

F. Chen, *National Chung Cheng University, Chiayi County, Taiwan*

Early intervention for dementia is beneficial, but providing adequate care for elders with early-stage dementia is challenging, especially in rural areas. The study focuses on a newly developed and well-received program in Taiwan where intervention is delivered via a community care station in rural communities. To unpack the inner workings of the program and to derive a blueprint for the care model, the study aims to: (a) identify the goals and objectives of the community care station, (b) investigate the roles and functions of the stakeholders, and (c) construct conceptual frameworks of practice in the model, taking into account influences at both individual and structural levels. This qualitative study was conducted in a community care station primarily led by a community development center and local volunteers. The researcher conducted field observation and in-depth interviews with people from the primary stakeholder groups involved in the care station, including the elders, their caregivers, professionals, and volunteers for their perceptions and experiences. Findings showed that the station relied heavily on the collaboration among stakeholder groups, and their interactions created an uplifting atmosphere and a healing environment. They used various approaches to integrating local customs and mobilizing community resources. By recruiting professionals' support, the community care station provided health promotion activities. Additionally, the station provided family caregivers with respite support. Essentially, it was a model "developed in the community and delivered by the community," which materializes "aging-in-place," and fosters the potential of sustainability, important qualities to target in the search of long-term care models.

CAREGIVERS' BURDEN AND EDUCATION LEVEL: DOES SUBJECTIVE HEALTH MEDIATE THE ASSOCIATION?

S. Schnitzer², M. Oedekoven², K. Amin-Kotb², P. Gellert², K. Balke¹, A. Kuhlme², 1. *National Association of Statutory Health Insurance Physicians, Berlin, Germany*, 2. *Department of Medical Sociology, Charité Berlin, Berlin, Germany*

The present study investigated the following hypotheses: (1) Caregivers with high educational attainment show lower levels of perceived physical and mental burden than caregivers with low education. (2) The association between the caregiver's perceived burden and their education level is mediated by their subjective health status. The analysis was based on a population survey of 6087 residents of Germany aged 18 and over. 966 persons were identified as caregivers. Burden of caregiving, socio-demographic characteristics and subjective health were assessed using standardised questionnaires. Logistic regression and mediation analyses were performed. 50% of all caregivers reported an increased physical burden, while 71% felt mentally

burdened. Caregivers with a higher level of education had lower odds of feeling physically burdened by caregiving (OR: 0.66; CI: 0.48–0.92). This association diminished, if additionally adjusted for health status. Persons with a higher education level had increased odds of feeling mentally burdened by caregiving compared with caregivers with lower education level – even after adjustment for health parameters. In both models, subjective health was found to have a significant mediation effect, explaining 55% and 22%, respectively, of the total effect. Better educated caregivers had lower odds of feeling physically burdened by caregiving; this was related to their good health status. The greater mental burden of caregivers with a higher education level may result from feared losses of autonomy, which increase with higher investment in education. Support and counselling services should therefore be optimised, taking account of socioeconomic status, so that solutions tailored to caregivers' individual circumstances are provided.

MOVING FROM FRAGMENTED TOWARD AN INTEGRATED SYSTEM: A NEW LONG-TERM CARE POLICY IN FAST-AGING COUNTRY

T. Chiu¹, H. Yu¹, W. Lai², H. Li³, E. Tsai⁴, Y. Chen¹, 1. *Institute of Health Policy and Management, National Taiwan University, Taipei, Taiwan*, 2. *Central Taiwan Joint Services Center, Executive Yuan, Taichung, Taiwan*, 3. *Quixotic Implement Foundation, Nantou, Taiwan*, 4. *Shuan Lien Social Welfare Foundation, Taipei, Taiwan*

Taiwan, one of the fastest aging countries in the world, started its first long-term care (LTC) plan, version 1.0, in 2008. In 2017, the LTC plan version 2.0 began a new era with the goal of integrating Taiwan's fragmented LTC service system. The new plan aims to establish an integrated community-based LTC system with health care and disability prevention care included. The model comprises three tiers of service agencies, including community-based integrated service centers with a day care center as base (Tier A: flagship stores); service centers with specialties (Tier B: specialty stores); and LTC stations targeting frail community-dwelling older adults and providing drop-in services toward preventing further disabilities (Tier C: corner stores). In the new plan, the role of Tier A stores needs to coordinate the LTC services provided by Tier B and Tier C stores. Our study explored the challenges to implementing LTC plan version 2.0 through in-depth interviews with three tiers of facilities. The preliminary findings show four major challenges to implementing LTC plan version 2.0: (1) First, although three tiers of service are defined, the plan lacks a mechanism for integration across tiers. (2) The mechanism for payment across different tiers was unclear, which may jeopardize the integration of services. (3) The role and function of Tier C stores in the new plan also seemed unclear. (4) LTC plan version 1.0 remains a challenge for version 2.0.

PARTICIPATORY RESEARCH WITH MOBILITY ASSISTIVE TECHNOLOGY USERS: AUDITS AND PHOTO DOCUMENTATION

A.N. Mahmood¹, C. Bigonnesse¹, T. Mahal¹, L. Kleinschroth¹, B. Mortenson², K. Martin Ginis², 1. *Gerontology, Simon Fraser University, Vancouver, Manitoba, Canada*, 2. *University of British Columbia, Vancouver, British Columbia, Canada*

Context: The neighbourhood environment influences mobility and participation of older adults especially those using mobility assistive technology (AT). Documentation of environmental barriers/facilitators in neighbourhoods by AT users can enable them to vocalize and advocate their needs for mobility and participation. Methods: The 89-item "Stakeholders Walkability/Wheelability Audit in Neighbourhoods" (SWAN) tool was developed to collect objective built environmental data across five domains: functionality, safety, destinations, aesthetics and social aspects. The tool was used by 24 participants with mobility disability to collect data in three municipalities of Metro Vancouver, British Columbia in Spring/Summer 2016. The audit was supplemented by photographs of barriers and facilitators in these five domains. Results: Audit and photographic data demonstrated that slopes, absence of or improperly designed curb cuts posed mobility hazards. This was further aggravated by uneven and poorly maintained sidewalks. AT users felt unsafe in areas shared with cars and bikes. Public spaces, amenities and street furniture, when present, were not always accessible creating participation barriers. Participants showcased these findings to other stakeholders at forums in their cities to highlight the need for more accessibly designed streets, sidewalks and infrastructure. The forums helped start the dialogue among different stakeholders to identify opportunities for partnerships and interventions. Conclusion: The SWAN tool is a resource for diverse groups of older adults to systematically document their neighbourhood environment with audits and photographs and engage other stakeholders to initiate environmental changes in their communities. The process can help them to be informed partners in neighbourhood physical planning and decision-making processes.

VOLUNTEERING AS PRO-SOCIAL BEHAVIOUR IN OLDER ADULTS: A PHOTOVOICE EXPLORATION OF PARTICIPATION

A.N. Mahmood¹, J.C. Lay², S. Petrozzi³, C.A. Hoppmann²,
1. *Gerontology, Simon Fraser University, Vancouver, Manitoba, Canada*, 2. *University of British Columbia, Vancouver, British Columbia, Canada*, 3. *Kitsilano Neighbourhood House, Vancouver, British Columbia, Canada*

The purpose of this community based research is to better understand the motivations and facilitators of volunteering as older adults engage in their typical life routines and environments. As part of a mixed-method multi-year project, this paper presents findings from the participatory photo-elicitation part of the study. Data from a community sample of 100 adults aged 51–85 years living in Metro Vancouver is presented here. During a 10-day period, participants used iPad minis to capture photos representing prosocial behaviour (i.e. to give of themselves to others) opportunities they encountered in their daily activities. They used the photos to reflect on their experiences by making voice recordings and completing questionnaires at the end of each day. Each participant captured, on average, 14 photos (range 4 - 55). Findings reveal that the majority (87 %) of photos captured times when participants chose to engage, rather than refrain, from behaving prosocially. Photo descriptions revealed a range of prosocial behaviours, e.g., support with instrumental activities of daily living (IADL), volunteer activities for organizations, symbiotic (reciprocal) social support, small acts of kindness, teaching activities, and support with

activities of daily living (ADL). Prosocial behaviour were typically with friends and family or those in a formal caregiving arrangement, but also included service providers and strangers. The findings demonstrate that a variety of volunteer pro-social behaviour takes place in diverse formal and informal social contexts. This finding will help develop community-based intergenerational programs for diverse groups of older adults.

MEASURING QUALITY IN THE UNITED STATES (U.S.) PROGRAM OF ALL-INCLUSIVE CARE FOR THE ELDERLY (PACE)

M. Stewart¹, K. McNealy², N. Dunton³, 1. *Econometrica, Inc, Bethesda, Maryland*, 2. *Sundance Research Institute, Sundance, Wyoming*, 3. *University of Kansas, Kansas City, Kansas*

PACE provides comprehensive medical and social services to certain frail, community-dwelling elderly individuals in the U.S., most of whom are dually-eligible for Medicare and Medicaid benefits. An interdisciplinary team of health professionals works with PACE participants to coordinate care; the comprehensive service package enables them to remain in the community rather than receive care in a nursing home.

Econometrica, under contract to the Centers for Medicare and Medicaid Service (CMS), is developing quality measures for PACE nationwide. This late-breaker will summarize efforts to date to develop, specify, and test the following performance measures relevant to PACE Organizations and their participants:

- Fall Rate
- Falls With Injury Rate
- Pressure Ulcer Prevalence Rate
- Pressure Ulcer Prevention Set for Participants With Pressure Ulcers
- 30-Day All-Cause Readmission Rate
- Percent of Participants with Advance Directive/Surrogate Decision Maker
- Percent of Participants with Annual Review of Advance Directive/Surrogate Decision Maker
- Percent of Participants Not in Nursing Homes
- Percent of Participants with Depression Receiving Treatment
- Influenza Immunization
- Staff Influenza Immunization
- Pneumococcal Immunization
- Emergency Department Utilization

All of the above measures are at different phases of development, which will be detailed in the poster along with the high level steps of endorsement by the National Quality Forum (NQF) in the U.S. Given the increasing interest internationally in the PACE model, the authors believe attendees will be curious about both the model and the intent to develop measures that are meaningful given the uniqueness of PACE.

REMOTE MONITORING TECHNOLOGIES IN LONG-TERM CARE, CARE TEAM ORGANIZATION, AND TRAINING

J. Spetz, A. Kottek, *University of California, San Francisco, San Francisco, California*

Remote monitoring programs aim to enhance the patient's and provider's surveillance of chronic conditions to

anticipate and identify exacerbations, thus avoiding unnecessary emergency room visits, re-hospitalizations, surgeries, premature death, and excess costs. This study, which reports newly-completed qualitative data analysis, examines how remote monitoring programs are preparing and leveraging the health care workforce to manage patients with chronic illness and long-term care needs who are living at home. We conducted 20 semi-structured interviews with health care providers, managers/administrators, and technicians who are part of care teams that utilize remote monitoring technologies, and with authors of research trials investigating remote monitoring technologies. A multidisciplinary team approach was associated with more positive biometric and health care system outcomes. Because registered nurses' experience allows them the independence to perform assessments while simultaneously communicating and acting upon data, they are the primary health professionals involved in remote monitoring programs in the United States, with lower-skill health workers providing support. A range of clinical experience and skills are critical for successful telemonitoring programs. Nurses must rely on critical thinking skills and their ability to verbally assess patients, ask the right questions, and make clinical judgments. Protocols that include customizing parameters to the patient, close monitoring, and case management with input from the whole care team appear to be the best approach. To fully achieve the potential of remote monitoring, programs should invest robustly in training. An expanded effort to share information across remote monitoring programs would accelerate learning and enhance success.

FACTORS OF BURNOUT AND ITS SOCIO-DEMOGRAPHIC CHARACTERISTICS AMONG STAFF IN LOCAL CENTERS IN JAPAN

M. Ohwa, H. Ishikawa, *School of Human Welfare Studies, Kwansai Gakuin University, Nishinomiya, Hyogo, Japan*

Comprehensive Community Support Centers (CCSC) in Japan were established when LTCI Law was revised in 2006. The number of CCSC has been increasing and it is necessary to improve the quality of professional staff in CCSC because they have to work with various and complicated cases. This study aims to clarify factor structures of burnout and describe its socio-demographic characteristics among professional staff in CCSC in Japan.

Subjects were selected randomly and the survey was conducted by mail in February, 2011. There were 1145 respondents from social workers, care managers, and nurses who were working in CCSC. The revised Japanese version of the Maslach Burnout Inventory (MBI) was used as a dependent variable. Organizational factors such as social support, locus of control and so forth, were independent variables.

As a result of principal factor analysis, three factors such as "emotional exhaustion", "depersonalization", and "personal accomplishment" were extracted with 15 items. The reliability (cronbach's alpha) was 0.794 for EE, 0.810 for DP, and 0.811 for PA. The results of one-way ANOVA using burnout scores by socio-demographic variables showed that there was a significant difference of their ages and years of experience.

The result indicated that three factors of burnout were extracted in this study. There was no significant difference among three professionals such as social workers, senior care

managers, and nurses. There was a significant difference of ages and years of experience. This result suggested that it has been necessary for local authorities to put experienced professionals in position in CCSC.

DETERMINANTS OF JOB-SEEKING STATUS AMONG THE ELDERLY IN TOKYO

S. Watanabe¹, Y. Fujiwara², K. Nonaka², M. Kuraoka², E. Kobayashi², U. Minami², 1. *Graduate School of Gerontology, J. E. Oberlin University, Shiki, Saitama, Japan*, 2. *Tokyo Metropolitan Institute of Gerontology, Tokyo, Japan*

In Japan, the labor force participation rate between ages 65 to 69 are 52.2% for males and 31.6% for females in 2015. National survey showed that furthermore 32% of males and 24% of females can work depending on conditions for this age group. Promotion of employment for the elderly has become a major issue in Japan. To identify the job-seeking status among the elderly in Japan, we conducted a mail survey with questions about demographics, personal status, social activities, economic status, WHO-5, self-rated health, instrumental activities of daily living (IADL score of TMIG Index of Competence), and job-seeking status to 3261 people randomly extracted from 65–84 years old residents in Tokyo in 2016. We used data of 920 non-working people (338 male and 582 female) with a mean age of 74.3 (SD=5.6), excluding 400 working people out of 1320 who responded in all items. Only 53 people (5.8%) out of 920 were in job seeking. Binominal logistic analysis was conducted with job-seeking status as the dependent variable, with gender, age, educational status, economic status, number of chronic diseases, WHO-5, self-rated health and IADL score as independent variables. Only gender (male/female, RR=1.94), age (RR=0.842), and economic status (borderline/secure, RR=2.77, be in difficulties/secure, RR=9.97) were significantly related to job seeking status. It was thought that the working motivation of the elderly in Japan was very high, but job-seeking behavior rate was not so high. The study findings suggested that economic poverty was more important factor than functional capacity for job-seeking behavior.

ADULT DAY CENTRES AND THEIR OUTCOMES ON CLIENTS, CAREGIVERS, AND THE HEALTH SYSTEM: A SCOPING REVIEW

M. Ellen^{1,2,3}, P. Demaio³, A. Lang⁴, M.G. Wilson³, 1. *Jerusalem College of Technology, Jerusalem, Israel*, 2. *University of Toronto, Toronto, Ontario, Canada*, 3. *McMaster University, Hamilton, Ontario, Canada*, 4. *McGill University, Montreal, Quebec, Canada*

Purpose of the study: Adult day centers (ADCs) offer a heterogeneous group of services that provide for the daily living, care, nutritional, and social needs of older adults. We sought to conceptually map and identify key gaps and findings from literature focused on ADCs, including the types of programs that exist and their associated outcomes on improving health and strengthening health systems.

Design and Methods: We conducted a scoping review by searching five databases for studies evaluating the outcomes of ADCs specifically for community-dwelling older adults. Included studies were conceptually mapped according to the methods used, type of outcome(s) assessed, study population,

disease focus, service focus, and health system considerations. The mapping was used to derive descriptive analyses to profile the available literature in the area.

Results: ADC use has positive health-related, social, psychological and behavioral outcomes for care recipients and caregivers. There is a substantial amount of literature available on some ADC use outcomes, such as health-related, satisfaction-related and psychological and behavioral outcomes, while less research exists on issues of accessibility and cost-effectiveness.

Implications: As the population ages, policymakers must carefully consider how ADCs can best serve each user and their caregivers with their unique circumstances. ADCs have the potential to help shape health system interventions, especially those targeting caregivers and people requiring long-term care support. Due to the variation among types of ADC programs, future research on ADCs should consider different characteristics of ADC programs to better contextualize their results.

COMMUNITY-LEVEL SOCIAL CAPITAL AND SOCIAL ISOLATION IN JAPAN: A MULTILEVEL PANEL STUDY

M. Saito^{1,2}, K. Kondo^{3,4,2}, J. Aida⁵, N. Kondo⁶, T. Ojima⁷, 1. Faculty of social welfare, Nihon Fukushi University, Chitagun, Aichi, Japan, 2. Center for well-being and society, Nihon Fukushi University, Nagoya-shi, Aichi, Japan, 3. Center for Preventive Medical Sciences, Chiba University, Chiba-shi, Chiba, Japan, 4. Center for Gerontology and Social Science, National Center for Geriatrics and Gerontology, Obu-shi, Aichi, Japan, 5. Department of International and Community Oral Health, Tohoku University Graduate School of Dentistry, Sendai-shi, Miyagi, Japan, 6. Department of Health and Social Behavior, School of Public Health, The University of Tokyo, Bunkyo-ku, Tokyo, Japan, 7. Department of Community Health and Preventive Medicine, Hamamatsu University School of Medicine, Hamamatsu-shi, Shizuoka, Japan

Social isolation, which can result in solitary death, is one of major problem in Japan. Although individual characteristics among isolated individuals have been revealed, community-level factors remain unclear. Therefore, we examine the association between social isolation and community-level social capital. We used longitudinal panel data from 2010 and 2013 from the Japan Gerontological Evaluation Study, a nationwide survey involving 58,683 functionally independent older people nested within 381 communities. We defined social isolation as contact with friends less than “a few times a year”. Respondents were categorized to “continuous non-isolation”, “change to isolation”, “continuous isolation”, and “change to non-isolation”. Social capital was measured by community-level health related social capital scale including civic participation, social cohesion, and reciprocity (Saito et al. 2017) from the 2010 survey. Multi-level Poisson regression analysis was adopted, controlling for individual-level social capital, age, sex, educational attainment, marital status, IADL, household income, and population density. A marked difference was observed in the proportion of “change to isolation” at the community level (3.1% to 40.4%; mean: 14.8%). In addition, each individual-level social capital dimension showed protective associations with “change to isolation” and “change to non-isolation”.

Furthermore, even after controlling for the above variables, protective associations were observed between community-level reciprocity scores and “change to isolation” (prevalence ratio: 0.95, 95% confidence interval: 0.88–0.97). On the other hand, no association was found between community-level social capital and “change to non-isolation”. These results suggest the potential of a population approach for the prevention of social isolation among older people.

CROSS-NATIONAL COMMUNITY CASE STUDIES OF RESILIENCE AND AGING

L. Skemp, Niehoff School of Nursing, Loyola University Chicago, Chicago, Illinois

Resilience, the ability to recover from difficult or challenging situations is inherent to healthy aging. Contextual and social determinants of health influence the cultural capital that communities can access and resources that individuals might use to respond to aging challenges. This is particularly important in communities that are managing the double burden of disease, outmigration of the young and environmental uncertainty. Three ethnographic community case studies are described and compared; an immigrant community in the rural United States, a multi-ethnic urban community in the United States, and a rural Caribbean village. A description of the contextual background, life experiences and social networks of typical elders within these communities highlight the importance of neighbors, friends, family, and social organizations (both formal and informal) to resilience and aging. Contextual factors of social, political and economic uncertainty are highlighted. Conversely, inflexible social structures and rigid rules, impact on resilience of communities and individuals. Discussion and comparison of evidence-based community capacity building programs provides insight into how local community capacity emerges within diverse cultural contexts. Recommendations for culturally informed research, policy, and practice are highlighted.

FURTHER EDUCATION ON ABUSE OF PATIENTS IN NEED OF LONG-TERM CARE: DEMAND AMONG GERMAN FAMILY DOCTORS

P. Schnapp¹, A. Berzlanovich², S. Eggert¹, R. Suhr¹, 1. Center for Quality in Care, Berlin, Berlin, Germany, 2. Medical University of Vienna, Vienna, Austria

Previous surveys have asked local and regional samples of physicians about their demand for further education about elder abuse, and found majorities of respondents indicating such demand. We present results from the first nationally representative study of this topic. We focus on education about physical restraint and neglect of patients in need of long-term care. A postal survey of a probability sample of German family physicians was conducted. Respondents were randomly assigned to receive a questionnaire on either restraint or neglect, with analogous content in both questionnaires. Questionnaires had been pretested and their psychometric properties optimized. Response rates are 17% (n = 253) for restraint and 19% (n = 284) for neglect. About half of the respondents express an interest in education, with the share significantly higher for neglect than for restraint. Relative interest in specific topics is similar across conditions, with the topic “distinguishing signs of abuse from symptoms due to other causes” the most popular. In logistic regressions,

significant predictors of interest are attitudes towards preventing abuse of patients in need of long-term care as the family physician's responsibility, lack of confidence in one's abilities to tackle such abuse (both conditions), the proportion of the respondent's patients who are in need of long-term care, and the respondent's knowledge about patients' previous victimization (neglect condition only). We conclude that there is high interest in education about these topics and call for research that examines whether relatively positive attitudes towards restraint are due to a lack of knowledge about alternatives.

THE STRUCTURE OF PROFESSIONAL ADVICE NETWORKS IN LONG-TERM CARE: INFLUENCES AND IMPLICATIONS

J. Keefe¹, J. Meng², J.E. Squires^{3,4}, M. Doupe⁵, C. Reid⁶, G. Cummings⁷, J.A. Knopp-Sihota⁸, C.A. Estabrooks⁷, 1. *Mount Saint Vincent University, Halifax, Nova Scotia, Canada*, 2. *Michigan State University, East Lansing, Michigan*, 3. *University of Ottawa, Ottawa, Ontario, Canada*, 4. *Ottawa Hospital Research Institute, Ottawa, Ontario, Canada*, 5. *University of Manitoba, Winnipeg, Manitoba, Canada*, 6. *University of British Columbia, Okanagan, Kelowna, British Columbia, Canada*, 7. *University of Alberta, Edmonton, Alberta, Canada*, 8. *Athabasca University, Athabasca, Alberta, Canada*

The Advice Seeking Networks in Long Term Care Study used social network analysis to understand the informal advice networks of senior leaders in Canadian long term care (LTC), with the goal of using this knowledge to inform future efforts to more effectively disseminate quality improvement innovations. In this abstract we describe one main component of the study, a quantitative analysis of the structure and determinants of interpersonal advice networks in the sector. At each of the 958 LTC facilities spanning 11 of Canada's 13 provinces and territories, we asked one senior leader to complete a survey identifying individuals who were informal sources of advice about quality improvement. Using exponential random graph modeling to analyze data from 482 respondents (RR, 52%), we found that a single advice-seeking network appears to span the nation, with opinion leaders and boundary spanners who act as key sources of advice located in each province and territory. Geographic proximity exerted a strong effect on network structure, with only 3% of advice seeking relationships crossing provincial boundaries. The effect of facility owner-operator model was more modest and varied across regions. A majority of individuals (61%) identified as sources of advice in the network were professionals who were outside our original sample and not employed in LTC facilities, such as regional and provincial health administrators.

USING INTER-ORGANIZATIONAL NETWORK ANALYSIS FOR QUALITY IMPROVEMENT IN LONG-TERM CARE

A.M. Beacom¹, J. Meng², S.A. Chamberlain¹, J.W. Dearing², W.B. Berta³, J. Keefe⁴, J.E. Squires^{5,6}, C.A. Estabrooks¹, 1. *Faculty of Nursing, University of Alberta, Boston, Massachusetts*, 2. *Michigan State University, East Lansing, Michigan*, 3. *University of Toronto, Toronto, Ontario, Canada*, 4. *Mount Saint Vincent University, Halifax, Nova*

Scotia, Canada, 5. *University of Ottawa, Ottawa, Ontario, Canada*, 6. *Ottawa Hospital Research Institute, Ottawa, Ontario, Canada*

The Advice Seeking Networks in Long Term Care Study used social network analysis to understand the informal advice networks of senior leaders in Canadian long term care (LTC), with the goal of using this knowledge to inform future efforts to more effectively disseminate quality improvement innovations. In this abstract we describe one main component of the study, a quantitative analysis of the structure and determinants of inter-organizational advice networks in the sector, and of how these networks compare with interpersonal advice networks. At each of the 958 LTC facilities spanning 11 of Canada's 13 provinces and territories, we asked one senior leader to complete a survey identifying individuals who were informal sources of advice about quality improvement, and LTC facilities that were seen as models for quality care. We used exponential random graph modeling and quadratic assignment procedure correlation analysis to analyze data from 482 respondents (RR, 52%). Compared with interpersonal advice networks, the inter-organizational networks were more dense and interconnected and featured more relationships that spanned provincial boundaries. As in the interpersonal networks, opinion leading and boundary spanning LTC facilities were identified in all provinces and regions, but opinion leadership in the inter-organizational networks was more centralized around a smaller number of facilities recognized as exemplars of quality residential care. These differences between the two types of advice networks suggest the value of understanding and utilizing both to disseminate best practices throughout the sector.

POPULATION AGING AND THE GLOBAL ECONOMY: WEAKENING DEMOGRAPHIC TAILWINDS REDUCE ECONOMIC GROWTH

D. Baxter², G. Donehower¹, W.H. Dow¹, R.D. Lee¹, 1. *School of Public Health, University of California at Berkeley, Berkeley, California*, 2. *Baxter Consulting, Berkeley, California*

Expansion of the working age population has been a powerful engine of the global economy in recent decades, with the resulting demographic "tailwinds" accounting for 48% of annual economic growth from 1990–2015. These tailwinds will slow, however, with rapid global aging in upcoming decades. Building on detailed country-specific economic models and data on age profiles of labor, consumption and savings from the National Transfer Accounts project, we estimate how population changes will affect national incomes to 2040 under likely future demographic scenarios. We predict that global demographic tailwinds will be only 31% as strong in the 2015–2040 period as compared to 1990–2015. Tailwinds that added 1.3% per year to global economic growth during 1990–2015 will drop to only 0.4% per year from 2015–2040. Cumulatively, this projection implies that the global economy in 2040 will be 20% smaller under projected 2015–2040 population trends than it would have been if the population trends of 1990–2015 had continued. In the United States, tailwinds will drop by 0.8% per year, only slightly better than the 0.9% drop in other high income countries. Many low and middle income countries will experience similar

slowdowns to economic growth, although countries earlier in the demographic transition will see rising demographically-driven economic growth, such as a 0.4% increase in Nigeria's tailwind. A major exception is China, which we project will transition from a 1.5% annual tailwind to a 0.6% headwind as China's working age population actually began to shrink in 2016.

SESSION 915 (POSTER)

ARTHRITIS

PREDICTORS OF KNEE OSTEOARTHRITIS IN COMMUNITY-DWELLING OLDER WOMEN: A 4-YEAR LONGITUDINAL STUDY

N. Kojima¹, M. Kim¹, K. Saito³, H. Yoshida¹, H. Hirano¹, S. Obuchi¹, T. Suzuki², H. Kim¹, 1. *Tokyo Metropolitan Institute of Gerontology, Tokyo, Japan*, 2. *National Center for Geriatrics and Gerontology, Obu, Japan*, 3. *Yokohama City University, Yokohama, Japan*

The present longitudinal cohort study was conducted to identify predictors of knee osteoarthritis in community-dwelling elderly Japanese women. Baseline data were collected in the autumn of 2008 and follow-up data were collected in 2012, both at the Tokyo Metropolitan Institute of Gerontology. One thousand two hundred eighty-nine women aged 75–85 years living in Itabashi Ward, Tokyo, participated in the baseline assessment; subsequently, 992 participants with no history of knee osteoarthritis at baseline were reexamined after 4 years. The follow-up assessment included 952 participants, 867 of whom provided information about knee osteoarthritis. Baseline assessment included measurements of anthropometry, physical fitness, blood components, lifestyle, and past history of diseases. A logistic regression analysis incorporating age and history of diseases as moderator variables (forced entry method) revealed that a higher body mass index (≥ 22.25 kg/m²), slower walking speed (≤ 78.94 m/min), lower serum albumin level (< 4.1 g/dL), higher serum creatinine level (> 0.56 mg/dL), higher HbA1C (≥ 5.4 %), and low frequency of soy product consumption (\leq once/2 days) at baseline were independent predictive factors of knee osteoarthritis incidence during the 4-year follow-up period. This prospective cohort study suggested that parameters related to obesity, decline of motor, hepatic, and renal functions, and westernized dietary culture compose the causes of knee OA incidence in Japanese elderly women. These results could contribute to the design of knee OA prevention programs for elderly women.

COMPARISON OF PHYSICAL FUNCTION BETWEEN FALLERS AND NON-FALLERS AMONG OLDER ADULTS WITH ARTHRITIS

J. Kim, M. Lee, J. Song, *Korea University, Seoul, Korea (the Republic of)*

Falls are the second leading cause of accidental death worldwide and are major cause of personal injury, especially for older people. Although arthritis has been identified as one of the risk factors of falls and its prevalence increases with age, there has been little information about

risk factors of falls for this group of population. The purpose of this study was to identify risk factors of falls, particularly physical function aspects, among older adults with arthritis. Using a sample of 3491 community-dwelling older adults with arthritis from the 2014 Korean National Older Adults Life Survey, this study investigated level of physical function of the subjects by comparing fallers (n=1174) from non-fallers (n=2317) group. Physical function of the subjects was evaluated by the Korean versions of Activity of Daily Living (K-ADL) and Instrument of Activity of Daily Living (K-IADL). Independent sample t-tests, ANOVAs, and Chi-square tests were mainly used. Significant differences ($p < .01$) between fallers and non-fallers were found for demographic and general characteristics such as age, sex, living with spouse, number of generations with living, education, working status, economic status, diagnosis with dementia, number of medication, smoking, drinking, and degree of exercise. Fallers had significantly ($p < .0001$) more ADL and IADL limitation (13.54% and 31.91%, respectively) compared to non-fallers (7.18% and 21.37%, respectively). The findings of this study suggest that interventions to promote physical function would be beneficial to prevent falls of older adults with arthritis. Correspondence to Jun-Ah Song (jasong@korea.ac.kr).

PSYCHOLOGICAL STATUS MEDIATES THE BIPHASIC RELATIONSHIP BETWEEN OSTEOARTHRITIS AND FALLS

S. Mat³, C. Ng^{2,1}, M. Tan⁴, 1. *Department of Rheumatology & Immunology, Singapore General Hospital, Singapore, Singapore*, 2. *Duke-NUS Medical School, Singapore, Singapore*, 3. *Ageing and Age-Associated Disorders Research Group, Faculty of Medicine, University of Malaya, Kuala Lumpur, Malaysia*, 4. *Division of Geriatric Department, Faculty of Medicine, University of Malaya, Kuala Lumpur, Malaysia*

Several barriers have prevented adequate evaluation of falls in OA: the lack of homogeneity in OA diagnostic tools used and the heterogeneous nature of OA itself. Therefore, a holistic evaluation of OA and falls using analogous OA definitions to clinical practice is important. This was a case-control study involving 389 individuals aged ≥ 65 years (229 fallers, 160 non-fallers). Cases were fallers with ≥ 2 falls or one injurious fall over the past 12 months. Osteoarthritis was defined using three difference criteria: radiological (Kellgren-Lawrence (KL)), clinical and self-reported physician-diagnosed. Severity of symptoms were assessed using the Western Ontario and McMaster Universities Arthritis Index (WOMAC) questionnaire. The total WOMAC score was categorized to asymptomatic, mild, moderate and severe symptoms. Fear of falling (FoF) and psychological status were measured with the short falls efficacy scale-international (FES-I) and the Depression, Anxiety and Stress Scale (DASS-21) respectively. Individuals with radiological OA and 'mild' symptoms had reduced risk of falls compared to those with no reported symptoms [OR: 0.402 (0.172–0.940), $p = 0.042$]. Individuals with clinical OA and 'severe' symptoms had increased risk of falls compared to those with 'mild' OA [OR: 4.487 (1.883–10.693), $p = 0.005$]. The relationship between mild symptoms and reduced risk of falls

was attenuated after controlling for increased anxiety, while the association between severe symptoms among elderly with clinical OA and falls was no longer statistically significant when adjusted for increased FoF. Our findings suggest the previous conflicting evidence on OA and falls is explained by the apparent biphasic relationship based of different diagnostic criteria. The mediating effect of psychological factors for this relationship emphasize the urgent need to develop effective treatment strategies for psychological factors associated with falls.

CULTURAL ADAPTATION OF FIT & STRONG! FOR PORTUGUESE OLDER ADULTS—FIRST STEPS

N. Duarte^{1,2}, S.L. Hughes³, M. Paul^{1,2}, 1. UNIFAI (ICBAS-University of Porto), Porto, Portugal, 2. CINTESIS, Porto, Portugal, 3. University of Illinois Chicago, Chicago, Illinois

Osteoarthritis (OA) is a major cause of disability in older adults world-wide. Fit & Strong! (F&S) is an 8-week evidence-based physical activity program for older adults with OA that has significantly improved strength and mobility out to 18 months (Hughes et al., 2010). We are currently translating the program in Portugal. We have translated the program manual and materials and are examining acceptability using focus groups with participants, providers and experts, followed by a randomized pilot of the adapted program. The participant focus group examined opinions about group exercise, characteristics of F&S, knowledge of arthritis, barriers to exercise, and the advantages of translating the program name into Portuguese. Participants were a convenience sample from a Day Care Center with lower extremity joint pain (n=11; 54.5% female), a mean age of 79.5 (SD=8.0), 54.5% of whom attended school for 4 years. Results indicated good receptivity to the program with schedule being the main concern identified. Participants reinforced the importance of having music during the sessions, and suggested changes in the program name. These results and those forthcoming from focus groups with providers and experts, and the pilot, will help to inform the cultural adaptation of the program, its implementation and evaluation.

ENVIRONMENTAL FACTORS AND ONSET OF RESTRICTED MOBILITY OUTDOORS IN OLDER ADULTS WITH OSTEOARTHRITIS

M. Rantakokko¹, R. Wilkie², 1. Gerontology Research Centre, University of Jyväskylä, Jyväskylä, Finland, 2. Research Institute for Primary Care Sciences, Keele University, Staffordshire, United Kingdom

The study examines how environmental factors contribute to the onset of restricted mobility outside the home among older adults with osteoarthritis. This was a prospective cohort study of adults aged 50 years and over with osteoarthritis (N=1802). Logistic regression tested the association between the onset of restricted mobility outside the home and health, sociodemographic and perceived environmental barriers (hills and steep slopes, inaccessible public buildings, poor pavement condition, lack of access to public parks or sport facilities, heavy traffic or speeding cars, and poor weather). The potential moderating role of environmental

barriers on the association between health factors and onset was examined using interaction terms and stratified analysis. Of 1802 participants, 13.5% (n=243) reported the onset of restricted mobility outside the home at three-year follow-up. Walking disability, anxiety, depression, cognitive impairment and obesity, and all environmental barriers were associated with onset after adjustment for confounders. There were significant but less than multiplicative interactions between hills and steep slopes that make it difficult to move outdoors with walking disability (p=.030), anxiety (p=.037), depression (p=.002) and cognitive impairment (p=.029); poor pavement conditions and anxiety (p=.036), and heavy traffic or speeding cars and depression (p=.036). For older adults with osteoarthritis, environmental barriers have a greater role on its impact when associated morbidities and walking disability exist. Awareness of environmental barriers is important when aiming to maintain mobility and activities outside the home despite health conditions in older adults.

ALTERATIONS IN STEPPING KINETICS AND LEG STRENGTH ARE ASSOCIATED WITH KNEE ARTHRITIS ASYMMETRIES

T. Gonzales¹, H.J. Hernandez¹, B.A. Seamon¹, D. Pennington¹, V. McIntosh¹, M.R. Blackman^{1,2,3}, M. Harris-Love¹, 1. Clinical Research Center, Washington DC VA Medical Center, Washington, District of Columbia, 2. School of Medicine and Health Sciences, George Washington University, Washington, District of Columbia, 3. School of Medicine, Georgetown University, Washington, District of Columbia

Knee osteoarthritis (OA) is a chronic disease characterized by articular cartilage damage, pain, and weakness. Ambulating stairs is a leading source of pain in people with OA, and disease progression may be marked by asymmetrical gait abnormalities. The purpose of this study was to assess relative peak knee extension torque and Step-Up-and-Over (SUO) test performance asymmetries in individuals with knee OA. Forty-six male Veterans with knee OA (age = 61.6 yrs. \pm 5.6) enrolled in the study. Functional performance was assessed via the SUO test, which involves ascending/descending an 8-inch box on a force plate. SUO test outcomes included force-time parameters representing step-up force, step-down force, and force-time curve smoothness. Peak torque was measured using isokinetic dynamometry (180 deg/s). Self-reported symptoms and physical function were evaluated using the Knee Injury and Osteoarthritis Outcome Score (KOOS). Force-time curve smoothness was the only SUO test outcome significantly different in the less involved leg (mean = -8.27 \pm .55) compared to the more involved leg (mean = -8.48 \pm .57, $p < .001$), and was not associated with KOOS subscale scores. Relative peak torque was greater in the less involved leg (mean = .27 \pm .12) versus the more involved leg (mean = .23 \pm .11, $p = .019$) and was directly associated with the pain ($r = .53$, $p < .001$) and function ($r = .41$, $p = .006$) KOOS subscale scores. While leg strength is an important component of physical status in those with knee OA, force-time curve smoothness may reflect an important aspect of lower-limb motor coordination that affects gait asymmetries during stair ambulation.

SESSION 920 (POSTER)

AVENUES FOR AGING IN PLACE II

ROLE AWARENESS OF HOME-VISIT NURSES IN MULTIDISCIPLINARY COLLABORATION

M. Kimata, *Institute of Gerontology, The University of Tokyo, Tokyo, Bunkyo-ku, Japan*

To elucidate role awareness of home-visit nurses in multidisciplinary collaboration to enhance coordination between home medical and nursing care, self-administered questionnaires were mailed to 145 home visiting nursing station administrators and home-visit nurses in six municipal districts working to enhance coordination between home medical and nursing care. Survey items included home-visit nurses' characteristics and their reasons for participating in multidisciplinary collaboration. Analysis involved grouping subjects by years of experience at home visiting nursing stations (<10 or ≥10 years), and using SPSS Statistics Ver. 22 to compare reasons home-visit nurses participated in multidisciplinary collaboration. Sixty valid survey responses (41.4%) were analyzed. Home-visit nurses participated in five multidisciplinary collaboration situations (home medical care promoting councils, face-to-face meetings, multidisciplinary case conferences, community care conferences, public awareness-raising events) for six different reasons (resolving multidisciplinary collaboration problems, acquiring new users, sharing home medical and nursing care community problems, expanding home-visit nursing use, improving user care quality, educating one's own workplace staff). Comparing the results of the two groups regarding multidisciplinary collaboration situations and home-visit nurses' reasons for participating, those with ≥10 years of working experience gave significantly higher ratings ($P < 0.05$) for: community care conferences in "resolving multidisciplinary collaboration problems"; multidisciplinary case conferences, community care conferences and public awareness-raising events in "sharing home medical and nursing care community problems"; and home medical care promoting councils and public awareness-raising events in "expanding home-visit nursing use." Home-visit nurses with longer working experience were found to participate in multidisciplinary collaboration with an awareness of their different roles.

PROMOTING COMMUNITY-BASED ELDER CARE IN CHONGQING, CHINA

N.R. Hooyman¹, B.B. Cochrane¹, T. Luo², L. Prueher¹,
1. *University of Washington, Seattle, Washington*, 2. *First Affiliated Hospital Chongqing Medical University, Chongqing, China*

This poster describes an ongoing, community-based, elder care project involving the University of Washington and the Seattle-Chongqing Sister City Association in partnership with the First Affiliated Hospital of Chongqing Medical University and the Qinggang Senior Care Center in Chongqing, China. While the number of quality skilled nursing and assisted living facilities is growing in Chongqing's greater metropolitan area of around 30 million residents, there are relatively few community-based services to support older adults aging in the community near their families and friends. The purpose

of this partnership is to introduce community-based care policy and program initiatives -- such as care transition models, aging friendly and dementia friendly communities, and evidence-based wellness programs -- to staff from the hospital and senior care facility and to learn from them about both the barriers to the implementation of such models and the strengths offered by other care models in their city. This multiphase project involves a multidisciplinary group of UW faculty visiting Chongqing to understand their elder care services and introduce current community-based care models; a Chongqing delegation visiting Seattle to attend a regional conference on Elder Friendly Futures and visit community-based services and facilities; a pilot testing of new care models in Chongqing; and sharing geriatric education programs and tools for enhancing low-cost elder care networks. This poster identifies the opportunities and challenges with such collaborations, lessons learned and strategies relevant to other groups seeking to develop similar partnerships that have policy-level implications.

PERCEPTIONS OF AGING IN PLACE: A FOCUS ON LOW INCOME AND OLDER ADULTS

C.R. Bolkan¹, B. Mandal², E. Kim¹, 1. *Washington State University, Vancouver, Washington*, 2. *Washington State University, Pullman, Washington*

Many initiatives to support aging in place are based primarily on the views of policy makers, healthcare professionals, and researchers, rather than on the perspectives of representative samples of older adults, particularly those with low incomes who may have limited resources to age in place. Guided by community-based participatory research (CBPR) principles, in partnership with local aging services organizations, we surveyed a representative sample of adults aged 60+ and family caregivers ($N = 363$, *mean age* = 73) via computer-assisted-telephone interviews (CATI) that addressed health, caregiving, transportation, access to and utilization of a variety of community and health services/resources, community strengths/weaknesses, and other needs regarding aging in place. We found that most respondents indicated good/excellent health (67%), despite almost 50% also reporting at least one chronic condition or serious illness. This may indicate a future need for expanded support in remaining at home, yet only 44% of respondents were currently aware of aging support services in the region. Further, we found disparities in awareness of aging support services by education and income: specifically, those with high school or less education ($p = 0.04$) and with household incomes of less than \$30,000/year ($p = 0.02$) were significantly less likely to identify support that could help them to age in place. In order to develop more effective interventions to support aging in place for a diverse population of older adults, their perspectives, experiences, and input must be incorporated into practice and policy, especially for underserved and hard-to-reach populations.

MUTUAL SUPPORT HAPPINESS HOMES: AN ALTERNATIVE FORM OF AGING IN PLACE IN RURAL CHINA

C. Zhang², N. Muramatsu^{1,3}, 1. *Division of Community Health Sciences, School of Public Health, University of Illinois at Chicago, Chicago, Illinois*, 2. *Division of Social*

Security, College of Humanities and Development Studies, China Agricultural University, Beijing, China, 3. Institute for Health Research and Policy, Chicago, Illinois

In 2007 a Mutual Support Happiness Home (MSHH) emerged as a grass-root movement in a rural village whose population was rapidly aging. By 2014, 79,521 MSHHs were established throughout rural China. Despite this rapid growth, little is known about MSHHs. This study describes MSHHs' history and key features and identifies their current challenges and future directions based on a two-month field research and a literature review. The first MSHH was born in a building with 12 rooms and 24 beds, converted from an abandoned primary school. The mission was to have older "empty nesters" live together and support each other to remain in their community as long as possible. This model appealed to rural governments looking for cost-effective ways to address rural seniors' needs, adult children with filial responsibilities, and older adults wishing to remain in their community. MSHHs quickly evolved into a governmental policy. Funds are provided by central and local governments for construction, by Village Collectives for daily operation, and by older residents and families for living and health care expenses. MSHHs have no paid staff. Older residents serve as administrators and staff. The agreement co-signed with the Village Committee facilitates adult children to fulfill their filial obligation through financial support and regular visits. MSHHs constitute an innovative and acceptable, yet transitional model for rural communities. To develop MSHHs into a sustainable model, they should be formally integrated into a rural old support system to serve as old-care resource centers for all villagers and informal caregivers.

EXPLORING COMMUNITY LIVING FROM A LIFECOURSE PERSPECTIVE: TOWARD LIFECOURSE POLICY OPTIONS

E. Loughlin, National University of Ireland, Galway, Galway, Ireland

Ageing and disability are part of the lifecourse trajectory, with disability adding another dimension to the ageing process. Older people and persons with disabilities share a common vulnerability in respect of community living and in relation to maintaining autonomy and independence. Further, the ability of people belonging to each group to connect and interact is often stifled through inadequate policies that leave them susceptible to heightened risks of institutionalization. The ageing-disability nexus provides the rationale for greater cooperation between actors in each sector in order to achieve common goals such as inclusive, accessible and age-friendly communities. This paper presents the results from an emerging conceptual framework that has arisen from a documentary analysis of key Irish and international community living law and policy as well as evidence relating to independent living, ageing-in-place and the lifecourse. Evidence from the international literature suggests that older people and persons with disabilities express a common desire to live and age in their communities. However, in many countries, policies have often developed from silo-specific perspectives that do not necessarily support the aspirations of those for whom they are enacted. Understanding the conceptualization of community living is therefore important for policy innovation that seeks to support older people and persons

with disabilities to realize, enhance and maintain meaningful community living. Exploring community living as refracted through the lens of the lifecourse perspective adds valuable depth of understanding to the interpretation of the intent and purpose of policy and how it may be better translated into practice.

ENVIRONMENTAL DESIGN, ACTIVITY AND INTERACTION IN CARE FACILITIES FOR OLDER PEOPLE

S. Nordin^{1,2}, K. McKee¹, M. Wallinder¹, L. von Koch², H. Wijk³, M. Elf¹, 1. Department of Education, Health and Society, Dalarna University, Falun, Sweden, 2. Karolinska Institutet, Stockholm, Sweden, 3. Gothenburg University, Gothenburg, Sweden

Older people living in residential care facilities spend most of their time within the home due to high levels of frail health and are depending on the physical environment for their daily life activities and interactions. There is a need for a deeper understanding on the complex relationships between older people and the quality of the physical environment in long-term care. The aim of this study was to explore how environmental factors influence resident activities and interactions at two care facilities. A mixed-method approach was applied. The quality of the physical environment was assessed by the Swedish version of the Sheffield Care Environment Assessment Matrix (S-SCEAM). Activities and interactions of older people were assessed through an adapted version of the Dementia Care Mapping (DCM), and data on residents' emotional states were collected via the Observed Emotion Rating Scale (OERS). Walk-along interviews with older people, care staff and relatives were conducted and field notes were taken. The results indicate that the environmental design influenced activities and interactions among older people. Private apartments and dining areas had high environmental quality scores at both care facilities, and safety aspects was highly supported while the overall layout had lower quality. Despite high environmental quality in general, several factors were found to limit residents' activities and interactions. These findings stress the importance of optimising long-term care by focusing on environments that are accessible and can offer possibilities for residents to use the facility independently.

BUILDING AN AGING IN PLACE COMMUNITY IN URBAN SHANGHAI: AN ETHNOGRAPHIC ASSESSMENT OF CCHC MODEL

G. Shen, The Institute of Anthropological and Ethnological Studies, Fudan University, Shanghai, China

Under the auspices of the Shanghai Municipal Government, server programs aimed at building ageing in place communities have been piloted since 2014 for the purpose of providing community based services for homebound elders. In actual practices, however, these well-intentioned programs failed to match the real needs of the ageing population owing to its lack of service options and narrow coverage. To address this problem, a "Continuing Care Home-based Community" (CCHC) model was piloted in a designated community in Yangpu District in March 2016. The CCHC model is essentially a joint venture between the government and social organizations. With its promises to

offer a comprehensive eldercare service package, the CCHC model is welcomed by the recipients at present. This paper offers an ethnographic assessment of the likely impact of the CCHC model on the everyday life of the elders in the community under study as well as a tentative discussion of its applicability in the near future.

TRENDS AND PATTERNS OF SELF-REPORTED ELDERLY MORBIDITY IN KERALA: FUTURE PROBLEMS AND POLICY PROSPECTS

K. Paul¹, R. Sengupta², 1. *Tata Institute of Social Sciences, Mumbai, Mumbai, Maharashtra, India*, 2. *Jawaharlal Nehru University, Delhi, Delhi, India*

Kerala has achieved highest rank on literacy rate, life expectancy, emigration, HDI index and wage rates in India. The state is currently undergoing an epidemiological transition with a swift change in the disease profile of its population. We analyzed the trend and pattern of the burden of self-reported elderly morbidity (ICD classification) in the states of Kerala using three rounds of (52nd, 60th, and 71st) NSSO data. Descriptive analysis is carried out to understand the prevalence of self-reported morbidity variation over a period of two decades while the multivariate analysis is performed to identify the determinants of various types of ailments. The major concern is the considerable increase the trends of CVDs and NCDs. The results are quite alarming as there has been an eight fold increase in the prevalence of CVDs in the last two decades while the prevalence NCDs has risen by three times within last two decades. The rising incidence of CVDs and NCDs has been observed among the elderly and urban women in the state. Therefore, a huge pressure on the public health system is very likely shortly with the double burden of both communicable and non-communicable disease. Hence, an effective and responsive public health system is called for to make health care services available for NCDs and CVDs at the primary level. Health promotion measures may be taken to inform elderly people inculcate healthy habits. To ameliorate caregiving, the involvement of family will be most critical. So, Government needs to implement an elderly oriented policy to the betterment of their condition.

DEVELOPING A RESIDENCY PROGRAM FOR NOVICE THERAPISTS IN HOMECARE PRACTICE: THERAPY GATEWAY PROGRAM

S. Rushanan¹, E.C. Wang-Hsu^{1,2}, 1. *Penn Medicine, Bala Cynwyd, Pennsylvania*, 2. *Drexel University, Philadelphia, Pennsylvania*

Background: The demand for homecare services has increased rapidly as the populations in the U.S. ages. A common perception is that homecare is not a suitable first job for new graduates, due to their lack of experience. We developed the Therapy Gateway Program (TWP) in 2012 as a pilot residency program to recruit young therapist to meet the growing need of workforce.

Aims: 1. To provide supportive structures to novice therapists to build upon their clinical experience and professionalism in the home health practice. 2. To promote home health as a meaningful and rewarding career to novice therapists.

Method: Eleven new-hired novice therapists went through the TWP homecare residency program from 2012 to 2016.

The program uses the ICF model, self-reflection journals, evidence-based practice, and ongoing mentorship. Novice therapists spent from 12 to up to 18 months of their employment engaged in various activities to help their transition to the home care environment.

Results: After four years, ten of the eleven novice therapists (91%) are successfully employed at this home health agency. All ten therapists have become independent and productive in their clinical positions. Eight therapists were promoted to higher clinical levels based upon their performance. One therapist left the program after one month to pursue a different job.

Discussion and implications: The TWP model provided the resources needed to assist new graduates in their transition from academics to homecare practice. This model may be further expanded and structured into a formal and widely accepted homecare residency program for novice therapists.

REDESIGNING AND RETROFITTING EXISTING COMMUNITIES TOWARD LIFETIME NEIGHBOURHOODS

B. Chen^{1,2}, Y. Liu^{1,2}, 1. *Department of Urban Planning and Design, Xi'an Jiaotong-Liverpool University, Suzhou, Jiangsu Province, China*, 2. *Research Institute on Ageing and Society, Xi'an Jiaotong-Liverpool University, Suzhou, China*

China has the largest number of the elderly among all ageing countries. However, little attempt has been made to accommodate the growing need for the elderly. This research aims to provide an insight into this phenomenon, focusing on issues relating to the built environment. Following the current trend of 'ageing-in-place', it intends to provide a critical view on the re-design and retrofits of existing communities, using projects located in Suzhou as examples, where the elderly (i.e. age over 60) has accounted for more than 24% of the local population by 2014. Based on literature review and case studies worldwide, a series of issues have been summarized as benchmark criteria for age-friendly communities. Then local communities (e.g. Zhuhui New Village, Living Bank Community, Olive Bay Community, etc.) are studied through such lens – by comparing the target communities against the benchmark criteria, it is found that several important issues (including necessary facilities and services) have not been well addressed in the existing communities, though they tend to be taken into account in the design processes more often from a longitudinal perspective. Onsite semi-structured interviews and focus groups have also been conducted to explore the relative importance of these issues in the given context, in line with the changing needs (e.g. physical and psychological needs) of different families over time. Some early findings (e.g. evidence on age-friendly communities) will be incorporated into the redesign/retrofit guidance for existing communities and thereby inform the transformation of local neighbourhoods towards lifetime standards.

ENVIRONMENTAL BARRIERS AND DISABILITY IN ELDERLY LIVING IN AN APARTMENT COMPLEX WITHOUT AN ELEVATOR

E. Duim¹, M.L. Ferrer^{1,2}, E.S. Sartor², T. Dahy², A.L. Gonçalves², M.C. Silva², C.M. Buchalla¹, 1.

Epidemiology, University of São Paulo, São Paulo, São Paulo, Brazil, 2. São Francisco University, São Paulo, São Paulo, Brazil

The diversity and heterogeneity in aging is a challenge to public policy makers and services in order to provide “aging in place”, especially to developing countries such as Brazil. Objective: To identify and to analyze the association between disabilities and environmental barriers in older adults living in a multi-storey apartment complex with no elevator. Methods: a cross-sectional study with older adults living in a apartment building for lower-income families subsidized by the government in a neighborhood in a medium-sized town in Brazil. Semi-structured interview was conducted using environmental factors such as those proposed by the International Classification of Functioning, Disability and Health. To assess disability the WHODAS 2.0 (12 item) was applied. Results: 96 older adults were interviewed with mean age 69.9 (± 7.3) years, 68.8% were female, living in the same place for 14.1 (± 6.2) years. 35% of all of them were living on the first floor. The mean score of WHODAS 2.0 was 20.7 (± 17.7) points and the major disability identified was to walk long distances (32%). Environmental barriers were appointed by few people: 20% of them recognized stairs as a major problem, followed by the lack of accessibility in public transportation (25%) and sidewalk hazards (22.9%). The association between perceived barriers and disability was moderate ($r=0.41$). The need of an elevator was indicated by one person only. Conclusion: There is association between disability and environmental barriers. However it suggests that older people in Brazil have difficulties to detect the role of environmental barriers in their functioning.

THE IMPACT OF THE LOCAL ASSOCIATIONS FOR THE ELDERLY IN ISRAEL TO THE QUALITY OF LIFE OF OLD ADULTS

Y. Brick, *Gerontology, University of Haifa, Jerusalem, Israel*

This paper deals with the special contribution of the Local Associations for the Elderly in Israel. There are 124 such Associations, who develop and operate a variety of services for the elderly people in the community, in cooperation with the local municipalities and the government.

The purpose of this paper is to present the special contribution of the associations by looking into the structure, their financial stability, the operation, their cooperation with the local municipalities and the unique contribution to the network of services for the elderly and cosciently on the quality of life of the elderly.

The paper is based on a study which was not published yet. The data was collected from the year 2013 and was based on a questionnaire which was sent to the chair people and the CEO's of the associations, 84 where received. In addition, a different questionnaire was sent to the directors of the services for the elderly in the local municipalities.

The findings of the study show that that most of the associations are balanced financially with no deficit (64%). Most of the associations are providing a wide range of services for the elderly, 86%- day care centers, with the average of 130 participants, 81% - supportive communities, with the average of 312 participants, 67% - social clubs with 212 beneficiaries, and 66% physical activities programs with the average of 148 participants. The average number of

volunteers in these associations was 47 who contributed 424 hours per month, 82% of them of 65+. More than half of the associations employed professional volunteers.

Both, the leaders of the associations and the directors of services in the municipality indicated that the relationships are good. The directors of the associations indicated that the cooperation with the municipalities is average or high and 66% of the directors of the municipal services answered that the relationships are good.

The main conclusions from the study are that the associations are financially stable, administer a large spectrum of services, employ many volunteers and make a significant contribution to the quality of life of the elderly in the community.

USING A POLICY APPROACH TO FACILITATE EVOLVING NEEDS OF ACTIVE AGEING

K. Wong¹, S. Kwok², 1. *The Open University of Hong Kong, Hong Kong, Hong Kong, 2. Vocational Training Council, Hong Kong, Hong Kong*

The continuously growing ageing population is both an opportunity and a threat on the quantity and quality of healthcare professionals and novice workers concerned. This comes along with an increasing demand on informal carers who could help facilitate elderly to age at their community. This study conducted in Hong Kong described healthcare issues that were associated with ageing in place. It also examined obstacles for the youths to join the elderly care workforce, and the crucial role of government's involvement. Targeting at allied health professionals, elderly and their relatives, and youths, both quantitative questionnaire survey and qualitative focus group were employed. Results revealed a high demand of paraprofessional care providers with appropriate therapeutic and soft skills. Since majority of the young old in Hong Kong was well-aware of their health conditions, community healthcare training programmes that are offered by nurses and allied health professionals were urgently required to facilitate self-care. Almost all youths participated in this study realised the challenges resulting from the ageing population and were eager to pursue t studies and careers in clinical healthcare. However, they had hesitation in joining the workforce as non-professional community healthcare workers with poor reputation and social status. Lack of professional recognition, clear career ladder and a transparent master pay scale were other key obstacles that avert youths from joining the field. Such information provided valuable insights to the Government and a comprehensive policy approach involving different level of governance was proposed to cater the needs of ageing population.

THE EFFECT OF INCREASE IN GERMAN LONG-TERM CARE INSURANCE SUBSIDIES FOR SENIOR-FRIENDLY HOUSING

B. Joo, *TU Dortmund University, Dortmund, North Rhine-Westphalia, Germany*

The market of home modifications for older adults is expanding, which is especially supported by German long-term care insurance. Based on §40 of Book XI of Social Code (SGB XI), this insurance system, which aims at “improvement of the home environment”, promotes home-based long-term care for older adults rather than nursing

home care. This research intends to examine the effect of the increase in German long-term care insurance subsidies for senior-friendly modification of older adults' living space. A qualitative research (semi-structured interview and participant observation) was conducted to investigate the impact of the subsidies for senior-friendly home modification, which has increased from €2,557 to €4,000 since January 2015. For data collection, two groups were included as study targets: eight experts working in the industry and public services and 12 insured older adults. With the eight experts, face-to-face interviews were conducted. The interviews were recorded, transcribed, and analyzed using the qualitative content analysis method developed by Kuckartz (2016). Participant observation was added to retrace the decision-making process of the insured people. This study found that after the increase in subsidies, the demand for senior-friendly home adaptations increased substantially. Following the increase in the requests for subsidies, the long-term care insurance funds began to examine applications more strictly to prevent abuse of subsidies. Furthermore, the price of home modification increased partially after the policy change; thus older adults have not received benefit from the increase in subsidies to the extent it was initially expected. The results of this study suggest the importance of improving market transparency in home modifications and reinforcing on-site assessment of housing environments of grant applicants so as to meet their actual needs and to achieve expected policy outcomes.

SESSION 925 (POSTER)

BIOLOGY OF AGING

EFFECT OF ZINC SUPPLEMENTATION ON SERUM ALBUMIN LEVEL IN ELDERLY

D. Ngestingisih, *Geriatric Subdivision of Internal Medicine, Biochemistry Departement, Diponegoro University, Semarang, Jawa Tengah/ Central Java, Indonesia*

Background: Aging has been associated with increased oxidative stress, physiological-biochemical changes and impaired organs function. Those changes, might alter albumin homeostatic level in elder population due to nutrient intake insufficiency, organs degeneration, and oxidation of pre-formed albumin. Zinc was an essential trace element which functioned as co-factor of enzymes, liver protector and present antioxidant activity inside human body. We suspected zinc supplementation would enhance elder's serum albumin level.

Aim: This study was to determine the effect of zinc supplementation on serum albumin level in elder populations.

Methods: In this randomized control trial, with pre and post-test control group design, we included 31 elder people who lived in Unit Rehabilitasi Sosial Pucang Gading Semarang. Samples were randomly divided into two groups. Treatment group (16 people) were daily supplemented with 40 mg, whereas control group (15 people) were placebo supplemented. Both treatment last for 8 weeks. Albumin level analysis was performed before and after the trial. The data was then evaluated with Wilcoxon and Paired t-test.

Results: The result showed that the average level of serum albumin improved in both groups. Treatment group resulted in significant increase of mean albumin level by $0,5 \pm 0,23$ g/dl, $p < 0.001$ while the changes observed in placebo group were not significant ($0,2 \pm 0,61$ g/dl, $p = 0,175$).

Conclusions: Zinc supplementation could improve serum albumin level on elder subject.

SESAMIN AND SESAMIN COMBINED WITH ALPHA-TOCOPHEROL IMPROVE AGE-RELATED KIDNEY DYSFUNCTION

S. Shimoyoshi¹, D. Takamoto¹, H. Masutomi², Y. Kishimoto², A. Amano², Y. Ono¹, H. Shibata¹, A. Ishigami², 1. *Institute for Health Care Science, Suntory Wellness Limited, Soraku-gun, Kyoto, Japan*, 2. *Tokyo Metropolitan Institute of Gerontology, Tokyo, Japan*

Background/objectives: Oxidative stress is closely associated with aging. Sesamin, a natural ingredient contained in sesame (*Sesamum indicum*) seed and oil, has potent anti-oxidative activities in mice and humans, and could increase the bioavailability of α -tocopherol (VE). Kidney is an organ susceptible to aging, and often results in the age-related dysfunction. However, the effect of sesamin on aging kidney is unclear. The aim of this study is to clarify the effects of sesamin or sesamin+VE on age-related kidney dysfunction.

Methods: Twenty-months-old male C57BL/6N were divided into three groups. They were fed CRF-1 diet (old control; OC), CRF-1 containing 0.2% sesamin (SE) or 0.2% sesamin plus 0.2% VE (SE+VE) for five months. Six-months-old mice were fed CRF-1 (young control; YC). Blood and kidney samples were collected and blood urea nitrogen (BUN), histopathological changes and lipofuscin deposition were evaluated. Differential expression of genes related to oxidative stress and inflammation was examined.

Results: BUN level was significantly higher in OC (29.4 ± 3.65 mg/dL) compared to YC (19.1 ± 1.08 mg/dL, $p < 0.01$). SE+VE decreased BUN level compared to OC ($p < 0.05$). Lipofuscin deposition, an age-related change of kidney, was significantly reduced in SE or SE+VE. The gene expressions of NAD(P)H oxidase, chemokine and adhesion molecules were significantly elevated in OC and suppressed in SE or SE+VE compared to OC.

Conclusion: These results suggest that sesamin or sesamin combined with α -tocopherol are protective to age-related kidney dysfunction through its anti-oxidative and anti-inflammatory effects.

ASSOCIATION BETWEEN SERUM TESTOSTERONE AND BRAIN VOLUME AMONG COMMUNITY MIDDLE-AGED AND OLDER ADULTS

C. Liang^{1,2,3}, M. Chou^{1,2}, Y. Lin^{1,3}, L. Chen^{4,2}, 1. *Center for Geriatrics and Gerontology, Kaohsiung Veterans General Hospital, Kaohsiung City, Taiwan*, 2. *Aging and Health Research Center, Institute of Environmental and Occupational Health Sciences, National Yang-Ming University, Taipei, Taiwan*, 3. *Division of Neurology, Department of Internal Medicine, Kaohsiung Veterans General Hospital, Kaohsiung, Taiwan*, 4. *Center for Geriatrics and Gerontology, Taipei Veterans General Hospital, Taipei City, Taipei City, Taiwan*

Studies showed that testosterone is associated with cognitive function; However, few evidence proved the association between serum testosterone levels and brain volume of different area. The I-Lan Longitudinal Aging Study (ILAS), which randomly invited community-dwelling people aged 50 years and older for study, were retrieved for study. Free Testosterone (FT) levels were obtained from total testosterone, SHBG, and albumin by the Vermeulen method, and free androgen index (FAI) was defined as serum total testosterone (nM/L) divided by serum SHBG (nM/L). The total brain volume (TBV), gray and white matter volume, cerebrospinal fluid volume (CSF), and total intracranial volume (TIV) evaluated by MRI. Among 456 subjects (239 males, mean age: 64.0±8.5), we found that serum testosterone, FT and FAI were lower in women than in men (30.1±18.0 vs 491.6±176.2 ng/dL, $p < 0.01$; 0.398±0.284 vs 7.784±2.269 ng/dL, $p < 0.01$; 2.242±2.103 vs 37.015±13.325, $p < 0.01$). Multiple linear regression showed that TBV/TIV ratio, FT and FAI were significantly correlated in men, but not in women, after adjustment for age, educational levels, type 2 diabetes, hypertension and dyslipidemia, smoking, alcohol drinking, skeletal muscle mass, physical activities, cognitive function, depressive symptoms, and serum levels of homocysteine. Analysis of different parts of brain volume showed that FT and FAI were positively correlated with gray matter/TIV ratio and negatively correlated with CSF/TIV ratio. However, There was no correlation between serum testosterone levels and WMV/TIV ratio. Moreover, the FAI, compared with serum testosterone and FT, is more significantly association with multiple cognitive domain.

VITAMIN D INSUFFICIENCY AND MUSCULAR FATIGABILITY AMONG OLDER WOMEN

G. Duval¹, A. Schott², Y. Rolland³, H. Blain⁴, O. Beauchet⁵, C. Annweiler¹, 1. *Geriatric Medicine, Angers University Hospital, Angers, France*, 2. *Lyon University Hospital, Lyon, France*, 3. *Gérontopôle, Toulouse, France*, 4. *Montpellier University Hospital, Montpellier, France*, 5. *McGill University, Montreal, Quebec, Canada*

Background: Vitamin D affects physical performance in older adults. Effects on muscles, notably on muscle strength, remain yet unclear. The objective of this cross-sectional study was to determine whether vitamin D insufficiency was associated with triceps brachii muscle fatigability in community-dwelling older women.

Methods: A randomized subset of 744 women aged ≥75 years from the French EPIDOS cohort was categorized into two groups according to vitamin D insufficiency (i.e., serum 25-hydroxyvitamin D concentration ≤30 ng/mL). Triceps brachii muscle fatigability was defined as the loss of strength between two consecutive maximal isometric voluntary contractions. Age, body mass index, comorbidities, use psychoactive drugs, physical activity, first triceps strength measure, hyperparathyroidism, serum concentrations of calcium, albumin and creatinine, season and study centers were used as potential confounders.

Results: Triceps fatigability was more prevalent among women with vitamin D insufficiency (n=671) compared to the others (27.3% versus 12.3%, $P=0.006$). The serum concentration of 25OHD was inversely associated with the between-test change of triceps strength (adjusted $\beta=-0.09$,

$P=0.044$). Vitamin D insufficiency was positively associated with triceps fatigability (adjusted OR=2.65, $P=0.009$).

Conclusions: Vitamin D insufficiency was associated with muscle fatigability in this cohort of community-dwelling older women. This is a relevant new orientation of research toward understanding the involvement of vitamin D in muscle function.

HDL-C AND LDL-C ARE ASSOCIATED WITH BMD IN PREMENOPAUSAL AND ELDERLY WOMEN RESPECTIVELY

Y. Choi^{1,2}, J. Shin³, J. Jee¹, S. Cho¹, 1. *Center for Health Promotion, Samsung Medical Center, Seoul, Korea (the Republic of)*, 2. *Sungkyunkwan University School of Medicine, Seoul, Korea (the Republic of)*, 3. *Department of Family Medicine, Gangnam Severance Hospital, Yonsei University College of Medicine, Seoul, Korea (the Republic of)*

Recent studies have explored the association between serum lipids and bone mineral density (BMD). However, the results are inconsistent and studies for premenopausal women are very sparse. For the investigation without confounding effects of menopause, we analyzed the data collected from premenopausal women in early 40s and elderly women aged 70 and older, and comprehensive physiologic markers were included. Our Korean study population was consisted of 3,953 premenopausal women (age range 40~44, mean age 42.3±1.3) and 986 elderly women (70~92, 73.8±3.5). BMDs were measured by dual X-ray absorptiometry at lumbar spine (LS), femoral neck (FN), and total hip (TH). Height, percent body fat, and fasting serum measures of total cholesterol (TC), HDL-C, LDL-C, triglyceride, hsCRP, albumin, glucose, gamma-glutamyltransferase (GGT), estradiol, thyroid-stimulating hormone, and estimated GFR were included in the analyses. Multivariate linear regression models were used to examine relationships between BMD (dependent variable) and other variables. After adjusting for covariates, HDL-C was negatively associated with BMD at LS ($\beta = -0.052$, $p = 0.004$), FN ($\beta = -0.064$, $p = 0.000$), and TH ($\beta = -0.073$, $p = 0.000$) in premenopausal women. In elderly women, LDL-C was negatively associated with BMD at LS ($\beta = -0.104$, $p = 0.001$), FN ($\beta = -0.057$, $p = 0.068$), and TH ($\beta = -0.064$, $p = 0.042$). Our results suggest that serum lipids are inversely correlated with BMD and the pattern is different among young and old women.

AGING-DEPENDENT CG HYPERMETHYLATION D GENE EXPRESSION OF GSTM1 INVOLVED IN T CELL DIFFERENTIATION

S. Yeh¹, K. Yang^{1,2,3}, L. Lin⁴, M. Lee⁵, C. Hsieh⁶, C. Lin⁶, 1. *Institute of Long-Term Care, Mackay Medical College, New Taipei City, Taiwan*, 2. *Institute of Biomedical Science, Mackay Medical College, New Taipei City, Taiwan*, 3. *Department of Medical Research, Department of Pediatrics, Mackay Memorial Hospital, Taipei, Taiwan*, 4. *Department of Nursing, Hungkuang University, Taipei, Taiwan*, 5. *Department of Medical Research and Development, Show Chwan Memorial Hospital, Changhua, Taiwan*, 6. *Department of Medical Research, Mackay Memorial Hospital, New Taipei City, New Taipei City, Taiwan*

This study investigated whether aging was associated with epigenetic changes of DNA hypermethylation on immune gene expression and lymphocyte differentiation. We screened CG sites of methylation in blood leukocytes from different age populations, picked up genes with age-related increase of CG methylation content more than 15%, and validated immune related genes with CG hypermethylation involved in lymphocyte differentiation in the aged population. We found that 12 genes were associated with promoter or exon one DNA hypermethylation in the aged group. Two genes, GSTM1 and LMO2, were chosen to validate its aging-related CG hypermethylation in different leukocytes. Modulation of aging-associated GSTM1 methylation may be able to promote Th1 immunity in the elders.

HIGHER FREQUENCY OF MICRONUCLEUS IS ASSOCIATED WITH SARCOPENIA IN AN ELDERLY FREE-LIVING COMMUNITY

G.M. SilvaTavares^{1,2}, V. Manfredini¹, J. Mezzomo¹, A.A. Güllich¹, I. da Cruz³, M.G. Gottlieb², 1. *physiotherapy, Federal University of Pampa, Uruguaiiana, Rio Grande do Sul, Brazil*, 2. *Pontifícia Universidade Católica do Rio Grande do Sul, Porto Alegre, Rio Grande do Sul, Brazil*, 3. *Universidade Federal de Santa Maria, Santa Maria, Rio Grande do Sul, Brazil*

Micronuclei is considered an important biomarker to monitor the health of individuals or populations exposed to different biological and environmental stressors. The aim of this present study was to verify the frequency of micronuclei lesions and the association with, muscle mass, lifestyle and health status in elderly residents in a free-living community. A cross-sectional observational investigation was performed on a sample of 168 elderly (60 males, 108 females) residents of a free-living community were included in this study. The blood sample was collected for a micronuclei assay. Social demographics, muscle mass, lifestyle and health status were also evaluated. The sample was categorized in two groups: lower micronucleus frequency (LM, < 5 micronuclei/1000 nuclei) and higher micronucleus frequency (HM, ≥ 5 micronuclei/1000 nuclei). In the percentile distribution, 50% of the sample presented ≥5 micronuclei/1000 nuclei (the HM group). The mean age of sample was 68.41 ± 6.13. The mean micronucleus frequency was 5.87 ± 2.75 micronuclei/1000 nuclei. Only smoking habit ($p \leq 0.002$) and sarcopenia ($p \leq 0.021$) were significantly associated with higher micronucleus frequency. Higher frequency of micronucleus is associated with sarcopenia, independent of sex, age and smoking habit in an elderly sample.

SESSION 930 (POSTER)

CANCER

EFFECTIVENESS OF ADJUVANT CHEMOTHERAPY FOR OLD PATIENT (70 YEARS OR OLDER) IN STAGE III COLON CANCER

K. Yi-Hung, Y. Yu-Wen, H. Jui-Chu, *Chang Gung Memorial Hospital, Chiayi, Taiwan, Chiayi, Taiwan*

Background Surgery and postoperative adjuvant chemotherapy has been recommended for stage III colon cancer, especially in younger patients. In old patients (aged 70 years or older), the benefit is not so clear.

Methods This study was a retrospective observation of patients with stage III colon cancer who underwent curative surgery between January 1995 and December 2004 at the Chang Gung Memory Hospital. The disease-free (DFS) and cancer-specific survivals (CSS) of the old patients were calculated using univariate analysis with the Kaplan–Meier method and compared using the log-rank test. The Cox regression model was used for multivariate analysis for the confounding factors.

Results A total of 645 patients with stage III colon cancer were initially enrolled and stratified by age (≥ 70 , $70 >$ and ≥ 50 , younger than 50). The 50.5, 80.6 and 85.0 percent of three groups received adjuvant chemotherapy after curative surgery. No significant difference existed in 5-year CSS between old patients receiving adjuvant chemotherapy ($n=108$) and those who had surgery along ($n=106$) (72.2 vs. 65.2%, $P=0.323$, Fig. 1A), whereas adjuvant chemotherapy improved 5-year DFS (54 vs. 48.8%, $P=0.039$, Fig. 1B). However, multivariate analysis for 5-year DFS and CSS found an independent benefit for adjuvant chemotherapy in old patients with stage III colon cancer (in DFS, hazard ratio, 0.582, 95% confidence interval, 0.394–0.860, $P=0.007$; in CSS, hazard ratio, 0.035, 95% confidence interval, 0.0335–0.960, $P=0.035$).

Conclusions A multimodal approach in old patients with stage III colon cancer improved oncological outcomes.

OUTCOMES AFTER BREAST CANCER SURGERY IN NURSING HOME RESIDENTS: A NATIONAL STUDY

V.L. Tang^{1,2}, R. Sudore^{1,2}, K.E. Covinsky^{1,2}, C.S. Ritchie^{1,2}, S. Zhao¹, E. Finlayson¹, 1. *Medicine/Division of Geriatric Medicine; Division of Hospital Medicine, University of California San Francisco, San Francisco, California*, 2. *San Francisco VA Medical Center, San Francisco, California*

Background: Over 60% of cancer-related operations in nursing-home residents occur for breast cancer. We studied functional and mortality outcomes after breast cancer surgery in nursing-home women.

Methods: We identified long-term stay nursing-home residents age ≥ 65 who underwent inpatient breast cancer surgery in 2003–2009 using Medicare and Minimum Data-Set (MDS). We examined 30-day mortality and hospital re-admission rates, stratified by procedure (lumpectomy, mastectomy, lymph node dissection with lumpectomy or mastectomy [LND]). In multivariate analysis, we examined factors associated with 1-year mortality. Functional status was measured by assessing the degree of dependence in seven activities of daily living (ADL): MDS-ADL scale with a 2 point difference as clinically significant.

Results: We identified 4,180 subjects (age: 82 ± 7 , 48% dementia). Residents experienced significant functional decline that persisted 1 year after surgery (MDS-ADL score: lumpectomy: -3.4, mastectomy: -2.9, and LND: -2.5). Thirty-day readmission and mortality were high after surgery: lumpectomy: 26% and 9%, mastectomy: 14% and 4%, and LND: 15% and 2%, respectively. One-year all-cause mortality was high: lumpectomy: 42%, mastectomy: 31%, and

LND: 26%. In a multivariate analysis, poor baseline MDS-ADL score before surgery was strongly associated with 1-year mortality-- lumpectomy: HR 2.6 (95%CI:1.5–4.4), mastectomy: HR 2.1 (95%CI:1.5–2.9), and LND: HR 1.9 (95%CI:1.5–2.5).

Conclusions: Among nursing-home women residents who undergo breast cancer surgery, 30-day hospital readmission and mortality are high, as is 1-year all-cause mortality. Poor baseline function prior to surgery was strongly associated with 1-year mortality. Individualized goal-oriented care (i.e., hormonal therapy or symptom management only) should be considered.

ASSOCIATION BETWEEN FRAILTY AND READMISSION AFTER GASTRECTOMY IN OLDER PATIENTS WITH GASTRIC CANCER

Y. Choe, J. Joh, Y. Kim, *Chonnam National University Hwasun Hospital, Hwasun, Chonnam, Korea (the Republic of)*

Background: The incidence of gastric cancer in older people has been increased. Because older patients are at increased risk of postoperative complications and mortality, preoperative risk assessment in this population is important. In this study, we want to know if preoperative assessment of frailty could be useful for predicting the postoperative outcome in gastric cancer patients

Methods: We investigated 223 patients (136 men and 87 women) over 65 years old underwent gastric cancer surgery from April 2012 to March 2015. We used the Study of Osteoporotic Fractures (SOF) frailty index to assess the frailty. In order to find the predicting factors for readmission within 1-year of discharge after gastrectomy, we used logistic regression model.

Results: Total 26 (11.7%) patients readmitted within 1-year after gastrectomy. Patients in “robust” group had a readmission rate of 4.4% and 19.1% in “pre-frail and frail” group. After adjusting age, gender, Eastern Cooperative Oncology Group (ECOG) performance statue (score \geq 1), histological type and stage (III, IV), the frailty (pre-frail and frail) was revealed predicting factor for readmission within 1-year of discharge after gastrectomy (Odds Ratio (OR) 5.74, 95% Confidence Interval (CI) 1.78–18.48, $p=0.003$).

Conclusion: Preoperative risk assessment including frailty evaluation can predict the readmission within 1-year of discharge after gastrectomy. Thus, frailty assessment can help physicians to identify the risk and inform patients and their families of the risk for better decision making process in gastric cancer treatment

FACTORS CONTRIBUTING TO FALLS IN OLDER BREAST CANCER SURVIVORS

J. Blackwood, M. Huang, E. Neuman, M. Godoshian, L. Pfalzer, *Physical Therapy, University of Michigan--Flint, Linden, Michigan*

INTRODUCTION: In older adults, cancer and its treatment affect multiple body systems, leading to functional impairments, limited balance and impairments in walking, and thus contributing to an increased falls risk. The purpose of this study was to examine the health-related factors (physical, cognitive) contributing to falls in breast cancer survivors who were actively being treated (Active) versus those

who were not receiving active treatment for their cancer (Non-Active).

METHODS: This cross-sectional study used data from the Surveillance, Epidemiology and End Results national cancer registry and Medicare Health Outcomes Survey linkage. Forward stepwise logistic regression analyses were completed to assess the contribution of health-related variables (difficulty walking or getting out of a chair, balance problems, and cognitive function) to falls in older breast cancer survivors.

RESULTS: Sample included 8187 cases. In the Active group (n=4045), 27% reported falling and 40% had balance/walking difficulties while those numbers were 35% and 24% respectively in the Non-Active group (n=4142). Impaired cognitive function (difficulty with memory/concentration) was present in 18% (Active) and in 13% (Non-Active). Logistic regression modeling indicated that difficulties with memory/concentration and balance problems were significantly associated with falls in the Active group. In the Non-Active group the presence of balance problems was the only significant variable contributing to falls ($p<0.01$).

CONCLUSIONS: In older breast cancer survivors under active treatment for cancer, cognitive function and balance/walking problems were both significantly associated with falls. Future research needs to delineate the impact of cancer-specific factors on functional mobility.

HEALTH CARE PROFESSIONALS' PERSPECTIVES OF CARING FOR PATIENTS WITH HEPATOCELLULAR CARCINOMA

L. Hansen, S. Rosenkranz, A. Schroeder, W. Naugler, *Oregon Health & Science University, Portland, Oregon*

Background: Hepatocellular carcinoma (HCC) is the second leading cause of cancer related mortality in the world. It is often diagnosed at an advantaged stage. Due to the numerous physical and psychological symptoms and the number of treatments patients receive, management is extremely complex and may best be done by a multi-disciplinary liver tumor board. Research is lacking on these tumor boards and on health care professionals' (HCPs) perspectives on the challenges they face in caring for patients with HCC.

Aim: To examine challenges in symptom management, treatment therapies, and care of patients with HCC from the perspectives of urban and rural HCPs.

Methods: The study used a prospective, descriptive design. Semi-structured interview data were obtained from 10 HCPs employed at an urban hospital, and 8 at urban and 8 at rural primary health care clinics. Data were analyzed using conventional content analysis.

Results: Tumor boards are a trustworthy and valuable resource but high number of referrals, access to treatment, and lines of communication are barriers to care. Lack of knowledge, expertise, and specialties make it difficult for rural HCPs to manage and coordinate the care for patients. Lack of follow-up care with primary care providers, inability by specialists to manage non-cancerous issues, and lack of continuity of care jeopardize symptom management.

Conclusions: Focus should be on improving communication between referring providers, patients, and multi-disciplinary care groups. Referral to palliative care should happen early in the treatment process. Early screening and regular

surveillance should be implemented for patients with liver cirrhosis.

PARTITIONING OF TIME TRENDS IN MORTALITY OF LUNG CANCER AMONG OLDER U.S. ADULTS

I. Akushevich, A.P. Yashkin, J. Kravchenko, F. Fang, A.I. Yashin, *Duke, Durham, North Carolina*

Direct evaluation of lung cancer mortality from SEER data is challenging because of uncertainties in evaluating the population at risk at the time of death. We overcome this problem by proposing a new approach for the calculation of cancer-specific mortality rates through the evaluation of multiple components contributing to total mortality and applying it to lung cancer patients. Specifically, the time-trend of lung cancer mortality is the result of three competing processes: changes in incidence rate, stage-specific survival, and ascertainment at early stages. Our approach estimates the contribution of each of the above components to the overall mortality trend. Using SEER data, we found that lung cancer mortality increases in females and decreases in males over the study period (1988–2012). The main contributions to the change in mortality trends for both genders are incidence rates (increasing in females and decreasing in males). Trends in incidence explain more than 50% of total lung cancer mortality trend. The remaining percentages are explained by increased ascertainment at early stages, improved survival, and prevailing trends in mortality for the general population. These patterns held for analysis of histotype-specific groups (adenocarcinoma, squamous-cell carcinoma, and small-cell carcinoma) with the exception of the increased role of incidence in adenocarcinoma in males and ascertainment at early stages for squamous-cell and small-cell carcinoma. The methodology developed in this study increases the range of analysis that can be accomplished with SEER data and can serve as an additional tool for improvement in the quality of health outcomes research.

DEFINING LUNG CANCER DIAGNOSTIC PATHWAYS IN THE PRIMARY CARE SETTING IN MONTRÉAL, QUÉBEC

S. Khare, I. Vedel, G. Bartlett, *Family Medicine, McGill University, Montreal, Quebec, Canada*

Lung cancer is the leading cause of cancer-specific mortality in Canada, with the highest mortality observed in Québec. Incidence rates for lung cancer peak at 80–84 years of age with a median age at diagnosis of 71. Thus, the death toll due to lung cancer is concentrated among the elderly. The five-year survival rate for lung cancer is a dismal 17%. This is because lung cancers are often diagnosed at a late stage of disease when treatment options are limited. Interventions to reduce delays in diagnosis require an examination of diagnostic pathways and an understanding of the factors that influence these pathways. As patients in Canada must present in primary care before being referred to specialist care, the primary care interval within the larger diagnostic interval is a fundamental component of the diagnostic pathway. This study aims to examine lung cancer diagnostic trajectories in the primary care setting, and explore patient, disease, and health-care system factors that contribute to the diagnostic process. An explanatory sequential mixed-methods design will be employed in two phases. Phase one will involve the

identification of diagnostic pathways through latent profile analysis using clinical and administrative databases along with structured patient interviews, while phase two will use semi-structured patient interviews to explore contributing factors to late diagnosis. The findings from this study will provide an evidence base from which targeted interventions can be formed to reduce or eliminate unnecessary and avoidable delays in lung cancer diagnosis.

THERAPEUTIC PATIENT EDUCATION AND COUNSELLING IN GERIATRIC ONCOLOGY

H. Villars¹, M. Champarnaud¹, L. Balardy¹, F. Nourhashemi^{1,2}, *1. Geriatric Department, Toulouse University Hospital, Toulouse, France, 2. U558 Inserm, Toulouse, France*

Therapeutic patient education (TPE) has largely demonstrated its efficiency in the care of patients suffering from chronic conditions, as defined by the World Health Organization (WHO). At the same time TPE has been implemented in Oncology, particularly in the field of pain management but not only, considering cancer as a 'chronic condition'. Moreover, in the early 2000s, Geriatric Oncology has begun to emerge as a discipline. Indeed, as the incidence of cancer regularly increases during the life, cancerous pathologies are prevalent in subjects over 65 years, and the care of these subjects is raising very different issues and challenges from those of younger patients (polypathology and co-morbidity, iatrogenesis, cognitive disorders and dementia, sensory deficits, role of caregivers...). TPE has secondary followed this development in getting adjusted to the specific needs of this population. Because of its global, multidimensional and holistic character, TPE now appears as an interesting tool in Geriatric Oncology. Some educational programs have been created, implemented and evaluated but only a few are specifically addressed to the geriatric population. This communication is a brief review of Therapeutic Education Programs designed for geriatric patients suffering from cancer and hematological conditions.

CONTINUE OR STOP: A QUALITATIVE ANALYSIS OF MAMMOGRAPHY SCREENING DECISION FOR OLDER WOMEN

M.R. Pappadis¹, S. Krishnan¹, S. Weller¹, A. Tan², E. Jaramillo¹, K.M. Sheffield¹, J.S. Goodwin¹, *1. University of Texas Medical Branch, Galveston, Texas, 2. The Ohio State University, Columbus, Ohio*

There is insufficient evidence to determine the benefits and harms of screening mammography for women aged 75 and older. Therefore, guidelines emphasize on shared decision-making. This study aimed to understand older women's mammography screening decision, physician's role in their decision, and their willingness to discontinue screening. Using stratified sampling based on age (70–74 vs. 75+), race/ethnicity (Non-Hispanic Blacks, Hispanics, Non-Hispanic Whites) and education (≤high school vs. >high school), fifty-six older women with no breast cancer history participated in semi-structured interviews to discuss their decision-making process and preferences for screening. Iterative, comparative thematic analyses revealed that the majority of the older women desired to continue screening. Women aged 75+ tended to discontinue, whereas those aged 70–74

tended to continue screening. Seventy-seven percent of the older women stated that their physician initiated the discussion regarding continuing/discontinuing screening, whereas 18% initiated the discussion, 1% were influenced by a relative and only 4% stated involvement in shared decision-making, describing the process as a 'mutual thing between us' or 'both [of us].' Most women followed their physician's recommendations for screening. Nearly 80% of those continuing mammography had no personal desire to stop, even for those aged 75+ (38%). Some of the reasons why a continuer may discontinue mammography screening were health, physician recommendation, harms, evidence or beyond the age of 80. This study suggests a need for improved communication between physicians and older women regarding the benefits and harms associated with mammography screening.

SESSION 935 (POSTER)

CAREGIVING III

KINSHIP CAREGIVER STRESS, BURDEN, HEALTH, SOCIAL SUPPORT, AND NEEDS

M. Trail Ross, D. Kang, S. Cron, *The University of Texas Health Science Center at Houston, Houston, Texas*

Background: Kinship caregivers including grandparents, other relatives, and friends increasingly assume greater responsibility of raising their "kin" children. These caregivers experience increased stress, depression, and poorer health. Because of limited legal relationship, kinship caregivers are often denied from obtaining services, information, and financial assistance.

Aims: 1. Assess the needs of primary kinship caregivers. 2. Compare levels of stress, caregiver burden, health status, and social support between grandparent and non-grandparent caregivers.

Methods: Two hundred fifty-five kinship caregivers completed mailed standardized questionnaires.

Results: Over half of the sample were responsible for caring for other kins living with them. Forty-eight percent expressed need for financial resources, followed by 36% being interested in information about foster care and adoption. Thirty-two percent were interested in learning about stress management. Preferred method for receiving information varied, including email, websites, workshops, newsletters, and video. The majority had access to a computer and internet service.

Although the majority of the caregivers were employed fulltime, grandparent caregivers were less likely to be employed, more likely to be widowed or divorced, were caring for more children, and had a lower level of education compared with non-grandparent caregivers.

Grandparent caregivers were significantly older, more stressed, and scored lower on physical and social functioning, role participation, and bodily pain. They also had significantly lower social support and social interaction, and more burden impact on health.

Conclusion: The needs assessment and comparison of kinship caregivers shed light on future studies, interventions, and services for these caregivers.

IN THEIR OWN WORDS: HOW FAMILY CAREGIVERS OF PEOPLE WITH DEMENTIA DEFINE RESILIENCE

S. O'Dwyer^{1,2}, W. Moyle², T. Taylor², J. Creese², M. Zimmer-Gembeck², 1. *Medical School, University of Exeter, Exeter, United Kingdom*, 2. *Griffith University, Brisbane, Queensland, Australia*

There is a growing body of research on resilience in family caregivers of people with dementia, but caregivers' voices are noticeably absent from it. The aims of this study were to explore: (1) caregivers' definitions of resilience; (2) the factors caregivers consider to be associated with resilience. Twenty-one in-depth interviews were conducted in Australia with people who were currently, or had previously been, caring for a family member with dementia. Transcripts were analysed thematically and three themes emerged: Being Resilient, Becoming Resilient, and Characteristics of the Resilient Caregiver. Although caregivers struggled to define resilience, the vast majority considered themselves resilient. Caregivers identified a range of traits, values, environments, resources, and behaviours associated with resilience, but there was no consensus on the relative importance or causal nature of these factors. Caregivers also considered resilience to be domain- and context-specific, but did not agree on whether resilience was a trait or a process. These findings highlight both the importance of including caregivers' voices in resilience research and the limitations of the extant literature. Future research on resilience in family caregivers of people with dementia must be theoretically sound, methodologically rigorous, and reflect the lived experience of caregivers. After this session, participants will be able to discuss the challenges of conducting research on resilience in family caregivers and identify directions for future research.

FINDING MEANING IN DEMENTIA FAMILY CAREGIVING: A PILOT STUDY

R. Pang, D. Lee, *The Nethersole School of Nursing, The Chinese University of Hong Kong, Hong Kong, Hong Kong*

Although there is a body of knowledge indicating that finding meaning has a positive impact on the caregivers' wellbeing, little is known about the actual process of how caregivers of persons with dementia find meaning in their caregiving experience. This pilot study has provided insights into how Chinese family caregivers of persons with dementia find meaning in their caregiving experience and adapt to their caregiving role. Grounded theory methodology was employed in this study. Unstructured, in-depth interviews were conducted with seven primary caregivers who were taking care of a family member with dementia at home. Data were analyzed using constant comparative method. The results showed that the process of finding meaning consists of four stages: questioning, exploring, accepting, and transforming. Caregivers went through these four stages as they struggled to regain a sense of control over the changing caregiving situation. Caregivers who could successfully go through the four stages have demonstrated a higher motivation to care and a better wellbeing. For those caregivers who could not progress through the four stages, they were trapped in the stages of questioning and exploring. They were struggling to find ways to manage the situation and felt hard to accept the situation. These caregivers were more depressed and had a higher level of caregiving burden. These

findings suggest that interventions can aim at assisting caregivers to regain a sense of control over the changing caregiving situation, in order to help caregivers find meaning in their experience and adapt to their caregiving role.

CAREGIVING TRANSITIONS AND LIFE SATISFACTION OF INFORMAL CAREGIVERS

R. Keller, *APOLLON University of Applied Sciences, Bermen, Germany*

In the Western world, about two third of care recipients are in home care. This fact holds also for Germany: 70 percent of care recipients are cared for at home. Most of the caregivers are family members without any professional background in caregiving. To date, little is known about how caring for a close relative influences life satisfaction of caregivers in the long run. This study seeks to fill the gap by focusing on the process of transitions into and out of their caregiver role. Further, I examine how the caregivers' life satisfaction develops after these incisive life events.

The analyses are based on the data of the German Socio-Economic Panel, which provides annual information about caregiving situations in German households and life satisfaction since 1997. Using panel data allows to capture intraindividual changes by controlling time constant unobserved heterogeneity. The longitudinal research design also enables to identify effects of adjustment processes in terms of life satisfaction with respect to transitions into and out of caregiving situations.

As expected, life satisfaction decreases after transitioning into the caregiving status and—in contrast to the findings of the vast majority of cross-sectional studies—remains stable over the time of caregiving. When analyzing the period that marks the transition out of caregiving, the picture is rather heterogeneous. It seems that women recover more quickly than men from this strenuous event that is often associated with the death of the care recipient. After recovery, life satisfaction increases constantly for both genders.

FINANCIAL COSTS OF CAREGIVING OVER THE LIFECOURSE

S.L. Porterfield, H. Shen, *Social Work & Gerontology, University of Missouri - Saint Louis, St. Louis, Missouri*

Many research studies have documented the balancing of work and family life among adults who have caregiving responsibilities. This balance is more tenuous when the care recipient has significant disabilities or special needs. While many parents reduce work hours while their children are young, the work force ties of those whose children have disabilities that affect functioning into adulthood remain weak for a longer period of time, moderated by lower health status among these caregivers. In the US, 70% of working-age adults with disabilities live with relatives; 55% with a parent who is age 60 or older. This paper examines the health and pension costs of caregiving, specifically whether women who are or have been caregivers are more or less likely to hold a pension in their own name, whether there is a significant difference in the value of private pension holdings, given age and health status, and whether these differences persist when total household pension values are compared among women

who are, or are not caregivers. Data for women aged 40–69, who have not yet retired, are drawn from the combined 2001, 2004 and 2008 panels of the US Survey of Income and Program Participation (n=40,552). Women caring for disabled or elderly relatives are significantly more likely to report fair/poor health status (28%) and more sick days (13 on average), and are less likely to have pension savings (23.6% & 32.2% respectively) than those caring for children or no one (15% report fair/poor health; 49.5% have pension savings). In addition, the odds of owning and value of pensions held by those caring for non-elderly, disabled family members are significantly lower than those of other caregiver types, controlling for socio-demographic characteristics. Additional testing shows health status is a significant mediating factor, accounting for just over 26% of the effect of caregiving on individual pension value if caring for an adult with disabilities. Caregiving for a working-age adult with disabilities is associated with poorer health status and lower pension savings at both the individual and household levels. Newly adopted policies such as the ABLE Act in the US may provide some support for these families. Additionally, caregiving could be rewarded through the Social Security system, as it is in several European countries, improving the financial strain on these households in their retirement years.

LONG-TERM EFFECTS OF DIFFERENT TYPES OF CAREGIVING ON DEPRESSION IN OLDER ADULTS

S.C. Hu, *National Cheng Kung University, Tainan City, Taiwan*

Caring family member is a matter of stress and may increase depressive symptoms in elderly. This study aimed to examine the long-term effects of caregiving on depression of older adults and compared whether elder caregivers felt more depression than child caregivers, and whether child caregiving can ease depressive symptoms among dual caregivers. We used the dataset of nationally representative samples from Taiwan Longitudinal Study of Aging, and four waves of survey were analyzed, including 1996, 1999, 2003, and 2007. After excluding institutional older adults and poor physical functions (ADL>0), a total of 2250 sample was recruited. Caregivers were divided into 4 types: non-caregivers, elder caregivers, child caregivers, and dual caregivers (who care elder and children at the same time). Depression was measured by CESD scale. The generalized estimation equation (GEE) was used to analyze the long-term effects of repeated measured data.

Comparing with non-caregivers, elder caregivers had significantly higher score of depression (95% C.I.=0.25~1.89), child caregivers had lower score of depression (95% C.I.= -0.59~0.00), and dual caregivers appeared nonsignificant impact on depression. Regarding caregiving times, the child caregivers who provided 2 waves of caregiving had significantly lower depressive score (95% C.I.= -1.06~-0.24), whereas the elder caregivers who provided 1 wave of caregiving had significantly higher depression score (95% C.I.=0.18~1.95). Taking care of older adults is more stressful than taking care of children. Child caregiving can significantly reduce depression in older adults; however, it is not enough to relief depressive symptoms for dual caregivers. Future policy should pay more attention on elder caregivers.

FINDING NEW MEANINGS AND CONNECTION IN FAMILY DEMENTIA CAREGIVING BY ENHANCING INTERNAL COPING

J. Wang, L. Yong, W. Chan, E. Ho, Y. Wong, K. Peh, *Tsao Foundation, 298 Tiong Bahru Road #15-01 Central Plaza Singapore 168730, Singapore, Singapore*

Background: Caregiving for People with Dementia (PwD) is often a psycho-emotional challenge to family members. However, caregiver support addresses usually, if not entirely, only resource coping for family caregivers. This paper presents an approach focus on psycho-emotional coping as applied by a gero-counselling team based in Singapore. The team is part of a community based health and psychosocial care services specially for older persons and their family caregivers.

Method and result: Over a three year period, the team working with more than 70 family caregivers through individual counselling and support groups, we identified and intervened common issues affecting emotional well-being of caregivers. Two issues were the most challenging to family caregivers: communication breakdown with the PwD and the loss of meaningful family activities. As a result, family caregivers often experienced emotional distress including sadness, frustration and helplessness. Counselling focused on internal coping enabled acceptance and adjustment of expectations. The outcomes of counselling were usually positive. Many were able to find new possibilities and hopes in connecting with their loved ones, and were able to resume caregiving with more positive outlook.

CAREGIVING FOR GRANDCHILDREN AND DEMENTIA CAREGIVING: NOT THAT DIFFERENT AMONG HISPANICS

L.C. Arevalo-Flechas^{1,2}, M. Martinez^{1,2}, B. Flores², 1. GRECC, *South Texas Veterans Health Care System, San Antonio, Texas*, 2. *The University of TX HSC at San Antonio, San Antonio, Texas*

Hispanic older adults assuming caregiving roles continue to increase in unprecedented numbers. Development of programs to assist these caregivers to manage their stress and the demands placed on them has also increased. However, the vast majority of these programs are developed focusing more on the specific needs and characteristics of the care-recipients than on caregiver commonalities determined by cultural values. At the core of Hispanic culture are: *Familismo*, collectivism, *personalismo*, *marianismo*, and *respeto*.

We aimed to compare the experience of older Hispanic family caregivers of relatives living with Alzheimer's disease or related dementias (ADRD), and Hispanic grandparents caring for their grandchildren as a result of parental substance abuse disorders. We conducted a content analysis of qualitative ethnographic interviews of these two populations of caregivers. While the realities of daily caregiving duties were of different nature (dementia vs. childrearing), regardless of care-recipient, caregivers provided narratives supporting the themes: duty to family first, sense of satisfaction, willingly sacrificing, sense of purpose, physically exhausting, emotionally draining, financially straining, role challenges, role captivity, legal stressors, fear, and major stressor. More commonalities than differences were found. Caregivers differed in the root cause of fear (institutionalization vs. children

placement in foster care), and the major stressor in their lives. For grandparents the stressor was the perceived or actual continued parental substance abuse. In addition to culturally congruent evidence-based programs to assist Hispanic caregivers to manage their levels of stress, urgent policy changes are needed to support Hispanic family caregivers regardless of age /type of care-recipient.

VOLUNTEER CARE FOR AN AGING POPULATION: HIGHER QUALITY OF LIFE FOR CARING AND CARE RECEIVING PEOPLE?

Y. Rubin, *University of Applied Sciences, Fulda, Germany*

Aging is increasingly accompanied by themes of care. While younger and fitter elderly are invited to participate in the context of voluntary activities the older take advantage of this offers.

The debate on the organization of care and treatment of an aging population follows two main lines of discussion:

One is on the context of social change and political necessities. While the number of aging people is increasing, welfare state security systems do not seem suitable to cope with the associated (expected) challenges. The other main line to these developments is that family support systems are precarious as less and less resources are available for the acquisition of necessary care due to an increasing focus on gainful employment.

From a feminist point of view "care" is understood as a social practice that involves the whole of the paid and unpaid care work. It has to be equipped with identifiable structural conditions such as material and time resources, in both the private as well as in public spaces.

This paper presents results of a qualitative research with people who are engaged as volunteers for support services for elderly in rural areas. The main question is how volunteer care manifests in and for an aging population and in which kind gender differences continue.

DEVELOPING A CARER IDENTITY AND NEGOTIATING EVERYDAY LIFE THROUGH SOCIAL NETWORKING SITES

F. Andrasson, J. Andreasson, E.J. Hanson, *Faculty of Health and Life Sciences, Linnaeus University, Kalmar, Sweden*

Research highlights that a key overarching reason why family carers do not utilize support services is that many people who perform the duties of caregiving do not necessarily self-identify as a carer. Understanding the development of carer identities may thus be understood as crucial for the utilization of different health services directed towards carers. Based on the EU funded Innovage project, this project aims to describe and analyse how older carers supporting and caring for an older person understand and socially negotiate their life situation and identity as carers on a Swedish online social forum. Theoretically the project departs from a constructionist approach and methodologically it has been inspired by a specifically designed method for studying the cultures and communities that emerge from online computer-mediated or Internet-based communications, called netnography. The results indicate that in the process through which a carer role is acquired, a significant change in self-perception occurs. The presence or absence of recognition for the older carers' capacity, is understood as filtered through the needs of the

cared for person, making the carer identity into an invisible self. At the same time, the opportunity for online communication may help to create a virtual space of social recognition through which negative and positive experiences attached to caring can be discussed. The significance of online communication is here understood as the possibility to be recognized, and feel empowered by other carers.

FRIEND CAREGIVERS OF OLDER ADULTS IN THE UNITED STATES: HOW DO THEY COMPARE TO OTHER INFORMAL CARERS?

T.A. LaPierre, *University of Kansas, Lawrence, Kansas*

This study increases our understanding of the characteristics and contributions of friend caregivers of older adults, as well as the positive and negative consequences they experience as the result of providing care and the different supports they utilize in providing care. Similarities and differences between friend caregivers and various types of kin caregivers (e.g. adult children, siblings, grandchildren) and other non-kin caregivers were investigated using bivariate and multivariate statistical analyses. Data come from 928 unpaid, non-co-resident caregivers in the United States 2011 National Study of Caregiving. Friend caregivers were significantly different than certain types of kin caregivers on many, but not all characteristics, contributions, and consequences examined. For example, friend caregivers were more likely than certain types of kin caregivers to be female, to be single, to live alone, to receive emotional support, and to participate in caregiver support groups. They were less likely to be sole caregivers, to use respite, and to experience negative caregiving consequences. Multivariate analyses reveal potential explanations for differences in contributions and consequences. Implications for policy and practice related to informal caregivers are discussed, as well as the implications of study design on the population of caregivers being examined.

CAREGIVER FAMILY THERAPY: A PILOT STUDY OF TREATMENT FIDELITY, ACCEPTABILITY, AND EFFICACY

K. O'Malley, 1. *Psychology, VA Puget Sound American Lake Division, Puyallup, Washington*, 2. *University of Colorado Colorado Springs, Colorado Springs, Colorado*

Physical and psychological health problems associated with caregiving for a chronically ill family member are well documented (Connell et al., 2001; Magliano et al., 2005), and caregiver interventions are effective in reducing feelings of burden and increasing feelings of competence (Pinquart & Sörensen, 2006). Tailored interventions incorporating family systems are among the most effective treatments for family caregivers (Belle et al., 2006; Mittleman et al., 2004; Zarit, 2009). Caregiver Family Therapy (CFT) was developed over a 10-year period; however, it has not been evaluated for treatment fidelity or efficacy, the gold standard for assessing evidence-based practices. This study aimed to assess treatment fidelity, acceptability, and efficacy in a help-seeking population. 11 caregivers seeking services at the UCCS Aging Center between September 1, 2015 and May 1, 2016 were asked for their voluntary participation in this study. Treatment fidelity was assessed by therapists, clients, and expert raters throughout the intervention period.

Therapists adhered to and skillfully implemented CFT in weekly sessions with caregivers, Wilks' Lambda = .81, $F(1, 148) = 35.75$, $p < .01$, $\eta^2_p = .20$, and more time was spent in session on targeted than non-targeted goals. CFT was found to be highly acceptable ($M = 10.91$, range 0–18) and satisfying to caregivers ($M = 3.96$, range 0–4) in this study. Outcome data was positive, and improvement was found in positive aspects of caregiving, $t(9) = 3.44$, $p = .01$, $\eta^2 = .56$. CFT appears to be a promising approach to reducing burden and increasing competence in caregivers.

SESSION 940 (POSTER)

COGNITION

EFFECT OF SSRIS ON COGNITIVE FUNCTION OF GERIATRIC PATIENTS WITH OBSESSIVE COMPULSIVE DISORDER

L. Kouti¹, H. Ansari², A. Torbati³, 1. *Clinical Pharmacy, Ahvaz Jundishapur University of Medical Sciences, Ahvaz, Iran (the Islamic Republic of)*, 2. *Headache Clinic at University of California, San Diego (UCSD), San Diego, California*, 3. *Northshore University Hospital at Northwell Health, Brooklyn, New York*

SSRIs are the most chosen treatment for obsessive compulsive disorder (OCD). Some studies have reported the effects of SSRIs on cognitive function, but the results are conflicting. Geriatric patients are usually more vulnerable to drugs that affect memory and cognitive function. The purpose of this study is the assessment of SSRI effect on cognition of geriatric patients with OCD.

Patients aged 65 years and above, diagnosed with OCD and naïve to therapy, with no complaints or history of memory loss, were eligible for entering this study. Cognitive functions of those who were willing to participate and an SSRI drug was prescribed for, were assessed by Mini-mental state examination (MMSE) test. MMSE scores of patients were recorded at four points, before taking the drug, after 3, 5 and 8 weeks of drug therapy.

25 patients with the mean age of 67 ± 1.8 years (68% male and 32% female) entered our study. Their mean MMSE score prior to medication was 24.3. At 3, 5 and 8 weeks of treatment, the mean scores were 22.9, 21.04 and 20.66 respectively. With a p-value of <0.0001 , the gradual decline was significant. Gender, level of education, onset of disease, patient's response to the treatment, or drug agent did not have a relationship with this decline.

The MMSE scores of our patients over the consecutive weeks of taking SSRI drugs lowered significantly. It seems that the use of SSRIs in geriatric patients with OCD, can cause cognitive dysfunction in the acute phase of treatment.

USE OF THE GOLDSMITHS MUSICAL SOPHISTICATION INDEX IN OLDER AMERICAN ADULTS: A FEASIBILITY STUDY

D. Petrovsky, R.H. Hamilton, P.Z. Cacchione, *University of Pennsylvania, Philadelphia, Pennsylvania*

The purpose of this feasibility study was to determine older American adults' ability to understand the terminology used in the Goldsmiths Musical Sophistication Index

(Gold-MSI). The Gold-MSI was designed in the United Kingdom to measure musical sophistication on a broad range of musical expertise, skills, achievements and related behaviors. The Gold-MSI is different from its predecessors in that it assesses musical behaviors outside of instrumental practice and years of formal music training. We administered the Gold-MSI to 32 community-dwelling older adults (age 55 and older) living in the Northeast. The sample consisted of older adults from a Program of All-inclusive Care (PACE) (n=8), five participants from the Alzheimer's Disease and Research Center's choral group and nineteen were recruited using snowball sampling. The sample consisted of 25 females and 7 males with an average age of 68.3 and mean 15.5 years of formal education. The majority of adults were White (n=15), or Black (n=14), with one Hispanic, one American Indian and one who chose not to answer. Participants varied in their musical background. On average, participants scored lower (70.43) compared to the average scores reported in the norms (81.58) established in the original reliability and validity study in the UK. Three PACE participants identified minor difficulties in answering questions with double negative statements. The participants did not indicate any difficulty understanding the meaning of the questions when filling out the index. This feasibility study supports the use of the Gold-MSI with older adults living in the US.

CHRONIC PAIN PREDICTS ACCELERATED MEMORY DECLINE AND DEMENTIA

E.L. Whitlock¹, L. Diaz-Ramirez², M. Glymour², J. Boscardin², K.E. Covinsky², A.K. Smith², 1. *Anesthesia & Perioperative Care, University of California, San Francisco, San Francisco, California*, 2. *University of California, San Francisco, San Francisco, California*

Chronic pain is highly prevalent among the elderly and in cross sectional studies is associated with cognitive deficits upon detailed neuropsychiatric testing. Using a nationally-representative population-based study, we investigated the association between pain at cohort inception and longitudinal measures of memory and dementia probability over the following 12 years.

We studied Health and Retirement Study (HRS) participants who were interviewed in both 1998 and 2000. "Chronic pain" was defined as being often troubled by moderate or severe pain in both the 1998 and 2000 interviews. Based on data from each biennial telephone-based HRS evaluation through 2012, memory z-score and dementia probability were calculated from the validated HRS cognitive battery using published methodology. Linear mixed effects models were used to estimate the effect of chronic pain on the slope of an individual longitudinal cognitive trajectory, adjusted for baseline demographic, economic and health factors.

The 10,065 subjects (mean age 73 in 2000, 60% female) underwent a median of 5 biennial cognitive evaluations. Of these, 1,120 (11%) reported chronic pain. After controlling for other predictors in the model, chronic pain was associated with 7.5% (95% CI 2.8–12.2%) more rapid relative increase in dementia probability, and 10.3% (95% CI 3.9–16.8%) faster memory z-score decline, compared to those with no pain.

We conclude that, at a population level, there is a modest but significant independent association between chronic pain and subsequent accelerated cognitive decline. Chronic pain may place elders at risk of accelerated memory loss and dementia.

BENEFICIAL EFFECTS OF PERILLA OIL AND BRAIN TRAINING INTERVENTION ON COGNITION IN ELDERLY JAPANESE

M. Hashimoto¹, K. Yamashita², K. Matsuzaki¹, S. Kato³, O. Shido¹, 1. *Shimane University Faculty of Medicine, Izumo, Japan*, 2. *Department of Nursing, Faculty of Nursing, The University of Shimane, Izumo, Japan*, 3. *Kato Hospital, Jinjukai Healthcare Corporation, Izumo, Japan*

Perilla oil contains 60% α -linolenic acid and exhibits the function of ω -3 fatty acids. It is utilized as an energy source in the brain. In this 6-month randomized, placebo-controlled trial, we verified the effects of perilla oil and brain training on the cognitive function and mental health of healthy elderly Japanese individuals.

Independent elderly individuals aged ≥ 65 years (n = 158, 71.4 \pm 0.4 years) were randomized to four groups (placebo, perilla oil, brain training, and brain training with perilla oil). Perilla oil (7 [Editor1] g) was administered every day for 6 months. Brain training was performed according to Shichida brain training. Cognitive function was assessed at baseline and after 6 months of intervention using the Mini-Mental State Examination and Frontal Assessment Battery (FAB). Mental health was assessed using the apathy and Zung self-rating depression scales; biochemical factors were measured in the participants' blood.

The plasma and erythrocyte plasma membrane α -linolenic acid levels significantly increased in the perilla oil and brain training with perilla oil groups. The mean changes in FAB "intellectual flexibility" scores from baseline to month 6 were significantly greater in the brain training with perilla oil group.

These results suggest that a combination of brain training and perilla oil improves age-related cognitive decline in elderly people with very mild cognitive impairment.

EFFECTS OF COGNITIVE LEISURE ACTIVITY PROGRAMS ON COGNITION IN MCI: A RANDOMIZED CONTROLLED TRIAL

T. Doi¹, J. Verghese², H. Makizako¹, K. Tsutsumimoto^{1,3}, R. Hotta¹, S. Nakakubo¹, T. Suzuki^{4,1}, H. Shimada¹, 1. *Department of Preventive Gerontology, Center for Gerontology and Social Science, National Center for Geriatrics and Gerontology, Obu, Japan*, 2. *Albert Einstein College of Medicine, Bronx, New York*, 3. *Japan Society for the Promotion of Science, Tokyo, Japan*, 4. *J.F. Oberlin University Graduate School, Tokyo, Japan*

Participation in cognitive leisure activities is reported to be associated with reduced risk of dementia in older adults in observational studies; however, there are no definitive clinical trials examining whether cognitive leisure activities reduce the risk of cognitive decline. To test the hypothesis that a long-term, structured cognitive leisure activity program is effective on cognition in older adults with mild cognitive impairment (MCI), a high risk for dementia. The study was designed a 3-arm, single-blind randomized controlled trial.

Participants were 201 Japanese adults with MCI (mean age: 76.0, 52% women). Participants were randomized into 1 of 2 cognitive leisure activity programs (60 minutes weekly for 40 weeks): dance (n = 67) and playing musical instruments (n = 67), or a health education control group (n = 67). At 40 weeks, the dance group showed improved story memory recall scores compared with controls (mean change dance group 0.73 vs. controls 0.01; $P = .011$), whereas the music group did not show an improvement compared with controls (mean change music group 0.35; $P = .123$). Both dance (mean change 0.29; $P = .026$) and music groups (mean change 0.46; $P = .008$) showed improved Mini-Mental State Examination scores compared with controls (mean change -0.36). Long-term cognitive leisure activity programs involving dance or playing musical instruments resulted in improvements in memory and general cognitive function compared with a health education program in older adults with MCI.

MONTREAL COGNITIVE ASSESSMENT VS. ROWLAND UNIVERSAL DEMENTIA ASSESSMENT SCALE FOR COGNITIVE SCREENING

C. Brymer, C. Sider, A. Evans, B.Y. Lee, K. Taneja, J. Morgenstern, R. Naqvi, *medicine, western university, London, Ontario, Canada*

Our study involved 208 consecutive patients seen in an outpatient memory clinic in London, Ontario, Canada (63 with diagnosis of mild dementia, 86 with diagnosis of mild cognitive impairment, 59 with normal cognition) for whom both a MoCA (Montreal Cognitive Assessment) and RUDAS (Rowland Universal Dementia Assessment Scale) could be completed. The sensitivity and specificity of both measures were assessed for detection of mild cognitive impairment and dementia. Using a cutoff score of 25 or less for both, the MoCA had a sensitivity of 97% to detect dementia, with only 31% specificity, while the RUDAS had a 94% sensitivity to detect dementia, with 54% specificity. The MoCA at 25 or less had a sensitivity of 95% and a specificity of 69% to detect mild cognitive impairment, while the RUDAS at 25 had a sensitivity of 81% and a specificity of 88% to detect mild cognitive impairment. RUDAS score variation with educational attainment is significantly smaller than MoCA score variation ($P < 0.01$). The RUDAS is significantly briefer than the MoCA as a cognitive screening tool, and demonstrated similar sensitivity for dementia, with much better specificity for dementia and mild cognitive impairment, in an outpatient memory clinic.

COGNITIVE PATTERN ACCORDING TO AGE

Z. Barrou¹, L. Dourthe¹, S. Greffard¹, B. Dieudonné¹, L. Zerah¹, J. Cohen-Bittan¹, H. Valler¹, M. Verny^{1,2}, 1. *Centre de gériatrie Hôpital Pitié salpêtrière (APHP), Paris, France, 2. Université Pierre et Marie Curie et UMR8256 (CNRS), Paris, France*

Introduction: when comparing patients with early-onset Alzheimer's disease (EOAD) (before 65 years) and late-onset Alzheimer's disease (LOAD), there have been conflicting results. In general, EOAD patients have more difficulties in non-memory domains including language, visuospatial skills and executive functions. We tested the effect of age on cognitive patterns among our geriatric population of AD, with higher ages than in the literature.

Method: prospective data collection on consecutive patients with mild AD (MMSE > 20). Individualization of two groups: young patients (YP) ≤ 75 years, elderly patients (EP) ≥ 85 years. All patients underwent clinical examination, neuropsychological assessment, laboratory workup and brain imaging.

Results: 22 YP and 52 EP (72.8 \pm 2 and 87.6 \pm 2 years) were included. Groups were comparable for socio-educative level, ADL and IADL scores, geriatric depression scores, neuropsychiatric inventory scores and MMSE scores (24.1 \pm 2 and 24.0 \pm 2). We mainly observed that EP had poorer results for semantic fluencies (Isaac set test, animals) and recall of social events. There were no differences for phonetic fluencies and executive functioning. We also observed that EP were slower on the TMT A, had worse performance in abstract praxis and Rey figure copy. There was no significant difference in episodic memory.

Conclusion: In patients with mild AD, cognitive patterns differ between patients younger than 75 years and those older than 85 years. The main finding is a more pronounced semantic impairment in older patients, in accordance with a previous literature report comparing EOAD (mean age 60.6 years) and LOAD (mean age 77.9 years).

THE CONSTRUCT OF RESILIENCE IN THE FACE OF HEALTH-RELATED ADVERSITY AMONG COMMUNITY-LIVING ELDERLY

Y. Kobayashi^{2,3}, H. Sugisawa³, R. Kariya⁴, H. Osada³, 2. *University of Human Arts and Sciences, Saitama, Saitama, Japan, 3. J.F. Oberlin University Graduate School of Gerontology, Machida, Tokyo, Japan, 4. Doctoral Course of Gerontology, J.F. Oberlin University, Machida, Tokyo, Japan, 5. Institute for Gerontology, J.F. Oberlin University, Tokyo, Japan*

Decline of physical, psychological, and life functions is an inevitable consequence of aging. Interestingly, it has been reported that psychological factors, such as the purpose in life, has an effect on physiological aspects of aging, such as cognitive decline. This study, based on previous research, the purpose in life was considered as one construct of resilience. Resilience, defined as a psychological trait that promotes recovery and maintains life functions in the face of health-related adversities including illnesses, was investigated among community-living elderly people in Japan. Participants (N=20, mean age 81.45 years, Age range 72–92 years, 80% women) were recruited for the study by community care managers and volunteer workers. Episodic interviews were conducted with the participants about their thoughts, efforts and ideas for promoting recovery and maintaining life functions in the face of health-related adversity that they had experienced after approximately 60 years of age, following even a slight recovery. Responses from transcripts revealed four themes: Activation (acceptance of novelty, resolute will, natural pose, and trust of intuitions), Purpose in life (affirmative acceptance, meaning, past feelings in overcoming difficulties, and goals in life), Relationship preferences (enjoyment of contact with others, support seeking, and willingness to serve), and Health consciousness (health for life, industrious attitude, assessment, and sensitivity to information). It is suggested that these four constructs are linked in a chain reaction. The results of this study will contribute to the development of

preventive psychological interventions for dementia among the aging population in Japan.

VITAMIN D INSUFFICIENCY AND COGNITIVE TRAJECTORIES IN OLDER ADULTS: THE RANCHO BERNARDO STUDY

G.A. Laughlin, D. Kritz-Silverstein, J. Bergstrom, E. Reas, S. Jassal, E. Barrett-Connor, L.K. McEvoy, *University of California San Diego, La Jolla, California*

Evidence of a role for vitamin D in cognitive aging is mixed and based primarily on extreme vitamin D deficiency. We evaluated the association of vitamin D with patterns of change in cognitive function in community-dwelling adults living in a temperate climate with year-round sunshine. This is a longitudinal study of 1058 older adults (median age 75) who had cognitive function assessed and serum vitamin D (25(OH)D) measured in 1997–99 and were followed with up to three repeat cognitive function assessments over a 12-year period. Overall, 13.5% (n=145) of participants had vitamin D insufficiency (<30 ng/ml); only 3% had vitamin D deficiency (<20 ng/ml). Adjusting for age, sex, education, and season of blood draw, vitamin D insufficiency was associated with poorer baseline performance on Mini-Mental Status Exam (MMSE) ($P=0.013$), Trails Making Test B (Trails B) ($P=0.018$), Category Fluency ($P=0.006$) and Long Term Retrieval ($P=0.016$), but was not related to the 12-year rate of decline for any test. For those with vitamin D insufficiency, odds of poor cognitive function at baseline were 63% higher ($P=0.033$) for MMSE, 78% higher ($P=0.013$) for Trails B, and 2-fold higher ($P<0.001$) for Category Fluency and Long Term Retrieval, and the risk of developing impaired Trails B performance during follow-up was 67% ($P=0.013$) higher. Although the possibility of confounding by concomitant poor health cannot be excluded, these results suggest that even moderate vitamin D insufficiency may contribute to reduced cognitive function in older adults.

MOTOR IMAGERY OF GAIT WITH AGING: MENTAL IMAGERY STRATEGY AND BODY POSITION MATTER

O. Beauchet¹, G. Allali², 1. *Medicine, McGill University, Montreal, Quebec, Canada*, 2. *Geneva University, Geneva, Switzerland*

The imagined version of Timed Up and Go test (iTUG) is an efficient clinical way to assess age-related changes in highest levels of gait control. This study aims 1) to examine the effects of the MI strategy (i.e.; egocentric versus allocentric representation) and the body positions (standing, sitting, lying down) for the time needed to complete the iTUG, and 2) to compare TUG performances under different MI strategies and body positions in healthy young and older adults. A total of 60 healthy individuals (30 young participants 26.6 ± 7.4 years with 48.3% women, and 30 old participants 75.0 ± 4.4 with 40.0% women) were recruited in this cross-sectional study. Times of the pTUG and iTUG and the TUG delta time, used as outcomes. The strategies of gait MI (i.e.; ego versus allocentric representation) were recorded. Older participants used more frequently the allocentric representation compared to young adults, regardless the body position ($P \leq 0.001$). Multiple linear regressions showed a significant increase of iTUG time with age ($P \leq 0.008$), except in model

non-adjusted on MI strategy. Allocentric MI strategy was associated with significant decrease in iTUG ($P \leq 0.015$), whereas lying down position was associated with increase in iTUG ($P \leq 0.04$). The results showed an aging effect while imagining gait characterized by a change in representation from ego to allocentric representation. Furthermore, lying down position represents the more accurate position of the real performance in comparison to other positions.

THE RIGHT KIND OF SMART? EMOTIONAL INTELLIGENCE AND COGNITIVE IMPAIRMENT IN OLDER ADULTS

O. Saad^{1,4}, L. Zysberg³, J. Heinik², R. Ben-Itshak², A. Zisberg¹, 1. *The Cheryl Spencer Department of Nursing Faculty of Social Welfare and Health Science, University of Haifa, Israel, Haifa, Israel*, 2. *The Psycho-Geriatric Institute, Sorasky Medical Center, Tel Aviv, Tel-Aviv, Tel-Aviv, Israel*, 3. *Gordon College of Education, Haifa, Israel, Haifa, Haifa, Israel*, 4. *JCT - Jerusalem College of Technology - Lev Academic Center, Jerusalem, Israel*

Background: Health psychology, emphasizes the potential of individual resources in effectively adapting to health challenges. Older adults with cognitive impairment (CI) suffer depletion of individual resources (e.g.: intelligence, certain personality traits, etc.) that jeopardizes their ability to adapt and function. Emotional intelligence (EI), a relatively new concept, holds promise as a pivotal resource for health challenges that until recently went unnoticed. In this pilot study we examined the distribution and inter-correlations among individual resource measures against a cognitive impairment measure to test EI's potential role as a resource for older adults coping with CI.

Methods: Applying a correlational study design, 66 older adults (mean age 77.92 ± 6.83), 60% of whom were women, were recruited from a memory clinic in central Israel. The participants showed a broad spectrum of cognitive function on Montreal Cognitive Assessment (MoCA) scores 15–30), ranging intact through Mild Cognitive Impairment to dementia. General intelligence (GI), EI, Instrumental ADL (IADL), social support and comorbidities were assessed.

Results: EI positively associated with IADL ($r=.37$; $p<.01$) GI ($r=.26$; $p<.05$) and social support ($r=.27$; $p<.05$). In a regression analysis controlling for intervening factors EI did not correlate with MoCA while showing associations with GI ($\beta=.26$; $p<.05$), IADL ($\beta=.21$; $p<.05$) and education level ($\beta=.42$; $p<.01$).

Conclusions: As GI decreases with CI, EI remains relatively intact as an individual resource. This first of its kind evidence supports the possibility that EI may serve as a resilient resource in older adults with CI that may facilitate coping with the challenges of this condition.

COGNITIVE FUNCTIONING IN LATER LIFE: BENEFITS OF SPIRITUAL RESOURCES

N. Lekhak, T. Bhatta, J. Zauszniewski, *Nursing, Case Western Reserve University, Cleveland, Ohio*

Spiritual resources have been used by human beings from time immemorial to reduce psychological distress and in healing. Primarily based on racially homogenous smaller clinical studies, previous research have suggested positive influence of meditation and prayers on memory and brain functioning

associated with cognition. Despite extensive research on its role in enhancing mental health, there has been relatively little attention paid to its significance in mitigating cognitive decline in later life. This study synthesizes Proactive Adaptation Model and Resourcefulness Theory to explore whether spiritual resources can be proactively utilized to reduce the later life risk of cognitive decline. Drawing from a racially heterogeneous subsample (n=1159) from Health and Retirement survey, this study investigated the effect of meditation and prayers on changes in cognitive functioning among older adults. Results based on generalized estimating models suggest statistically significant positive effect of prayers (0.50, $p < 0.05$) on cognitive functioning at baseline. While positive, the effect of meditation on cognition at baseline was not statistically significant (0.15, $p = 0.4$). We also observed slight gain in cognitive functioning among older adults practicing meditation (0.03, $p < 0.05$) and prayers (0.03, $p = 0.08$). Furthermore, we documented significantly higher cognition among older adults with higher level of education and lower cognitive functioning among African American. Consistent with prior literature, our study highlights positive cognitive health benefits of spiritual resources and provides much needed research evidence to design effective community level interventions to reduce the risk of cognitive decline in later life.

OLDER VETERANS WITH TYPE 2 DIABETES: A1C AND COGNITIVE FUNCTION

P. Lee^{1,2}, E. Guerrero-Berroa^{3,4}, J. Schmeidler⁴, M. Schnaider-Beer^{3,4}, R. West^{3,4}, M. Sano^{3,4}, N. Alexander^{1,2}, J.M. Silverman^{3,4}, 1. *University of Michigan, Ann Arbor, Michigan*, 2. *Veterans Affairs Ann Arbor Healthcare System, Ann Arbor, Michigan*, 3. *James J. Peters Veterans Affairs Medical Center, Bronx, New York*, 4. *Icahn School of Medicine at Mount Sinai, New York, New York*

Poor glycemic control (i.e., high A1c) among older adults with type 2 diabetes (DM) is associated with high risk of cognitive impairment across various domains of cognitive assessments. Older Veterans with DM have not been well studied. We hypothesized that high A1c is associated with worse executive function among older Veterans with DM.

We performed preliminary analysis of the baseline data from 61 Veterans with DM (aged 60 years or older) recruited from 2 VA health systems for a computerized cognitive training study. None had dementia diagnosis or Clinical Dementia Rating scale ≥ 1 . A finger-stick blood sample was analyzed using a point-of-care A1c analyzer to obtain A1c results. Five cognitive domains were assessed - Episodic Memory, Executive Function, Attention/Working Memory, Language/Semantic Categorization, and Psychomotor Speed. The association between A1c and cognition was examined using multiple linear regressions, adjusting for age and education.

For 61 Veterans (2 females), means were age 70 years, 14 years education, and 7.4% A1c. A1c was significantly associated with cognition only for Executive Function at one VA center (n=31, mean 7.9% \pm SD 1.4, range 6–11%). Higher A1c was associated with better executive performance ($\beta = 0.40$, $t = 3.61$, $p = 0.001$, partial $r = 0.59$), explaining 0.31 of the variability in performance ($R^2 = 0.41$).

This preliminary result of unexpected positive association of executive function with higher A1c may reflect recruitment of Veterans with high and variable A1c at that center.

Ongoing recruitment and increased sample size will be needed to verify this result.

BRAIN GAMING EFFECTS ON MILD COGNITIVE IMPAIRMENT: A SYSTEMATIC REVIEW

P. Sood¹, S. Kletzel², C. Ciro³, J. Machtinger⁴, D.R. Dawson⁵, P.C. Heyn⁴, 1. *University of Florida, Gainesville, Florida*, 2. *VA, Chicago, Illinois*, 3. *The University of Oklahoma Health Sciences Center, Oklahoma City, Oklahoma*, 4. *University of Colorado, Denver, Colorado*, 5. *University of Toronto, Toronto, Ontario, Canada*

Objective: To systematically review and synthesize the research findings regarding the effects of brain gaming interventions on cognitive function of older adults with cognitive impairments (CI).

Methods: A systematic search was conducted using PRISMA guidelines. A combination of key terms (i.e. brain gaming, older adult, dementia, cognition) were used to search for relevant literature on common electronic databases (MEDLINE, PubMed, EMBASE, CINAHL, PsycInfo, Cochrane Library Databases). Two level eligibility criteria were used to identify potential peer-reviewed manuscripts: 1) titles and abstracts were carefully reviewed by reviewers; and 2) full manuscripts that passed Level 1 review were retrieved for inclusion consideration. Frequencies, ranges, means and standard deviations were used to evaluate the studies characteristics and quality.

Results: 766 studies were identified as potential for inclusion. 215 studies were excluded as duplicates. 515 abstracts were screened for Level 1 review accordingly to a priori criteria. 51 abstracts passed level 1 review and underwent full manuscript review (Level 2). Seven articles met full eligibility criteria for data extraction. Total sample of 396 older adults (77 yrs \pm 6) with CIs including dementia were analyzed. Studies' treatment ranged from 20 minutes session to 100 minute session. Primary outcomes were memory, learning, executing function, and visuospatial attention and depression as secondary. Five out of seven studies showed positive cognitive effects from the brain gaming interventions.

Conclusion: Our results suggest that brain gaming has an overall positive effect on the cognitive function of older adults with CI. Although, high level of evidence-based research studies are recommended to reach conclusive results.

IS GAIT USING DUAL TASK POSSIBLE TO DETECT COMMUNITY DWELLING ELDERLY WITH COGNITIVE DECLINE?

Y. Shiba¹, T. Yamagami², T. Ueda³, S. Tanaka⁴, S. Anzai⁵, 1. *Kitasato University, Sagami-hara-shi, Kanagawa-ken, Japan*, 2. *Gunma University, Maebashi-shi, Japan*, 3. *Sanno Rehabilitation Clinic, Tokyo, Japan*, 4. *Takasaki University of Health and Welfare, Takasaki-shi, Japan*, 5. *Tokyo Metropolitan Institute of Gerontology, Tokyo, Japan*

In Japan, due to the increase of old-old, Aging-Associated Cognitive Decline (AACD; Levy, 1994) qualifiers are rapidly increasing. The number of AACD group was 13 (age 74.7 \pm 2.8), and the healthy group was 6 (age 71.8 \pm 3.7). We had the participants to walk a 9m walking way, of 5m measuring distance made by connecting 2 "Walk Way" (ANIMA Corp.), plus 2m acceleration distance and 2m deceleration distance, 2 trials each of fastest possible gait (Speed up walking; S) and dual task gait of calculating while walking (Dual

task walking; DT) in the respective order. Further, intervention task for the DT group was, to chant the answer of calculation starting from 70 minus 7 for the first trial and 50 minus 7 for the second trial, and continue to take away 7. We carried out “Five Cog” for detection of AACD elderly (Yatomi, 2006). The significant differences in gait characteristics between the two groups within the DT task were, gait speed ($P=0.037$), cadence ($P=0.058$), stride ($P=0.149$). On the other hand, there were no differences seen in the S task (n.s.). The S task (Shinkai, 2000), said to be beneficial as a good predictor of vital functions, could not detect AACD elderly. Within the DT task, since there was a gait speed decrease, it is possible to be beneficial as one of screening tasks to detect AACD elderly. It could be possible even for non-specialists, in a short time to detect AACD elderly, by adding a DT task to widely popular gait test.

EFFECTS OF DUAL TASK SWITCHING WORKING MEMORY TRAINING ON COGNITIVE FUNCTIONS IN THE ELDERLY

N. Trushkova¹, N. Ermolina², G. Zelano¹, 1. *Rehabilitation Research Center “Armonia”, Aprilia, Latina, Italy*, 2. *Astrakhan State University, Astrakhan, Russian Federation*

Objectives: Several studies suggest that the human ability to rapidly and accurately switch between tasks multiple times and to focus attention on the currently relevant response set employs working memory capacity. This ability decreases with age and that’s why older people have great difficulty in dual-task performance and TMT part B tests. Moreover, TMT-B has been proven to be a single predictor to predict dementia. We hypothesized that Dual Task Switching Working Memory Training (Dual Task-SWMT) where both motor and cognitive task requires working memory might improve not only task-switching ability but also the working memory capacity in healthy older adults. The purpose of this study was to examine the benefits Dual Task-SWMT on cognitive functions specially in the working memory capacity in healthy subjects

Methods: The study subjects were 50 healthy adults, 21 men and 29 women, aged ≥ 73 years, cognitive status screened ($MMSE>25$). We proposed them to perform Dual Task-Switching Working Memory Training that we have created one hour twice a week for 24 weeks. At the beginning and at the end of treatment, participants received a cognitive assessment that included Mini-Mental State Examination (MMSE), Forward and Backward Digit Span Test, Rey’s Auditory Verbal Learning test, TMT-A, TMT-B.

Results: The cognitive assessment showed statistically significant improvement in all the scores tested (t-test performed), including the TMT-B ($p<0.05$).

Conclusions: These findings indicate that Dual Task-SWMT where both motor and cognitive task requires working memory may serve as an efficient way to improve cognitive performance on healthy adults.

MOTOR-COGNITIVE TRAINING IMPROVES BALANCE AND COGNITION OF PATIENTS WITH PARKINSON’S DISEASE

J.R. Bacha, K.G. Silva, T.B. Freitas, G. Gomes, L. Viveiro, E. Varise, C. Torriani-Pasin, J. Pompeu, *Department of Physical Therapy, Speech Therapy and Occupational*

Therapy, School of Medicine, University of Sao Paulo, São Paulo, São Paulo, Brazil

Objective: To investigate the effects of motor-cognitive training on individuals with Parkinson disease (PD) compared with community dwelling elderly. **Method:** This is a randomized clinical trial, in which participated five elderly people [mean age 68.3 (2.03) years] and five patients with idiopathic PD [mean age 67.7 (2.1) years, stages 1–3 in the Hoehn and Yahr scale]. Participants underwent 14 training sessions of one hour of duration each one, twice a week. Training was conducted in groups with a maximum of five elderly. The program included challenging exercises for balance and cognition, including warming up, strengthening, flexibility, aerobic training, gait, balance and transfer training. Participants were assessed pre and post-test and after 30 days [follow-up (FU)]. Cognition and balance were assessed by the Montreal Cognitive Assessment (MoCA) and Mini-Balance Evaluation Systems Test (Mini-BESTest), respectively. Study was registered in Brazilian Registry of Clinical Trials (RBR-27kqv5). **Results:** Both groups showed improvement on balance and cognition post-test with maintenance of its effects on the FU. However, this improvement was substantial in the elderly group, but there was no difference between groups. The mean (SD) scores in scales evaluated in the elderly were: Mini-BESTest were: 26.9 ± 3.4 (pre-test), 29.4 ± 3.7 (post-test) and 28.7 ± 2.8 (FU); MoCA were 24.0 ± 5.2 (pre-test), 26.7 ± 3.3 (post-test) and 26.9 ± 4.4 (FU). The mean (SD) scores of PD patients on Mini-BESTest were: 24.0 ± 3.9 (pre-test), 24.4 ± 4.1 (post-test) and 26.3 ± 3.7 (FU); MoCA were 21.3 ± 4.5 (pre-test), 23.6 ± 5.5 (post-test) and 23.4 ± 4.5 (FU). **Conclusion:** The proposed intervention promoted improvement on balance and cognition in PD patients and community dwelling elderly.

ASSESSMENT, HOME SAFETY AND THE COGNITIVE PERFORMANCE TEST: A DISCONNECT IN PRACTICE OR PURPOSE?

S. Davidson^{1,2}, R. Emonts², M. Rotman², 1. *Occupational Therapy, Baycrest Health Sciences, Toronto, Ontario, Canada*, 2. *University of Toronto, Toronto, Ontario, Canada*

Home safety is crucial for older adults. Occupational therapists use performance-based assessments (PBAs) to predict clients’ occupational capacity and provide recommendations for needed supports to ensure safety. Occupational therapists face barriers with using PBAs in practice due to their complexity and variability. The Cognitive Performance Test (CPT) is a widely sourced standardized PBA, regularly utilized with the older adult population, and is reportedly challenging to administer and score. Currently there is a lack of knowledge about challenges associated with the use of PBAs. This study will explore occupational therapists’ perspectives on challenges they experience when using the CPT, and aim to produce strategies to remediate the disconnect of the CPT’s use in practice. Six occupational therapists, from various clinical programs at a geriatric hospital, participated in scoring of a recorded CPT administration and an audio-recorded focus group. Participants discussed the challenges and strategies associated with the CPT in practice. Using multiple analyst triangulation, the transcribed recordings underwent thematic analysis to uncover main themes.

Clinicians expressed personal qualities influencing their practice of “being” an occupational therapist, influences of the environment affecting their use of the CPT and identified patterns that they noticed while participating in the occupation of “doing” the CPT. The knowledge gained from this study can enhance clinician awareness of challenges associated with using the CPT and provide opportunity for occupational therapists to reflect upon their fit as clinicians within their practice environment, while utilizing a standardized assessment to help with the significant challenges that often accompany discharge.

CESSATION OF WALKING DURING DIVIDED ATTENTION TASK IN OLDER ADULTS WITH COGNITIVE IMPAIRMENT

S.M. Borges^{1,2}, M. Radanovic², O.V. Forlenza², 1. *Santa Cecília University, Santos, Sao Paulo, Brazil*, 2. *Laboratory of Neurosciences - LIM27; Department and Institute of Psychiatry Faculty of Medicine, University of São Paulo, Sao Paulo, Sao Paulo, Brazil*

The aim of the present study was to evaluate if older adults with Mild Cognitive Impairment (MCI) and mild Alzheimer's Disease (AD) patients stop walking during a functional mobility test with or without divided attention (dual task paradigm). We examined functional mobility in 104 older adults (42 with MCI, 26 with mild AD, and 36 cognitively healthy controls) using the Timed Up and Go test (TUG) under four experimental conditions: TUG single task, TUG plus a cognitive task (listing animals), TUG plus a manual task (holding a full glass of water) and TUG plus a cognitive and a manual task (performing the listing animals while carrying a full cup of water). Statistically significant differences between the mean time of execution were found in all four experimental conditions when comparing MCI and controls ($p < .001$), AD and controls ($p < .001$), and when comparing MCI and AD patients ($p < .05$). However members of all groups stopped walking while talking in TUG cognitive dual task (controls: $n=02$; 5.6%, MCI: $n=17$; 40.5% and AD: $n=19$; 73.1%; $p < .001$) and TUG plus a cognitive and a manual task (controls: $n=02$; 5.6%, MCI: $n=21$; 50% and AD: $n=19$; 73.1%; $p < .001$). These findings demonstrate the influence of cognitive impairment in divided attention task, especially cognitive dual task, during functional mobility. This data is relevant, because the termination of walking during the TUG indicates a loss in executive function and, consequently, increased risk of falls in older adults with cognitive impairment.

IS COMBINED MOTOR LEARNING COGNITIVE TRAINING THE EFFECTIVE TOOL TO IMPROVE COGNITIVE FUNCTION?

N. Trushkova¹, N. Ermolina², G. Zelano¹, 1. *Rehabilitation Research Center “Armonia”, Latina, Italy*, 2. *Astrakhan State University, Astrakhan, Astrakhan, Russian Federation*

Objectives: Several studies suggest that the brain maintains neuroplasticity even in older age and can benefit from mental training. A successful brain training program should preferably include a range of different tasks, that should be less automatic and more complex, in order to involve a multitude of functions. Numerous studies have claimed evidence that motor learning provides a great variety of exercises and offers neuroplastic benefits to the brain. We hypothesized

that combining cognitive exercises with motor learning training might improve cognitive functions in healthy older adults.

The purpose of this study is to examine the benefits of combined motor learning and cognitive exercises training on cognitive functions in healthy subjects.

Methods: The study subjects were 48 healthy adults, 17 men and 31 women, aged ≥ 74 years, cognitive status screened (MMSE >25). We proposed them to perform one hour of motor learning activity combined to cognitive stimulation exercises based on novelty and variability twice a week per 24 weeks. At the beginning and at the end of treatment, participants received a cognitive assessment that included Mini-Mental State Examination (MMSE), Digit Span Test, Rey's Auditory Verbal Learning test, TMT-A, TMT-B.

Results: The cognitive assessment showed statistically significant improvement in all the scores tested (t-test performed), the most significant was in MMSE (mean=1,6; $p < 0.001$).

Conclusions: These findings indicate that motor learning combined to cognitive stimulation exercises may serve as an efficient way to improve cognitive performance on healthy adults. We also discussed several directions for future combined training studies.

SUBJECTIVE COGNITIVE IMPAIRMENT IN INDIAN OLDER ADULTS: CLINICAL AND SOCIAL PROFILE

V. Kumar¹, G.R. Desai¹, S.K. Yadav¹, P. Chatterjee¹, A. Chakrawarty¹, A.B. Dey^{1,2}, 1. *Geriatric Medicine, AIIMS, New Delhi, New Delhi, Delhi, India*, 2. *AIIMS, New Delhi, New Delhi, Delhi, India*

Aims & objectives: To detect cognitive impairment among older people with subjective memory complaints in a tertiary hospital setting AIIMS.

Methods: In a cross-sectional study involving patients attending the “Memory Clinic” of the Department of Geriatric Medicine 200 patients, aged 60 and above, with subjective memory complaints were included. A detailed evaluation of the cognitive status, functional status and co-morbidities was done as per various validated scales. Socioeconomic and other demographic characteristics were obtained from the caregivers. The diagnosis, management and follow up of patients were carried out in the memory clinic.

Results: Out of 200 patients, 158 were males and 42 were females. Mean age was 67.5 years and the number abruptly declined after the age of 85 years. Most of the patients were living with their spouse and children, economically dependent and were from middle income group. GDS score was significantly associated with cognitive impairment. Cognitively impaired patient were more depressed as compared to normal participants (p value -0.000). Polypharmacy, urinary incontinence, vision and hearing impairment are also significantly associated with cognitive decline. Previous history of falls and dental problems were also found to have significant effect on cognitive performance of the patients. Alzheimer's disease (AD) (49%) and Vascular dementia (42%) were the main causes of dementia in cases. The common co-morbidities were hypertension, diabetes mellitus, cerebro-vascular accidents, and COPD. The most interesting result was that patients who themselves were concerned about cognitive decline had better scores than those who were presented by family members.

Conclusions: Subjective cognitive impairment is the very serious evolving issue in elderly and it should not be ignored as it may help to focus on future dementia cases. Geriatricians should develop clinical protocol to manage cognitive decline in old age without depending on neurologist and psychiatrists.

HIGH ANTICHOLINERGIC COGNITIVE BURDEN IS ASSOCIATED WITH URGENCY INCONTINENCE IN ELDERLY POPULATION

U. Cintosun, I. Naharci, T. Turker, E. Bozoglu, S. Oguz, A. Ozturk, H. Doruk, *Geriatrics, Gulhane Medical School, Ankara, Turkey*

Urgency urinary incontinence (UUI) is involuntary leakage of urine associated with urgency. Medications with anticholinergic cognitive burden (ACB) are considered as a risk factor for cognitive limitations and decreased physical functionality. Our aim was to investigate whether high ACB will be an independent risk factor for UUI in elderly or not.

The analysis was carried out on 1050 subjects aged ≥ 65 years. Out of those, 189 were eligible to meet the study criteria. They were divided into two groups: The study group included subjects with UUI (n:82) and the control group included those without UUI (n:107). ACB was calculated for each subject by adding the score of each drug and classified as having absent (ACB=0), low (ACB=1 or 2), and high (ACB ≥ 3) anticholinergic properties based on ACB scale.

Age, gender and cognitive status did not differ between groups. There was more subjects with definite and possible ACB in the study group compared to the control group (17.3% and 29.6% vs. 1.9% and 25%; $p < 0.001$). In multivariate regression analysis high ACB was found to be a risk factor for UUI (OR: 11.2; CI: 2.333–53.776; $p = 0.003$) while low ACB not (OR: 1.652; CI: 0.809–3.376; $p = 0.168$).

We found that high ACB is an independent risk factor for UUI. Central effects of medications with ACB and their functionality-limiting effects are possible causes of UUI in this population. Further randomized and controlled studies are needed to enlighten the causal relationship between ACB and UUI.

SESSION 945 (POSTER)

COGNITION III

THE IMPACT OF THREE COGNITIVE TRAINING INTERVENTIONS ON OLDER ADULTS' LIFESPAN ACROSS FIVE YEARS

L. Ross¹, A. Stanford¹, C. Phillips¹, M.L. O'Connor², J. Dodson³, F. Cortez², 1. *Human Development and Family Studies, The Pennsylvania State University, University Park, Pennsylvania*, 2. *North Dakota State University, Fargo, North Dakota*, 3. *University of Alabama at Huntsville, Huntsville, Alabama*

Lifespan is the purposeful movement throughout one's environment and is a central aspect of healthy aging. As fluid cognitive abilities are strongly linked to lifespan, targeted cognitive interventions may preserve lifespan in older adults. The objective of this study was to assess the effects of three

separate cognitive interventions (reasoning training, speed of processing training, and memory training) on changes in older adults' lifespan across 5 years. Participants (age range 65–94, $M = 73.64$) randomized to a no-contact control condition (n=698) were compared to those randomized to: reasoning (n=694), speed of processing (n=702), and memory (n=703) training using multilevel modeling. Intention-to-treat (ITT, randomization to training conditions) and dosage (treatment-received via number of training sessions) analyses were conducted. Models were adjusted for age, race, attrition, gender, mental status, driving status, study location, and residential status (i.e. living alone or not). Results revealed no significant group differences in the ITT analyses. However, dosage models revealed that more sessions of speed of processing [95% CI: .0002, .0098] and reasoning [95% CI: .0002, .0100] training predicted greater lifespan across the five years relative to the control group. Participants randomized to memory training did not differ from the control group in lifespan across five years [95% CI: -.0044, .0055]. This is the first study to show that two cognitive interventions (reasoning and speed of processing training), but not memory training, transferred to maintained lifespan across five years. Future research should investigate the mechanisms of these far transfer effects.

MODERATE ALCOHOL USE AND COGNITIVE PERFORMANCE OVER TIME AMONG OLDER ADULTS

D. Herring, D. Paulson, *University of Central Florida, Orlando, Florida*

Individual trajectories of cognitive aging can vary widely and are affected by numerous lifestyle factors¹. Moderate alcohol use among older adults is known to confer protective effects with regard to cognition and other health outcomes²⁻⁵. However, less is known about how moderate drinking relates to rate of change between cognitive domains and the timing of emergence of moderate use-associated benefits.

The purpose of this study was to explore older adults' self-reported alcohol use over time in relation to their cognitive performance over a period of eight years. Data for the 856 participants was obtained from the ADAMS sample of the HRS, a longitudinal, cohort study on health, retirement, and aging conducted by the University of Michigan. Participants were predominantly female (58.6%) and Caucasian (76.9%). The mean age at baseline was 81.56 years (SD=7.17) and average years of education was 10.03 years (SD=4.35).

A series of latent growth curve models examined the effects of moderate use on rate of change in cognitive performance over time for each measure (relating to domains of Fluency, Executive Functioning, Visuospatial, and Memory). After controlling for education, medical burden, and marital status, moderate drinking was consistently significantly associated across cognitive measures with increased baseline functioning ($p \leq .05$), but did not have a significant effect on rate of change over time.

These findings suggest that the effect of moderate alcohol use on cognition emerges prior to the time period captured by available data (age 73), and that these differences appear to persist throughout later life.

ALCOHOL INTAKE AND COGNITIVELY HEALTHY LONGEVITY: THE RANCHO BERNARDO STUDY

E. Richard¹, D. Kritz-Silverstein¹, G.A. Laughlin¹, T. Fung², E. Barrett-Connor¹, L.K. McEvoy¹, 1. *Radiology, University of California, San Diego, La Jolla, California*, 2. *Harvard University, Boston, Massachusetts*

Moderate alcohol consumption has been associated with reduced mortality, but the association of alcohol with cognitively healthy longevity has not been well characterized. Here we explored the association between alcohol intake and cognitively healthy longevity among 1353 community-dwelling adults. Frequency and amount of alcohol intake was assessed by questionnaire in 1984–1987. Cognitive function was assessed at approximate 4 year intervals beginning in 1988–1992 through 2007–2009. Multinomial logistic regression was used to examine the association between alcohol intake and a three level outcome: cognitively healthy longevity (living to at least age 85 without cognitive impairment), survival to age 85 with cognitive impairment (defined as an MMSE score > 1.5 standard deviations below expectation for age, sex, and education), or death before age 85, with adjustment for numerous health and lifestyle factors. Only 17% of participants reported no alcohol intake; 48% reported drinking near-daily. Most drinkers (48% of the sample) consumed a moderate amount of alcohol (≤ 1 drink/day for women and those over age 65; ≤ 2 drinks/day for men under age 65). Relative to nondrinkers, those who drank near daily had 2–3 fold higher odds of cognitively healthy longevity versus cognitive impairment ($p < .05$) or death before 85 ($p < .001$). Compared to nondrinkers, moderate or heavy drinkers had significantly higher odds of cognitively healthy longevity versus cognitive impairment or death before age 85 (p 's $< .05$). Although excessive drinking is associated with significant mortality and morbidity, our results suggest that frequent, moderate alcohol intake may play a role in promoting cognitively healthy longevity.

UNDERSTANDING THE RELATIONSHIP BETWEEN RETIREMENT AND COGNITIVE HEALTH

J. Godin¹, O. Theou², J. Armstrong², M. Andrew^{1,2}, 1. *Nova Scotia Health Authority, Halifax, Nova Scotia, Canada*, 2. *Dalhousie University, Halifax, Nova Scotia, Canada*

Researchers have examined the association between cognition and retirement; however, results are inconsistent and the direction of the relationship is unclear. Risks may be context dependent. Retirement may be viewed by some as an opportunity to pursue interests and hobbies, whereas others may derive meaning and benefits from employment. Our purpose was twofold: 1) examine whether cognitive impairment predicts future employment status (i.e., retirement) and whether employment status predicts future cognitive impairment; and 2) explore predictors of cognitive impairment in employed, retired, and not employed individuals over the age of 50. We conducted secondary analyses of data from the first five waves of the English Longitudinal Study on Aging. In cross-lagged growth curve models ($N=6492$) adjusted for age, sex, education, social vulnerability, frailty, and baseline cognition or employment status, being retired was associated with better future cognitive function ($b=-.19$, $p < .001$) and a 10% unit increase in cognitive impairment was associated

with lower odds of being retired in the future ($OR=0.93$, $p < .05$). In nonlagged growth curve models ($N=10125$), on average retired individuals had less cognitive impairment ($b=-0.93$, $p < .01$), but accumulated cognitive deficits more quickly than employed individuals. In general, cognitive deficits accumulated with age ($b=0.64$, $p < .01$); however, being employed and having higher education offered some protection. Increasing frailty was associated with faster cognitive decline. Retirement does not necessarily lead to decreasing cognitive function. Understanding the link between retirement and cognition can facilitate the development of appropriate interventions to help people maintain cognitive health in retirement.

IQ, REPETITIVE THOUGHT, AND INFLAMMATION IN OLDER ADULTS: REPETITIVE THINKING MAY BENEFIT HEALTH

S. Segerstrom, A. Scott, R.G. Reed, *Psychology, University of Kentucky, Lexington, Kentucky*

Higher IQ correlates with lower systemic inflammation, which in turn reduces risk for disorders of aging. The present study examined the role of repetitive thought (RT) in the relationship between IQ and interleukin (IL)-6, an inflammatory marker. RT is thinking attentively, repeatedly, and frequently about oneself and one's world and is characterized by Valence (positive-negative), Purpose (searching-solving), and Total quantity (much-little). Estimated IQ and RT dimension scores were assessed at baseline in a sample of older adults ($N=120$, $Age=74$ years), who had blood drawn up to 10 times semiannually ($n=799$). Models included IL-6 covariates: BMI, chronological age, and statin medication. Higher IQ was associated with lower IL-6 ($t(120)=2.03$, $p=.045$). Of the RT dimensions, only more Total RT predicted lower IL-6 ($t(124)=3.26$, $p=.001$), an effect that was not moderated by Valence or Purpose. In a test of mediation, more Total RT accounted for part of the effect of IQ on IL-6 (indirect effect = -0.06 [$CI = -0.14, -0.002$]). There was also a significant interaction between IQ and Total RT ($t(119) = 2.64$, $p=.009$), in which more Total RT was more strongly associated with lower IL-6 for people with lower IQ. Although some forms of RT such as worry may have negative health correlates for older adults, engaging in RT *per se* can be healthy insofar as it also encompasses planning, cognitive processing, and coping. Older adults with higher IQ were more likely to engage in RT, but older adults with lower IQ benefitted the most in terms of systemic inflammation.

LONGITUDINAL CHANGES IN PHYSICAL FUNCTION-COGNITIVE FUNCTION RELATIONSHIPS IN OLDER ADULTHOOD

B. Sprague¹, C.B. Phillips², L. Ross¹, 1. *The Pennsylvania State University, University Park, Pennsylvania*, 2. *Arizona State University, Phoenix, Arizona*

Evidence suggests increasing interconnectedness of physical and cognitive functions in older adulthood, and possible co-occurring terminal declines on approach to death. Newer statistical techniques such as time-varying effects modeling (TVEM) allow researchers to explore how the magnitudes of these relationship differ across time without imposing traditional assumptions like linearity. Using time-to-death

in years as the time-varying metric, we examined relationships between physical function (Turn 360, grip strength) and specific cognitive domains (processing speed, reasoning, and memory) in a subsample of 429 healthy community-dwelling older adults aged 65–91 (mean age = 76.0, 62.7% female, 82.3% Caucasian, mean MMSE = 27.4). After controlling for baseline age, sex, education, race, and general health, associations between Turn 360 and processing speed strengthened and then stabilized around 7.5 years prior to death (estimate = $-.1$, $p < .05$). Increases in relationship magnitudes followed by stabilization were also found between grip strength and memory (estimate = $.1$, $p < .05$), processing speed (estimate = $.1$, $p < .05$), and reasoning approximately at 7.5, 10 and 12 years prior to death, respectively. These results partially support prior findings that time-to-death may be an important time metric to examine relationships between physical and cognitive function in older adults. Although the relationship magnitudes remained stable until death, these results may not generalize to less healthy samples. These results also demonstrate the utility of TVEM as an exploratory tool. Future work should replicate and extend these findings to more diverse, at-risk samples.

APOE EFFECTS ON COGNITION FROM MIDDLE CHILDHOOD TO THE CUSP OF MIDDLE ADULTHOOD

C.A. Reynolds¹, A. Smolen², B.C. Haberstick², J.C. DeFries², S.J. Wadsworth², 1. *University of California, Riverside, Riverside, California*, 2. *Institute for Behavioral Genetics, University of Colorado, Boulder, Colorado*

APOE is a well-established genetic risk factor for cognitive aging and dementia, but its influence on cognition in childhood through early adulthood is inconclusive. We examine cross-sectional and longitudinal relationships of APOE on cognitive performance in individuals now approaching midlife (30–45 years) from the ongoing Colorado Adoption/Twin Study of Lifespan behavioral development and cognitive aging study (CATSLife), with over 30 years of follow-up from parent studies (Colorado Adoption Project, Longitudinal Twin Study). We conducted an analysis on a subset of participants who participated in cognitive assessments between middle childhood and early adulthood with available APOE genotyping. Cross-sectional analyses of WAIS subtests in adolescence ($M_{age} = 16.42$, $SD_{age} = .73$; $N = 401$) accounting for sibling clustering, sex and age suggested that APOE e4 carriers perform significantly more poorly at age 16 on the WAIS Vocabulary, Digit Span, Picture Completion and Object assembly subtests ($p < .05$; d 's $.27$ – $.34$). Longitudinal growth analyses of specific memory, spatial and speed abilities between middle childhood and early adulthood (7–35 years; $N = 436$) suggested that APOE e4 alleles were associated with poorer memory performance on a paired associates task (Names and Faces delayed, $p < .05$), and with dampened nonlinear gains on a spatial rotations task across age (ETS Card Rotations, $p < .02$). These findings suggest that APOE is associated with differential cognitive performance earlier than midlife, particularly for memory and spatial abilities. We will extend analyses to the entire CATSLife sample ($N=1600$) and compare results to the international context.

DO MULTIPLE CONSTRUCTS EXPLAIN INCONGRUENT ASSOCIATIONS BETWEEN SUBJECTIVE MEMORY AND COGNITION?

W. Haavisto, J.A. Blaskewicz Boron, J. Beadle, C.M. Kelly, *University of Nebraska at Omaha, Omaha, Nebraska*

Many studies have demonstrated no (or weak) associations between self-evaluated and objective memory. The purpose of this study is to investigate whether such incongruent associations between the two constructs could be explained by better or worse self-assessments in reporting subjective memory. Participants from the 2000 wave of the Long Beach Longitudinal Study ($N=916$; age range: 29–98; mean age=69.17) were utilized. The four factors (frequency of forgetting, retrospective functioning, seriousness of forgetting, mnemonics usage) of the Memory Function Questionnaire (MFQ; Gilewski, Zelinski, & Schaie, 1990) were used for subjective memory. Four groups were created based on quartiles of scores across three cognitive domains (Immediate recall, Vocabulary, and Recognition Vocabulary). ANOVAs were used to analyze the data. Results indicated significant mean differences in frequency of forgetting for the groups based on immediate recall ($p < 0.001$), vocabulary test ($p < 0.05$), and recognition vocabulary ($p < 0.001$) performance, suggesting that people with higher scores in the various cognitive domains rated their subjective memory in frequency of forgetting higher. Significant mean differences in retrospective functioning emerged for the groups categorized based on vocabulary ($p < 0.001$), and recognition vocabulary ($p < 0.001$), suggesting that people with higher scores in these cognitive domains rated their subjective memory in retrospective forgetting poorer. People with better cognitive abilities appeared to be more optimistic about their frequency of forgetting and more pessimistic about their retrospective functioning. The findings support the work of Gilewski et al. and others that subjective memory is not a single construct; it comprises multiple factors that are highly distinctive.

FLUID COGNITIVE ABILITIES AND AUTONOMIC AND AFFECTIVE RESPONSE TO ACUTE STRESSORS IN OLDER ADULTS

K.L. Heffner, *Nursing and Psychiatry, University of Rochester Medical Center, Rochester, New York*

There is a need for more integrative understanding of the self-regulatory systems that promote older adults' stress adaptation. This study examined associations among three domains hypothesized to support adaptive capacity in response to challenge: fluid cognitive abilities, particularly attention and processing speed; flexible parasympathetic nervous system activity, indexed by high frequency heart rate variability (HF-HRV); and affect regulation. In a sample of 100 healthy adults 50 to 87 years of age (mean age = 60.7 years), controlling for age and education, better attention ability from the Repeated Battery for Neuropsychological Status was associated with greater HF-HRV decline and lower negative affect response to acute laboratory stressors, suggesting greater adaptive capacity. Stratifying the sample as more or less stressed based on Perceived Stress Scale scores, less stressed older adults showed no significant associations among fluid cognitive abilities and HF-HRV and negative affect in response to stressors. By contrast, among the more globally stressed participants, worse processing speed was

associated with smaller HF-HRV decline and larger increase in negative affect response. These findings support the growing recognition that the capacity to adapt to stressors is a function of multiple, overlapping regulatory systems. Further, there may be stronger functional dependencies among regulatory domains in the context of stress. Aging affects multiple regulatory domains, and can be accompanied by exposure to chronic stressors known to affect health, such as spousal dementia caregiving. As such, integrative models of stress adaptation are needed to identify intervention targets that promote adaptive capacity and well-being in older adults.

DTLA-A NEW SCREENING TEST FOR LANGUAGE IMPAIRMENT IN AGING

J. Macoir^{1,2}, M. Fossard³, L. Lefebvre⁴, L. Monetta^{1,2}, A. Renard⁵, T. Tran⁶, M.A. Wilson^{1,2}, 1. *Laval University, Quebec city, Quebec, Canada*, 2. *Centre de Recherche de l'Institut Universitaire en Santé Mentale de Québec, Quebec City, Quebec, Canada*, 3. *Université de Neuchâtel, Neuchâtel, Switzerland*, 4. *Université de Mons, Mons, Belgium*, 5. *Centre Leenaards de la mémoire, Lausanne, Switzerland*, 6. *Université de Lille, Lille, France*

Compared to cognitive functions such as working memory and executive functions, language appears to be mostly resistant to age-related decline. However, language is affected in the early stages of major forms of dementia and language deficits are at the core of the clinical portrait of primary progressive aphasia. Primary care providers are frequently faced with patients whose main complaints concern language problems in everyday and professional life. Up to now, no brief, accurate, screening test, which could be applied during routine office visits, was available for language deficits in neurodegenerative diseases. The aim of this study is to fill this important need by developing a handy, sensitive and brief detection test for language impairments in adults and aging. In this presentation, we describe the psychometric properties of the DTLA (Detection Test for Language impairments in Adults and Aging), a new screening test developed in four French-speaking countries (Belgium, Canada, France and Switzerland). We first present the development phase of the DTLA, then we provide normative data for healthy, community-dwelling, French-speaking people from the four countries. Finally, we report data on the convergent and discriminant validity of the DTLA as well as on its test-retest and internal consistency reliability. The use of the DTLA could improve the diagnosis of neurodegenerative diseases, especially those in which language is primarily affected. Ultimately, this will permit patients and their families to receive adequate services at an earlier stage of the disease.

EFFECTS OF MILD COGNITIVE IMPAIRMENT ON LINGUISTIC COMMUNICATION: A PILOT STUDY

N. Mahendra¹, M. Ifah², 1. *San Jose State University, Fremont, California*, 2. *California State University East Bay, Hayward, California*

Mild cognitive impairment (MCI) is a nosological entity increasingly recognized as a prodrome of dementia. As distinct types of MCI have been identified, it is well recognized that other cognitive functions besides memory are frequently affected. Linguistic communication measures are important cognitive biomarkers and our objective was to study the

effects of healthy older adults and persons with MCI on a language battery. Our secondary objective was to identify which language tasks might have greater clinical utility in identifying and quantifying MCI.

Subsequent to obtaining informed consent, we assessed 10 persons with MCI and compared their performance to healthy older adults and published norms for persons with Alzheimer's disease. Participants' medical history was obtained; hearing, vision and affect screened; cognitive function assessed, followed by administering a standardized language battery - the Arizona Battery for Communication Disorders of Dementia (ABCD; Bayles & Tomoeda, 1993). This test has been especially validated for distinguishing between the linguistic communication profile of young and old controls versus persons with AD.

Performance of persons with MCI was documented on 14 subtests of linguistic communication, mapping onto 5 broad constructs of Mental Status, Memory, Language Expression, Language Comprehension and Visuospatial Construction. Our results demonstrated that linguistic communication tasks that require episodic recollection (e.g. word learning, story recall), and more generative, narrative responses on discourse tasks (e.g. tasks requiring object description and concept definition) were especially sensitive to language changes accompanying MCI. Simpler tasks of linguistic communication (e.g. word or sentence reading comprehension; confrontation naming) did not reveal any differences from healthy older controls. Implications of these results for clinical assessment of persons with MCI will be discussed.

THE IMPACT OF NOISE AND WORKING MEMORY ON ONLINE PROCESSING OF SPOKEN WORDS: EYETRACKING EVIDENCE

B.M. Ben-David^{1,4}, G.M. Nitsan^{1,3}, A. Wingfield², 1. *Interdisciplinary Center Herzliya, Herzliya, Israel*, 2. *Brandeis University, Waltham, Massachusetts*, 3. *Haifa University, Haifa, Israel*, 4. *University of Toronto, Toronto, Ontario, Canada*

Among the complaints of older adults is a difficulty in speech recognition, especially in noisy backgrounds. This difficulty can interfere with maintenance of health and quality of life and can potentially affect the rate of cognitive decline. A central research question in speech recognition in older adults is the extent to which difficulties stem from bottom-up, sensory declines that degrade the speech input, and to what extent they stem from an age-related reduction in working memory.

We used eye-tracking as an on-line measure of spoken word recognition. Listeners hear spoken instructions that relate to an object presented in the visual display, while their eye movements are recorded. For example, hearing "touch the candle," with four objects displayed: candle, candy, dog and bicycle. As the speech signal unfolds, several alternatives are activated in response to phonemic information, i.e., CAND leads to *candy* and *candle*. In order to successfully achieve word identification, one has to inhibit phonological alternatives. Using eye-tracking, we tracked, in real-time, as the listener shifts his or her focus between *candle* and *candy*. We manipulated working memory load by using the digit pre-load task, where participants have to retain either one

(low-load) or four (high-load) spoken digits for the duration of a spoken word recognition trial.

We will present three separate studies. The data show that both noise and working memory can delay speech processing. With younger adults, data suggest that the two effects may interact. Preliminary data with older adults will be discussed.

THE SURVIVAL ADVANTAGE OF READING BOOKS

A. Bavishi, M. Slade, B. Levy, *Yale University School of Public Health, New Haven, Connecticut*

Although books can expose people to new people and places, whether books also have health benefits beyond other types of reading materials is not known. This study examined whether those who read books have a survival advantage over those who do not read books and over those who read other types of materials, and if so, whether cognition mediates this book reading effect. The cohort consisted of 3635 participants in the nationally representative Health and Retirement Study who provided information about their reading patterns at baseline. Cox proportional hazards models were based on survival information up to 12 years after baseline. A dose-response survival advantage was found for book reading by tertile ($HR_{T_2} = 0.83$, $p < .0001$, $HR_{T_3} = 0.77$, $p < .0001$), after adjusting for relevant covariates including age, sex, race, education, comorbidities, self-rated health, wealth, marital status, and depression. Book reading contributed to a survival advantage that was significantly greater than that observed for reading newspapers or magazines ($t_{T_2} = 98.8$, $p < .0001$; $t_{T_3} = 4956$, $p < .0001$). Compared to non-book readers, book readers had a 4-month survival advantage at the point of 80% survival. Book readers also experienced a 20% reduction in risk of mortality over the 12 years of follow up compared to non-book readers. Cognitive score was a complete mediator of the book reading survival advantage ($p = .04$). These findings suggest that the benefits of reading books include a longer life in which to read them.

IMPACT OF SOCIAL SUPPORT ON COGNITIVE FUNCTION IN CHINESE ELDERLY: ONE-YEAR FOLLOW-UP COHORT STUDY

S.L. Lin, *Department of Social Work, Chinese University of Hong Kong, Hong Kong, Hong Kong*

Background: The maintenance of cognitive function is the key dominant of older age wellbeing. Promoting successful cognitive aging is a major public concern to individuals and the field of public health. This study examines the association between perceived social support and cognitive function in a representative community sample of 82 Hong Kong Chinese Elderly.

Methods: Baseline data collection was completed in 2005 and included a 180-min face-to-face interview covering detailed assessments of physical and cognitive performance (Chinese version of Dementia Rating Scale, CDRS), health status, social support (from three types of network members including their children, relatives, and friends), and other life-style characteristics. The cohort was subsequently reevaluated in 2006, with reassessments of cognitive function.

Result: The mean age was 69 years old for the participants, of whom 78.05% were female. In the multiple linear regression, controlling for demographics variables, medical conditions, pulmonary function, grip strength, blood pressure,

Body Mass Index, and leisure activities, greater baseline social support from children was a significant predictor of better cognitive function (changes in adjusted CDRS for age and education) at the 1-year follow-up. Among three types of social support network, perceived children's willingness to offer help was strongest predictor.

Conclusion: Consistent with Western studies, social support from family is important for elderly Chinese people in Hong Kong. Strengthening social support among family members are highly recommended for preserving cognitive function during aging.

ACTIVITY INTERESTS AND TALENTS IN RELATION TO COGNITIVE PERFORMANCE: A PROSPECTIVE STUDY

B.P. Trubenstein¹, B.C. Haberstick², R. Corley², S.J. Wadsworth², C.A. Reynolds¹, *1. Psychology, University of California - Riverside, Riverside, California, 2. University of Colorado - Boulder, Boulder, Colorado*

Past research shows lifespan activity engagement provides multiple benefits to physical, emotional and cognitive health into late life. We investigated the prospective relationships between self-reported activity interests and talents with cognitive performance in a subset of participants taking part in the ongoing Colorado Adoption/Twin Study of Lifespan behavioral development and cognitive aging (CATSLife). Initial analyses evaluated associations of interest/talents, and cognitive performance beginning in late adolescence and approaching midlife (16 to 36 years; $N = 852$). Individuals rated 20 activities as to interests and talents (1=not at all to 5=very much). Activity types were classified into artistic (writing, music, visual arts), physical (team sports, swimming, skiing), or practical (cooking, carpentry, mechanics), and were correlated across assessments (r 's = .230 - .767). Cognitive performance was assessed from a battery of 14 tasks spanning verbal, spatial, memory and speed domains. Interests and/or talents in arts were positively correlated with better immediate and delayed performance on the Names and Faces Memory Task at years 16, 21, and 30 (r 's = .091 - .232). Interests and/or talents in physical and practical activities correlated with performance on the Card Rotations spatial task across assessments (r 's = .123 - .204), and practical activities with the Paper Form Board spatial task (r 's = .109-.274). These initial findings hint at possible influences, or environmental selection, of activity engagement and maintenance of memory and spatial abilities. We will extend analyses to the full CATSLife sample, consider activity and cognitive performance trajectories in tandem, and compare findings to the international literature.

SELECTIVE ATTENTION IN AGE-ASSOCIATED MEMORY IMPAIRMENT: AN ERP STUDY IN VISUAL SEARCH

A. Bujn¹, L. Lorenzo-López¹, A. Maseda¹, R. López-López¹, C. Diego-Diez¹, V. Valdiglesias², J. Millán-Calenti¹, *1. Gerontology Research Group, Instituto de Investigación Biomédica de A Coruña (INIBIC), Complejo Hospitalario Universitario de A Coruña (CHUAC), SERGAS, Universidade da Coruña, A Coruña, Spain, 2. DICOMOSA Group, Department of Psychology, Area of Psychobiology, Universidade da Coruña, A Coruña, Spain*

Age-Associated memory impairment (AAMI) may be related to a decline in selective attention. In this work, the potential attentional capture by task-irrelevant stimuli was examined in older adults with AAMI compared to healthy older adults using event-related potentials (ERPs).

A visual search task was employed, in which the participants had to detect the presence of a target stimulus that differed from distractors by orientation. To explore the automatic attentional capture, an irrelevant distractor stimulus defined by color was also presented without previous knowledge of the subjects. The N2pc component of ERPs, an electrophysiological indicator of the allocation of attentional resources, was analysed.

The results indicated that in both groups the N2pc component was present for target stimuli but not for task-irrelevant color stimuli. In addition, the latency of N2pc for targets was significantly delayed in AAMI patients compared to controls, although no differences in the amplitude of the component were found.

The delay in N2pc latency in AAMI subjects suggested they require more time than healthy seniors to shift their visuospatial attention onto the task-relevant information. However, the lack of significant differences between the groups in N2pc mean amplitude and scalp distribution suggested that the amount of attentional resources allocated to the target did not differ between older adult with and without memory impairment. The lack of N2pc component for irrelevant non-target stimuli indicated that the mechanism of top-down suppression of task-irrelevant information is preserved.

Funding: Xunta de Galicia (GPC2014/082)

THE IMPACT OF SELF-RELEVANCE AND TASK COMPLEXITY ON INFORMATION SEARCH DURING DECISION-MAKING

X. Liu, H. Peng, B. Pu, *Beijing Normal University, Beijing, Beijing, China*

Cognitive declines may negatively impact older adults to systematically search information, which might lead them to make decisions more based on the presence or absence of values on important dimensions (i.e., noncompensatory strategies) rather than consider all the information associated with each alternative (i.e., compensatory strategies). However, draw from selective engagement, self-relevance would increase older adults' motivation to engage in the task, which might result in more search behaviors. To investigate the impact of self-relevance and task complexity on information search during decision-making, the present study adopted a 2 (age: young, old) \times 2 (self-relevance: low, high) \times 2 (task complexity: simple, complexity) mixed design. We examined information search behaviors in 60 younger and 60 older adults using a process-tracing procedure with 6 decision matrices. Decision tasks varied in complexity, and half of them were considered as relevant to older than to younger adults, whereas the opposite would be true for the others. Results showed that older adults were more likely than younger adults to use compensatory strategies, and spent more time and searched more information during decision making. With self-relevance increasing, older adults used less compensatory strategies, while younger adults

changed strategies from noncompensatory to compensatory strategies. Increased in task complexity result in more information search, more time on decision-making, but adults of all ages still tend to use compensatory strategies. The results suggest that self-relevance may be more important than task complexity to determine older adults' information search behaviors during decision-making.

SESSION 950 (POSTER)

CULTURAL AND CROSS-NATIONAL RESEARCH

GLOBAL AGING AS LIFE COURSE EXPERIENCE: RESULTS FROM ETHNOGRAPHIC RESEARCH IN GHANA AND THE U.S.

A.L. Crampton, *Marquette University, Milwaukee, Wisconsin*

The discourse underlying population aging as a policy and practice concern has long been dominated by modernization and demographic transition theories. In this discourse, an older adult is defined by chronological age and is constructed as dependent (Aboderin 2004). For example, dependency ratios drastically simplify intergenerational caregiving and support. Anthropological research on aging helps document the limitations of this discourse in understanding the full range of experience people have as they grow older – that is, the culturally informed, locally specific, lived experience of people as they age. This paper first reviews the construction of older adulthood within dominant policy and practice discourse on population aging, and then contrasts this construction with results from sixteen months of ethnographic data collection in Ghana and the United States during 2004–5. Data analysis of how people experience the challenges of growing older in local contexts challenges dominant constructions of older adults as merely dependent, and offers a more nuanced, culturally informed life course perspective. Implications for policy include steps towards reforming global aging policy from addressing aging as a separate life stage of “old” and dependent to a life course experience in which growing older contributes to but does not define the role of older adults in family support systems and society.

WHY DO OLDER TURKISH IMMIGRANTS LIVING IN EUROPE USE HEALTH CARE SERVICES IN TURKEY?

N. Korkmaz Yaylagul, S. Yazici, *Akdeniz University, Antalya, Turkey*

Background: Turkish labor immigrants that moved to European countries around 1970's and have already reached the “old age”. Health care needs increase with advanced age as the number of chronic diseases increases. In the case of migration, retirement enables more flexible use of the country for treatment. Research has shown that satisfaction from health care services in host countries are among factors hindering the immigrants to consider remigration. Cross border health care practices of older Turkish immigrants have been found to differ from other nationalities.

The aim of the research is to evaluate the effect of interpersonal relations between health care providers and older Turkish immigrants on cross border health care use, the

perceptions and practices of older Turkish immigrants about the health care services in their host countries (Denmark (DK), Germany (D) and England (UK)) and Turkey.

Methods: A multi centered, qualitative cross sectional study was conducted with Turkish immigrants living in Copenhagen (DK), Hildesheim (D) and London (UK). Semi structured interviews were performed with 67 individuals aged between 50 and 83. All interviews were audio recorded, transcribed and submitted to thematic analysis.

Results: Using Glino's typology for cross border health service use, availability and perceived quality have been found to be push factors shaping cross border health care use. Practices were mainly towards early and right diagnosis. Language barrier however has come up as a theme but surprisingly did not affect the use and perceptions of cross border health care.

PUBLIC OR PRIVATE SERVICE DELIVERY? EMPLOYEES' ATTITUDES TO END-OF-LIFE CARE IN SIX EU COUNTRIES

M. Kylanen¹, S. Peltola¹, T. Smets², S. Payne³, K. Szczerbinska⁴, G. Gambassi⁵, R. Pasman⁶, L. Van den Block², 1. *The Department of Welfare, National Institute for Health and Welfare (THL), Tampere, Finland*, 2. *Department of Family Medicine and Chronic Care, End-of-Life Care Research Group, Vrije Universiteit Brussel (VUB) and Ghent University, Brussels, Belgium*, 3. *International Observatory on End-of-Life Care, Lancaster University, Lancaster, United Kingdom*, 4. *Unit for Research on Aging Society, Department of Sociology of Medicine, Epidemiology and Preventive Medicine Chair, Faculty of Medicine, Jagiellonian University Medical College, Krakow, Poland*, 5. *Università Cattolica del Sacro Cuoro, Rome, Italy*, 6. *EMGO Institute for Health and Care research, Expertise Center for Palliative Care, VU University Medical Center, Amsterdam, Netherlands*

Why should there be a distinction between public or private funded long term care for people at the end of their life? The conventional wisdom and the study of public administration is based on the belief that public and private organizations differ significantly. This paper argues that this statement is more a myth than a fact. Notwithstanding the number of public-private comparisons, comparative cross-country studies on employees' behavior and attitudes towards end-of-life care for older people are neglected in this area. This paper aims to explore similarities and differences between care staffs' behavior and attitudes towards end-of-life care for older people in public and private long term care facilities (LTCF) in six European countries: Belgium, Finland, Italy, the Netherlands, Poland and United Kingdom. As part of PACE project ("Comparing the Effectiveness of Palliative Care for Elderly People in Long Term Care Facilities in Europe" funded by the EU 7th Framework Programme), the survey data were collected in 2015 by recruiting a random sample of LTCFs in six countries. The results indicate more similarities than differences. Possible explanations between the sectors are explored, and the strengths and limitations of the study are discussed. Findings contribute in particular to the literature on public service motivation and public values and our understanding of how both public and private LTCFs serve public good. As a conclusion the paper suggests

that service delivery as a public/private service issue should be taken more seriously: care staff prefer to care older people as human beings.

THE EFFECTS OF COMMUNITY AND PUBLIC SUPPORT ON THE MENTAL HEALTH OF ELDERLY CHINESE

K.A. Zurlo¹, H. Hu², 1. *School of Social Work, Rutgers University, New Brunswick, New Jersey*, 2. *North China Electric Power University, Baoding, Hebei Province, China*

Economic reforms in China are associated with migration of young Chinese from rural to urban centers. This migration as well as the one-child policy and increased longevity have affected the well-being of the elderly, who largely remain in rural residences. An erosion of the cultural tradition of filial piety is related to the mental health of a growing elderly population, who is at-risk of increased depressive symptoms. We analyzed data from the China Health and Retirement Longitudinal Study that were collected in 2011. These data were from a nationally representative and publicly available dataset. We evaluated the associations between 2 types of social services (community-based and public support) and depressive symptoms in the Chinese elderly (≥ 60 years) with a focus on age differentials and type of residential registration (urban or rural hukou). The results indicated that components of community and public support were significantly and negatively associated with depressive symptoms. These components included having a senior center in the community, receiving a subsidy from the local agency, and receiving a pension. Also, the elderly living in a rural hukou had greater levels of depressive symptoms, and depressive symptoms in this population were most significantly and negatively affected by having a senior center in the community and receiving a local subsidy. These results suggest that specific types of social support may negatively affect depressive symptoms and provide opportunities for targeted interventions from community leaders and policymakers that improve mental health and well-being among a growing elderly population in China.

COMPARING PUBLIC DISCOURSE ON ELDER CARE IN FINLAND AND THE UNITED STATES

U. Koivula², A.T. Woodward¹, 1. *Michigan State University, East Lansing, Michigan*, 2. *Tampere University of Applied Sciences, Tampere, Finland*

Academic literature on elder care examines the quality of care, the structure of services, and the role of non-professional care. While fairly universal across developed countries, the cultural and social welfare contexts vary suggesting cross-country differences in how these issues are understood and addressed. The media both reflects and shapes what people regard as significant and is, therefore, one place to examine cross-cultural differences in approaches to care; however, studies that compare the discourse across countries with different social welfare structures are almost non-existent. In this study, we analyze print media published in four major newspapers in Finland and the United States. Using quality of care, structure of services, and non-professional care as our guiding framework, we conducted a thematic analysis of news reports, feature stories, and editorials published during May-June 2015 and March-April 2016. Quality of care was

the most common theme in Finnish media with a focus on: 1) harmful or dangerous care practices, 2) neglect or lack of care, and 3) care falling behind set quality requirements. Despite the differences in the welfare regime, cost of care to the individual was a common theme in both countries as was a focus on increasing home care and informal care. There are weak signals in both countries of innovations that co-mingle aspects of informal and formal care such as intergenerational housing, employment opportunities for older adults, and co-locating day care and adult day care centers. These tend to be based on local initiative rather than strategic, governmental planning.

BALIKBAYANS' STORIES OF RETURN: THE LIFE COURSE PERSPECTIVE AND INDIGENOUS METHODOLOGIES

K. Kalaw, *Dept. of SOCIO, GERO and SAS, University of Central Oklahoma, Edmond, Oklahoma*

This paper offers a rethinking of the life course perspective and contribution of a culturally sensitive approach in doing qualitative research. The life course perspective had proven its utility in the field of gerontology and invited several levels of analyses across fields of knowledge. With its key premises on human agency, linked lives, historical and geographical context and timing of life events, this enables an understanding of the present and emerging social realities prevalent in society. In this paper, the life course perspective is substantiated and informed through the use of indigenous methodologies. With the focus on labor migration as a salient feature of Philippine society, the paper offers a unique opportunity to investigate the potential discourse of the life course perspective, migration and aging. Through qualitative narratives, life stories and use of Filipino indigenous methodologies (FIM) among 6 male overseas Filipino workers from the gulf areas, their later life experiences as refracted by age is presented. More so, the family members of the returnees were interviewed to stress the role of culture and family dynamics throughout the migration process and foremost upon their return. Further, the paper suggests that migration is a collective understanding among family members and not solely a function of human agency in making choices. The paper ends with a reconsideration of inclusion of indigenous methodologies to enhance and maximize the efficacy of the life course framework useful for discussing implications for instruction and practice in educational research.

GERONTOGROWTH AND POPULATION AGING IN AFRICA: WHY DOES THIS DIFFERENTIATION MATTER?

A. Francisco, *1. Institute of Social and Economic Studies, Maputo, Maputo, Mozambique, 2. Eduardo Mondlane University (UEM), Maputo, Maputo, Mozambique*

Population aging is a major achievement of human development enjoyed by an increasing number of people around the world. In Africa, despite the remarkable increase in absolute terms, the proportion of African elderly is only 5% of the African population, against over 12% of the elderly population worldwide. No less important than the increase in the numbers is the remarkable global progress in quality of life and satisfaction of the elderly. At this level, most African

low-income countries are overrepresented as the worst countries for the elderly to live in, as shown by the *Global AgeWatch Index 2015*. According to HelpAge International the countries with the worst performance lack a comprehensive approach to policy framework to address the challenges posed by the aging of their populations. Although this conclusion is not entirely wrong, it needs careful attention and qualification: What does it mean to have a comprehensive approach to population aging in countries where increasing numbers of elderly, here designated 'gerontogrowth', is overshadowed by the rejuvenation of the younger population? Why people would worry in advance with a phenomenon that they still do not live or feel? Without questioning the new Index's potential this article shows that its explanatory power and reach can and should be substantially improved with a really more comprehensive analytical and methodological framework. A framework that articulates the concept of capabilities with crucial structural concepts of population dynamics, in the context of the different stages of global demographic transition, where the world's elderly population is integrated.

A COMPARATIVE ANALYSIS: DEPRESSIVE SYMPTOM AMONG KOREAN IMMIGRANT ELDERS IN TWO U.S. STATES

S. Kang¹, I. Kim², W. Kim², *1. Social Work, SUNY-Binghamton University, Binghamton, New York, 2. University at Buffalo School of Social Work, Buffalo, New York*

This study explored the influence of stress factors on depressive symptoms among Korean immigrant elders (KIE). We compared differential impacts of stressors (such as life-course disruption) and the availability of culturally sensitive services between KIEs living in two southwestern states (Arizona and Texas).

A total of 237 KIEs (Texas, 120 and Arizona, 117) participated in cross-sectional face-to-face interviews using a standardized survey. The Geriatric Depression Scale-Short Form was used to measure depressive symptom levels. Separate regression analyses were performed to identify common and different predictors in the two subsamples.

Total participant results revealed that location itself does not matter. However, the presence of culturally sensitive community-service-seeking behavior is an important predictor. The levels of life and family-relationship satisfaction were the only common significant predictors for depressive symptoms in both subsamples ($b = 1.671$, $p < .01$, $b = 1.416$, $p < .001$ for life satisfaction and $b = 1.182$, $p < .05$, $b = .684$, $p < .05$ for family relationship). For KIEs in Arizona (R square = .494), age upon arrival in US, level of English proficiency, and community-service-seeking behaviors were significant predictors of depressive symptoms. For KIEs in Texas (R square = .460), the frequency of meeting with a physician was a unique predictor.

The subsamples of Korean immigrant elders have unique correlates of depressive symptoms, reflecting differences in geographic location, immigration history, and availability of ethnic community resources. This suggests that community service providers need to take contextual differences into account when planning for intervention.

ELDERLY HEALTH DISPARITIES: TRANSLATING RESEARCH INTO PRACTICE

M. Blanco¹, D. Yee-Melichar¹, A. Boyle², K. Routt³, 1. *Gerontology, San Francisco State University, San Francisco, California*, 2. *Dominican University of California, San Rafael, California*, 3. *Magnolia Prime, Redwood California, California*

Information about health disparities among minority elders is growing. Policymakers and practitioners may find it difficult to translate this body of literature into effective and efficient healthcare delivery for minority elders. Easier access to information and programs on various health disparities and social health determinants will enable healthcare professionals, minority advocates, policymakers and practitioners to make better decisions on key issues that minority elders will face in the near future. U.S. Department of Health and Human Services Office of Minority Health launched a Youth Health Equity Model of Practice (YHEMOP) Internship Placement Program in Summer 2016 to support research in health disparities. The YHEMOP program gathers a team of experts across various disciplines and institutions including the Regional Health Equity Council in Region IX (RHEC IX) and San Francisco State University's Gerontology Program, to conduct a comprehensive literature analysis on elderly health disparities and to produce an annotated bibliography of key peer-reviewed articles, audiovisual resources and data websites. An executive summary (factsheet) will be drawn from this annotated bibliography and directed to relevant funding agencies and legislators with recommendations for their consideration and implementation in Region IX (Arizona, California, Nevada, Hawaii, and the Islands: American Samoa, Commonwealth of the Northern Mariana Islands, Federated States of Micronesia, Guam, Marshall Islands, and the Republic of Palau). The results of this research will be discussed with IAGG 2017 participants.

IMPROVING ADVANCE CARE PLANNING FOR OLDER LATINOS WITH CHRONIC ILLNESSES: A COMMUNITY-BASED APPROACH

F.R. Nedjat-Haiem¹, I.V. Carrion², S. Mishra³, 1. *School of Social Work, New Mexico State University, Las Cruces, New Mexico*, 2. *University of South Florida, Tampa, Florida*, 3. *University of New Mexico, Albuquerque, New Mexico*

Multiple factors contribute to educational barriers and low participation rates for advance care planning (ACP) among older Latinos. Innovative methods are needed to reach this vulnerable population with vital information to improve ACP and advance directive (AD) documentation. This paper examines a community-based approach for implementing an educational intervention in a Southern New Mexico rural community for older Latinos with multiple chronic health conditions.

Regardless of advancements in cultural competent practice for ACP, fewer Latinos participate in end-of-life (EOL) communication or document an AD. Multiple factors contribute to low participation in such care. While barriers exist, it is important to consider that all people need individualized care, especially when talking about dying and preparing ADs, to ensure they are well-informed about treatment options and have a voice in documenting EOL care preferences.

Additionally, older Latinos living in rural areas of Southern New Mexico are often harder to reach and may refuse to participate in research. Therefore, innovative methods are needed to meaningfully engage and share information on purpose and utility of ADs.

We used mixed-methods to study implementation of a culturally tailored, multifaceted intervention model—Improving Advance Care Planning (ACP-I Plan). ACP-I Plan is designed to overcome barriers to ACP with older Latinos, to start conversations early, before the active dying phase. Preliminary findings, based on data from 74 participants, suggest significant improvements in AD communication and documentation. 100% of participants were satisfied with the information. Findings have implications for conducting community-based research with older Latinos residing in rural geographies.

POST-SENTENCING COMPETENCE IN OLDER DEATH ROW INMATES

A. Albright, R.S. Allen, *University of Alabama, Tuscaloosa, Alabama*

The prison population in the United States is rapidly aging, with 10% of inmates in 2014 being over the age of 65. Older inmates experience many risk factors of dementia, particularly death row inmates who lack cognitive stimulation and exercise (one hour per day outside of cell). The average time between sentencing and execution is approximately 16.5 years. Under current U.S. law, older death row inmates who experience diminished competence following sentencing may still be executed. This is incongruent with: 1) *Ford v. Wainwright* which offers protection to those who cannot understand why and how they are to be punished, 2) *Atkins v. Virginia* which prohibits the execution of individuals with intellectual disabilities, and, potentially 3) the Eighth Amendment, which prohibits “cruel and unusual punishment.” Several states, including Georgia, Missouri, and Oklahoma, have in the past ten years proceeded with the execution of older death row inmates who exhibit diminished capacity to understand the antecedents and process of their execution. Specifically, Brandon Astor Jones, who was first sentenced to death in 1979, was executed by the state of Georgia in 2016 despite evidence of dementia. Currently, the U.S. 11th Circuit Court of Appeals is considering the case of Vernon Madison, a 65-year-old Alabama inmate with dementia who has appealed his sentence of death based on cognitive incapacity. Cases such as these will become increasingly common due to the aging of the prison population; thus, the issue of post-sentencing competence should be considered by the United States legal system.

UTILIZATION OF COMMUNITY HEALTH COACHES TO IMPROVE CHRONIC DISEASE MANAGEMENT IN OLDER ADULTS

R. Little, *Public Health, ECU Brody School of Medicine, Ayden, North Carolina*

Aims: Low health literacy is prevalent in minority populations with chronic disease. This population is often unable to effectively self-manage their chronic disease. We hypothesized that the use of community health coaches could improve chronic disease self-management in older minority populations.

Methods: Three focus groups were conducted with participants utilizing community health coaches to support their disease self-management.

Results: Community health coaches were effective in helping participants improve their chronic disease self-management facilitating improved health outcomes as measured by weight loss, blood pressure reductions and care compliance.

Conclusion: These results suggest the use of community health coaches supporting older adults with limited health literacy fosters not only improvements in health conditions but also resulted in social determinants of health improvements for these participants.

MEETING THE NEEDS OF THE UNDERSERVED: STRENGTH-BASED TECHNIQUES TO INFORM POLICY AND PROGRAMMING

C.V. Browne, K.L. Braun, N. Mokuau, L. Kaopua, B. Kim, *Social Work, University of Hawaii at Manoa, Honolulu, Hawaii*

In the United States, the older population is becoming more racially and ethnically diverse. Researchers from Ha Kupuna National Research Center for Native Hawaiian Elders (funded by the DHHS, Administration for Community Living [ACL]) will provide a summary and update of their 10-year research plan, together with techniques for gathering data from underserved elders refined through lessons learned from a community-university collaborative partnership. These techniques include, but are not limited to, listening sessions, focus groups, key informant interviews, and surveys. Examples from the authors' experiences with indigenous elders will be discussed with program, policy, and research implications for other underserved groups including LGBT and people with disabilities.

PAID AND UNPAID WORK IN THE REPUBLIC OF KOREA AND THE UNITED STATES OF AMERICA

K.J. Johnson¹, S. Lee², J. Lyu⁴, 1. *Indiana University, Indianapolis, Indiana*, 2. *University of Massachusetts Boston, Boston, Massachusetts*, 4. *National Institute of Aging, Hallyum University, Chuncheon, Korea (the Republic of)*

Research from Western countries indicates participation in paid and volunteer work is related to human and social capital, yet less is known about factors related to these productive activities in East Asian countries experiencing rapid change. We investigate the prevalence and profiles of workers and volunteers in Korea and the U.S, countries with different cultures and institutional circumstances. We apply logistic models to analyze data from the 2012 Korean Longitudinal Study of Aging (KLoSA) and the 2012 American Health and Retirement Study (HRS). The analytic sample consists of 7,183 KLoSA respondents and 18,852 HRS respondents age 51 and older. The proportions of adults volunteering differ considerably between Korea (6%) and the U.S. (38%), while 43% and 46% of adults are working for pay in Korea and the U.S. respectively. Significant factors associated with voluntary work (e.g., female gender, religion, good health, absence of disability) are fairly similar in both countries. However, higher education, being unmarried, and working for pay are negatively related to volunteering in Korea only. Working for pay is negatively related to poor health,

disability, female gender, and being married in both Korea and the U.S. Yet, higher education and voluntary work are negatively associated with paid employment in Korea only. In contrast, both volunteering and paid employment are positively associated with higher education in the U.S. These results suggest it is familial and health-related factors more than formal education shaping contemporary participation in productive activities among older cohorts in Korea.

UNDERSTANDING THE MEDICARE PROGRAM AND RELATED SUBSIDIES: A RACIAL AND ETHNIC COMPARISON

L. Bakk¹, D. Oyler², T. Cadet³, 1. *Social Work, University at Buffalo, West Henrietta, New York*, 2. *Health Foundation of Western and Central NY, Buffalo, New York*, 3. *Simmons College, Boston, Massachusetts*

A major concern prior to the implementation of the Medicare Modernization Act was the complexity of the numerous coverage options. Understanding the structure and benefits of Medicare and its related subsidies is critical in the management of health for older adults. While evidence suggests that Blacks and Hispanics generally have lower health literacy than Whites, little is known about differences regarding Medicare knowledge. Using a convenience sample (n=944), this study examined the association between race, ethnicity, and Medicare comprehension. Logistic regression results indicated that older non-Hispanic Blacks (NHBs) and Hispanics have more concern about their ability to comprehend Medicare and the various coverage options than non-Hispanic Whites (NHWs). Understanding subsidies that can help pay for Medicare costs was also a greater concern among NHBs and Hispanics than NHWs. Accounting for gender, age, income, and geographic location had little impact on these findings. Moreover, individuals with an income less than 200 percent of the Federal Poverty Level reported greater concern about their ability to understand Medicare and related subsidies. Findings suggest that vulnerable populations – in particular, older NHBs and Hispanics – may face significant challenges comprehending their health care coverage and options that are available to help lower costs. This is concerning, particularly given racial and ethnic differences in health. To promote understanding, interventions are needed to increase education about the Medicare program and related subsidies. Further, understanding that differentials in comprehension exist is critical when evaluating policy alternatives in order to achieve more equitable access to health care and reduce disparities.

SESSION 955 (POSTER)

DEMENTIA AND ALZHEIMER'S DISEASE III

INTRODUCING TOUCH SCREEN APPLICATIONS TO PEOPLE WITH ADVANCED DEMENTIA THROUGH STAFF-CLIENT CO-PLAY

A.M. Hernandez¹, A.J. Astell^{1,2,3}, D. Theiventhiran^{1,4}, 1. *Research & Academics, Ontario Shores Centre for Mental Health Sciences, Whitby, Ontario, Canada*, 2. *The University of Sheffield, Sheffield, United Kingdom*,

3. *University of Toronto, Toronto, Ontario, Canada*, 4. *University of Ontario Institute of Technology, Oshawa, Ontario, Canada*

In long-term care, there is growing attention to clients' quality of life, including provision of pleasant and meaningful activities. There is also growing evidence that tablets are accessible for people living with dementia. Identifying pleasant technology-facilitated co-play activities for people with advanced dementia would be of benefit for both the individual and carers. Here we explore whether pre-existing iPad games can provide an avenue for engaging and enjoyable co-play activity for people with advanced dementia and carers. Ten participants with a dementia diagnosis and MOCA score of 8 or below and 5 staff co-played a strategic game, a familiar rule-based game, a coloring game, and a sensory game. In the first session, staff investigated which game was best suited, and this game was played on two subsequent sessions. Sessions were video-recorded and concluded with a patient questionnaire and staff interview. Face- and screen-view video recordings were used to: examine ability to play over time and engagement, examine successful features of game introduction by staff, and validate themes emerging from staff post-play interviews. We will present results on ability to learn, engagement and enjoyment of people with advanced dementia and recommendations on how to best introduce games. Pre-existing iPad games could provide an avenue for facilitating co-play activities in advanced dementia care. Incorporating staff experiences on game introduction and co-play into recommendations should support knowledge translation and enhance iPad game play for people with advanced dementia.

DEMENTIA CARE IN THE COMMUNITY: RELATIONSHIPS BETWEEN QUALITY OF LIFE, AGE, GENDER, AND CARER BURDEN

M. Boyd, R. Frey, *University of Auckland, Auckland, New Zealand*

Over 50% of all people with dementia (PWD) live in the community. Family members providing care for PWD are at risk of lowered quality of life due to the stress of caregiving. The aim of this study is to describe a comparison of level of anxiety, depression and quality of life for PWD living in the community and their carers in a large cohort of people receiving support in Auckland, New Zealand (N = 1071).

Correlational analyses were used to examine the relationship between the ages of the person with dementia (PWD) and their scores on two quality of life measures as well as measures of carer quality of life and stress. Measures include quality of life (DemQOL for PWD and WHOQOL for carers) and carer stress (Carer Reaction Assessment). There was a significant relationship between PWD age and quality of life (DEMQUOL), $r(99) = .20, p < .05$, suggesting that older PWD had better quality of life compared to younger PWD. There is also a significant relationship between PWD quality of life and caregiver quality of life $r(52) = .61, p < .01$. The analysis also showed that age and gender influenced perceived carer stress.

The results of this study suggest that perceived carer stress is influenced by age, gender, and overall quality of life. Those providing community interventions to support PWD should

assess for the multiple factors that can effect PWD and families influence quality of life and carer stress.

DALCROZE RHYTHMIC MUSIC PROGRAM FOR PEOPLE WITH DEMENTIA

J. Leners¹, J. Jacquemart², 1. *LTCF ALA and Pontalize, Ettelbruck, Luxembourg*, 2. *LTCF ALA, Erpeldange, Luxembourg*

Music as a universal communication can also easily be applied to persons with dementia, who have partially or totally lost their abilities to speak orally. Music listening and music production activate several brain areas responsible for cognition, sensori-motor activities and emotional regulation. The specific Dalcroze rhythmic music program which runs as a spontaneously music improvisation accompanied mainly by piano sessions to which the patients move following specific sequences. Positive effects are to see in saver balance, higher self-esteem, less falls, improved motor function and numerous non-verbal communication. The typical simplified music instruments can be used as soon as given to the patients, as they require no specific training to play music. The repetition of movements allows persons with dementia to imitate or to follow their own inner feeling. The leader of a Dalcroze rhythmic music program need specific qualities beside his musical back-ground, like personal competence to understand expressed emotions and a high degree of interpersonal communication skills. As most music excerpts are known to all patients from their adolescence, therefore even songs can easily be orally expressed, even though sentences are no more produced. It is important to note that regular sessions of at least one or two per week should be run for some six months in order to see positive effects in most of the persons with dementia. Side-effects are rare, major hypotension or cardiac arrhythmias may be seen as limited factors for inclusion.

POSTTRAUMATIC STRESS AND FLUID COGNITION: LONG-TERM OUTCOMES OF THE WORLD TRADE CENTER DISASTER

S. Clouston¹, R. Pietrzak², R. Kotov¹, M. Richards³, A. Spiro⁴, S. Mukherjee⁵, B. Luft¹, E. Bromet¹, 1. *Public Health, Stony Brook University, Stony Brook, New York*, 2. *Yale University, New Haven, Connecticut*, 3. *MRC Unit for Lifelong Health and Ageing at University College London, London, United Kingdom*, 4. *Boston University, Boston, Massachusetts*, 5. *Florida International University, Miami, Florida*

During the World Trade Center (WTC) attacks, responders who helped in search, rescue, and recovery endured multiple traumatic and toxic exposures. One-fifth subsequently developed posttraumatic stress disorder (PTSD), a chronic stress disorder that has been shown to be associated with risk of dementia in Veterans. To date only a few small studies have examined associations between intrusive stress and cognitive functioning. We fielded an objective neuropsychological battery to a sequential cohort of World Trade Center (WTC) responders (N=654) without any history of WTC-related head injury or any previous strokes who attended monitoring visits at the WTC health program on Long Island, NY. Data were linked with diagnoses of WTC-related PTSD, WTC-exposures, and other WTC-related conditions.

WTC exposure was associated with poorer cognitive function, but this association was attenuated upon adjustment for PTSD. Analyses revealed that having current PTSD was associated with slower reaction time and processing speed as well as poorer working memory and cognitive throughput. In subdomain analyses, associations were concentrated amongst those who reported re-experiencing symptoms in the years immediately following the WTC disaster (in all cases, standardized effect sizes ranged from 0.85–1.20 SDs and $p < 1.2E-04$). Traumatized individuals are increasingly believed to be at higher risk of cognitive impairment and incident dementia. Results from this study support existing studies, showing that intrusive stress influences a broad range of cognitive functions absent traumatic head injuries. Future studies should utilize brain imaging to examine the extent to which neurodegeneration may explain these associations.

TRAINING NEEDS AND EDUCATION FOR DEMENTIA CARE IN CHINA: THE PERSPECTIVES OF MENTAL HEALTH PROVIDERS

L. Xu¹, H. Hsiao², W. Deng³, I. Chi², 1. *The University of Texas at Arlington, Arlington, Texas*, 2. *University of Southern California, School of Social Work, Los Angeles, California*, 3. *University of California in Los Angeles, Los Angeles, California*

Purpose: The purpose of this paper is to identify needs of training and public education for dementia care including who should be the trainees, what would be the contents of training and how to deliver the training in China.

Methods: Using a purposive sampling method, data were gathered via four focus group discussions with 40 mental health providers in Beijing, China in 2011. Data were transcribed by two independent investigators, and then translated into English. Content analysis was employed to separately identify themes/codes among three researchers. Discrepancies were fully discussed until final agreement achieved.

Results: All participants agreed there is a huge need for training and public education on dementia care. Both formal (physicians, nurses, hospital administrators, community workers) and informal caregivers (family/non-kin hired caregivers) were identified as two groups for receiving the training. For formal caregivers, training topics for enhancing clinical knowledge of dementia (i.e., pathogenesis, clinical symptoms, approaches for dementia prevention) and clinical practice skills (i.e., diagnostic, caregiving, counseling, communicating skills) were identified. For informal caregivers, basic dementia knowledge and home-based caregiving skills such as safety, rehabilitation, and stress management strategies were identified as key training contents. Multilevel support from the government as well as community centers are considered as crucial in delivering the training and public education.

Conclusions: Culturally sensitive education and training specific for formal and informal dementia caregivers are urgently needed. Policy and program implications were discussed.

PREDICTION OF CAREGIVER BURDEN IN THE CONTEXT OF DEMENTIA-SPECIFIC DAY CARE

N.S. Park¹, D.A. Chiriboga¹, V.A. Molinari¹, M.M. Barnes², K.J. Herd², K. Gilbert², 1. *University of South Florida,*

Tampa, Florida, 2. *Alzheimer's Community Care, West Palm Beach, Florida*

Caregiving for a loved one with Alzheimer's disease and related disorder (ADRD) can lead to adverse caregiver outcomes. Among the interventions for those with ADRDs are day care programs. The purposes of the present study were to: (1) assess the caregiver burden among caregivers whose relative attended a dementia-specific day center; and (2) examine gender and racial/ethnic differences in caregiver burden. Data were collected by family nurse consultants in 10 day centers in Southeastern Florida, between February 2015 and January 2016. The centers are run as part of an Alzheimer's Community Care (ACC) intervention that operates under a comprehensive, community-based model of care. Caregiver burden was measured with the Zarit Burden Scale, which measures the caregiver's self-perceptions of the burden providing care. Among 306 day center participants, 60% were aged 80 or older, 67% female, 51% non-Hispanic White, 27% African American/Black, and 22% Hispanic/Latino. Over 75% of enrollees scored in the severely cognitively impaired category on the Brief Interview for Mental Status. About 10% of caregivers reported severe burden followed by 29% moderate to severe, 42% mild to moderate and 19% little to no burden. Caregiver burden was not differentially associated with gender of the care recipient. In racial/ethnic differences, African American caregivers were the least burdened. Interactions indicated that caregivers to Hispanic women were more burdened whereas caregivers to White women were less burdened. Considering that caregivers of Hispanic/Latina women are at greater risk of burden, more research is needed to understand gender and racial/ethnic differences in caregiver burden.

DEVELOPMENT OF AN INTERVENTION TO IMPROVE COMMUNICATION WITH PEOPLE WITH DEMENTIA IN NURSING HOMES

M. Machiels, S. Zwakhalen, S. Metzethin, J. Hamers, *Department of Health Services Research, CAPHRI School for Public Health and Primary Care, Maastricht University, Maastricht, Netherlands*

Nurses often report communication difficulties in caring for people with dementia (PWD). Evidence-based interventions to enhance communication are scarce. Therefore, we developed a theory-informed intervention using the Behavior Change Wheel with the aim to improve communication between nurses and PWD. First, ideal communication was defined (*targeted behavior*) based on the scientific literature, policy reports and consultations of experts (n=7). Second, a focus group meeting with relevant stakeholders (n=7) was organized and observations of nurses (n=9) and PWD (n=9) during daily nursing care were conducted to understand their *current behavior* and to identify *facilitators* and *barriers* for the targeted behavior. Reviewing the literature and consulting experts have shown that ideal communication has to be person-centered and therefore should be tailored to the needs and capacities of PWD. Furthermore, next to verbal communication, attention should be paid to non-verbal communication, including the use of pictograms, objects, and touch. Additionally, the environment has to be recognizable and comprehensible for PWD. However, the focus group meeting and observations have shown that current behavior of nurses

is often characterized by a task-oriented instead of person-centered approach. Furthermore, non-verbal communication (e.g., eye contact) is insufficiently used. Identified facilitators and barriers for the ideal communication relate to nurses' characteristics (e.g., knowledge, awareness, and skills), social influences, and other environmental factors (e.g., resources). These insights were used to develop a theory-informed intervention in close collaboration with relevant stakeholders (e.g., nurses, speech therapists, and policy makers). The systematic development of the intervention and its final version will be presented.

PAIRED INTEGRATIVE EXERCISE FOR PEOPLE WITH DEMENTIA AND CAREGIVERS (PAIRED PLIÉ STUDY)

W. Mehling, D. Marks, R. Woodstock, M. Ventura, J.D. Flatt, M.A. Chesney, D.E. Barnes, *University of California San Francisco, San Francisco, California*

We have recently developed a novel, multi-modal, group movement program for people with mild to moderate dementia and their primary caregivers called the Paired PLIÉ (Preventing Loss of Independence through Exercise) Program. The program is offered in community classes taught by trained exercise instructors to dyads of affected individuals with their caregivers. Paired PLIÉ is grounded in neuroscience and focuses on abilities that are relatively well-maintained in people with dementia (procedural 'muscle' memory, mindful body awareness, social connection). We have performed two pilot studies of 4 dyads each. The first pilot study met two days/week for 12 weeks followed by 3 monthly refresher classes. Study participants indicated that they preferred ongoing classes; therefore, the second pilot study met two days/week for 8 weeks followed by weekly classes for another 8 weeks. Qualitative results suggest noticeable improvements in physical function (ability to sit and stand), cognitive function (ability to express thoughts and feelings) and social function (ability to connect with others in a group setting) in affected individuals and greater acceptance and engagement in caregivers. Data analyses are ongoing. At the end of the second pilot study, all participants requested to continue the classes on a weekly basis. A larger randomized, controlled trial of the Paired PLIE program will begin in August, 2016.

BEING USEFUL IN RARE AND TYPICAL DEMENTIAS

E. Harding¹, M. Sullivan^{1,2}, R. Woodbridge², S. Crutch¹, *1. University College London (UCL), London, United Kingdom, 2. Brunel University London, London, London, United Kingdom*

Being useful, or doing something that serves a purpose, has implications for wellbeing and underpins Erikson's psychosocial developmental stage of generativity. However little attention has been given to the concept of usefulness in dementia research, with the literature extending to understanding activities which are meaningful for individuals, but not to those which explicitly benefit others or a cause. This work explores usefulness for individuals and families living with typical Alzheimer's Disease (tAD) and Posterior Cortical Atrophy (PCA), a rare dementia usually early in onset and characterised by dominant impairments in visual

processing. In-depth individual and dyadic interviews with 37 couples (17 with tAD; 20 with PCA) were conducted and analysed using grounded theory.

A sense of usefulness was challenged both practically, due to the specific impairments characterising each diagnosis (i.e. dominant perceptual versus memory difficulties), and existentially. Individuals and their family members attempted to manage practical challenges by renegotiating roles and responsibilities over time, with motivation to do so varying according to levels of insight and memory function.

A diagnosis of dementia and its impact on subjective feelings of usefulness may be best understood as a biographical disruption. Further, notions of usefulness in dementia may be most effectively explored through an interactionist lens within the context of the family system and extended social system. This work raises important questions about how being useful is conceptualised, accessed and assessed, and by whom, and has broader implications for wellbeing and the provision of support in these and other degenerative diseases.

MIDLIFE SHIFT WORK AND RISK OF INCIDENT DEMENTIA

K. Bokenberger¹, A.K. Dahl-Aslan^{2,1}, I. Karlsson¹, T. Åkerstedt^{3,1}, N.L. Pedersen^{1,4}, *1. Karolinska Institutet, Stockholm, Sweden, 2. Jönköping University, Jönköping, Sweden, 3. Stockholm University, Stockholm, Sweden, 4. University of Southern California, Los Angeles, California*

Research examining the long-term effects of midlife shift work in relation to dementia risk is limited. The aim is to investigate the association between shift work and incident dementia in a population-based study.

Participants were 12,028 individuals from the Swedish Twin Registry (STR) born 1926–1943 i.e. at least 30 years of age upon receiving a mailed questionnaire in 1973 that included information on shift work history. A sub-sample of STR twins (n=8,953) who participated in a telephone interview in 1998–2002 also had data on duration of night work employment. Dementia diagnoses were obtained from Swedish national patient registers. Cox regression estimating hazard ratios (HR) was used for statistical analysis. Confounding factors such as age, sex, education, cardiovascular disease and type 2 diabetes were included in adjusted models. In a subsample of participants with genetic data (n=2,998), a genetic risk score (GRS) for morningness to assess circadian rhythm differences and APOE E4 status were considered in the models.

A total of 1,047 dementia cases (8.7%) were identified after a median of 41.3 years follow-up. History of any-type shift work (HR=1.22, 95% CI=1.07–1.40) and night work (HR=1.24, 95% CI=1.05–1.46) were associated with higher risk of dementia in multivariable-adjusted models. Dose-response relationships between dementia with any-type shift work duration and with night work duration were observed (p=0.002 and p=0.001 for linear trend, respectively). Adjusting for APOE E4 and GRS did not attenuate the associations.

In summary, findings indicate mid-life shift work history was significantly associated with increased dementia risk in later life.

EXPLORING THE USE OF GROUP DIGITAL ACTIVITIES FOR PEOPLE LIVING WITH DEMENTIA

E. Dove¹, K. Cotnam⁴, A.J. Astell^{1,2,3}, 1. *Ontario Shores Centre for Mental Health Sciences, Whitby, Ontario, Canada*, 2. *University of Toronto, Toronto, Ontario, Canada*, 3. *University of Sheffield, Sheffield, United Kingdom*, 4. *Oshawa Senior Citizens Centre, Oshawa, Ontario, Canada*

Meaningful leisure activities are an important part of well-being, although these activities become less accessible for people with dementia. While digital technologies provide an accessible form of entertainment, the way the technology is introduced, how people are taught to use it, and how players are supported during these activities is important to consider when working with this population. In this study, we explore the use of a motion-based technology (Xbox Kinect) as a group activity for people living with dementia.

The study was conducted in a community-based adult day program for people living with dementia. Participants were observed during a virtual bowling activity over a period of 12 weeks. Observations focused on; 1) methods for introducing, teaching, and supporting people to use this technology, 2) effects of repeated exposure on mastery of learned skill, and 3) the influence of the group dynamic on the activity.

The findings highlight the importance of training staff how to introduce, teach and support people with dementia during these digital activities. Approaches must be tailored to each individual's skills and abilities, including the use of verbal prompts, gesture demonstrations, and/or physical support for clients with mobility impairments (e.g. wheelchair users). Over time mastery was evident through reduced prompting, with some participants even offering cues to newer players. The group bowling activity provided a social activity, with participants engaging through positive encouragement, friendly competition, and reminiscing. The findings suggest motion-based digital activities have huge potential for people living with dementia to enjoy meaningful leisure activities.

THE PSYCHOSOCIAL APPROACH TO PATIENTS WITH EARLY-ONSET DEMENTIA AND THEIR CAREGIVERS

E. Makino, H. Kase, *Waseda University, Tokyo, Japan*

Background: The mental conflicts of the patients with early-onset dementia and their family caregivers are serious. Feelings of social isolation and negative emotions are especially so strong as to have an adverse effect on their relationship. The importance of reinforcing measures not only for elderly patients with dementia but also for those with early-onset dementia has also been shown in Japan. Previous studies have indicated the need of family support by intervention approach for both patients and family caregivers, but little has been put into practice. The purpose of this study was to clarify the changes of relationship between patients suffering from dementia and caregivers by using functions of CLR focusing on their communication.

Methods: The CLR Approach is an individualized reminiscence method using a life-story book based on each couple's memories. Seven sessions (2 hrs. for each) were conducted at each couple's home over a 12-week period, followed by a narrative analysis of the interview sessions.

Results: Four findings were observed: 1) patients with dementia regained a clear memory and exhibited self-esteem and Reduced anxiety; 2) caregivers remembered the past life of their partners, expressed gratefulness to them and exhibited a change of consciousness such as "recognition of their personality": 3) sympathy and appreciation were enhanced by their common memory: 4) positive feelings toward the couple's life was fostered by creating a life story book.

Conclusions: CLR can help couples struggling with early-onset dementia to reevaluate and rebuild their relationship to regain their dignity as a couple.

SESSION 960 (POSTER)

DEMENTIA III

KNOWLEDGE TOWARD DEMENTIA AMONG MEDICAL STUDENTS IN BRAZIL

V.F. Mayoral^{1,2}, M. Garuzi¹, J. Cabral¹, A.G. Leite¹, R. Thomazi¹, D. Veiga Antonangelo¹, P.J. Villas Boas¹, A.F. Jacinto¹, 1. *Medical Clinic, Universidade estadual Paulista Julio de Mesquita Filho, Botucatu, Brazil*, 2. *State University of Botucatu, Botucatu, Sao Paulo, Brazil*

Dementia is common in the elderly and its prevalence has increased in the last decades. Curricula of the Brazilian Medical Schools include teaching of dementia issues, but there are no reports in the medical literature about quality of this teaching. A study on the knowledge towards dementia among hundred fifty-five students in the final of the last semester of the medical graduation (2 public medical schools-FMB/UNESP and EPM/UNIFESP, has been proposed. In this transversal study, a British self-administered instrument (already culturally adapted to Brazil) on knowledge towards dementia was used; 92(59.7%) had good training on cognitive impairment during their undergraduate medical course, and of these, 67(58,7%) had only theoretical basis. 142 (93.4%) reported taking extracurricular courses them during under graduation course. The students obtained a mean of 6.9 on the general knowledge score, considering a scoring scale from 0 to 14 points. The results can be used in the analysis of mandatory content during medical training. Curricula of the Medical Schools should be in line with epidemiological aspects of the country.

EXPERIENCE AND PERCEPTION OF NURSES ON DEMENTIA CARE IN GERIATRIC WARDS IN A SINGAPORE HOSPITAL

P.S. Yoon, Z. Di, *Geriatric Medicine, Changi General Hospital, Singapore, Singapore*

Caring for persons with dementia in the geriatric wards of an acute hospital is challenging. This study in Changi General Hospital, Singapore, was to explore, understand and interpret the nurses' experience, aiming to improve the current care approach. This was a qualitative exploratory study using phenomenological method with purposive sampling. Inclusion criteria were nurses, with at least 2 years of experience of working in the geriatric wards. 3 semi-structured focus group interviews, facilitated by a researcher trained in focus group facilitation, were conducted over the period of

1 month, with a total of 12 participants. These were audio-recorded and transcribed verbatim. Data analysis was done using thematic content analysis. The mean age of participants were 38.5 years old, with a mean 18.5 years of nursing experience with 10.5 years in geriatric wards. The experience described was categorized into 3 themes: 'Reality of caring', 'Priority of caring' & 'Challenges of caring'. Issues discussed include clinical, ethical, system & environmental challenges, and psychological and professional reality. Coping of challenges (both emotionally and problem-focused) were also discussed. The perceived experience was generally more positive than those quoted in literature. Conflict existed between perceived optimal care of patients and routine hospital practices. A more dementia-centred and elderly friendly approach with flexible workflow and improved resources was advocated.

EFFECT OF MELATONIN OVER SLEEP QUALITY IN OLDER ADULTS WITH MILD TO MODERATE DEMENTIA

R. Morales, G. Guajardo Álvarez, C. Camara Lemarroy, D.G. Gamez Treviño, A. Arredondo Jaime, E. Hernandez Maldonado, R. Salinas Martinez, *Geriatrics, Universidad Autónoma de Nuevo León, Monterrey, Nuevo León, Mexico*

Background: Sleep disturbances are common in patients with dementia. Melatonin treatment is purported to improve sleep, and benefit those patients. **Methods:** Randomized, placebo-controlled, double blind clinical trial. Older adults with mild to moderate dementia with poor sleep quality were included and randomized to receive melatonin (5 mg, by mouth, once daily) or placebo for 8 weeks. PSQI was assessed at baseline and every 2 weeks. Mini mental state examination (MMSE), Katz and Lawton Brody score were assessed at baseline and last visit. Numerical variables were compared using student T test and repeated measures ANOVA; and Chi square test for categorical variables. (IBM SPSS version 17.0). **Results:** 22 patients were included, 12 in Melatonin Group (MG) and 10 of placebo group (PG). There were no statistical differences for gender (MG: 58% and PG: 50% females) and mean age of 82.4 ± 6 (MG) and 84.9 ± 2 (PG). There was no statistical difference between groups at baseline: GDS, MMSE, evolution of dementia, comorbidities or medication use and PSQI (MG:13.4 ± 3.1 and PG:13.3 ± 3.8, p=0.9). In melatonin group, there was a statistical significant decrease from baseline and all subsequent evaluations, reaching 6.8 ± 3.6 (a reduction of 6.6 points) at week 8 (p=0.01). There was no statistical difference of PSQI for placebo group through the study (9.4 ± 5.4 at week 8, p=0.4). **Conclusions:** We found a significant improvement in PSQI scores in melatonin group and no adverse events were reported. Treatment with Melatonin is safe, tolerable and effective in improving quality of sleep in older people with dementia.

BARRIERS AND FACILITATORS TO GUIDELINE USE IN DEPRESSION AND ANXIETY IN PARKINSON'S DISEASE OR DEMENTIA

Z. Goodarzi¹, H. Hanson^{1,2}, N. Jette¹, S. Patten¹, T. Pringsheim¹, J. Holroyd-Leduc¹, *1. University of Calgary,*

Calgary, Alberta, Canada, 2. Alberta Health Services, Calgary, Alberta, Canada

Background: Despite the availability of clinical practice guidelines for the management of depression or anxiety in dementia or Parkinson's disease (PD), these comorbidities remain under-diagnosed and under-treated.

Objectives: Our primary objective was to understand the barriers and facilitators associated with the implementation of high quality CPGs for depression and anxiety in patients with dementia or PD.

Methods: Focus groups and interviews were conducted with participants experiencing PD, their caregivers and physicians involved in the care of persons with dementia or PD in Calgary, Alberta. The Theoretical Domains Framework and Behaviour Change Wheel were used to guide data collection and perform a framework analysis. Evidence from the available guidelines was compared to reported physician behaviours.

Results: A total of 33 physicians and 7 PD patients/caregivers participated. We were unable to recruit patients/caregivers with dementia. Data were divided into three categories based on the barriers and facilitators to the implementation of guideline recommendations for diagnosis, management and the use of the guidelines. An overarching theme was the lack of evidence for depression or anxiety disorders in dementia or PD. This was more prominent for anxiety versus depression. Other themes included the lack of consistency between guidelines, lack of clarity in the language used, lack of applicability to the practice population, and impractical or out of date recommendations. Patients noted difficulties with communication of symptoms and access to services.

Conclusions: Although there are available guidelines, physicians have difficulty with the implementation of certain recommendations due primarily to a lack of evidence.

ENGAGING PEOPLE WITH DEMENTIA IN USING AN ELECTRONIC PILL DISPENSER: RESEARCH PROTOCOL

M. Tellier^{1,2,3}, L. Demers^{1,2}, C. Auger^{1,3,4}, *1. Occupational Therapy, Université de Montréal, Laval, Quebec, Canada, 2. Centre de Recherche de l'Institut Universitaire de Gériatrie de Montréal (CRIUGM), Montréal, Quebec, Canada, 3. Centre de Recherche Interdisciplinaire en Réadaptation (CRIR), Montréal, Quebec, Canada, 4. Centre de Réadaptation Lucie-Bruneau (CRLB), Montréal, Quebec, Canada*

Many studies show that people with dementia are able to learn skills, but findings concerning their ability to use technologies are inconsistent. Therefore, details about active ingredients that make intervention using technologies successful are needed. This study describes the development and evaluation of a rehabilitation approach integrating specific learning strategies that engage people with mild Alzheimer Disease (AD) and their caregivers, in managing their medication with an electronic pill dispenser. Phase 1 will consist in developing an approach that is based on the state of knowledge concerning the cognitive profile of people with AD and their learning capacities. Validation of this approach will be iterative and involve semi-structured interviews with nine key actors (three persons with AD, three caregivers and three health professionals). Content analysis will help to identify which elements should be modified in order to maximize the

acceptability and coherence of this approach. In phase 2, five dyads (person with AD and caregiver) will be implicated in the evaluation of the efficacy of this approach with an ABA multiple baseline across participants design. Medication management will be quantified using an observation chart and will also be filmed once a week to be rated by blinded evaluators. Phase 3 will involve five semi-structured interviews with the caregivers to understand their experience. This study could become a proof of concept that a rehabilitation approach, integrating evidence-based training strategies that engage people with mild AD and their caregivers in using technology, can improve task performance in a home environment.

SESSION 965 (POSTER)

DEMOGRAPHIC PERSPECTIVES ON AGING

WHAT ARE THE UNIQUE DEMOGRAPHIC TRENDS AND PATTERNS FOR GLOBAL AGING?

W. He, *US Census Bureau, Washington, District of Columbia*

While it is well known that the world population is aging, what may surprise some is the variation and diversity among world regions and countries. Using population estimates and projections data from the U.S. Census Bureau's International Data Base, this poster illustrates the unique demographic trends and patterns for global aging by region and country.

In the near future, the countries of Europe and North America will continue to lead the world in aging. However, Asia and Latin America are experiencing an unprecedented speed of aging due to rapid fertility decline in the past 30 years. In contrast, Africa will remain young through 2050.

This poster presents multiple indicators of aging, including size of older population, share of 65 and older in total population, speed of aging, dependency ratios, and median age. These data provide answers to multiple demographic questions: Which world region is the oldest now and in 2050? What are the differences in fertility levels among regions? What are the 25 oldest countries now and in 2050, and where does the United States rank? What is the speed of aging for countries, measured in doubling of percent 65 and older (or is it tripling)? How do the two population billionaires, China and India, differ in aging? How do the components of the dependency ratio change over time at the country, region, and world level? These data will inform researchers, health practitioners, policymakers, and families, allowing them to better understand and prepare for further global aging.

DIVERGENCE AND CONVERGENCE: HOW DO INCOME INEQUALITIES IN MORTALITY CHANGE OVER THE LIFE COURSE?

J. Rehnberg, J. Fritzell, S. Fors, *Aging Research Center, Stockholm, Stockholm, Sweden*

Do inequalities in health increase or decrease with age? Evidence is not conclusive and competing theories arrive at different conclusions. This study aim to examine the income inequality in mortality in a synthetic cohort aged 30 to age 99 between the years 1990 to 2009, following each individual for 19 years. We use Swedish register data with 4 772 044

individual observations. We calculate the accumulated probability of death for age between 31 and 99. This approach takes into account selective mortality.

The largest relative difference in mortality between low income and high income is at age 55 (RR: 3.7). The largest absolute difference in mortality between low income and high income is at age 82 (10 % difference). Both measures decrease after their peak, with relative inequality converging at age 90 and the absolute inequality converging above age 95.

The results support the age-as-a-leveler theory as we see a closing of the mortality gap between high and low income at the oldest ages. The results also support the cumulative disadvantage theory; as absolute inequalities increase at younger ages. We find support for both theories but during different periods over the life course depending on what measure we look at.

The findings in this study highlight the need for careful consideration when choosing what measures we use to assess inequality. This choice can even be seen as a normative judgment by the researcher and need to be explicit.

WHO LIVES ALONE? TRENDS OVER TIME IN THE CHARACTERISTICS OF SWEDEN'S SOLITARY LIVING OLDER ADULTS

B.A. Shaw¹, N. Agahi², S. Fors², C. Lennartsson², J. Fritzell², *1. SUNY at Albany, Albany, New York, 2. Aging Research Center, Stockholm, Sweden*

Sweden maintains one of the world's highest rates of older adults who live alone, and the number of solitary living older adults in Sweden continues to rise. Given the potential health impact of living alone, it is critical that the factors which select individuals into the living alone arrangement be understood. While prior studies have examined the determinants of living alone among older adults, few have examined how these determinants may have changed over recent decades, as the overall rates of living alone during old age have stabilized and declined in Sweden. The purpose of this study is to assess how the associations between living alone and a variety of socioeconomic, social, behavioral, and functional factors have changed in successive cohorts of older adults in Sweden, from 1992 to 2014. Data come from the Swedish Panel Study of Living Conditions of the Oldest Old (SWEOLD), a nationally representative survey of adults aged 77 and older who are living in Sweden. Our findings suggest that today's population of older men who live alone in Sweden are more likely to be socioeconomically disadvantaged and functionally impaired compared to previous cohorts of solitary living older men in Sweden; similar patterns were found in women, but were not statistically significant. These findings indicate that while successive cohorts of the oldest old have generally seen improvements in socioeconomic status, health and functioning over recent decades, the cohorts of men who live alone have become increasingly disadvantaged.

MORTALITY TRENDS IN ELDERLY INDIVIDUALS IN A BRAZILIAN WESTERN AMAZON CAPITAL CITY

P.C. Bezerra¹, G. Torres², *1. Center of Health and Sport Sciences, Federal University Of Acre, Rio Branco, Acre, Brazil, 2. National School of Public Health, Rio de Janeiro, Rio de Janeiro, Brazil*

Objective: To analyze the trends of general mortality as well as of that resulting from diseases of the circulatory system in elderly individuals in Rio Branco between years 1980 and 2012. **Methodology:** Study on a secondary database of the System of Information on Mortality in Brazil, according to the International Classification of Diseases. The gross mortality rate of people aged 60 years or older in the capital of Acre state, Rio Branco, located in the Western Brazilian Amazon, was calculated. The standardized mortality rate was obtained by the direct method, based on the world population as the standard population. The trend analysis was performed by the *JoinPoint Regression*, which calculates the inclination of the straight line segment, or annual percent variation with a 95% confidence interval. **Results:** General MR was higher among males and among individuals aged 80 years and older for all the years analyzed. It also showed a tendency to reduction, thus increasing longevity in this population. Mortality resulting from diseases of the circulatory system was more frequent in relation to other death causes; however, it showed tendency to decrease over the years, which was more pronounced in women and among the elderly aged 70 years or older (VPA -2,98; CI -3,7 to -2,1). **Conclusion:** Primary health care must be trained on the care of this population in order to ensure that the trend to increase in the number of years of life is accompanied by improvement or maintenance of good health, quality of life and health promotion.

EDUCATIONAL GRADIENTS IN MORTALITY AMONG OLDER ADULTS IN SINGAPORE: 6 YEARS' FOLLOW-UP

A. Chan¹, S. Ma³, Y. Saito², 1. *Duke-NUS Medical School, Singapore, Singapore*, 2. *Nihon University, Tokyo, Japan*, 3. *Ministry of Health, Singapore, Singapore, Singapore*

The effect of education on adult mortality is well known based on studies conducted in western countries. People with higher education tend to have lower mortality, in general. The effect is not always clear and/or significant in the studies conducted in Asian countries. In this study, we examine the effect of education on mortality among older adults in Singapore based on a longitudinal survey conducted in 2009 and mortality follow-up by Ministry of Health. The baseline survey is a nationally representative of community dwellers aged 60 and above in 2009. The sampling frame consisted of a random sample of 8,700 individuals. Combined with information from decedent questionnaires in two follow-up surveys conducted in 2011 and 2015, and mortality matching in 2012 and 2016, we will have relatively complete information on mortality among those who participated in the baseline survey. Using this data we examine mortality patterns by sex and education.

LONGITUDINAL PERSPECTIVES ON HOMEOWNERSHIP FOR MEXICAN ORIGIN ELDERLY

P. Cantu, J.L. Angel, *The University of Texas at Austin, Austin, Texas*

Objectives: To examine health and financial correlates of homeownership longitudinally for Mexican Origin elderly individuals over the age of 65.

Methods: We analyze data from multiple waves (Waves 1–7) of Hispanic Established Populations for the

Epidemiologic Study of the Elderly (H-EPESE). Our focus is specifically on the health and financial situation of elderly individuals as well as familial considerations, such as number of surviving children and child's marital status. We will first examine the correlates of home ownership at baseline and follow up (Waves 1 and 7). We will then explore changes in household rosters and living arrangements between waves (All waves). Finally we will need use a competing risk model to take into account mortality and loss to follow up in the survey (Waves 1 and 7).

Results: Preliminary analysis shows that Mexican Origin Elderly exhibit high rates of ownership at baseline (64%) as well as at follow up (58%). What is less clear is what the roles of mortality and transfer of ownership are. Furthermore we not yet fully characterized living arrangements within households.

Discussion: Previous research on cross sectional correlates of home ownership have revealed that motivations for of Mexican Origin Elderly living with others are clearly more complex than simple filial piety considerations might hold. Extended living arrangements provide concrete financial and instrumental benefits for both elderly parents and their adult child caregiver. This research will build upon these ideas by adding longitudinal analysis.

HOUSEHOLD ARRANGEMENT TRANSITIONS AMONG GRANDPARENTS

Y. Chen, *Brandeis University, Waltham, Massachusetts*

Census reports shown that grandparents living with grandchildren fare worse in economic and health status than their counterparts living in other types of households, and the number and percentage of grandparents living with grandchildren have increased since 1990s. This study investigated the determinants and patterns of household arrangement transitions among middle-aged and older grandparents, with focuses on racial-ethnic differences as well as households where grandparents are living with their grandchildren. This study is among the few national and longitudinal investigations into this issue.

Using survival analysis and data from the 1998–2012 Health and Retirement Study, this study found that white grandparents were less likely to co-reside with grandchildren, and among them, moving from co-residing with grandchildren to living as a couple was higher in number and frequency than that among their black and Hispanic counterparts. Higher resources (grandparents' socioeconomic resources, retirement, and health) strongly decreased the probability of co-residing with grandchildren among white grandparents, but barely decreased this probability among black and Hispanic grandparents. Having a child living nearby or/and a deceased child increased the probability of moving to skipped-generation households among black and Hispanic grandparents, but not among white grandparents.

The results suggest that black and Hispanic grandparents are more likely than white grandparents to co-reside with grandchildren in response to children's needs. White grandparents are more likely than black and Hispanic grandparents to co-reside with grandchildren when lacking resources. This study has implication on how racial and ethnic variations in intergenerational relations may influence grandparents' wellbeing.

EXPLORING THE REPRODUCTIVE CELL CYCLE THEORY OF AGING IN SOCIAL DATA

J.A. Yonker, *University of Wisconsin-Madison, Madison, Wisconsin*

The Reproductive Cell-Cycle Theory of Aging (RCCTA) posits that hypothalamic-pituitary-gonadal axis (HPG axis) hormones fundamentally regulate cellular change (division, differentiation, and apoptosis). Balanced HPG hormone signaling is critical to normal growth, development, and maintenance from conception through the reproductive period. However, when this becomes unbalanced in later life (i.e., post-menopausal endocrine dyscrasia), dyotic signaling to somatic and reproductive tissues drives senescence. The RCCTA predicts that the longer the HPG axis is maintained in equilibrium, the longer an organism will live and the lower the likelihood of illness or functional deterioration.

Using longitudinal survey data from the Wisconsin Longitudinal Study, I test whether age of menopause—a proxy for onset of endocrine dyscrasia—is associated with a range of health outcomes for a cohort of women over a two-decade follow-up (approximate ages 55–72). These include: mortality; major illnesses; multiple self-reported measures of health; multiple measures of physical functioning; and multiple domains of cognition.

I find a pattern of results indicating that earlier menopause is associated with greater risk of death, greater risk of vascular illnesses (hypertension, cardiovascular disease, heart attack, and stroke), greater risk of osteoporosis, poorer self-reported health, poorer physical functioning (ADL/IADL), and poorer cognitive functioning. These results are robust to typical demographic, socioeconomic, and health behavior controls. Other reproductive factors, such as number of children and natural versus surgical menopause, are not significant after controlling for age of menopause. However, there is some evidence that use of hormone replacement therapy (HRT) may attenuate the negative effects of earlier menopause.

SESSION 970 (POSTER)

DISABILITY, IMPAIRMENT, AND MOBILITY

USING PERFORMANCE-BASED ADL/IADL DATA TO EXPLORE A SELF-REPORT MODEL OF PRECLINICAL DISABILITY

P. Toto, L. Terhorst, J.C. Rogers, M. Holm, *Occupational Therapy, University of Pittsburgh, Pittsburgh, Pennsylvania*

Background: Preclinical disability is a transitional state between the onset of impairment in functioning and dependence in activities of daily life (i.e. disability). Preclinical disability in older adults can serve as an early warning and critical intervention point for prevention of further decline and adverse events. However, methods for identifying preclinical disability in older adults are not well developed and have been limited to self-report.

Objective: This study examined a classification model of preclinical disability based on self-report using performance-based measures of activities of daily living (ADL)/instrumental ADLs (IADL) in older women.

Methods: We conducted a secondary data analysis of ADL/IADL performance data collected using the Performance Assessment of Self-Care Skills (PASS). Participants were community-dwelling older women (N=217) with chronic conditions representing five primary diagnostic groups. After constructing a first-order confirmatory factor analysis model using the three factors included in the preclinical disability model based on self-report (i.e. intrinsic, extrinsic, assistance), we assessed model appropriateness using goodness of fit statistics.

Results: The overall model fit was acceptable. Intrinsic and assistance variables had strong loadings on the intended factors; one extrinsic variable had strong loadings on the intended extrinsic factor. Intrinsic and assistance factors were highly correlated and the extrinsic factor was moderately associated with intrinsic and assistance.

Conclusion: Our performance data provides preliminary support for a preclinical disability classification model based on self-report. Both self-report and performance based measures that quantify use of intrinsic factors, extrinsic factors, and assistance may be effective methods for identifying preclinical disability in older adults.

HOW AND HOW MUCH CAN LEISURE ACTIVITIES MEDIATE PROGRESSION TOWARD FUNCTIONAL DISABILITY?

Y. Chen, Y. Tu, R. Chang, D. Chen, T. Chiang, H. Yu, *Institute of Health Policy and Management, National Taiwan University, College of Public Health, Taipei City, Taiwan*

The aims of this study were to investigate (1) whether and (2) the extent to which the trajectory of Taiwanese older adults' leisure activities (LA) mediated the potential association between their sociodemographic factors and their functional disability trajectory. Longitudinal data from four waves of the Taiwan Longitudinal Study on Aging (TLISA), collected between 1996 and 2007, were used for analysis (N = 3,429). A parallel-process latent growth curve modeling was adopted to evaluate the mediational process of LA between sociodemographic factors (age, gender, education, self-rated health, comorbidities, and depression) and the outcome process of functional disabilities.

When mediated by baseline level of LA, five sociodemographic factors—age, gender, education level, self-rated health, and number of comorbidities—had significant and negative mediating effects on baseline or change in functional disability, thus improving disability outcomes. However, four of the sociodemographic factors (age, education level, and number of comorbidities), when mediated through the rate of change in LA, were found to have significant and positive mediating effects, which indicated these older adults were less likely to increase LA engagement over time and therefore increased disability levels. The proportion of effects mediated by the LA trajectory ranged from 0% to 318%.

ROLE OF FAMILY RELATIONSHIP ON DEATH ANXIETY CAUSED BY DISABLED CHILDREN AND PARENTS' DEPRESSION

C. Yoo, *Seoul National University, Seoul, Korea (the Republic of)*

Death anxiety of older parents caring for children with intellectual disability (CID) include not only worries about

their own death but also the circumstance that they could no longer care for their disabled children. This study investigates whether satisfaction of family relationship (SoFR) can moderate the effects of death anxiety caused by disabled children (DACDC) on older parents' depression. Sample includes 279 parents aged 60 and over who participated in the Korean National Survey on Individuals with Developmental Disabilities and their Families in 2011. DACDC was used as independent variable; depression was used as dependent variable; and SoFR was used as moderator. Socio-demographics were controlled. In order to address research objectives, multiple regression analyses were used. The model fit was solid and major findings are as follows. Older parents with higher levels of SoFR were less likely to be influenced by DACDC compared to those with lower levels of SoFR, indicating that SoFR moderates the relationship. Specifically, when the level of SoFR is high, the relationship between DACDC and depression is negative, so positive family relationships can decrease the negative effect of DACDC on depression, significantly. However, when the rate of SoFR is low, the results were reversed. The findings suggest that the SoFR was verified as moderating variable in the relationship between DACDC and depression. In order to develop practice and policy implications for mitigating negative effects of DACDC on older parents' depression, these results should be taken into account.

IMPACT OF DISABILITY ON ACCESS TO DIABETES CARE AMONG OLDER ADULTS WITH DIABETES

S. Chun, K. Chan, P. McCallion, L. Ferretti, J. Shi,
University at Albany SUNY, Cambridge, Massachusetts

Although previous studies have established a strong association between diabetes and disability, little is known regarding the impact of disability on access to diabetes care among older adults with diabetes. The purpose of this study is to examine the impact of disability on accessing diabetes care among older adults who are living with diabetes. This study used survey data from the 2014 Behavioral Risk Factor Surveillance System (BRFSS). The sample included adults age 50 and over who have diabetes. Multivariate logistic regression analysis was conducted to examine the impact of disability on accessing diabetes care among older adults with diabetes. Two dependent variables were identified to measure diabetes care access: (1) receipt of a course or class on managing diabetes and (2) visit to a health professional in the past year for diabetes. 47.30% of the sample reported not having received diabetes education and 10.86% did not visit health professionals for diabetes in the past year. Older adults with diabetes who had disabilities were more likely to have received diabetes management education (OR=1.17, $p<0.01$), but were less likely to have visited health professionals for diabetes (OR=0.80, $p<0.05$). Compared to White and Black, Hispanic (OR=0.62, $p<0.01$) and Asian (OR=0.47, $p<0.01$) elders were much less likely to have received diabetes education. The results suggest that further efforts are needed to facilitate visits to the health professionals regarding diabetes for diabetic elders with disabilities. Additionally, language and culturally-specific diabetes education should be promoted to reach more Hispanic and Asian older adults with diabetes.

PHYSICAL PERFORMANCE AND ADVERSE HEALTH EVENTS IN OLDER ADULTS WITH DEMENTIA

T. Eagen, E. McGough, R.G. Logsdon, S.M. McCurry,
M. Cagley, A. Cunningham, L. Teri, *Rehabilitation Medicine, University of Washington, Seattle, Washington*

Community-dwelling older adults with dementia are at increased risk for adverse health events, including falls. Physical performance measures, including gait speed, short physical performance battery (SPPB) and performance-oriented mobility assessment (POMA), may help clinicians better understand the occurrence of falls and health events in older adults with dementia. An in-home physical performance assessment was conducted in 82 older adults with dementia (mean Mini Mental Status Exam (MMSE) = 16.41) at baseline. Adverse health events were collected (via caregiver report) one month later, defined as a fall or health occurrence requiring medical attention. All participants were in the non-intervention stage of an exercise intervention study (Reducing Disabilities in Alzheimer's Disease). At baseline, physical performance measures included gait speed (m/sec), SPPB, and POMA. Participants demonstrated impaired lower extremity function and high fall-risk (mean gait speed = 0.73 m/s, SPPB = 6.89, POMA = 22.84). At one-month follow-up, 18 (22%) participants had an adverse health event. Interestingly, participants with adverse health events had higher baseline scores on the SPPB (mean = 8.28) compared to those without an adverse health event (mean = 6.61) ($p = 0.048$), and were slightly younger (mean = 77.01 vs. 80.93; $p = 0.05$). There were no statistically significant differences in MMSE or gender (male = 50% vs. 61%) between the two groups. This group of participants with higher health events may represent older adults with cognitive impairment who remain active despite elevated fall risk. This finding is important for clinical care and the development of health services for older adults with dementia.

EVALUATING A PEER-LED FALLS APPROACH TO FALLS PREVENTION EDUCATION FOR OLDER PEOPLE

A. Hill¹, L. Khong², R. Berlach², K.D. Hill¹, 1. *School of Physiotherapy and Exercise Science, Curtin University, Perth, Western Australia, Australia*, 2. *The University of Notre Dame Australia, Fremantle, Western Australia, Australia*

Health education is an important means of raising older people's knowledge and awareness about falls prevention. This study aimed to evaluate the effect of delivering a new peer-led falls prevention education presentation on older community-dwelling peoples': 1) beliefs and knowledge about falls prevention; 2) motivation and intention to engage in falls prevention strategies; compared to delivering an existing presentation. A two-group quasi-experimental pre-test post-test design was used. A new falls prevention education program was designed, which incorporated adult learning and behavior change principles. This new presentation was delivered to intervention groups and the existing presentation was delivered to control groups. Response to the presentation was measured at baseline, immediately post-presentation and at one-month follow-up. Beliefs, knowledge, motivation and intention outcomes were compared across these three points of time, within and between the

intervention and control groups, using generalized estimating equation modelling. Participants (control $n=99$; intervention $n=133$) in both groups demonstrated significantly increased levels of belief and knowledge about falls prevention, and intention to engage in strategies over time, compared to baseline. The intervention group was significantly more likely to report they had developed an action plan to undertake to reduce their risk of falling compared to the control group [OR=1.69, 95% CI (1.03–2.78)]. Women in both groups were significantly more likely to report increased knowledge, intention to take action and development of an action plan to reduce their risk of falling. Peer led education could form an effective component of health programs that target falls prevention.

RELATIONS BETWEEN NEUROPSYCHIATRIC SYMPTOMS AND INSTRUMENTAL ACTIVITIES OF DAILY LIVING IN MCI

T. Ginsberg, C. White, M. Forsberg, N. Alterman, A. Patel, T. Cavalieri, A. Chopra, D.J. Libon, *Rowan SOM NJISA, Stratford, New Jersey*

Mild cognitive impairment (MCI) is viewed as a prodrome often leading to the emergence of a dementia syndrome. Past research suggests that despite relatively intact neurocognitive functioning, some MCI patients can present with mild Instrumental activities of daily living (IADL) dysfunction. However, less is known about how and or if neuropsychiatric symptoms affect IADLs in MCI. In the current research neuropsychiatric symptoms, along with memory test performance, were obtained in patients diagnosed with MCI. Regression analysis were conducted to assess the relative contribution of neuropsychiatric illness and memory impairment as related to IADL functioning. All participants were evaluated by a multidisciplinary team including a neuropsychologist, geriatric psychiatrist, and a social worker. Participants were diagnosed with MCI using Jak, Bondi et al., (2008) criteria (M age=76.39±5.96; M education= 14.00±2.46; M MMSE=26.78±2.06). IADLs were assessed using E-Cog (M 1.83±0.51). Neuropsychiatric symptoms were calculated as the total score derived from the Neuropsychiatric Inventory (M 8.27±7.62). Delay recognition memory was assessed using the California Verbal Learning Test-II ($z = -.23 \pm 1.17$). Step-wise regression accounted for .381% of variance ($R = .617, R^2 = .381$ df=1, 18, $F=4.73$ [1, 18; $p < .043$]). In the final model neuropsychiatric illness entered first ($\beta = .461$; $p < .023$) followed by recognition memory test performance ($\beta = -.403$; $p < .043$). Follow-up regression analysis found greater IADL dysfunction associated with greater apathy ($R = .710, r^2 = .505$, [4,16], $p < .018$, $\beta = .990$, $p < .003$). These data suggest that both cognitive and neuropsychiatric status should routinely be assessed when IADL impairment is suspected. These data also suggest that behavioral health treatment could significantly improve IADL dysfunction in MCI.

PAIN, VETERAN STATUS, AND FRAILTY AMONG OLDER AMERICAN MEN

L. Quach^{4,1}, D.R. Gagnon^{2,1}, E. Dugan⁴, R. McLean^{3,1}, M. Yang⁴, K. Cho^{1,3}, J.A. Burr⁴, *1. VA Boston Healthcare System, Boston, Massachusetts, 2. Boston University, Boston, Massachusetts, 3. Harvard Medical School, Boston,*

Massachusetts, 4. University of Massachusetts Boston, Boston, Massachusetts

Relatively little is known about if or how pain and Veteran status are related to frailty. Our objectives were to determine the association between pain and frailty among community-dwelling older men, and examine how combat experience among Veterans might modify this association. The study sample included 3,136 men from the 2012 Health and Retirement Study, a nationally representative sample of older Americans (mean age 77, range 68–99). The dependent variable was based on a frailty index that included at least three of the following: 1) weight loss of $\geq 10\%$; 2) difficulty lifting 10 pounds; 3) no physical activity or being tired all the time; 4) vision impairment, 5) cognitive impairment. Key independent variables were reporting trouble with pain, Veteran status, and combat experience (fired a weapon in combat). Multivariable logistic regression was used to calculate the odds of frailty by pain status, and military experience, adjusting for age, race, marital status, education, income, and comorbidities. Twelve percent of the men were frail, one-third reported trouble with pain, 39.3% non-veterans, 6.2% and 54.5% veterans with and without combat experiences respectively. Men reporting pain had twice the odds of frailty as those without pain. In stratified analyses, and non-Veterans showed a similar association between pain and frailty. Veterans trouble with pain increased the odds of frailty by 2.7 times compared to non-Veterans, and there was no association between pain and frailty among Veterans with combat experience. Further research is needed to understand how military experiences are related to frailty in later life.

AM I JUST TIRED OR UNABLE TO DO DAILY TASKS? IMPACT OF PERSONALITY AND FATIGUE ON FUNCTIONAL HEALTH

J. Kim¹, Y. Baek¹, A. Jasper¹, P. Martin¹, L.W. Poon², *1. Iowa State University, Ames, Iowa, 2. University of Georgia, Athens, Georgia*

The purpose of this study was to assess the impact of personality and fatigue on functional health in old and very old adults. The participants included 239 centenarians and 82 octogenarians from the Georgia Centenarian Study. Multiple linear regressions were performed to assess the relationship between NEO personality domains and facets (neuroticism, extraversion, trust, competence, and ideas), fatigue, and functional health (activities of daily living). Results indicate a significant direct effect for fatigue to functional health, $\beta = -.30, p < .001$, when controlling for demographic variables (age, gender, and ethnicity), such that lower levels of fatigue are associated with higher independent functioning. In addition, the personality domains extraversion, $\beta = -.40, p < .001$, and neuroticism, $\beta = .16, p < .05$, along with the NEO personality facet ideas, $\beta = -.17, p < .05$, were significantly associated with fatigue when controlling for demographic variables. The results indicate low levels of extraversion and ideas along with high levels of neuroticism predict higher levels of fatigue. These findings not only add to the existing body of knowledge regarding functional health in older adulthood, it sheds light on the impact of enduring personal factors and fatigue on functioning in later life.

DIFFERENCES BETWEEN AGING WITH DISABILITY AND DISABILITY WITH AGING IN HEALTH TRAJECTORY

C. Yoo, *Seoul National University, Seoul, Korea (the Republic of)*

This study aims to (1) estimate the trajectory of self-rated health (SRH) among Korean older adults with disabilities, (2) examine its associated factors including sociodemographic, health behaviors, and environmental factors (3) test whether there are differences between aging with disability and disability with aging in the health trajectory and its associated factors. Sample includes 341 older adults with disabilities who participated in the Korea Social Welfare Panel Study (KSWPS), which is a nationally representative data. We used KSWPS data from 2006 to 2015. In order to address the research objectives, we used (1) latent growth curve modeling to estimate the trajectory and its associated factors and (2) multi-group analysis to examine differences between aging with disability and disability with aging. The model fits were solid and major findings are as follows. (1) Korean older adults with disabilities presented increasing SRH trajectory with time. (2) Age, education, income, employment status, number of outpatient visits & physical checkup, amount of alcohol consumption, social support and residential environment were associated with the SRH trajectory. (3) The SRH trajectory and its associated factors differed between aging with disability and disability with aging. The findings suggest that (1) older adults with disabilities tend to increase SRH with time, (2) SRH trajectory is associated with sociodemographic, health behaviors, and environmental factors, and (3) SRH trajectory and its associated factors differed between aging with disability and disability with aging. Based on these findings, we will discuss implications on practice/policy for health of older adults with disabilities.

SOCIAL SUPPORT AND STRAIN COMBINE TO PREDICT CHANGES IN ACTIVITIES OF DAILY LIVING

L. Hawkey¹, M. Huisingh-Scheetz², L.J. Waite¹, *1. Academic Research Centers, NORC at the University of Chicago, Chicago, Illinois, 2. University of Chicago Medicine, Chicago, Illinois*

Social engagement and social support have been associated with disability onset and severity (Mendes De Leon, 2003; Seeman et al., 1996). However, the context in which support is experienced can affect its impact on health outcomes. In married couples, for example, the benefit to health status of support from friends was diminished the greater the strain in friendships (Walen & Lachman, 2000). In the present research, we consider the impact of combinations of baseline support and strain on changes in the ability to conduct activities of daily living. We use two waves of data, five years apart, from the National Social Life, Health and Aging Study (N=2,261). Social support and social strain are each dichotomized to contrast high and low support, and high and low strain, in relationships with friends and family separately. Regression models, run separately for men and women (Seeman et al., 1996), are adjusted for age, race/ethnicity, education, income, marital status, and social activity. In women only, respondents with distressed relationships with friends (high strain embedded in low support) exhibited a larger increase in disabilities over a five-year period than

respondents with ambivalent relationships with friends and family (high strain embedded in high support). Contrary to expectations, women with positive relationships with friends and family (high support embedded in low strain) had larger increases in disabilities than women with ambivalent relationships with friends (high support embedded in high strain). Results highlight the importance of contextualizing the effects of support and strain, especially in women, and especially in relationships with friends versus family.

MEANING OF TRAUMATIC BRAIN INJURY TO OLDER ADULTS

M.T. Vogel, H.J. Thompson, *Health Services; Social Work, University of Washington, Lake Forest Park, Washington*

Traumatic brain injury (TBI) among the growing population of older adults in the United States is a paramount public health concern. In-depth, patient-centered analyses of the experiences of older adults who have sustained TBI are relatively absent from the literature. Therefore, the objective of this phenomenological study is to explore the perceptions of older adults who have sustained a TBI and how the perceived meaning of the injury experience changes over time. Qualitative inductive content analysis was used to analyze the data derived from this multiple case study design (N=12) of longitudinal, semi-structured interviews. Interviews were conducted with participants at 1 week, 1, 3, 6, and 12 months post-injury. A conceptual model derived from the data was created to visualize the change in perceived meaning of TBI among older adults. Results from this study can be used for developing patient-centered provider training and interventions for traumatic brain injury that will be easily translated into home, care and community settings.

THE MEDIATING EFFECT OF DISABILITY TRAJECTORY ON DISABLEMENT FACTORS AND LONG-TERM CARE USE IN TAIWAN

H. Yu¹, Y. Chen¹, Y. Tu³, D. Chen², T. Chiang¹, *1. Institute of Health Policy and Management, National Taiwan University, Taipei, Taiwan, 2. Institute of Health Behaviors and Community Sciences, National Taiwan University, Taipei, Taiwan, 3. Institute of Epidemiology and Preventive Medicine, National Taiwan University, Taipei, Taiwan*

Taiwan has a fast-aging population, and it is expected to see an associated increase in the number of older adults with disabilities. We aimed to understand whether Taiwanese older adults' disability trajectories mediated the association between disablement process factors and later long-term care (LTC) service use. Data were from the nationally representative Taiwan Longitudinal Study on Aging Survey, 1996–2007 (N = 3,429). Trajectories of disability in activities of daily living and instrumental activities of daily living were identified by using growth mixture modeling. Structural equation modeling was applied to examine the effect of disability trajectory as mediator on disablement process factors, such as demographics, number of comorbidities, depression, and leisure activities (LAs), and on later LTC service use. Three distinct disability trajectories were identified among the group of surveyed older adults: healthy (N = 2,998, 87.43 %), progressive disability (N = 363, 10.59 %), and maintained disability (N = 68, 1.98 %). These disability trajectories, either progressive disability or maintained disability

trajectory, were found to have a positive mediating effect on the association between disablement process factors (older, lower educational attainment, larger number of comorbidities, and depressive symptoms) and greater use of LTC services. However, encouraging older adults to engage in LAs reduced later use of LTC services through both total and significant mediating effect of postponing development of disability trajectory in older Taiwanese adults. These findings suggest that an active lifestyle is important for older adults' physical health and to decrease the societal burden of LTC service use.

RACIAL DIFFERENCES IN UNMET ADL NEEDS AND CONSEQUENCES OF UNMET ADL NEEDS AMONG OLDER MEN

L. Parker, R.J. Thorpe, *Health, Behavior, & Society, Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland*

Unmet need for activities of daily living (ADL) among disabled older adults can lead to adverse consequences resulting in worsening health outcomes. Previous studies have identified race and gender as risk factors for unmet ADL need, however few studies have examined this among older men. Using baseline data from the National Health and Aging Trends Study, the study aimed to examine if racial differences in unmet ADL need, and its associated adverse consequences, exists among 2,777 older men. For each ADL domain disability-related need for assistance was calculated, and the prevalence of adverse consequences of unmet need. Black men had a higher prevalence of unmet need with household activities for doing laundry (64.7% vs. 38.8%), shopping (52.5% vs. 27.8), and meal preparation (36.5% vs. 20.2%) than White men ($p < 0.001$). Further, Black men had a higher prevalence of needing assistance for going outside the home (16.0% vs. 12.5%), and with one or more mobility tasks (28.4% vs. 23.6%) than White men ($p < 0.05$). With respect to adverse consequences, White men had a higher prevalence of mistakenly taking prescribed medicine than Black men (21.0% vs. 12.2%) ($p < 0.05$). Black men had a higher prevalence for staying in bed (8.23% vs. 1.5%) ($p < 0.001$), and experiencing one or more adverse consequences of unmet need for mobility tasks (4.4% vs. 2.9%) ($p < 0.05$). Efforts to reduce the observed disparities in unmet need and adverse consequences should be a key priority among older men.

MOTIVATION FOR PHYSICAL ACTIVITY MEDIATES MOBILITY IMPROVEMENT IN HIV-INFECTED OLDER ADULTS

K.N. Shah¹, Z. Majeed¹, T. Senn¹, D. Walck², F.V. Lin¹, 1. *University of Rochester, Rochester, New York*, 2. *Warner School of Education, Rochester, New York*

We previously demonstrated the effect of a self-determination theory (SDT) guided physical activity (PA) counseling intervention on multiple mobility outcomes among HIV-infected older adults (HOA). However, the mechanism underlying the intervention effect is unclear. Here we investigated the intervention effects on PA motivational regulation and assessed whether PA motivational regulation mediates the intervention's effect on mobility in HOA. Community-dwelling HOA with mobility impairments

($N = 67$) were randomized to a 12-week intervention group or a usual care control group. PA motivational regulation, battery of mobility tests (physical performance test and gait speed) and PA level were assessed at baseline and post-intervention. Fifty-nine participants completed the study (M age = 55 years; M CD4 count = 675 cells/mm³; duration since HIV diagnosis = 17 years; 39% female). The two groups were similar in their demographic and clinical characteristics. Regulatory motives for PA such as amotivation reduced and introjected and identified regulation increased in the treatment group compared to the control group. Mobility and PA level were higher in the treatment group compared to the control group post-intervention ($p < 0.05$). Increased introjected and identified regulation mediated the interventions effect on PA and gait speed, respectively. Our findings suggest that a PA counseling intervention grounded in SDT can improve motivational regulation for PA in HOA. Increases in introjected and identified regulation mediated the effects of the intervention on mobility outcomes. These results underscore the role of interventions targeting the internalization of PA motivational regulation in preventing mobility limitations.

A LONGITUDINAL PERSPECTIVE ON POWER MOBILITY USE BY OLDER USERS

D. Labbé^{1,2}, B. Mortenson^{1,2}, P.W. Rushton^{3,4}, L. Demers^{3,5}, B. Miller^{1,2}, 1. *Occupational Science and occupational therapy, University of British Columbia, Vancouver, British Columbia, Canada*, 2. *Rehabilitation Research Program and GF Strong Rehabilitation Research Lab, Vancouver, British Columbia, Canada*, 3. *Université de Montréal, Montreal, Quebec, Canada*, 4. *CHU St-Justine research center, Montreal, Quebec, Canada*, 5. *Centre de recherche de l'institut universitaire de gériatrie de Montréal, Montreal, Quebec, Canada*

Power wheelchairs (PWC) are essential devices, especially for people with severe disability. Research has suggested that PWC can have a positive impact on mobility, participation and well-being. However, they may also be problematic in terms of usability, safety, and cost. Currently, little is known about power mobility use over time. This study investigates user experiences of PWC over time, from a life-span perspective. A series of four semi-structured qualitative interviews (baseline, 3 months, 1 year, 2 years) were conducted with 21 participants recruited in Vancouver, Montreal and Québec city (Canada). They shared their daily experience of power mobility, the changes in use over time, and what were the barriers and facilitators in their environment. The analysis identified four main themes. "Things are different now" described how participants use of power mobility changed over time because of their changing physical capabilities and evolving power mobility experience. "Being in the world" explored the feeling of freedom and the opportunities of participation associated with the PWC. "It's my legs" explored how participants learned to use their devices and how it related to their sense of self. "Not sure what to expect" described the physical and attitudinal barriers encountered. The findings emphasize that the experience of power mobility is not static. This study provides new insights on the experience of a group of PWC users, and thus will help stakeholders to

understand the complexity of power mobility provision and user's engagement in meaningful activities

VALIDITY OF A SCALE TO MEASURE COMMITMENT TO HIP PROTECTORS AMONG CARE PROVIDERS IN LONG-TERM CARE

A.M. Korall^{1,5}, J. Godin², I. Cameron³, F. Feldman⁴, P. Leung^{4,7}, J. Sims-Gould^{5,6}, S.N. Robinovitch^{1,5}, 1. *Biomedical Physiology & Kinesiology, Simon Fraser University, Burnaby, British Columbia, Canada*, 2. *Nova Scotia Health Authority, Halifax, Nova Scotia, Canada*, 3. *University of Sydney, Sydney, New South Wales, Australia*, 4. *Fraser Health Authority, Surrey, British Columbia, Canada*, 5. *Centre for Hip Health & Mobility, Vancouver, British Columbia, Canada*, 6. *University of British Columbia, Vancouver, British Columbia, Canada*, 7. *The New Vista Care Home, Burnaby, British Columbia, Canada*

Hip fractures are a major threat to healthy aging, often triggering declines in health, mobility, quality of life, and even death. Wearable hip protectors represent a promising strategy to prevent hip fractures, but uncertainty surrounding their efficacy exists due to poor user adherence. In long-term care (LTC), adherence may depend on the commitment of caregivers to support use of hip protectors among residents, but empirical evidence is limited. Therefore, our objective was to develop and test the psychometric properties of a scale to measure caregiver commitment to hip protectors. We wrote 15-items to measure three components of commitment: affective (belief in value), cognitive (belief in efficacy), and behavioural (willingness to act). We surveyed 535 paid caregivers (92% female) from thirteen public LTC homes in British Columbia, Canada. Responses were subjected to exploratory factor analysis (EFA) and internal reliability testing. EFA supported a higher order structure, with two factors. Affective and cognitive items loaded highest on Factor 1, and behavioural items on Factor 2. Both factors loaded onto a higher order factor. One item was removed due to low loadings. Cronbach's alpha coefficients for the affective/cognitive subscale, the behavioural subscale, and the full scale were .97, .87, and .96, respectively. Overall, 8% of the variability in commitment was explained by LTC home. Mean commitment was lower in caregivers with 20+ years of tenure, and those aware of a resident breaking their hip despite being protected ($p < 0.01$). Findings could inform policy and practice to enhance caregiver commitment to hip protectors in LTC.

"NEXT STOP . . . THE BLINK BLINK PLACE"

E.E. Liang, *Art for All, Hong Kong, Hong Kong*

Report and study of how a group of visually impaired elderly residing in nursing home, in their last stage of life worked hand in hand with artists through a yearlong therapeutic expressive arts program, co-created an arts event: "Next Stop ... the Blink Blink Place". An art exhibition of multiple arts discipline, showcasing not just the wit and genius of their lives, but also in their own creative process, the way to peace, imagination and self worth. End of life becomes an envision future they are looking forward to: "When we are at the last stop of life, must there be only fear? No! there's happiness waiting! we know, we see it in our mind's eye!"

EFFECTS OF DUAL TASKING ON AUDITORY SELECTIVE ATTENTION IN THREE DIFFERENT ENVIRONMENTS

A. Helseth, T. Leeder, S. Myers, M. Schieber, J.A. Blaskewicz Boron, *University of Nebraska Omaha, Omaha, Nebraska*

Performing attention-demanding tasks in a Virtual reality (VR) environment may show promise for improving fall prevention programming. Twenty healthy older adults (749 years) completed a Dichotic Listening task with three auditory selective conditions: non-forced (NF), right forced (RF), and left forced (LF). Tasks were performed in a non-walking single task session (ST) and in both virtual reality (VR) and non-virtual reality (NVR) dual-task sessions on a self-paced treadmill. All individuals tested for normal hearing (20 dB) at low frequency (500) in both right and left ears, including the five that wore hearing aids. Repeated measures ANOVAs ($p < 0.05$) were used to examine condition (NF, RF, LF) and environment (ST, VR, NVR) comparisons with the right and left ear responses and spatial temporal gait parameters as dependent variables. Results showed right and left ear dichotic measures in the VR environment approached significance ($p = 0.057$) in comparison to the ST and NVR environments. Specifically in the VR condition, the FL condition approached significance ($p = 0.056$), for both right and left ear responses compared to the FR condition. Gait results showed a significant increase for double support time in the NVR compared to the VR environment ($p < 0.05$). Right step time in the VR environment also had a significant main effect ($p = 0.047$) while dual-tasking. These preliminary results suggest that a VR environment may positively influence dual-task performance, as both gait and cognition scores were better. Further investigation of dual tasking in a VR environment will strengthen methods and application of fall prevention programming for older adults.

SESSION 975 (POSTER)

ELDER ABUSE

ELDER ABUSE BY PERSONS WITH SUBSTANCE USE AND/OR MENTAL HEALTH CONDITIONS: RESULTS FROM THE NEMS

T. Labrum, P. Solomon, *School of Social Policy & Practice, University of Pennsylvania, Philadelphia, Pennsylvania*

Persons who commit elder abuse have long been known to disproportionately have indicators of substance use and/or mental health conditions (SUMHC). However, few studies have examined factors related to elder abuse by persons with SUMHC vs. persons without such conditions. Such information is important for developing more targeted interventions. Using data from the National Elder Mistreatment Study, the current analysis examined victim, perpetrator, and interaction characteristics between cases of elder mistreatment in which the perpetrator has indicators of SUMHC vs. not having such indicators. Chi-square and Mann-Whitney-Wilcoxon non-parametric tests were performed. 210 perpetrators of emotional mistreatment were reported to have indicators of SUMHC with 412 perpetrators reported to not have such indicators. 57 perpetrators of physical mistreatment were

reported to have indicators of SUMHC with 38 perpetrators not having such indicators. Emotional mistreatment committed by persons with SUMHC was associated with the following characteristics: perpetrator—unemployment, history of involvement with police, and limited friendships; victim—female gender, greater emotional problems, and history of greater emotional mistreatment; interaction—co-residence, and reporting of mistreatment to authorities. Physical elder mistreatment by persons with SUMHC was associated with police involvement of perpetrator and history of greater physical mistreatment of victim. These findings indicate that victims of elder mistreatment by persons with SUMHC are in particular need of support and services as they appear to have greater histories of mistreatment and experience greater emotional problems. Perpetrators with indicators of SUMHC particularly seem to struggle in occupational and social functioning, which should be addressed in interventions.

PSYCHOLOGICAL ELDER ABUSE IN PERSPECTIVE: MEASURING SEVERITY LEVELS OR POTENTIAL FAMILY CONFLICTS?

A.J. Santos^{1,2}, B. Nunes², I. Kislaya², A.P. Gil^{3,2}, O. Ribeiro^{4,1}, 1. *Institute of Biomedical Sciences Abel Salazar, University of Porto, Porto, Portugal*, 2. *Epidemiology Department, National Health Institute Doutor Ricardo Jorge, Lisbon, Portugal*, 3. *CESNOVA Centre for Sociological Studies of the Universidade Nova de Lisboa, Lisbon, Portugal*, 4. *CINTESIS, Institute of Biomedical Sciences Abel Salazar, University of Porto, Porto, Portugal*

Psychological Elder Abuse (PEA) assessment is described with different thresholds. This study aimed to examine how the prevalence of PEA and the phenomenon's characterization varied using two different thresholds.

Participants from the cross-sectional population-based study, Aging and Violence (n=1123), answered three questions regarding PEA. The less strict measure considered PEA as a positive response to any of the three evaluated behaviors. The stricter measure comprised the occurrence, for more than 10 times, of one or more behaviors. A multinomial regression compared cases from two measures with non-victims. Relative risk ratios (RRR) were computed to show the relative likelihood of being victim in each group with a given characteristic.

Results show different prevalence rates and identified perpetrators. The two most prevalent behaviors (ignoring/refusing to speak and verbal aggression) occurred more frequently (>10 times). Prevalence nearly tripled for "threatening" from the less strict measure (1–10 times) to the stricter (>10 times). Most of the same RRRs were found for both groups of victims. Cohabiting differentiated PEA cases occurring >10 times: individuals experiencing more frequent abusive behaviors (>10 times) are more likely to live as a couple or as a couple with children.

Rather than a specific threshold between PEA and "normal" family conflicts, the results suggest PEA as a continuous phenomenon with different severity levels. Development of a valid and reliable measure for PEA that includes different ranges is needed.

ELDER ABUSE: MAIN EVOKED EMOTIONS

A.J. Santos^{1,2}, B. Nunes², A.P. Gil^{3,2}, O. Ribeiro^{4,1}, 1. *Institute of Biomedical Sciences Abel Salazar, University of Porto, Porto, Portugal*, 2. *Epidemiology Department, National Health Institute Doutor Ricardo Jorge, Lisbon, Portugal*, 3. *CESNOVA Centre for Sociological Studies of the Universidade Nova de Lisboa, Lisbon, Portugal*, 4. *CINTESIS, Institute of Biomedical Sciences Abel Salazar, University of Porto, Porto, Portugal*

The emotional complexity inherent to older adult's emotional response to Elder Abuse (EA) highlights the importance of considering individual differences and the varied emotional response patterns.

The study explores the main emotions and feelings evoked by older adults experiencing abuse by a relative.

The data was collected by convenience sampling of 495 older adults self-reporting EA in four institutions. Responses to an open question were classified in four categories: (i) negative thoughts, such as shame, doubt, remorse, envy, frustration, guilt, loneliness; (ii) negative and forceful emotions such as hatred, anger or disgust; (iii) negative and not in control emotions such as anxiety, fear and panic; and (iv) negative and passive emotions such as disappointment; sadness; resentment or bitterness.

A very similar proportion of individuals reported both passive (35.3%) and not in control emotions (34.1%). Less common were the forceful (17.2%) and negative thoughts (13.4%) categories.

Individuals from the oldest age group (80+) tended to select less frequently forceful or thoughts (e.g., anger or sadness) and more frequently not in control emotions (e.g., fear and worry). Compared to EA perpetrated by spouses or partners, abuse at the hands of children and grandchildren elicits more frequently not in control and passive emotions and less frequently forceful emotions.

Overall, the results indicate the preponderance of emotions (e.g., passive and not in control) that reflect a reduced sense of mastery over the environment and feelings of helplessness. Different elicited emotional patterns may be associated with individual and EA characteristics.

SUPPORT STRATEGY IMPACT ON HARMFUL BEHAVIOUR OF CAREGIVING RELATIVES AGAINST RELATIVES WITH DEMENTIA

M. Neise, R. Kaspar, S. Zank, *University of Cologne, Cologne, Germany*

According to a stress-related paradigm, caring for a relative suffering from dementia represents a considerable burden for caregiving relatives and may evoke potential harmful behaviour (PHB) as well as abuse (*elderly abuse*). The long-term trajectories of caregivers' PHB have not been well explored, and there is no consistent evidence with respect to the influence of intra-individual and external support strategies on the development of caregivers' PHB over time. This study explores trajectories of PHB in caring for a relative with dementia and estimates the impact of individual coping strategies and the use of external support services. Caregivers' PHB was followed over five measurement points at nine month intervals (n=888 respondents at baseline). In a first step of analysis, we estimated individual intercept and slope factors for caregivers' PHB using censored

growth-curve modelling. Second, we explored the effects of care receivers' cognitive status and decline over time, caregivers' individual coping strategies (i.e. accepting coping, reaction suppression, planning and concentration) and the use of external support services (i.e. family support, day care services, outpatient services) on PHB level and trajectories. Factors with well-established impact on caregiver PHB, such as housing situation or mobility status, were used as covariates in all analyses. The results show a significant decline in the magnitude of PHB over time. Moreover, individual coping and external support strategies contribute significantly to the observed variance with respect to the level and trajectory of PHB in caring for a relative with dementia.

MISTREATMENT AND RESILIENCE AMONG OLDER CHINESE ADULTS, AND THE MODERATING ROLE OF SOCIAL SUPPORT

Y. Yang, M. Wen, S. Salari, *University of Utah, Salt Lake City, Utah*

Elder mistreatment has been found to be associated with a range of health and psychological outcomes. Research on the relationship between elder mistreatment and psychological resilience, however, is lacking. The present study explored the association between mistreatment and psychological resilience and examined the possible moderating role of social support on this proposed link, using a sample of 432 community-dwelling older adults aged 60–79 years interviewed in 2014 from Linxi County, Inner Mongolia, China. We examined reports of the presence of any mistreatment (verbal, financial, or physical). We measured social support using the 8-item family and friends support subscale of the Multidimensional Scale of Perceived Social Support (MSPSS), while resilience was measured by a seven-item scale used in previous studies. Ordinary least-squares (OLS) regression analysis confirmed a significant association between mistreatment and resilience. Mistreatment victims reported lower resilience than non-victims, net of demographic/socio-economic characteristics and health status. A significant moderating effect of elder mistreatment \times social support on resilience was also found ($p < .05$), indicating that social support moderated the direct relationship between mistreatment and resilience. Mistreatment victims were less likely to experience low resilience when they had high social support. Mistreatment seemed particularly detrimental to resilience among respondents with low social support. Findings reveal that intervention programs aiming to improve older adults' psychological wellbeing should consider enhancing social support, especially for those who were abused.

RESPECT SENIORS: STATISTICAL ANALYSIS OF THE CALLS RECEIVED FROM JANUARY 2003 TO DECEMBER 2015

N.G. Berg^{1,2}, D. Langhendries², D. Giet³, 1. *Geriatric, CHR de la Citadelle Liege Belgium, Liege, Belgium*, 2. *Respect Seniors, Namur, Wallonia, Belgium*, 3. *University of Liege, Liege, Belgium*

Context:

The fight against elderly abuse is effective on the whole territory of the Walloon region since 2003 at first on basis of associations working together and since 2009 on a legal basis with the RESPECTSENIORS association.

The most media known action is a freefone 0880 30 330
Statistical analysis of the calls received during period from January 1st, 2013 to December 31st, 2015

I. Total of received calls: 27271

Contacts with not recognizable contents: 2093

Contacts with recognizable contents: 25178

Contacts concerning mistreatment: 17352

II. Mentioned elderly abuse cases treated: 7609

Most of the announced abuses are financial and psychological violence.

The "mentioned victims" are women in 71 %, men in 20% and a group of people in 8% of the cases.

74% of the victims live at home.

25% of the callers are the elderly abused persons themselves.

The mentioned author of abuse or negligence is a family member in 64% of the situations.

The rate of anonymity is high: 23% of the callers, 42% of the mentioned authors, 31% of the victims.

The victim lives alone in 25% of the cases.

MEASURING FINANCIAL VULNERABILITY TO EXPLOITATION AND LACK OF CAPACITY THROUGH A PSYCHOSOCIAL LENS

L.J. Ficker, E. Gross, L. Hall, P.A. Lichtenberg, *Institute of Gerontology, Wayne State University, Detroit, Michigan*

Longitudinal research indicates that young-old, better educated and depressed elders were more vulnerable to financial fraud, a major form of financial exploitation. Lachs & Han's model (2016) describes financial vulnerability to exploitation primarily as an age-related phenomenon characterized by declines in cognition and money management skills, among other health, psychological and social variables. The purpose of this study was to test the psychosocial factors in this model to determine if they could identify seniors at risk for financial exploitation or lack of financial capacity, without objective cognitive or money management data. These psychosocial factors included anxiety about finances, depression, social isolation, loneliness, and environmental stressors (e.g., financial dissatisfaction). Perceived cognitive impairment was included as a psychological factor that has demonstrated association to health and mobility problems in previous research. Data was collected from 200 community-dwelling elders from both urban and suburban settings with a variety of education levels and financial resources (~ 50% African American and 50% White non-Hispanic) who were all in the process of making a major financial decision. Two logistic regression analyses were used to predict financial exploitation since age 60 and financial decision making capacity. Age, education, race, and psychosocial vulnerability were the independent variables. Psychosocial vulnerability was the only significant predictor of financial exploitation and also predicted financial capacity with age emerging as an additional significant factor. Psychosocial vulnerability is an under-recognized construct in prevention of financial exploitation and potential lack of decisional capacity, which has important implications for financial and health professionals.

WHAT DISTINGUISHES DEPRESSED ELDER ABUSE VICTIMS: ABUSIVE EXPERIENCE OR INDIVIDUAL CHARACTERISTICS?

A.J. Santos^{1,2}, B. Nunes², I. Kislaya², A.P. Gil^{3,2}, O. Ribeiro^{4,1},
1. *Institute of Biomedical Sciences Abel Salazar, University of Porto, Porto, Portugal*, 2. *Epidemiology Department, National Health Institute Doutor Ricardo Jorge, Lisbon, Portugal*, 3. *CESNOVA Centre for Sociological Studies of the Universidade Nova de Lisboa, Lisbon, Portugal*, 4. *CINTESIS, Institute of Biomedical Sciences Abel Salazar, University of Porto, Porto, Portugal*

Often studied correlates of Elder Abuse (EA) include depression or depressive symptom; assumed to be of particular importance and often conceptualized as both a risk factor for and a consequence of EA.

The study was designed to (a) estimate proportion of older adults self-reporting EA that screened positive for depressive symptoms; and (b) examine whether individual characteristics and/or abusive experience aspects correlate with depressive symptoms.

The data was collected by convenience sampling. Participants were 510 older adults self-reporting experiences of abuse in family setting enrolled in a cross-sectional victims' survey through four institutions.

Depressive symptoms were assessed through the 5 items Geriatric Depression Scale. Poisson regression was used to determine the prevalence ratio (PR) of screening depressive symptoms according to individual and abusive experience covariates: sex; age group; cohabitation; perceived social support; chronic diseases; functional status; violence type; perpetrator and number of conducts.

More than half (66.3%) reported 3 or more depressive symptoms and almost half (46.8%) screened positive for 4 or 5 depressive symptoms. Women (PR=1.18, 95% CI=[1.04–1.35]), individuals perceiving low social support level (PR=1.36, 95% CI=[1.16–1.60]) and with long-term illness (PR=1.17, 95% CI=[1.02–1.33]) are associated with increased risk for screening depressive symptoms. In regards to abusive experience only the number of abusive conducts increased the prevalence ratio (PR=1.07, 95% CI=[1.05–1.09]).

Results suggest preponderance of individual, rather than abusive experience characteristics, on the prevalence ratio of screening depressive symptoms.

INTERGENERATIONAL ELDER ABUSE: WHY IT IS SO HARD TO ASK FOR HELP

B. Dow^{1,2}, F. Vratsidis¹, M. Joosten¹, A. Walmsley³, J. Blakey³, 1. *National Ageing Research Institute, Royal Melbourne Hospital, Victoria, Australia*, 2. *University of Melbourne, Melbourne, Victoria, Australia*, 3. *Seniors Rights Victoria, Melbourne, Victoria, Australia*

The very nature of elder abuse – harmful behaviour by a trusted family member – takes a heavy toll on emotional wellbeing, making it difficult to take action. In this study we sought to understand the outcomes of abuse from the older person's perspective. Twenty-four people who had experienced elder abuse and sought help were interviewed. Twenty-three had been abused by their adult son (16) or daughter (7). Most were living with the perpetrator at the time of the abuse (18). Most experienced psychological/emotional abuse (21), or financial abuse (19), with the two usually occurring

together. Physical abuse was reported in 7 cases and social abuse in three.

Participants felt ambivalent about the situation they were in – they wanted the abuse to stop but did not want to have to take action to make it happen. They were concerned about how their child was dealing with what they saw as the reason for the abuse (mental illness, financial difficulties, marital breakdown), and they were worried about the consequences to their parent–child relationship if they took decisive action against their child to stop the abuse.

Their advice to others in the same situation was to recognise it early and to take action. To service providers their advice was they needed to know that they were there (advertise your service) and to be given the time and space to make their own decision about intervention, based on knowing what their options were. They also wanted help for the perpetrator.

ABUSE OF OLDER CHINESE BY FAMILY CAREGIVERS

E. Yan¹, G. Fang², 1. *The Hong Kong Polytechnic University, Hong Kong, Hong Kong*, 2. *The University of Hong Kong, Hong Kong, Hong Kong*

The present study examined rates and factors associated with elder abuse by family caregiver in a cross-sectional sample of 1002 older Chinese in the People's Republic of China (PRC). High rates of abuse and neglect were observed with 52.6% of care-recipient reporting neglect, 40.8% financial exploitation, 16.5% verbal abuse, and 1.2% physical abuse. Results of logistic regression analyses showed that neuropsychiatric symptoms, cognitive impairment were prominent factors associated with different forms of mistreatment. A rewarding pre-morbid relationship with the caregiver and use of emotional focused coping mitigated abuse.

FEMICIDE IN LATER LIFE: THE ROLE OF POLICY IN PREVENTION

S. Salari, *Family and Consumer Studies, University of Utah, Salt Lake City, Utah*

Severe family violence can result in injuries or death across the life course. Policy and structural conditions create cross-national variations, particularly in methods (such as use of firearm, asphyxiation or beatings) and outcome (i.e., survival versus fatalities). Utilizing multiple data sources, this research provides insight into prevalence and characteristics of lethal incidents in later life. According to 2012 U.S. FBI Supplemental Homicide Reports, eldercide (persons 60 and over) represents about 7.3% of the nearly 14,000 annual U.S. homicides. Gender patterns exist, where men are more often murdered, but the offenders tend to be acquaintances or strangers. Women's killers are more likely current or former spouse/cohabitants, reflecting "femicide" among family members. Female vulnerability for those age 60 and over includes those who know they are endangered, as well as others who remain unaware. Perpetrators who are suicidal represent a unique threat to women in long term relationships, particularly those with no known history of violence. A sample of 225 U.S. intimate partner homicide suicide events illustrates cases where offenders varied in motives and lethal methods. For comparison purposes, international variations in elder fatalities are discussed, with special attention to firearm regulations and victim rights. Typical services

for battered women, such as protective orders and shelters, may not be ideal for older victims. Prevention strategies to reduce male suicidality and limit firearm availability in cases of domestic violence or mental illness could help reduce U.S. femicide. Adaptations are important to adequately respond to the aging of the population.

HUMAN DIGNITY AND THE RIGHT OF PERSONHOOD: LEGAL PROTECTION FOR ELDERS AT HOME IN GERMANY

A. Schwedler¹, N. Konopik², L. Schulz², F. Oswald², M. Wellenhofer¹, L. Salgo¹, G. Zenz², 1. *Faculty of Law, University, Frankfurt, Germany*, 2. *Faculty of Educational Sciences, Frankfurt, Germany*

Most older people wish to stay and be cared for in their own home. In Germany approx. 1.25 million people are cared for without any professional help, usually with great effort and attention. However, domestic care by relatives is also known to be a risk of elder abuse. The research project "Human Dignity and the Right of Personhood of People depending on Long-Term Care at Home - Legal Protection for Carers and the Cared-For" deals with elder abuse in German domestic care settings from a legal and social sciences perspective. The aim of the research project is to develop a regulatory framework providing aid-oriented prevention and intervention in family care of vulnerable elders by public agencies and courts. First, empirical data on the situation in family care for older people will be analysed. Second, the existing legal framework of family care will be examined with respect to gaps and potentials for the protection of vulnerable elders. In a third step, recommendations for legislation and administration will be developed in exchange with practitioners. Preliminary results with respect to the first two steps of the analysis disclose a lack of legal regulations on the issue of elder abuse in family care, especially in comparison with German legislation on child protection. Thus, the legal framework should reinforce prevention of care problems by giving more efficient support to carers and permit legal intervention in case of abuse. The proposed legislation should take account of the high value of the individual self-determination right.

FEAR OF PHYSICAL, EMOTIONAL, AND FINANCIAL EXPLOITATION AMONG OLDER ADULTS

E. Grinshteyn, *University of San Francisco, San Francisco, California*

Much, though not all, of the previous research has shown that older adults have higher levels of fear of victimization than younger adults. However, it is not well understood whether older adults are afraid of the types of victimization they are most at risk of and whether they are afraid of those who are most likely to perpetrate crimes against older adults.

Pilot data were collected among community dwelling older adults in Nevada (n=467). Questions regarding financial, physical, and emotional abuse were asked as well as from whom they were afraid of each type of abuse. Questions were also asked regarding demographics, social cohesion, neighborhood safety, gun ownership, and other risk and protective factors.

The majority of older adults report feeling "not afraid" of financial victimization (56%), physical victimization (54%),

and emotional victimization (54%). However, when asked which they were most afraid of, 42% reported being most afraid of financial victimization, 34% reported being most afraid of emotional victimization and 34% reported being most afraid of physical victimization. Older adults were most often afraid of strangers for all three forms of victimization and rarely afraid of family members. A higher proportion of older adults were afraid of acquaintances with respect to financial abuse.

These data provide insight into which types of crimes older adults are afraid of, from whom they fear abuse, and protective and risk factors associated with each. It seems that fear is somewhat well aligned with risk, however it is not clear that older adults are suspicious of the most common perpetrators.

MISTREATMENT ACROSS THE LIFE COURSE AS A MAJOR PREDICTOR OF ELDER ABUSE: A CANADIAN NATIONAL STUDY

L. McDonald, *University of Toronto, Toronto, Ontario, Canada*

Few researchers have claimed that abuse at an earlier stage in life may be a risk factor for elder abuse later in life. Indeed, the elder abuse literature frequently highlights that the social learning model causes abuse in later life, the argument being that abusers learn how to be violent from witnessing or suffering from violence. The aim of this research was to test the hypothesis that if an older person was abused earlier in their lives, they were more likely to be abused as older adults. A national telephone survey was conducted to estimate the prevalence of five forms of elder abuse in community dwelling older Canadians who were 55 years and older. A representative, stratified sample of 8,163 Canadians completed the survey, the largest study to date. Information was collected about socio-demographic factors, health, wealth, risk factors for abuse, and prevalence for the usual five subtypes of abuse. Unlike other prevalence studies, a life course perspective was the guiding theoretical framework. The analyses included descriptive statistics about the sample, bivariate analyses correlating the risk factors with abuse and a logistic regression model with the main the predictors of abuse. The results showed, in order of importance, higher depression scores as measured on the C-DES, having been abused as an adult (25–54), a child (1–17) a youth (18–24), having higher unmet ADL/IAD needs, not feeling safe with those closest to respondent, geographical location; being single compared to being married and lastly, being female were significant ($p \geq .001$) predictors.

SESSION 980 (POSTER)

EMOTIONS AND AGING

OVER-RELIANCE ON THE MOUTH AREA IN THE VISUAL SCANPATHS ARE ALSO OBSERVED WITH OLDER EMOTIONAL FACE

Y. Dion-Marcoux, C. Blais, D. Fiset, H. Forget, *Université du Québec en Outaouais, Gatineau, Quebec, Canada*

Previous studies have shown that aging is associated with a reduced accuracy at recognizing some facial expressions (Calder et al., 2003; West et al., 2012). It has been proposed that this deficit is linked with altered visual scanpaths: elderly fixate more the mouth area than younger participants (Wong et al., 2005). However, these results were obtained using pictures of young individuals' face instead of individuals of the same age group as the participants. This study therefore compared the visual scanpaths of older ($N=31$; $M_{age}=71.8$) and younger adults ($N=31$; $M_{age}=22.6$) during the recognition of facial emotions displayed by young and older faces (five identities each). The task consisted in categorizing the six basic emotions, while eye movement were recorded. Accuracy scores were calculated for each expression and stimulus age. A repeated-measures ANOVA conducted on participants' accuracy scores revealed an interaction between participant's age, stimulus age and emotion [$F_{(5,300)}=7.13$, $p<.001$]. Paired t-tests indicated that young adults were more accurate than older adults with fear, no matter the stimulus age [$t_{(61)}=8.57$, $p<.001$, $t_{(61)}=-3.32$, $p<.01$ with young and old faces respectively]. They were also more accurate with sadness [$t_{(61)}=6.89$, $p<.001$], but only when they were displayed by young faces, as well as with disgust [$t_{(61)}=-4.49$, $p<.001$], and neutral [$t_{(61)}=-3.10$, $p<.01$] when they were displayed by older faces. Moreover, the ratio of fixations duration on the eye vs. the mouth was significantly higher for younger than older adults [$t_{(57)}=2.22$, $p=.03$]. These results confirm that the visual scanpath of adults is altered, even when older face stimuli are used.

HOW AND WHEN DO OLDER ADULTS EXPERIENCE BETTER EMOTIONAL WELL-BEING?

S. Raposo, T. Sims, J. Barnes, L.L. Carstensen, *Stanford University, Stanford, California*

According to socioemotional selectivity theory (SST; Carstensen & Lang, 1996; Lang & Carstensen, 2002), perceiving time as limited motivates people to selectively structure their daily lives in ways that enhance emotional meaning and experience. To our knowledge, however, no studies have tested whether future time perspective is associated with emotional well-being as a function of selectivity. We predicted that positive emotional experience results when time is perceived as limited and environments provide opportunities to be selective. In Study 1, a life-span sample of 177 adults (aged 18–93) reported their future time perspective (Carstensen & Lang, 1996). We operationalized selectivity as participants' perceived level of autonomy and environmental mastery (using subscales of Ryff's Psychological Well-Being Scale; Ryff, 1989). Participants also reported emotional experience on 35 occasions randomly sampled over one week. Positive emotional experience was calculated by subtracting mean negative affect from mean positive affect, disaggregated by arousal level (e.g., low arousal positive–high arousal negative). We found that limited future time perspectives predicted greater low-arousal positive emotional experience, but only for people who reported a high level of perceived selectivity. These findings demonstrate that perceiving time as limited enhances emotional experience under conditions that permit selectivity. Results from a related study of emotional experience and inescapable daily stressors in family caregivers will also be presented. The findings lend support

to SST's claim that enhanced emotional experience in people who perceive a limited future is due to selectivity, and help to clarify the understanding of age-related improvements in emotional functioning.

IS DAILY PHYSICAL ACTIVITY PLEASANT FOR OLDER ADULTS? BETWEEN- AND WITHIN-PERSON ASSOCIATIONS

T. Nakagawa¹, M. Kabayama², K. Matsuda², S. Yasumoto², Y. Gondo², K. Kamide², K. Ikebe², 1. *University Research Priority Program "Dynamics of Healthy Aging", University of Zurich, Zurich, Switzerland*, 2. *Osaka University, Suita, Japan*

Interventional and experimental studies suggest that physical activity improves well-being across one's lifespan. However, if and how daily physical activity influences well-being in advanced old age in natural settings is yet to be elucidated. An intensive longitudinal study was conducted with older adults (aged 82 – 85 years; $N = 38$) over seven days. Daily positive affect and physical activity were measured using daily diaries and accelerometers, respectively. Positive affect was reported at the end of each day, and physical activity was assessed by the average walk counts per hour every day. Between-person physical activity was positively associated with daily affect, thus indicating that a more active person exhibited higher positive affect. However, physical activity and positive affect was negatively associated within-person; On days when a typical older individual was more physically active, he/she experienced lower positive affect. Gender, mental health, and Body Mass Index did not moderate this within-person association. These findings indicate that, although usual physical activity could increase positive affect, i.e., feelings of energy, daily physical activity might decrease it in older adults. Practitioners and clinicians should recognize the short- and long-term effects of physical activity on the well-being of very old individuals. Future studies are required to further explore the underlying mechanism and understand how age-related changes limit a within-person revitalization process.

AGE AND THE RELATIONSHIP BETWEEN STRESS, AFFECTIVE REGULATION, AND LIFE SATISFACTION

P. Goodwin, R.C. Intrieri, *Western Illinois University, Macomb, Illinois*

Attachment theory posits a relationship between affect regulation and well-being (Mikulincer, Shaver, & Pereg, 2003). Mikulincer et al. (2003) proposes the attachment system becomes activated via exposure to a stressor. Activation of the system leads the individual to engage in proximity-seeking behavior(s) as a way of managing distress. In the event that proximity-seeking fails, the individual relies upon secondary attachment strategies in order to regulate distress associated with perceived stress (i.e., hyperactivating versus deactivating regulation of emotion). The current study examines whether age influences the relationship between stress, affective regulation and life satisfaction. 155 younger adults and 130 community-dwelling older adults participated in a study examining affective experience and daily life. The sample of 155 young adults includes 71 women and 84 men with an average age of 20.29 ($SD = 1.92$). The sample of 131 older adults includes 80 women and 51 men with an average age

of 67.568 ($SD = 8.873$). All participants completed a modified version of the Day Reconstruction Method (DRM). In addition, participants completed several measures of psychosocial functioning, including the Perceived Stress Scale and the Satisfaction with Life Scale. Comparing younger and older adults, the current analysis examines the construction of a path model linking perceived daily stress and general life satisfaction, with attachment-related styles of affect regulation (i.e., anxiety or avoidance) serving as mediators. Results indicate a well-fitting model ($CFI = .952$, $SRMR = .041$), suggesting the relationship between daily stress, affect regulation, and well-being is similar for younger and older adults.

A DAILY DIARY ANALYSIS OF THE RELATIONSHIP BETWEEN STRESS, EMOTIONAL SUPPORT, AND POSITIVE AFFECT

H. Chai, J. Hyun, *Human Development and Family Studies, The Pennsylvania State University, University Park, Pennsylvania*

Stress and emotional support are two of the main elements that influence everyday well-being. Although previous studies show that stress functions as a risk against positive affect and receiving support enhances positive affect, how these relationships differ by gender in daily basis remain largely unknown. Therefore, using the respondents aged 45 and higher in the second wave of the National Study of Daily Experiences (NSDE) from the Midlife in the United States (MIDUS) survey, this study looked at the relationship between stress, emotional support, and positive affect ($N = 1,618$) and how gender moderates these relationships.

The results showed that on days when individuals experienced stress, both men and women showed lower positive affect compared to stress-free days. However, women showed more decrease in positive affect than men. As for receiving emotional support, whereas women showed lower positive affect on days when they received social support, men did not. Additional analysis showed that women seek more support on days they showed lower positive affect. These results show that women are psychologically more vulnerable to both stress and receiving support compared to men, presumably due to women's higher emotional reactivity to daily dynamics. Also, considering that women are usually the providers rather than receivers of support, women may not have received enough support they needed. Not receiving adequate support could have hindered women from obtaining benefit from getting support. In conclusion, this study shows that daily stress and emotional support can have different implications on emotional well-being for men and women.

AGE-RELATED IMPACT OF ABILITY AT IDENTIFYING FACIAL EXPRESSION ON UTILIZATION OF VISUAL INFORMATION

Y. Dion-Marcoux, C. Blais, H. Forget, D. Fiset, *Université du Québec en Outaouais, Gatineau, Québec, Canada*

Previous studies have shown that aging is associated with difficulties at recognizing some facial expressions (Calder and al., 2003; West and al., 2012). Circelli et al., (2013) showed that this alteration in performance is linked to changes in the older adults' visual scanpaths. We recently showed that

despite displaying different visual scanpaths, older and younger participants use the same facial features on average to accurately categorize the basic facial expressions (Dion-Marcoux et al., 2016). However, we also observed some heterogeneity in the ability of our participant to categorize expressions, and these differences in the ability may be linked to the visual strategies used. This study compared the impact of ability at categorizing expression on the use of visual information of older ($N=31$; $M_{age}=71.8$) and younger adults ($N=31$; $M_{age}=22.6$). The Bubbles method (Gosselin & Schyns, 2001) was used to measure information utilization during a facial expression categorization task of basic emotions displayed by young and elderly faces (five identities each). A separate facial expression categorization task was used to measure ability. Classification images representing the visual information that was correlated with the ability at identifying facial expressions were separately obtained for each facial expression, facial age, and participants' age group. The results showed that participants' ability modulate the visual information utilized by older, but not younger, adults. Future analyses will allow verifying if the older participants with the highest performance alteration reveal visual strategies that differ from those of young participants, and if these differences can predict their alteration.

THE INFLUENCE OF AGE ON EXPERIENCING SELF-CONSCIOUS EMOTIONS IN DAILY LIFE

H. Wang, H.H. Fung, *Chinese University of Hong Kong, Hong Kong, Hong Kong*

By using data from 1996 General Social Survey (GSS), we explored the relationships between age and people's experience of self-conscious emotions. 1447 participants (aged 18 to 89 years) reported the number of days in which they had experienced shame, embarrassment, and pride in last 7 days. Correlation analysis showed that participants' self-reported happiness positively correlated with the frequencies of pride experiences ($r = .118$, $p < .001$), while negatively correlated with the frequencies of both shame ($r = -.081$, $p < .01$) and embarrassment experiences ($r = -.075$, $p < .01$). Hierarchical regression results showed that older adults tended to experience less embarrassment ($\beta = -.062$, $p = .026$) and pride ($\beta = -.058$, $p = .033$) in daily life. In addition, males had higher frequencies of pride experiences ($\beta = 0.084$, $p = .002$) than females. The results implies that older adults may be skillful at avoiding not just negative emotions and also positive emotions such as pride that may hinder their interpersonal relationships.

THE ROLE OF PERSONALITY IN EMOTIONAL REACTIVITY: A COMPARISON BETWEEN OLDER AND YOUNGER ADULTS

P. Steenhaut^{1,2}, I. Demeyer², R. De Raedt², G. Rossi¹, 1. *Vrije Universiteit Brussel, Brussels, Belgium*, 2. *Ghent University, Ghent, Belgium*

Despite the losses older adults (OA) experience, they demonstrate more emotional wellbeing than younger adults (YA). According to the socio-emotional selectivity theory, OA are better in regulating emotions. They also seem to react physiologically less strongly to emotional stimuli than YA. Moreover, in YA a link between personality and emotional

reactivity has been found. This study investigates whether emotional reactivity and its link with personality differs between YA and OA. To do this 120 YA (25–50 years) and OA (65+) were recruited. Personality was measured with the MMPI-2-RF-PSY-5-*r* and BFI scales. Physiological measures (HRV, SCL, fEMG (corrugator, zygomaticus)) were assessed while participants viewed a happy and sad film. Subjective reactivity (VAS) was registered after each film. We found that OA had stronger subjective reactivity for happy and sad films than YA, but that the only difference in physiological reactivity was that YA showed more arousal (SCL) during the happy film. OA's stronger subjective reactivity to sad films was related to higher scores on neuroticism and negative emotionality. In YA, negative emotionality went along with more frowning (corrugator) during sad films. Moreover, in YA, neuroticism was related to less arousal when seeing the happy (trend significant) and sad films, and higher HRV during the happy film. To conclude, differences in physiological reactivity to emotional stimuli between OA and YA are limited, which implies that techniques like biofeedback don't need to be adapted to ageing. Relationships between personality and reactivity were, with the exception of neuroticism in YA, in the expected directions.

GIVING AND RECEIVING SOCIAL SUPPORT IN LATER LIFE ELICITS UNIQUE BLENDS OF EMOTIONS

D. Wang, *University of Southern California, Los Angeles, California*

While the benefits of social integration and support on well-being in later life are well-documented, research has largely focused on the perspective of the support-recipient. Growing evidence suggests parallel benefits for support-giving, but the psychological pathways remain unclear. We investigated whether a brief experimental manipulation of reflection regarding one's support-giving or support-receiving behavior elicited distinct cognitive-affective states. 203 subjects age 55 and over completed a 30-minute online experiment in which they were randomly assigned to write about their roles as support-givers, support-receivers, or the previous day's activities. After the writing manipulation, subjects completed assessments of feelings of social connectedness, positive and negative affect, and self-achievement. Written narratives generated in response to the writing manipulation were also analyzed with the Linguistic Inquiry and Word Count software to assess expression of each cognitive-affective state. Those in the support-giving group had lower levels of self-reported negative affect, and higher levels of perceived social contributions ($p < .05$) and accomplishment ($p < .05$), compared to the support-receiving group. Text analyses show that those in the giving group had greater expressions of achievement and lower expression of negative emotion than those in the receiving group, while those in both the giving and receiving conditions had greater expressions of positive emotion, social connectedness and achievement than the neutral condition. Findings indicate that support-giving and receiving are associated with common, as well as unique, cognitive-affective states, suggesting shared and unique pathways through which each may be linked to well-being.

SESSION 985 (POSTER)

END-OF-LIFE AND PALLIATIVE CARE

COMPREHENSIVE ASSESSMENT UPON HOSPICE ADMISSION: WHAT DRIVES NON-COMPLIANCE?

N. Zheng, N. Sherif, Q. Li, I. Broyles, N. Chong, J. Frank, F. Rokoske, *RTI International, Waltham, Massachusetts*

The Centers for Medicare & Medicaid Services Hospice Quality Reporting Program recently proposed a hospice comprehensive assessment composite quality measure (QM). This QM assesses whether patients received all seven critical care processes at admission, as measured by the seven currently implemented QMs. These QMs address important physical symptoms and patient preferences regarding life sustaining treatments and support for spiritual/existential concerns. To construct the composite QM, we used the Hospice Item Set—standardized patient-level hospice quality data—from 1,215,247 patients in 3,922 hospices discharged from 10/2014 to 09/2015. The performance scores varied across hospices. On average, hospices performed a comprehensive assessment for approximately 70% of patients, but 5% of low-quality hospices performed a comprehensive assessment for 30% or fewer of their patients. We constructed the composite QM iteratively, omitting one care process each time, and compared scores. We found that comprehensive pain assessment, which addresses multiple characteristics of pain symptoms, was the least frequently completed process. Our findings revealed that the comprehensive pain assessment is most often the missing portion of the overall comprehensive assessment. Strategies focusing on this care process will yield overall quality improvement. Additional results from factor analysis, Cronbach's alpha and item-response theory analyses will be available and inform whether the seven care processes can be statistically reliably combined into one composite QM and the level of difficulty of completing each care process in order for the hospice to complete the comprehensive assessment.

The abstract is sponsored by the Social Research, Practice, and Policy Section of The Gerontological Society of America.

A REVIEW OF CLAIMS BASED QUALITY INDICATORS USED TO MONITOR THE MEDICARE HOSPICE BENEFIT

M. Plotzke¹, T. Christian¹, P. Gozalo², J. Teno³, *1. US Health, Abt Associates, St. Louis, Missouri, 2. Brown University, Providence, Rhode Island, 3. University of Washington, Seattle, Washington*

Through the Medicare Hospice Benefit (MHB), hospices submit claims containing information that allows policy makers to identify outcomes with large variation across hospices. Identifying outliers that have poor outcomes can help policy makers improve the MHB and increase the quality of care being provided. Our research identifies hospices that are outliers in the provision of hospice services along five different quality indicators (QIs): Provision of General Inpatient care days, Provision of skilled visits at the end of life, Average lifetime length of stay, Live discharge rates, and Nursing minutes provided per day. QIs are calculated using 100%

of Medicare hospice claims from January 1, 2010 through September 30, 2014. For each indicator, hospices are grouped into deciles. We count how many times a hospice appears in the highest three deciles for each indicator to determine which hospices are outliers. Out of 3,946 hospices, there are 15 hospices which are in the highest three deciles for all five indicators. 235 hospices are in the highest three deciles for four or five indicators. The majority of hospices in the highest three deciles for four or five indicators are located in the south census region (72.3%). 8.8% of for profit hospices have four or more QIs in the three highest deciles compared to only 1.8% of other hospices. The average spending per beneficiary for hospices with four or more QIs in the highest three deciles is \$27,365 compared to \$15,441 for hospices with 3 or fewer indicators in the highest three deciles.

OLDER ADULTS WITH ADVANCED HIV/AIDS AND THEIR INFORMAL CAREGIVERS' COMMUNICATION ON END-OF-LIFE CARE

V.H. Raveis¹, M. Carrero¹, D. Karus¹, P.A. Selwyn², 1. *New York University, New York, New York*, 2. *Montefiore Medical Center, Bronx, New York*

Little is known about the priorities and end-of-life care preferences of older adults living with advanced HIV/AIDS, although palliative and end-of-life issues are essential aspects of their care. Even less attention has been focused on their informal support network, who provide emotional support, practical assistance and function as surrogate decision-makers. Data is drawn from a mixed methods investigation on care preferences and life goals at the end-of-life. Older (50+), minority (59%-Black, 28%-Hispanic), low-income adults living with advanced HIV/AIDS and their informal caregiver (n= 29 dyads) completed a survey and comprehensive interview in English or Spanish. Both patients and caregivers reported a high communication quality -- 83% (patients) 72% (caregivers) 'definitely agreed' that: "Caregiver knows kinds of treatment patient would want if patient got too sick for speak for him/herself". The narratives substantiate that while there is concordance on a number of important care considerations, fundamental differences in choice of end-of-life care co-exists within some dyads. When present, these differences intensify caregivers' distress associated with their execution of surrogate decision-making. The accounts also document that shared misperceptions of consensus on the care choice can occur within a dyad. Further the reports revealed the fluid and situational nature of patients' priorities for care; resulting in some instances in the caregivers being unaware of the change. Appreciation of the complexity of these issues, and recognition of the necessity to include social context considerations, will enhance timely communication between the health care team, patient and caregiver to facilitate person-centered care.

ENVISIONING AND DEVELOPING A SYSTEM TO MEET LAST STAGES OF LIFE CARE NEEDS OF PATIENTS AND FAMILIES

M. Chiu^{1,2,3}, V. Wesson^{1,2,3}, S. Meerai^{3,5}, L. Nelles^{3,4}, A. Grek^{1,2,4}, J. Sadavoy^{1,2,3}, 1. *Department of Psychiatry, Mount Sinai Hospital, Sinai Health System, Toronto, Ontario, Canada*, 2. *Department of Psychiatry, University of Toronto, Toronto, Ontario, Canada*, 3. *Cyril & Dorothy,*

Joel & Jill Reitman Centre for Alzheimer's Support and Training, Mount Sinai Hospital, Toronto, Ontario, Canada, 4. *Outpatient Geriatric Psychiatry Clinic, Mount Sinai Hospital, Toronto, Ontario, Canada*, 5. *Lunenfeld-Tanenbaum Research Institute, Sinai Health System, Toronto, Ontario, Canada*

A multiple-perspective qualitative study applying the Appreciative Inquiry (AI) framework was carried out with the goal of (re-)building the system of care for individuals in their last stages of life in Ontario, Canada. The "Discover" and "Dream" phases within the AI framework aimed at understanding what factors enable patients and their family caregivers to positively perceive and appropriately access available services and supports in the current system of care. 26 clinically frail elderly patients and/or their family caregivers were interviewed, and their lived experience and encounter with the system were documented and coded using grounded theory principles. Rich narratives revealed the needs of patients and caregivers, and the barriers and supports they faced while attempting to navigate Ontario's system for care. They identified the following processes as potential platforms for positive changes: diagnosis, prognosis, assessment, access, resources, advocacy, and communication. Patients'/Caregivers' narratives were presented to 11 expert stakeholders from different professional groupings – medical, social, legal and ethics, administration and policy – who were then interviewed as part of the "Design" and "Destiny" phases within the AI framework. Expert stakeholders considered patients/family caregivers' lived experience in the broader context, and made recommendations on how to motivate and implement a path and vision for system change. Stakeholders commented on the need for professional training in communicating sensitive issues with patient/family, public education and awareness regarding hospice and palliative care, enhanced advocacy supports, an expanded model for applying palliative care principles, and the need for different professional sectors to work collaboratively towards these goals.

LIVE DISCHARGE FROM HOSPICE: SOCIAL WORK PERSPECTIVES

S. Wladkowski¹, C. Wallace², 1. *School of Social Work, Eastern Michigan University, Ypsilanti, Michigan*, 2. *Saint Louis University, Saint Louis, Missouri*

Hospice and palliative care is holistic support for individuals living with terminal illness throughout the illness and bereavement for the caregivers. However, some individuals who enroll onto hospice services do not decline as quickly as determined by current regulations leading to what is referred to as a 'live discharge.' This interruption can impact the physical and psychosocial care needs for individuals and caregivers and leave hospice clinicians with questions with how to best support them.

Between 2010 and 2012, which is the most recently collected data on live discharge, 10.6% of hospice patients across the US were discharged alive from hospice care (CMS, 2014). As hospice enrollment continues to increase, it is expected the numbers of individuals discharged alive will also grow (Campbell, 2015) and the need for specialized support for both patients and caregivers will be critical. Social workers as hospice clinicians are positioned to offer

substantial support to individuals and their caregivers who experience a live discharge.

This qualitative study (N=24) explored the current practices of hospice social workers across the US engaged in the live discharge process. Results from this study emphasize the need to bridge the gaps between policy and practice. Specifically, the challenges of hospice social workers to replicate or supplement the holistic support and unique services hospice provides for individuals discharged alive, and suggests further research to develop an assessment framework to identify appropriate support for patients and their caregivers who no longer meet hospice eligibility requirements.

INDELIBLE MEMORIES: THE IMPACT OF END-OF-LIFE DECISIONS ON BEREAVED CAREGIVERS

D.P. Waldrop, J. McGinley, *University at Buffalo, Buffalo, New York*

Advance care planning (ACP) is a process which involves the consideration of end-of-life wishes, communication about them with family and providers and their written documentation. ACP can both clarify and facilitate a person's end-of-life wishes. Yet, caregiving for a dying person remains one of life's most distressing experiences. Beyond treatment decision-making, ACP has the potential to relieve distress, assist older people with life closure and ease the transition to bereavement. The purpose of this study was to investigate how ACP and provider communication influenced end-of-life care and caregivers' adaptation in bereavement. This mixed-methods longitudinal study involved in-depth interviews with 67 caregivers at 4 and 10 months after a loved one died in hospice care. Quantitative data was collected using the Core Bereavement Items (CBI) and categorical questions about health and coping. Qualitative data was collected from open-ended questions about the caregiver's perceptions of the illness trajectory, experiences with end-of-life care and bereavement. CBI scores decreased over time ($T_1M=18.23$; $T_2M=15.76$); Self-reported health improved ($T_1M=2.57$; $T_2M=2.63$); Overall coping improved ($T_1M=2.05$; $T_2M=2.30$). However, 18% (T_1) and 6% (T_2) reported coping "Not too well" or "Not well at all." Qualitative data analysis yielded a theme of Indelible Memories with stories repeated at T_1 and T_2 about the intense recall of: (a) Unresolved misunderstandings, (b) Unexpected transitions; and (c) Undesired locations at death. These findings suggest the importance of ACP that is enhanced to encompass caregivers' needs and the opportunity to begin preparing for the dying process, loss and resulting grief.

IMPROVING END-OF-LIFE CARE FOR MINORITIES IN SOUTH FLORIDA: KNOWLEDGE, CHOICES, AND POLICIES

A.M. Perez², K. Ray², A. Turner³, N. Cook², K. Cerminara⁴, G. Suci², D. Cohn Steinkohl², 2. *College of Osteopathic Medicine, Master of Public Health program, Nova Southeastern University, Ft. Lauderdale, Florida*, 3. *College of Health Care Sciences, Nova Southeastern University, Ft. Lauderdale, Florida*, 4. *Shepard Broad College of Law, Nova Southeastern University, Ft. Lauderdale, Florida*

Ethnic and racial minority groups suffer disproportionately from higher rates of cancer and other chronic illnesses. However, research shows that minority groups utilize

hospice/palliative care services less than other groups. Many different factors seem to account for this disparity, among those, insufficient knowledge about hospice/palliative care services available and the exclusion of concurrent curative care once the person starts receiving hospice services. The Affordable Care Act, section 3102, has provided the opportunity to launch a three-year demonstration project for adults suffering with life-threatening illnesses where Medicare beneficiaries could receive hospice care while still receiving curative treatment for the life-threatening illness with the goal of improving access and quality of end of life care.

We conducted a study designed to ascertain the existing knowledge and choices of racial and ethnic minorities in South Florida regarding end-of-life care and to evaluate potential changes in interest and acceptance of Hospice care if curative treatment were offered concurrently with traditional hospice services. Results indicated that 30 percent of participants had little or no knowledge of what hospice or palliative care were, however, 71 percent favored end-of-life care that would concurrently provide curative treatment, comfort and supportive care. The results of this study could be used to inform policy makers and practitioners on alternatives and solutions to improve knowledge, access and quality of end of life care for ethnic and racial minorities in South Florida.

THE EXPERIENCES OF HOME HEALTH AIDES AFTER CLIENT DEATH: GETTING NOTIFIED AND REASSIGNED

A. Barooah¹, K. Boerner¹, H. Gleason¹, I. van Riesenbeck², O. Burack³, 1. *Gerontology, University of Massachusetts Boston, Somerville, Massachusetts*, 2. *APP Cologne-Academy for Applied Psychology and Psychotherapy, Cologne, Germany*, 3. *The New Jewish Home, New York City, New York*

This study explored the experiences of Home Health Aides (HHAs) following the death of a client. 80 HHAs who had lost a client in their care within the last two months participated. Data collection involved comprehensive semi-structured in-person interviews. We assessed how the HHAs were notified about the death of a client and how the process of reassignment to a new client was handled. Overall, being notified about client death prior to arrival at work resulted in more positive responses compared to notification upon arrival at work. Specifically, being called in advance by a client's family led to more positive and neutral experiences while being called by staff elicited more neutral or negative experiences. Reassignment to a new client was viewed as an adjustment for some HHAs, whereas others were eager to be reassigned as quickly as possible. More than three fourths of the HHAs who saw reassignment to a new client as a time of adjustment reported that it was a negative experience. Not having a speedy reassignment for those eager to be quickly reassigned and swift reassignments when they did not want to both led to a negative experience. HHAs who were temporarily reassigned had a negative experience and needed more hours. Findings have important implications for handling transitions around client death, suggesting benefits of a more mindful approach to notification after client death and thoughtfulness around reassignment.

GUIDANCE FROM UK EXPERTS ON HOW TO ENABLE BETTER END-OF-LIFE CARE AND FACILITATE HOME DEATHS

A. Ahmed^{1,2}, D. Kerwat^{1,3}, S. Wahid^{1,2}, S. Jamshaid^{1,2}, M. Sayma^{1,4}, D. Saleh^{1,2}, F. Oyewole^{1,2}, 1. *Imperial College Business School, London, United Kingdom*, 2. *Imperial College School of Medicine, London, United Kingdom*, 3. *Barts and the London School of Medicine, London, United Kingdom*, 4. *Peninsula College of Medicine and Dentistry, Exeter, United Kingdom*

Despite a growing desire amongst patients to spend their last days at home, many are unable to do so, leaving a lasting effect on both patients and families. We undertook a qualitative study with in-depth, semi-structured interviews in England, UK. A combination of face-to-face and telephone interviews were conducted with 33 experts in the field of end-of-life care. These included policy makers, academics and hospital and community healthcare professionals from leading UK organisations. Interviews were transcribed and thematically analysed. As a result, three overarching themes were identified: 'education'; 'planning' and 'managing people'. These were further divided into a total of 12 sub-themes containing practical guidance on enabling better end-of-life care. The theme of 'planning' contained seven subthemes including 'policy', 'cost' and 'coordination'. The 'education' theme included 'communication' and 'perceptions of death'. Of particular significance was the identification of the growing stigma and fear surrounding end-of-life amongst patients and healthcare professionals alike. 'Managing people' as a theme included the impact of 'patient preferences' and 'family influences' on enabling comfortable death at home. In conclusion, multiple barriers and facilitators to achieving death at home were identified in this study. The lack of training, education and funding within the National Health Service was highlighted, as was the importance of sociopolitical factors. These include the lack of social networks amongst elderly patients and the inequality of resource provision in hospitals and communities. We offer a list of recommendations to combat these barriers, paying specific attention to UK end-of-life policy and education.

PATIENT PREFERENCES FOR LIFE-SUSTAINING TREATMENT AND CONCORDANCE WITH THE POLST FORM

M. Henry, *NCQA, Washington, District of Columbia*

The Physician Order for Life Sustaining Treatment (POLST) Paradigm is a promising system for documenting treatment preferences of patients with advanced illness. Studies show that orders documented on POLST forms are largely concordant with care provided, but to align patient goals, preferences, and values with care provided, POLST forms must reflect patient goals, preferences and values. Using the Willingness to Accept Life-Sustaining Treatment (WALT) Instrument to elicit treatment goals, this study evaluated sensitivity of participants' preferences to treatment intensity and outcomes (cognitive impairment, physical disability, and probability of death), and alignment between WALT responses and POLST forms. A convenience sample of 42 residents with POLST forms was recruited from three nursing homes and two assisted living facilities. Participants' responses to the WALT and orders abstracted from participants' POLST forms were compared to evaluate alignment. Preferences remained stable across different treatment

intensity scenarios for 48% of participants and across different outcome scenarios for 33% of participants. Among 14 participants whose preferences were stable across all scenarios, eight articulated preferences that were fully aligned with their POLST. Three of 16 participants whose POLST ordered full treatment wanted comfort measures only. One of nine participants whose POLST form ordered comfort measures only wanted full treatment. Research is needed to develop decision-making strategies to assure that treatment-sensitive or outcome-dependent patient preferences are accurately reflected in POLST forms. Additionally, more research is necessary to understand the potential for misalignment between POLST forms and patient goals, preferences, and values to assure alignment with care provided.

POLICY CHALLENGES FACED BY THE CURRENT UK HEALTHCARE SYSTEM IN ACHIEVING PATIENT DEATH AT HOME

A. Ahmed^{1,2}, S. Jamshaid^{1,2}, D. Kerwat^{1,3}, F. Oyewole^{1,2}, D. Saleh^{1,2}, M. Sayma^{1,4}, S. Wahid^{1,2}, 1. *Imperial College Business School, London, United Kingdom*, 2. *Imperial College School of Medicine, London, United Kingdom*, 3. *Barts and the London School of Medicine and Dentistry, London, United Kingdom*, 4. *Peninsula College of Medicine and Dentistry, Exeter, United Kingdom*

Evidence suggests that the majority of patients wish to die at home. However, this is attainable for few.

A systematic literature review (SLR) was conducted with a mixed methods approach by analyzing qualitative and quantitative studies. In the SLR 3241 papers were retrieved. 72 primary data articles remained after the screening and filtering processes. Qualitative articles were synthesised using a meta-ethnography technique in order to develop key themes. Quantitative articles were analysed using a descriptive approach to highlight further themes. The emerging themes from the meta-ethnography synthesis and the analysis of the quantitative papers were amalgamated to produce a set of overarching barriers and facilitators.

6 barriers and 4 facilitators to achieving death at home were identified primarily from the meta-ethnography process. Further concepts of 'demographics' and 'interventions' were produced from the quantitative data analysis that had both barrier and facilitator components. The overarching topics included logistical issues in getting both the patient and equipment home, lack of continuity of care and geographic variation in resource provision, including 24/7 care, all that pertained to policy influence. In conclusion, this review shows that addressing these identified factors by reviewing and amending surrounding policy, could allow more patients to achieve death at home. However, it is important to acknowledge the qualitative nature of these results as such, further research is required to identify the relative impact that changing specific policies would have on patients' ability to achieve home death.

RESPONDING TO THE END-OF-LIFE OPTION ACT IN CALIFORNIA

L. Forbes, L. Petrillo, E. Dzung, K.L. Harrison, B. Scribner, B. Koenig, *Institute for Health & Aging, University of California, San Francisco, San Francisco, California*

The legalization of physician-assisted death in California, via the End of Life Option Act, expands the possible

pathways open to older adults facing the end of life. The law raises many questions, ranging from the practical to the philosophical. In order to prepare healthcare providers to care for adults who might request physician-assisted death, we invited 112 key stakeholders from across California to share their expertise in the areas of ethics, medicine, advocacy, and the law in a statewide conference. Six healthcare professionals and researchers from Oregon and Washington presented their experience with their states' laws, and California healthcare leaders led discussions on a range of topics. The goal of the conference was to identify issues providers and healthcare systems may consider in responding to the law, in order to expand and improve end-of-life care generally. We report major themes identified by participants: (1) All healthcare systems should develop policies that reflect the values of the organization; (2) Institutions must anticipate and address the implications for vulnerable patients, such as older adults, in order to mitigate harm; (3) Institutions should create policies that account for conscientious objection and moral distress among providers; and (4) Palliative care should be an essential part of the response. The process of developing a response to the End of Life Option Act provides healthcare systems the opportunity to reflect on the law's ethical and social implications and thereby implement system-wide changes that can benefit all patients facing the end of life.

VOLUNTEER-PARTNERED END-OF-LIFE CARE: A COMMUNITY INITIATIVE

V. Lou¹, K. Chan¹, A. Chan¹, A. Leung², K. Lam², F. Wong², B. Cheng³, C. Chan¹, 1. *Social Work & Social Administration, The University of Hong Kong, Hong Kong, Hong Kong*, 2. *S.K. H. Holy Carpenter Church, Hong Kong, Hong Kong*, 3. *Tuen Mun Hospital, Hospital Authority, Hong Kong, Hong Kong*

Providing choices on places to be cared during the end stage of life is considered as significant in achieving quality of death. In response to this pressing need, The Hong Kong Jockey Club Charities Trust initiated a Project in which a Volunteer-Partnered End-of-Life Care (VPEoLC) Model was developed to support community-dwelling elders with advance illnesses in Hong Kong. This paper will present a pilot test on the VPEoLC model. The VPEoLC model is developed under a collaborative effort of a social service agency and the palliative care unit of a hospital. It aims to optimize quality of life of dying patients through the seamless collaboration of volunteers, social care team, and hospital. It contains four core elements: 1) regular case review based on feedbacks from a service team with members from hospital palliative team, community social care team, volunteers, and family members; 2) C-I-E volunteer training (Classroom teaching-Internship-experiential training); 3) timely debriefing after each volunteer service; and 24-hours professional support. A pilot test was conducted on 14 elders. A pre-post-follow up design was adopted and participants were assessed on their symptoms, information needs, practical concerns, anxiety or low mood, family anxieties and feeling of being at peace with the Integrated Palliative care Outcome Scale. Data were collected from the clinical records. The pilot test results support the effectiveness of the VPEoLC model in

symptom control and emotional support. Learning from the pilot test will also be discussed.

DEVELOPMENT OF COLLABORATION INDEX BETWEEN NURSES AND CARE WORKERS IN END- OF-LIFE CARE

T. Nagahata¹, K. Eguchi¹, K. Yamaji¹, C. Matsuda³, M. Sasatani², K. Yamauchi¹, 1. *Osaka Prefecture University, Osaka, Japan*, 2. *Aino University, Osaka, Japan*, 3. *Setsuman University, Osaka, Japan*

Purpose: It is predicted that there will be an increasing need for in-house end of life care services at Japan's intensive care homes for the elderly. Therefore, collaboration between nurses and care workers will become essential in order to ensure the quality of nursing care. The purpose of this study is to develop a tool for both nurses and care workers to be used in order to conduct a self-evaluation on how they collaborate with each other.

Method: We conducted a qualitative and inductive analysis of semi-structured interview survey with both nurses and care workers. We then made a list of items as a suggestion for forming a collaboration index for each job. We examined the validity of the content of the suggested items by conducting an anonymous self-written questionnaire among nurses and care workers of intensive care homes for the elderly throughout the country. We considered items with a content validity index (CVI) above 0.8 to be valid, and those below 0.8 to be invalid. Those considered invalid were either deleted or the expression was revised according to the content of the free written comments.

Result: From the result of the analysis of the interview survey, for nurses' collaboration index, we drew out 74 items under 3 concepts. For care workers' collaboration index, we drew out 59 items under 3 concepts. Of the 74 items of nurses' collaboration index, 57 items scored above 0.8 on CVI, and 17 items scored below 0.8 (CVI 0.45 to 0.79), among which 8 items were deleted and 9 items were revised according to the content of the free written comments, finally leaving 66 items on the table. Among the 59 items of care workers' collaboration index, 38 items scored above 0.8 on CVI, and 21 items scored below 0.8 (CVI 0.61 to 0.79), among which 8 items were deleted and 13 items were revised according to the content of the free written comments, finally leaving 51 items on the table.

Conclusion: Based on the interview survey conducted among expert staff of intensive care homes for the elderly, we were able to form collaboration index that systematically organizes the content of collaboration between nurses and care workers.

A RELATIONAL MODEL OF AGING, ILLNESS, AND PALLIATIVE CARE AND ITS APPLICATIONS

M.M. Perkins^{1,2}, M.M. Ball¹, C.L. Kemp³, 1. *Department of Medicine, Emory University School of Medicine, Atlanta, Georgia*, 2. *Birmingham/Atlanta Geriatric Research, Education, and Clinical Center (GRECC), Atlanta, Georgia*, 3. *Gerontology Institute, Georgia State University, Atlanta, Georgia*

Relational perspectives continue to gain prominence in ethics in health and long-term care and in aging research. A key focus of this theoretical approach is the social nature

of personhood, including the ways individuals negotiate their individual and collective identities within interconnecting social, cultural, economic, political, and historic contexts. This approach promotes a critical analysis of and response to conditions at the micro-, meso-, and macro levels that threaten social justice and contribute to limitations imposed by age, disability, and illness. In this paper, we present a multilevel relational model of aging, illness, and palliative care that is derived from a synthesis of our previous empirical and theoretical research conducted over more than two decades in diverse residential care settings for older adults merged with salient concepts from the literature. Important concepts in the model include four intersecting and overlapping forms of “capital” (material, human, social, psychological) that shape older adults’ ability to cope with illness, decline, and other age-related challenges. We posit that these human conditions have both objective (objective conditions of individuals’ lives) and subjective (ways individuals define their situation and ability to cope) properties. We illustrate how the model is used as a guiding conceptual framework to inform research on end-of-life in assisted living (AL) as well as illness experiences outside AL (i.e., different clinic populations’ experiences aging with HIV/AIDS). Our examples highlight how the model can inform the study of illness and end-of-life experiences across care settings and is applicable to both qualitative and quantitative research.

WE’RE MAKING THIS UP AS WE GO ALONG: EARLY PERFORMANCE OF THE MEDICARE CARE CHOICES MODEL

L.F. Ralston, *Department of Health Promotion and Behavior, University of Georgia, Athens, Georgia*

Patients with terminal illnesses often do not take advantage of hospice services. Those who do tend to enter hospice care very near the end of life. The Centers for Medicare and Medicaid Services (CMS) has identified the requirement that hospice patients give up “curative care” as a major barrier preventing early use of hospice. The Medicare Care Choices Model (MCCM) is designed to address this problem by allowing patients with terminal diagnoses to receive hospice care without giving up curative care. Testing of the model began in January 2016 at 70 sites across the US. Almost immediately, conflicts between the model’s eligibility requirements and its aims became apparent. Further problems emerged in the realms of data collection, ordering of medical supplies, and the mismatch between workload and reimbursement. This presentation is based on experiences in the first four months of the MCCM at one of the test sites, Compassionate Care Hospice of Athens, GA, with input from a discussion group created for other participating sites.

FAMILY COMMUNICATION CONCERNING END-OF-LIFE CARE WISHES: A MIXED-METHODS STUDY

L.J. Peterson¹, D.J. Dobbs¹, K. Hyer¹, H. Meng¹, A. Gamaldo², K. O’Neil³, H. Buck⁴, 1. *School of Aging Studies, University of South Florida, Tampa, Florida*, 2. *Pennsylvania State University, University Park, Pennsylvania*, 3. *Ascension Health, St. Louis, Missouri*, 4. *College of Nursing, University of South Florida, Tampa, Florida*

EOL communication involving individuals, families, and health care providers is recognized as critical to reducing unwanted, aggressive end-of-life (EOL) treatment and providing high-quality EOL care. Research, however, has focused largely on doctor-patient communication. This study addressed the topic of individual-to-family communication. It used a mixed-methods design, with questionnaires (N=364) providing the quantitative data and focus groups (7 groups of 5–7 people each) drawn from the quantitative sample providing explanatory qualitative data. The quantitative analysis showed that 31% of the sample had not discussed their (EOL) treatment wishes with family members. In addition, 75% of the sample was female, 25% was Black and 23% was Hispanic. A logistic regression model was used to identify factors associated with whether a family conversation had occurred. We found that controlling for demographics and health, being Hispanic was associated with 67% lower odds of having the conversation (CI 0.13–0.82, p=.02). A lower level of family involvement with everyday health care decision-making was associated with 59% lower odds of having the EOL-care conversation (CI 0.27–0.60, p<.001). Also a low knowledge of palliative care was associated with 59% lower odds of having the conversation (CI 0.21–0.75, p=.004). The qualitative analysis identified several thematic obstacles to holding the conversation, including resistance and separation of family members, beliefs that the conversation is unnecessary, and fears of discussing death, in addition to a lack of awareness of tools to promote EOL-care conversations. Further analysis of these results could lead to the development of interventions to promote family EOL-care conversations.

CERTIFIED NURSING ASSISTANTS’ RESPONSE TO RESIDENT DEATH: POSITIVE AND NEGATIVE EFFECTS OF SUPPORT

H. Gleason, K. Boerner, A. Barooah, *University of Massachusetts Boston, Boston, Massachusetts*

Direct care workers provide the bulk of hands-on care to elders. Though this workforce is integral to the provision of quality long-term care, their role is often overlooked. Certified Nursing Assistants (CNAs), aides who provide care in skilled nursing facilities, work closely with residents, often for years, resulting in strong bonds. Yet, limited research has examined how this may impact their response to a resident’s death. This study conducted comprehensive semi-structured in-person interviews to explore the experiences of 140 CNAs who had lost a resident in their care within the previous two months. Quantitative and qualitative data were examined to determine to what extent CNAs felt there was support available to them, whether they sought out support, the type of support received and desired, and how the support impacted employment outcomes. Results indicated that only one third of CNAs felt there was supervisory support available to them, though over 60% felt they had the support of their coworkers. Only 16% sought support from their supervisor before the death and even fewer, 9%, sought it after. Yet, over half sought support from coworkers. These findings indicate that CNAs are not likely to seek out support from their supervisor but do experience coworker support in the context of resident death. Though perceived as helpful by the CNAs, support from coworkers was found to be positively linked

to burnout and grief suggesting that support from coworkers may not necessarily be protective against the negative impacts of resident death, but instead may increase distress.

OUTCOMES OF ADVANCE DIRECTIVES AND DURABLE POWER OF ATTORNEY AT END-OF-LIFE

D. Hoe, S. Enguidanos, *Gerontology, University of Southern California, Los Angeles, California*

Studies show that individuals at end-of-life (EOL) are more likely to have advance directives (AD) or a durable power of attorney (DPA). However, most of these studies do not investigate the outcomes of decision-making at EOL. This paper examines the association between individuals with ADs and DPAs and the care received by those individuals, and it compares the appointed decision maker to the actual decision maker at EOL. The study will use a nationally representative sample from the Health and Retirement Study (HRS) Core and Exit interviews conducted between 2008 and 2014, and it will compare its findings to those of Silveira, Kim & Langa (2010).

Analysis was conducted on data compiled from 5,000 participants age 60 and older and from proxies following participant death. 45.8% of decedents required decision-making, of whom 69.3% lacked decision-making capacity. About half (51.0%) of these decedents had advance directives and 68.3% had a DPA. However, there was only 15.1% agreement between the appointed decision maker and the actual decision maker. Logistic regression revealed that participant preferences for prolonged care (OR=12.64) and limited care (OR=2.63) were consistent with the care they received. Participants who elected comfort care were more likely to receive limited care.

These findings are consistent with those of Silveira, Kim & Langa (2010), who examined the HRS interviews conducted between 2000 and 2006, and thus further supports AD. More research is needed to understand the incongruence between appointed and actual decision makers at EOL.

ADVANCE CARE PLANNING IN GERIATRIC PRACTICE: A MONTEFIORE MEDICAL CENTER QUALITY IMPROVEMENT STUDY

D.F. Greenberg¹, H. Blumen^{1,2}, M. Ceide¹, R. Marx³, 1. *Montefiore Medical Center, Bronx, New York*, 2. *Albert Einstein College of Medicine, Bronx, New York*, 3. *University of Pennsylvania, Philadelphia, Pennsylvania*

In 2016, The Division of Geriatrics of Montefiore Medical Center received a grant through the New York Foundation for Elder Care to train primary care providers (PCP) in advance care planning (ACP) skills including: the explanation of prognosis and treatment options, clarification of the older adult's wishes, and the utilization of the new Medicare reimbursement code for advance care planning. A teaching module directed to the PCP was designed as a multidisciplinary consultation service using actual clinical cases presented by providers. Training in advanced care planning by the Geriatrics faculty was offered at the PCP sites. After initial implementation of this module, a quality improvement project conducted in the Division of Geriatrics during June 2016 through a chart review (n=101) examined the documentation of advance care planning discussions by

the geriatrics faculty at its Geriatric Ambulatory Practice. Demographic data included age (M age=82), gender (75%=women), ethnicity (42%=Latino), preferred language (77%=English) and cognitive impairment (42%). The rate of documented advance care plans (32%) was analyzed. Results reinforced the need for training of geriatricians in ACP as well. Limitations include recent transition to a new electronic medical record, which complicated documentation; whereas 49% of patients reviewed had ACP on file in the previous EMR, only 32% had such documentation in the new EMR. The teaching module was modified based on the study's findings to both improve the skills of attending physicians, fellows, and residents and to improve ACP conversations and documentation rates.

EFFECTS OF AN ADVANCE CARE PLANNING EDUCATIONAL PROGRAM FOR CARE STAFF IN AN ACUTE HOSPITAL

M. Hamayoshi¹, S. Goto¹, C. Matsuoka¹, K. Miwa³, A. Kono², M. Ikenaga³, 1. *Bukkyo University, Kyoto, Japan*, 2. *Osaka City University, Osaka, Japan*, 3. *Yodogawa Christian Hospital, Osaka, Japan*

Purpose: Advance Care Planning (ACP) is a crucial end-of-life care practice. However, an ACP educational program for care staff in an acute care setting has not yet been established.

The present study aimed to examine the effects of an ACP educational program in this clinical context.

Method: The design was a single-arm study to evaluate staff attitudes pre-and post-program. A 90-minute intervention program was attended three times, along with self-directed study. The study outcomes included attitudes towards Advance Directives (AD), the Death Attitude Inventory (DAI), and the Frommelt Attitude Toward Care of Dying scale (FATCOD-Form B-J).

Result: A total of 57 care staff participated in the entire program (average age was 44.6 years old (SD 7.8); 11 men). The most common occupational description was nurse (n=37). The scores on the attitudes towards AD scale increased from 9.96 (SD 1.0) to 10.3 (SD 0.9), which reached statistical significance (P=0.03). The score for 'death relief' in the DAI increased from 13.9 (SD 0.9) to 15.3 (SD 5.9), also P=0.03. The score for 'positive attitude for end of life care' in the FATCOD-Form B-J scale increased from 9.0 (SD 1.6) to 9.8 (SD 2.0), with P=0.01.

Conclusion: These results suggest that the present ACP educational program was effective at improving staff attitudes relating to three key domains: attitudes towards AD, death, and the care of terminally ill patients.

REDUCING EMERGENCY ROOM VISITS AND HOSPITAL DEATHS AT END-OF-LIFE FOR LONG-TERM CARE RESIDENTS

S. Kaasalainen¹, T. Sussman², P. Durepos¹, J. Ploeg¹, L. Venturato³, L. McCleary⁴, P.V. Hunter⁵, 1. *McMaster University, Hamilton, Ontario, Canada*, 2. *McGill University, Montreal, Quebec, Canada*, 3. *University of Calgary, Calgary, Alberta, Canada*, 4. *Brock University, St Catharines, Ontario, Canada*, 5. *University of Saskatchewan, Saskatoon, Saskatchewan, Canada*

Burdensome interventions and hospital use can negatively affect the quality of end-of-life (EOL) for long-term-care (LTC) residents and their families. The goal of this study was to examine Emergency Department (ED) use at EOL and hospital deaths for LTC residents, and explore with LTC staff ways to minimize hospital use.

This study used a mixed methods approach. Chart audits were conducted in four LTC homes in southern Ontario to capture trends in hospital use over a one-year period for the following indicators: (1) resident deaths at hospital versus LTC home; (2) ED visit in the last year, month, and week of life; (3) average number of ED visits/resident; (4) planned versus unplanned ED visits; (5) ED visits that became hospital admissions. These chart audit findings were presented to staff to raise awareness and stimulate reflections on local factors affecting hospital use at EOL. All deliberations were transcribed and thematically analyzed.

Chart audits revealed that 59% of residents across sites visited ED during the last month of life and 26% of resident deaths occurred in hospital. Staff expressed surprise at the amount of hospital use during EOL. Reflections suggested that clinical expertise, comfort with EOL communication, clinical resources and family availability for EOL decision-making could all impact non-desirable hospital use at EOL. Staff appeared motivated to address these areas of practice following this reflective process.

Localized chart data combined with group reflective opportunities can serve to raise awareness and engage staff in collective solutions to address hospital use at EOL.

SESSION 990 (POSTER)

END-OF-LIFE TREATMENTS AND SETTINGS

TRADITIONS, CHALLENGES, AND ADAPTATIONS: THE HMONG COMMUNITY'S END-OF-LIFE EXPERIENCE IN THE U.S.

Y. Her, T. Schroepfer, *University of Wisconsin, Madison, Wisconsin*

It has been over forty years since the first Hmong refugees arrived in the United States, and as the generations have sought to adjust to a new way of life, many elders have continued to honor their traditional healthcare beliefs and rituals concerning care at end of life. With much known about beliefs and rituals after death occurs, little is known about those practiced in the dying process. Studies have found evidence that lacking such information has resulted in misunderstandings and barriers between the Hmong and their health care professionals, who struggle to provide the Hmong with culturally competent care. This study sought to address this gap by conducting in-depth face-to-face interviews with 20 Hmong elders born in Southeast Asia, who are now living in the United States. The rich qualitative data provided by these elders was analyzed using conventional content analysis to identify and categorize the main themes. The results provide information regarding traditional beliefs and rituals surrounding end of life care, the challenges faced by the Hmong when seeking to practice these traditions, and adaptations made by some Hmong elders to integrate both

western and traditional medicines. In addition, insights were gained regarding the heterogeneity among Hmong elders due to those who have converted to Christianity and those who have chosen to remain steadfastly committed to their traditional practices. Implications for healthcare professionals and facilities seeking to provide culturally sensitive care to Hmong elders at end of life will be discussed.

DEVELOPING EXPERTISE IN END-OF-LIFE CARE THROUGH COLLABORATIVE REFLECTION: A QUALITATIVE INQUIRY

Y. Harasawa¹, R. Hirayama², C. Shimada², M. Ito², 1. *School of Nursing Graduate School of Nursing, Nagoya City University, Nagoya, Japan*, 2. *Tokyo Metropolitan Institute of Gerontology, Tokyo, Japan*

In Japan, with a steady increase in older adults who spend their final days in non-medical facilities such as nursing homes, staff members of such facilities are increasingly required to become prepared for end-of-life caregiving to older residents. Because of greater individual differences in terminal processes, however, there is no universal approach to older residents in an end-of-life phase; thus, it is necessary for staff members to accumulate practical knowledge to handle individualized cases through reflecting on and learning from their end-of-life care experiences. To provide staff members with the opportunity for such learning, we have developed *Collaborative Reflection Program*, where participants discuss their care experiences while giving feedback to each other. Guided by Korthagen's (1985) reflection model, namely ALACT, we sought to identify whether and how such learning process might occur among *Program* participants. To do so, we used audio-recorded data from multiple groups in which care workers and nurses from different nursing homes participated and, in line with the *Program* format, conversed on their end-of-life care experiences. Through systematic content analysis on transcripts of audio-recorded data, we found participants' narratives that represented two components of ALACT model: *awareness of essential aspects of experiences* and *creating alternative methods of actions*. Our findings indicated that the *Program* helped participants to reflect on and gain a new insight into their care experiences, suggesting the potential of the *Program* as a method for staff members of nursing homes to develop expertise in end-of-life care.

FACTORS AFFECTING KOREAN OLDER ADULTS' WILLINGNESS TO RECEIVE LIFE-SUSTAINING TREATMENTS

H. Noh, Y. Guo, G. Kim, *The University of Alabama, Tuscaloosa, Alabama*

Being one of the fastest aging countries, Korea is faced with various end-of-life (EOL) issues. However, little is known about what affects older adults' views toward EOL options, such as use of life-sustaining treatments (LSTs). To address the gap, this study aimed to examine the relationship between attitude toward LSTs and background characteristics among older adults in South Korea. Using a national survey data of 10,267 older adults, binomial logistic regression analysis was conducted to examine the likelihood of willingness to receive LSTs with background characteristics.

The correlations ($.02 \leq r \leq .04$) and tolerance statistics ($\geq .40$) were checked during preliminary analysis. Though very few participants (4%) agreed to receive LSTs, some significant relationships were found: those who were female (OR=.24, $p=.03$) and older (OR = .02, $p = .00$) and had higher geriatric depression score (OR = .05, $p = .02$) and more close friends and neighbors to talk openly with (OR= .08, $p = .00$) were more likely to agree to receive LSTs. However, those having any religion (OR= -.19, $p = .03$) were less likely to do so. This result suggests that religion in Korean culture may play a role in older adults' preference for LSTs and may provide a buffering effect against the pursuit of aggressive treatments. Our society should recognize the potential burden of LSTs among Korean older adults and should consider factors, such as gender, age, mental health, and social relationship, in EOL discussion about LSTs and alternative EOL care options.

INCREASING HOSPICE UTILIZATION IN THE PENSACOLA AREA: POTENTIAL MEDICARE SAVINGS

D.W. Durkin^{1,3}, A. Bolden³, 1. *Social Work, University of West Florida, Pensacola, Florida*, 3. *Center on Aging, Pensacola, Florida*, 3. *School of Social Work, University of Pittsburgh, Pittsburgh, Pennsylvania*

Research shows that older adults receive higher quality care under Hospice care compared to hospitalization or nursing home care and this care is also considerably less expensive. For example, the costs for hospital care, nursing home care, and Hospice care per day are \$6,200, \$620, and \$153 respectively. Despite the benefits in quality and cost, Hospice utilization rates at the end of life continue to be problematic. In addition, of those who use Hospice, 35% are enrolled for less than a week despite eligibility of up to 6 months.

Using 2010 Medicare data obtained from The Dartmouth Atlas of Health Care we found that the Hospice utilization rate for the Pensacola area during the last 6 months of life was 57% and that these patients were enrolled for an average of 27 days. The average Medicare expenditure in the 6 months prior to death was \$32,330.

Based on this information, we formulated the following research question: How much cost savings would there be if the Pensacola area increased the Hospice utilization rate by 5% and 10% respectively? If the utilization rate was increased by 5%, Medicare expenditures would decrease by \$1,616 per person. If the utilization rate was increased by 10%, Medicare expenditures would decrease by \$3,233 per person.

These findings suggest that even modest increases in the Hospice utilization rate would lead to significant cost savings for the Medicare program. In addition, these patients would receive higher quality care and most would be cared for in their home.

REASONS FOR JOINING A RIGHT-TO-DIE SOCIETY: DIFFERENCES DEPENDING BY ON THE CHARACTERISTICS OF MEMBERS

S. Cavalli¹, S. Beltrami¹, M. Pott², L. Stauffer², 1. *Centre of Competence on Aging, University of Applied Sciences and Arts of Southern Switzerland (SUPSI), Manno, Switzerland*, 2. *HESAV - University of Applied Sciences and Arts of Western Switzerland (HES-SO), Lausanne, Switzerland*

Right-to-die societies are becoming increasingly popular in Switzerland as in other countries. Members are more likely to be female, older, and better educated than the general population. However research has paid limited attention to personal reasons and motivations for joining.

This communication reports a survey of the membership of a Swiss right-to-society – EXIT A.D.M.D. Suisse romande. A self-administered questionnaire was sent by mail to a random sample of members aged of 65 years old and more. The answers of approximately 1,200 participants (about 30% response rate) provide insight into reasons that had led to a decision to join.

Motives for membership included the concerns related to their own end-of-life (*anticipation*), the commitment to right-to-die philosophy (*ideology*), and the past involvement with serious illness or deaths of loved ones (*experience*). Reasons for joining vary according to the characteristics of the members. For instance, women mention more personal experiences than men (because they are more likely to live critical events and play more often the role of caregiver); people with a high level of education, and the non-religious, have more resort to ideological motivations.

The combined analysis of the current age of the members and the length of membership in the society allows identifying different profiles. The “early joiners”, regardless of their current age, say more often to have adhered for ideological reasons. Among the most recent members, the older (75+) reported mainly concerns related to the end-of-life, while the youngest (65–74) cited more personal experiences.

“WHEN I SAID I WANTED TO DIE AT HOME, I DIDN'T MEAN A NURSING HOME”: END-OF-LIFE CARE TRAJECTORIES

M.J. Penning, D.S. Cloutier Fisher, *Sociology, University of Victoria, Victoria, British Columbia, Canada*

Given concerns around population aging and future health care costs, issues around end-of-life care have attracted increasing attention in recent years. Although the focus tends to be on reducing hospital deaths and increasing those that take place in people's own homes, many older adults end their lives in nursing home care. Yet, little is known regarding the pathways that lead older adults to end their lives in these settings, nor the factors that influence them. This study draws on a structural life course perspective and administrative data to examine the long-term care (LTC) trajectories experienced by older adults who end their lives in nursing home care (NH) and compare them to those of LTC recipients who end their lives in home and community-based care (HCC) or hospital care (HC) settings. The overall sequencing of care transitions is considered along with the role of social structural factors, social and economic resources, and health factors in influencing them. Data were obtained from client assessments on individuals aged 65+ who received publicly-subsidized LTC services in one Canadian health region and who died between April 1, 2008 and December 31, 2012 ($n=13,466$). Only 10.2% of clients died at home in the community. Most died in NH settings (56.5%) or in hospital following a transfer from NH (12.0%) care. Just over one-fifth (20.9%) died in hospital following a transfer from HCC. Multinomial logistic regression analyses reveal the importance of social structural factors, social and economic

resources, and health factors in shaping these trajectories. These findings support the utility of a structural life course perspective and suggest avenues for enhancing equitable and desirable end-of-life care.

ASSESSING PALLIATIVE CARE DELIVERY IN A NEURO ICU: PREDICTING END-OF-LIFE EXPERTISE

E. Mroz, S.B. Bluck, J. Baron-Lee, *University of Florida, Gainesville, Florida*

This study assesses palliative care implementation in the Neuro ICU of a large medical center. The expectation of death at admission is high, making comprehensive palliative care vital. The aim was to examine how providers' views of palliative care are related to their end-of-life (EOL) expertise. Forty-one providers responded to 25 questions (Likert-type scales) concerning their views of palliative care delivery. EOL expertise (e.g., ethical issues, clear definition of palliative care, avoiding futile care) was also assessed. Exploratory factor analysis of views of care delivery (Varimax rotation, 44.26% variance explained) resulted in three factors reflective of increasing levels of palliative care provision: initiating the process, providing basic comfort-care, and delivering holistic care. Linear regression analyses used these three factors to predict EOL expertise. Endorsing Delivery of Holistic Care predicts the use of ethics consults to aid complex care decisions ($B = .96, p = .001$) and avoidance of administering futile care ($B = .68, p = .05$). Endorsing Provision of Basic Comfort Care predicts greater previous palliative care involvement ($B = 1.23, p = .008$). Endorsing Initiation of the Process predicts having a more comprehensive definition of palliative care ($B = 2.34, p = .005$) and of Advance Directives ($B = 1.23, p = .013$). Results suggest that different ways of viewing palliative care exist even within a single unit and that these views are related to providers' expertise in dealing with ethical issues, end of life planning, and delivery of care.

PILOTING WEB-BASED INTERVENTIONS TO IMPROVE KNOWLEDGE OF PALLIATIVE CARE

E. Kozlov^{1,2}, B.D. Carpenter², 1. *Geriatrics and Palliative Care, Weill Cornell Medical College, NY, New York*, 2. *Washington University in St. Louis, St. Louis, Missouri*

Introduction: Palliative care is a team-based, specialty service that improves the quality of life for individuals with serious illness and their families. However, current research suggests that this life-improving service is drastically underutilized. Patient knowledge of a healthcare service is theorized to drive utilization. If people do not know what palliative care is, they cannot be expected to seek out or accept a referral for the service.

Objectives: The purpose of this study was to pilot an intervention to improve knowledge of palliative care for the general population.

Methods: Using a 2 (content) X 2 (format) between-subjects design, an age-stratified, web-based sample of 229 adults were recruited and randomized into four conditions: intervention video, intervention information page, control video and control information page. Palliative care knowledge was assessed using the Palliative Care Knowledge Scale (PaCKS), a 13-item true/false scale with strong psychometric properties. Data analysis utilized an ANCOVA with contrast

coding for two factors: intervention vs. control (intervention $n = 77$, control $n = 75$) and information page intervention vs. video intervention (reading $n = 43$, video $n = 34$).

Results: There was a significant difference between intervention group means at post-test ($M = 12.15, SD = 1.77$) and control group means ($M = 11.18, SD = 2.34$); $F(1, 139) = 11.10, p = .00, h_p^2 = .074$. There was no significant difference between the video intervention ($M = 12.00, SD = 1.97$) and the intervention page ($M = 12.29, SD = 1.61$); $F(1, 67) = .011, p = .92$.

Conclusions: This randomized control trial demonstrates that both educational videos and text-based interventions increase knowledge about palliative care services in the general population.

INTEGRATIVE AND HOLISTIC END-OF-LIFE CARE: INSIGHTS FROM A COMMUNITY-WIDE SURVEY IN CHINESE SOCIETY

C. Fong, A. Chow, C. Chan, *Department of Social Work, The University of Hong Kong, Hong Kong, Hong Kong*

Every year, there are over 40000 deaths in Hong Kong, affecting over 240000 individuals in the illness process and bereavement. Current end-of-life care (EoLC), which is mainly provided by health care settings, will fall short in meeting the growing demand. The World Health Assembly urged for international actions in strengthening interfaces between health care and social care settings. The Hong Kong Jockey Club Charities Trust initiated an EoLC project in response to the emerging needs, with this survey to understand the needs of the community.

A randomly drawn sample of household was invited to join telephone survey, and 1600 (62%) completed the study. The findings have four key points. Firstly, public knowledge of EoLC concept is limited. Only around 30% of participants ever heard of palliative care and EoLC. Advance directives were known to 13.4%. Secondly, EoLC is considered as a multi-dimensional care. Psychosocial care (30.4%) and spiritual care (14.7%) were the first and second most common content perceived by the participants. Thirdly, the location of EoLC provision is not restricted to hospitals (86.4%) but also social service centers (72.9%), residential homes (72.1%) and home (54.6%). Lastly, the primary wish in the last six months of life is found to be family-related. Nearly one in five responded that having good memories with family and friends was their first wish.

The findings suggest expansion of current care in time, content, location and unit of care. Public education, bio-psycho-social-spiritual model, hospital-community partnership and family-centered care are all the possible future directions.

PHYSICIANS' PERSPECTIVE: END-OF-LIFE CARE TREATMENT FOR OLDER ADULTS IN ALLAHABAD, INDIA

R. Gupta¹, V. Pillai², 1. *San Francisco State University, San Francisco, California*, 2. *University of Texas at Arlington, Arlington, Texas*

With globalization and shifts in cultural norms it becomes increasingly important to examine physician's role at end-of-life care of elderly (Marjolein, et al, 2012). The purpose of this qualitative study was to examine the practices and attitudes of physicians in Allahabad regarding EoL care. EoL

decision-making in India involves the mechanisms by which family members and physicians make decisions about care of elderly. Eol decision-making is challenging as it requires understanding of technical information regarding the use of life-sustaining treatments. Earlier research shows that in Asian countries it is against the cultural norms to disclose life threatening illness to the elderly, and this can cause conflict between the norms prevailing in the medical profession on the one hand and physicians' and families actual practices (Schaffer, 2007). Research in the US shows that a large number of physicians were not adequately trained in Eol care. There is dearth of research on Eol care in India. Thirty four in depth interviews on physicians were conducted. Transcribed data was translated from Hindi to English. Two researchers read the transcripts and found four major themes. 1) Eol decisions for elderly are made by family, along with physicians; 2) Prolonged unnecessary health care treatment for elderly was found among higher income groups, while neglect was common among lower class; 3) Few physicians in Allahabad were trained in geriatric care; 4) Risk of elder abuse at Eol is common, as elder's wishes are not discussed. Hospice and social workers need to be available for elderly in hospitals and at home.

EXPLORING SURROGATES' EXPERIENCES OF POLST DISCUSSIONS FOR INDIVIDUALS WITH ADVANCED DEMENTIA

H. Kim¹, C.K. Bradway¹, S. Hickman², M.T. Ersek¹, 1. *University of Pennsylvania, Philadelphia, Pennsylvania*, 2. *Indiana University-Purdue University, Indianapolis, Indiana*

The Physician Orders for Life Sustaining treatment (POLST) is a program to communicate and document patient treatment preferences as medical orders. It is often used for older adults with life-limiting illnesses including dementia. For individuals with advanced dementia, POLST is commonly discussed between surrogate decision makers (SDMs) and providers. However, information about SDMs' experiences of POLST discussions is lacking. Semi-structured interviews were conducted with family SDMs of older adults with advanced dementia following POLST discussions with providers. Interviews were analyzed using directed content analysis, and informed by three key concepts from the Communication and Surrogate Decision Making framework. Facilitators to effective communication and decision making included: SDMs' familiarity with end-of-life situations; providers' caring attitude and knowledge about the person and SDMs; SDMs' understanding of dementia as a terminal illness and knowledge about the person's wishes. Challenges included: unfamiliarity with medical terms and uncertainty about the best decisions for the person. Findings suggest that SDMs process information related to end-of-life care choices based on their previous experiences with healthcare situations and appreciate healthcare providers' attention to their and their loved ones' needs. SDMs' understanding of dementia influences the quality of medical decisions, and as a result, may impact quality of life for older adults with advanced dementia and their SDMs. Findings also highlight the importance of high quality communication between providers and SDMs. Future studies should address improved education for SDMs and clinicians to promote effective communication and improve end-of-life care planning.

COMPARING MEDICARE UTILIZATION PRE- AND POST-HOSPICE ADMISSION ACROSS PRIMARY HOSPICE DIAGNOSES

T. Christian¹, J.M. Teno³, P. Gozalo², M. Plotzke¹, 1. *Abt Associates, Cambridge, Massachusetts*, 2. *Brown University, Providence, Rhode Island*, 3. *University of Washington, Seattle, Washington*

We compare daily estimates of total Medicare utilization immediately prior to hospice admission with per diem payments during hospice election across common hospice principle diagnoses. We used Medicare Part A, B, and D claims to estimate average daily total Medicare utilization in the 180, 90, and 30 days prior to hospice admission. In the 180 days prior to hospice admission, median daily estimates of total Medicare utilization ranged from \$66.84 (Alzheimer's, Dementia, and Parkinson's) to \$217.46 (Chronic Kidney Disease); national average \$117.73. In the 30 days prior to hospice admission, median daily Medicare utilization ranged from \$105.24 (Alzheimer's, Dementia, and Parkinson's) to \$466.25 (Chronic Kidney Disease); national average \$266.84. Among all diagnoses, the median daily estimates of pre-hospice Medicare utilization for Alzheimer's, Dementia, and Parkinson's hospice admissions were consistently below the 2013 routine home care per diem rate of \$153.45. Average lifetime hospice utilization ranged from 27.3 days (Chronic Kidney Disease) to 119.3 days (Alzheimer's, Dementia, and Parkinson's); national average 73.8 days. Relatively little was known about how pre-hospice Medicare utilization compares to spending after hospice election. At present, no case-mix system exists in the Medicare hospice benefit to differentiate payments among patients. Additional analysis is needed to understand if hospice patients with differing characteristics (e.g., diagnoses) require different resource needs and if hospice payments are appropriately aligned with those requirements.

THE ROLE OF CARE HOMES IN PALLIATIVE AND END-OF-LIFE CARE

M.L. Johnson, *School for Policy Studies, University of Bristol, Bristol, United Kingdom*

Older people have been living and dying in Care Homes for many decades. But as life expectancy has extended and those who live longer lives do so largely in functional good health for much longer, the demography and epidemiology of dying and death have changed

dramatically. The latest available UK data for 2014 provide strong evidence of the rising numbers of old age deaths in Care Homes and previously unavailable material on the causes of those deaths. There emerges a new and important picture, which should be brought to bear in discussions about policies for end of life care. This presentation presents findings from an enquiry commissioned by Public Health England. It reveals distinctive patterns of multiple co-morbidities now bundled together as frailty, which require revised patterns of end of life care that rely more on sustained support rather than elaborate palliation.

EVALUATING COMMUNITY END-OF-LIFE CARE MODELS FOR OLDER PEOPLE WITH ADVANCED ILLNESSES IN HONG KONG

K. Chan, A. Chow, C. Chan, V. Lou, *The University of Hong Kong, Hong Kong, Hong Kong*

In Hong Kong, older non-cancer and cancer patients found to have 2.3 and 1.6 comorbid diseases respectively. Older patients, frequently suffer from chronic debilitating diseases, multiple disabilities, and distressing symptoms, need a holistic EoLC to meet the complex emerging needs. A 3-year project has been initiated by the Hong Kong Jockey Club Charities Trust to increase community engagement in EoLC by developing evidence-based community EoLC models for older adults in Hong Kong.

This presentation will describe five different models of community EoLC programme introduced by non-profit social service agencies in Hong Kong and the evaluation of these models. All organizations collaborated with hospital partners to provide community-based EoLC to families with older people with advance illnesses, with unique foci. While emphasizing the partnerships with health care system, these social care units strengthen the psychosocial care in the community. Models include volunteer-based model, assisted family-care model, non-cancer model, community-care model and residential home care model. A standardized comprehensive outcome and impact evaluation are carried out. Adopting mixed methods, assessments with older adults, family caregivers, and volunteers are implemented through pre-post-followup questionnaires as well as post-service qualitative interviews. Changes in symptoms, mental health, caregiving burden, quality of life, general health and complicated grief are assessed. Volunteer's changes in life satisfaction and life meaning are also appraised. Clinical data mining approach is adopted to analyze the impact as well.

NURSE-LED ADVANCE CARE PLANNING IN PRIMARY CARE FOR OLDER ADULTS WITH MULTIPLE CHRONIC CONDITIONS

D.E. Holland, C. Vanderboom, A.M. Dose, C. Ingram,
Mayo Clinic, Rochester, Minnesota

Advance care planning (ACP) can ensure people receive the care they value and prefer when they cannot speak for themselves, yet ACP participation is low. There is a need to identify an approach to the ACP process that promotes participation in high-quality ACP. Utilizing primary care nurses is one ACP engagement approach. Our pilot study sought to determine the feasibility and acceptability of ACP in primary care by nurses with older adults with multiple chronic conditions. The intervention involved two sessions between the nurse and patient that lasted approximately one hour each. Between the two sessions patients were requested to discuss their values, life goals and treatment preferences with family members. Patients completed the ACP Engagement Survey before and after the intervention. Individual interviews were also conducted with the patients and nurses. The majority of patients invited to participate agreed (41/67; 61%). The average participant was 66.2 years old with 9.6 diagnoses. The majority (61%) were female and White/non-Hispanic (98%). All but one of the 41 completed the intervention. Both process and behavior scores on the ACP Engagement Survey improved. Patients and nurse interviews indicated that they were satisfied with the intervention. Thirty-six of the 41 subjects (87.8%) completed an Advance Directive; all 41 identified a healthcare proxy decision maker. ACP conversations between nurses and patients in primary care are feasible and acceptable. Further study is warranted and would

benefit by exploring the early impact of ACP conversations on subsequent treatment decisions made by older adults with multiple chronic conditions.

SESSION 995 (POSTER)

ENVIRONMENT AND COMMUNITY INTEGRATION

CAN 'SOCIAL PRESCRIBING' HELP ADULTS WITH LONG-TERM HEALTH PROBLEMS TO AGE WELL?

S. Moffatt, M. Steer, S. Lawson, L. Penn, *Newcastle University, Newcastle upon Tyne, United Kingdom*

Social prescribing is the use of non-medical interventions to achieve sustained lifestyle change and improved self-care among people with long-term health conditions. Service users are supported to live healthier and more fulfilling lives, learn to manage their long term conditions and reduce health care dependency. Ways to Wellness (WtW, <http://waystowellness.org.uk/>) is the first UK organisation to deliver social prescribing at scale, serving an urban area with some of the most socio-economically deprived constituencies in England. The social prescribing model comprises referral to a 'Link Worker' trained in behaviour change methods who offers a holistic and personalised service to identify meaningful health and wellness goals, as well as connecting service users to community and voluntary groups and resources. Qualitative interviews were undertaken with 30 service users aged 40–74 with chronic and multiple long term conditions, and repeated again at 6 months. Service users reported many positive changes: improved physical activity, weight loss, reduced social isolation, improved mental health, and better long term condition management. After six months many difficulties in maintaining positive health-related changes were identified, yet largely overcome. Key elements of the success of this programme were the ongoing and personalised approach and the nature of the relationship with the 'Link Worker' in combination with actively engaging service users with community organisations. This 'dual' approach to ageing well with long term conditions recognises the need for individual change but through its community based approach, also addresses many of the deep-rooted social and economic barriers which compound long term health problems.

COMMUNITY DIAGNOSIS WITH LOCAL VOLUNTEERS AND CARE PROFESSIONALS IN AGE-FRIENDLY CITY INITIATIVES

A. Kono¹, N. Yoshiyuki¹, Y. Kanaya¹, T. Soga², 1. *Department of Home Health Nursing, Osaka City University, Osaka, Osaka, Japan, 2. Izumiotsu Community-based Integrated Center, Izumiotsu, Osaka, Japan*

Frail older adults can continue to live independently at home in cities that are age-friendly. The purpose of the present participatory action research is to identify the core concerns for building an age friendly city through community diagnosis involving volunteers and professionals, utilizing photovoice and surveys. The surveys were conducted previously and investigated the care needs of 710 frail older adults living in Izumiotsu City, Japan. The study

aftermath of disaster and IPV. The risk and resilience ecological framework guided the study (Corcoran and Nichols-Casebolt, 2004).

Data was derived from Gulf States Population Survey. The sample included 2,657 survivors of IPV. The design was a comparative design, Individual resilience the outcome variable, was operationalized using the Pearlin Mastery Scale (Pearlin et al., 1981).

A hierarchical multiple regression analysis indicated that risk factors explained 7% of variance in individual resilience, ($F(4,2657) = 120.24, p < .0001$). Protective factors explained an additional 12% of variance in individual resilience ($F(8, 2655) = 138.24, p < .0001$) above and beyond the variance explained by and accounted for by risk factors.

This study identified predictors of resilience among older adult survivors of IPV exposed to the *Deepwater Horizon* disaster. Results suggest the importance of providing specialized training to practitioners involved in postdisaster IPV victim assistance. Given the complexity of IPV within a post-disaster context, attention should be directed at both identifying and meeting the immediate postdisaster needs of older adult IPV victims.

PREDICTORS OF INDIVIDUAL RESILIENCY AMONG INDIVIDUALS AGE 65 AND OLDER IN POST-DISASTER SETTINGS

J. Liddell, R. Ferreira, *City Cultural and Community Interdisciplinary PhD Program, Tulane University, New Orleans, Louisiana*

Older individuals are especially vulnerable following disasters such as the BP Oil Spill, in large part due to social vulnerability factors such as economic constraints, health problems, and susceptibility to domestic violence. An investigation was undertaken to determine the unique resilience predictors associated amongst older adults (65 years and older) exposed to disaster. This research adapts disaster resilience conceptual models to investigate resilience and expands these models by investigating differences in age and by exploring how equitable and inequitable variables account for variation in resiliency scores.

Data was derived from the Gulf States Population Survey (GSPS). The final sample included 5,713 residents from 4 gulf-coast states. A total of 25 communities exposed to the BP Oil Spill were included. Resilience was defined by the Pearlin Mastery Scale. The study was a multilevel, repeated cross-sectional design with a three-level nested structure. A nonlinear analysis was done using an ordered multinomial response model with a log-link function and empirical Bayes Markov chain Monte Carlo estimation.

The results of the model testing clearly indicated inequitable disaster mitigation, with the social resilience, individual economic resilience and contextual economic resilience indicators explaining most variance in individual resilience. In all models, age was negatively associated with resiliency. Being female was protective across all models. The results of the model testing indicate inequitable disaster mitigation, with social and health, indicators explaining the most variance in individual resilience levels. An investment of resources is needed for older adults in post-disaster contexts.

A STUDY OF DISASTER SAFETY OF RESIDENTIAL WELFARE FACILITIES FOR THE ELDERLY

J. Jang, Y. Song, Y. Choi, S. Kim, S. Kweon, B. Park, W. Lee, *Busan National University, Busan, Korea (the Republic of)*

Design

In Korea, various kinds of residential welfare facilities for the elderly started to spring up everywhere after the 'Act on Long-term Care Insurance For Senior Citizens' had been newly enacted in July 2008. However, since the locations of such kinds of residential welfare facilities for the elderly are mostly located near the nature rather than places that can be easily accessed by the elderly, there have been often the cases that it is hard to respond to some kinds of disasters from the beginning. Especially, there have been many times of fires related to such facilities in Korea as well as with many number of the dead and the injured and huge amount of property damage. However, a method for taking measures for some disaster safety covering the whole area of such welfare facilities which have been sprout up everywhere.

Regarding to the disaster safety of the housing welfare facilities for the elderly, it is very important for preparing for the safety measures for the relevant space. In addition, it is necessary to consider the physical, psychological and social characteristics of the elderly as well as the characteristics of the relevant space when a disaster occurs. Therefore, in this study, it is intended to analyze on what kinds of effects the environment of the housing welfare facilities for the elderly and the physical, psychological and social characteristics of the elderly influence in case that a disaster occurs to the housing welfare facilities for the elderly while analyzing the elderly who live in various kinds of housing welfare facilities for the elderly (Facilities for the Aged, Group Homes for the Elderly and Welfare Housing for the Elderly) in Korea.

Method

The survey targets are 3 kinds of facilities, such as, the facilities for the elderly, Group Homes for the Elderly and Welfare Housing for the Elderly and the aged who live in such facilities. And the survey will be conducted for comprehending the physical, psychological and social characteristics of the elderly and the levels of the environments of such facilities compared to the accidents generated. The collected data shall be used for conducting a regression analysis using SPSS 22.0 in order to comprehend the relationship between the characteristics and the environments and what kinds of effects are influenced on the safety in case of a disaster.

EMERGENCY PREPAREDNESS IN COMMUNITY-BASED LONG-TERM CARE IN SOUTH CAROLINA AND ITS GLOBAL IMPLICATIONS

M.D. Bremseth¹, R.K. Green¹, S. Wright¹, R. Smith², 1. *Office of Human Services Research and Organizational Development, Clemson University, Knoxville, Tennessee*, 2. *South Carolina Department of Health & Human Services, Columbia, South Carolina*

The study examined the experiences of those served in community based long term care in South Carolina and their awareness of services available to them should they experience a critical incident, it explored to what extent are case managers informed consumers about these services and completed a plan with the participant in the event that he/she

may encounter such a situation, it looked at the participant's responses compared to a 2012 study and then gathered qualitative data the experiences with the recent flooding in South Carolina. Samples of 380 respondents in this population were surveyed by telephone.

The results indicated in the case of the latest emergency (major flooding) the majority were contacted by their case managers as the emergency was developing. 98% had access to TV, 77% cell phone, 71% the internet, and 68% the radio. 60% had an emergency safety plan in place, which included having a "go bag" with copies of medical records and financial records. 70% had a transportation plan in place. For those who are forced to stay in place 90% had extra medications, 80% extra food and 70% extra water. On the other hand there were problems with lack of backup heat, and battery power for communication devices. Comparing these findings to the earlier survey there was evidence of some major improvements in the preparedness of this population but still indicated areas that needed to be worked on. There may be well lessons to be learned that have global implications.

RELATIONSHIPS WITH PLACES: AN ETHNOGRAPHIC STUDY OF OLDER ADULTS IN DETROIT NEIGHBORHOODS

W.D. Bartlo, *Center on Health, Aging, and Disability, University of Illinois, Champaign, Illinois*

This seeks to extend psychosocial research that focuses primarily on counting number of connections and relationships with other people as a measure of well-being, through the lens of non-biological kinship connections. A theoretical approach that utilizes anthropological considerations of kinship is important to framing research on social isolation as relationships are at the core of understanding the affiliations and connections of individuals. I focus on the specific experiences of older persons in a particular location to elucidate the nature and practices of relationships in old age. The ethnographic data in this study highlight relationships with both others and spaces as key for shaping the experience of old age in a specific environment. Participants emerge as having negotiated a set of practices to pursue, maintain, and create place based relationships and spaces are reconsidered as to how they meet differing needs of an individual, both socially and physically. Using in-depth interviews from a multi-year ethnographic study in Detroit, Michigan with older current and former residents (n=32), I analyzed interview transcripts to identify key topics, themes, and patterns.

UNDERSTANDING PERSON-PLACE TRANSACTIONS IN NEIGHBOURHOODS: A QUALITATIVE-GEOSPATIAL APPROACH

C. Hand, D.L. Rudman, S. Huot, J. Gilliland, R. Pack, *School of Occupational Therapy, University of Western Ontario, London, Ontario, Canada*

Emerging research regarding aging in context reveals much about neighbourhood characteristics that relate to aging adults' health, participation and inclusion; however, in-depth information about the nature of person-place relationships is lacking. Shifting away from previous conceptualizations of place as static, a transactional perspective considers place as inseparable from the person, each shaping

the other through complex, ongoing transactions. The interwoven nature of person and place highlights the need to use methods that can examine this relationship in situ and explore meanings derived from places. Participatory geospatial methods (i.e. methods that involve the participant in collecting geospatial data) can capture situated details about place that are not verbalized during interviews or otherwise discerned, and qualitative methods can explore interpretations, both helping to generate deep understandings of the relationships between person and place. This presentation argues for applying qualitative-participatory geospatial approaches to this area of study and describes an innovative methodology. A study exploring how neighbourhood and person transact to shape a sense of social connectedness in older adults provided the basis from which we developed a combined qualitative-participatory geospatial methodology. Methods included global positioning system (GPS) tracking followed by map-based interviews, narrative interviews, and go-along interviews, with attention to integrating spatial and other forms of data during analysis. Findings indicate the unique understandings that each method contributes, the strengths and limitations of integrating geospatial with qualitative data, and the potential for this methodology to generate knowledge about person-place transactions that can inform practice, policy and research to promote older adults' well-being.

PERCEIVED NEIGHBORHOOD ENVIRONMENT, SOCIAL SUPPORT, AND PHYSICAL ACTIVITY AMONG ELDERLY JAPANESE

K. Harada¹, H. Sugisawa², Y. Sugihara³, S. Yanagisawa⁴, M. Shimmei⁵, *1. Jissen Women's University, Tokyo, Japan, 2. J.F. Oberlin University, Tokyo, Japan, 3. Tokyo Metropolitan University, Tokyo, Japan, 4. Tokushima University, Tokushima, Japan, 5. Hosei University, Tokyo, Japan*

The effects of perceived neighborhood environment and social support on the physical activity of young-old (65–74 years old) and old-old (≥75 years old) were examined. Data were obtained from a probability sample survey of 739 participants (≥65 years) living in two wards of Tokyo, Japan. The dependent variable was physical activity divided into active (engaged in 60 min or more per week) and inactive. The independent variables were the perceived neighborhood environment, measured by the International Physical Activity Questionnaire Environmental Module (IPAQ-E) and the social support from kin, neighbors, and friends for going out. Logistic regression analyses were conducted separately for both age groups, controlling for sex, education, employment, living arrangement, and functional capacity. Results demonstrated that access to shops and exercise facilities, social environments, and aesthetics were associated with being physically active among the young-old. The interaction between social environment and social support from kin was statistically significant among the young-old. Social environments, aesthetics, and social support from neighbors and friends were associated with being physically active among the old-old. These findings suggest that improving access to facilities might be effective for promoting physical activity among the young-old. Social environment (e.g., seeing many people walking) and aesthetics consistently correlated with

physical activity for both age groups. Findings also highlighted the importance of the social support from neighbors and friends for promoting physical activity for the old-old and the social support from kin as a modifier of the relationship between neighborhood environment and physical activity for the young-old.

EVALUATING THE NURSING PRACTICE ENVIRONMENT

I. Durosaiye, *University of Central Lancashire, Preston, United Kingdom*

Background: Nursing is a crucial part of the healthcare service delivery in the UK. However, an increasing number of ward nurses are leaving the profession prematurely, due to ill-designed hospital wards.

Objectives:

- Identify the typical ward elements in a hospital ward setting;
- Establish the design features that have the greatest impact on ward nurses in their job role; and
- Explore the personal constructs of nurses that should be supported by these design features through their embodiment in ward elements.

Methods: A focus group was conducted with six staff nurses. This was followed by semi-structured interviews with 20 ward nurses. The study concluded by performing a post-occupancy evaluation of three hospital wards where these nurses worked. The results of the post-occupancy evaluation were triangulated against those of the focus group and semi-structured interviews.

Results: The findings of this study:

- 1) Established a case for the periodic post-occupancy evaluation of hospital wards;
- 2) Identified the design features most essential for nurses in hospital ward setting; and
- 3) Illuminated the personal constructs of nurses that should be supported by these design features.

Conclusions: A supportive nursing practice environment is essential for the therapeutic healing of patients in contemporary nursing. To ensure that ward nurses continue in gainful employment for longer, there is a need for periodic assessment of how the architectural design features of hospital wards support ward nurses in their job role.

BUILT ENVIRONMENT, ACTIVE LIVING, AND THE COMPETITIVENESS OF A SENIOR-LIVING FACILITY

Z. Wang^{1,2}, E. Rahardjo³, 1. *Henan University, Kaifeng, China*, 2. *International Green, Chesterfield, Missouri*, 3. *Moseley Architects, Moseley Architects, Virginia*

Driven by a combination of facility competition and customer preference, developing quality built environments in a senior-living facility has become an important focus for the service providers. Limited is known regarding specific environmental design principles significant to facility competitiveness in the current state-of-art of development. From providing environmental supports of active living (including both physical and social activities), the benefits include enhanced resident well-being and eventually promoted facility competitiveness. This research investigates the associations between environmental design principals,

residents' physical and social activities, and reported facility competitiveness.

Case studies of 57 senior-living facilities in California and Virginia are conducted through on-site observations, face-face interviews, and an online questionnaire survey of facility officers and coordinators. Key attributes of facility design are summarized and measured at the site and building levels, including the factors of site planning, building layout, vertical configuration, and interior decoration. The Statistical Package for the Social Sciences are used to analyze objective data and identify significant factors. Content analyses are conducted to investigate participants' suggestions and preferences. Keywords and themes are identified. The presence of destinations for walking on the property, a self-described building layout, good visual and physical access to the outdoors, homey interior decorations and amenities contribute to residents' active living and facility competitiveness. The results will be discussed through the eyes of architects and academic researchers working together to examine what it means to design for facility competitiveness. Innovated design approaches are emphasized. Creditable research findings and design experiences are included.

EXPLORING CLIENT AND STAFF PERCEPTIONS OF ENVIRONMENTS IN ADULT DAY SERVICES (ADS) CENTERS IN TAIWAN

C. Liou¹, S.E. Jarrott², A. Kelly¹, 1. *Kent State University, North Canton, Ohio*, 2. *Ohio State University, Columbus, Ohio*

Purpose of Study: Although several studies have examined the impact of environments on quality of life outcomes for long-term care residents, scholars have put minimal emphasis on the environments of adult day services (ADS). In the United States, ADS centers are perceived as the place used by incompetent and impaired elders who are labeled as dependents or children (Diaz Moore, 2004; Salari & Rich, 2001). Little is known about the perceptions of ADS in other countries with different cultural backgrounds. This study aimed to examine the role of physical-spatial conditions/dimensions and social-interpersonal environments in two ADS facilities in Taiwan from staff and client perspectives.

Design and Methods: Data were collected from 23 interviews with staff and clients and 270 hours of participant observations. Authors triangulated field notes with interview transcriptions and analyzed them with open, axial, and selective coding.

Results: For staff, (a) spacious well-designed physical environments and supportive social and economic environments lead to good care interactions with clients and (b) unsupportive environments make care work more challenging and create negative effects on clients' lives. For clients, (a) social environment was more important than physical environment in affecting quality of life at centers and (b) different life experiences influenced their perceptions of and the interactions with ADS environments.

Implications: Our study reveals the complex interrelationships among ADS environments, staff perception, and clients' quality of life reflecting Taiwanese culture. Results can

be translated into action research by implementing supportive environments for both staff and clients at ADS centers.

SESSION 1005 (POSTER)

EPIDEMIOLOGY AND HEALTH DEMOGRAPHY

EFFECTS OF DIETARY DIVERSITY ON LONGITUDINAL CHANGES IN INFORMATION PROCESSING SPEED AT 40S TO 70S

R. Otsuka-Ito¹, Y. Nishita-Kodaira¹, C. Tange¹, M. Tomida¹, Y. Kato^{2,1}, T. Imai^{1,3}, F. Ando^{2,1}, H. Shimokata^{4,1}, 1. *National Center for Geriatrics and Gerontology, Obu, Aichi, Japan*, 2. *Aichi Shukutoku University, Nagakute, Aichi, Japan*, 3. *Doshisha Women's College of Liberal Arts, Kyoto, Japan*, 4. *Nagoya University of Arts and Sciences, Nisshin, Aichi, Japan*

The present study assesses the effects of dietary diversity on information processing speed among 1,766 men and women aged 40 to 79 years who participated in the first and follow up (second to seventh) waves of the National Institute for Longevity Sciences-Longitudinal Study of Aging at least once. Information processing speed was assessed using a component of the Wechsler Adult Intelligence Scale-Revised at all waves. Dietary diversity was determined using the Quantitative Index for Dietary Diversity based on a three-day dietary record at the first wave. Sex- and age decade-stratified, general linear, mixed models comprised fixed effects of dietary diversity (high/low groups), age at the first wave, years of follow-up, interactions, and covariates (education, living alone, family income, smoking, body mass index, energy intake, and medical history). The results indicated that the effects of dietary diversity were marginally significant for males aged in their 40s, 50s, and 70s ($p < 0.06$), suggesting that more dietary diversity was associated with better information processing speed. Regardless of dietary diversity (high/low groups), information processing speed increased with aging during the 40s and decreased in 60s and 70s in both sexes ($p < 0.05$). Interaction between dietary diversity and follow-up years revealed a significant interaction effect only among females aged in their 70s ($p = 0.04$), and information processing speed decreased less in groups with high than low diversity (-0.34 vs. -0.58 points/year). In conclusion, daily intake of various foods might help to protect information processing speed decline in females aged in their 70s.

TB TRANSMISSION IN OLDER POPULATIONS: A RE-EXAMINATION OF RISK GROUPS

G.A. Noppert, *Duke University, Durham, North Carolina*

Background: Despite a low tuberculosis (TB) incidence nationwide, stark disparities in TB incidence persist, particularly along lines of relative social disadvantage. While TB incidence among older populations is typically driven by reactivation of latent TB infection (LTBI), understanding the extent to which recent transmission of TB is occurring in older populations may move us closer to TB elimination.

Methods: We used Michigan surveillance data on 1,236 TB cases reported during 2004–2012 to examine the association between age and recent transmission of TB. We used multivariable modified Poisson regression models to examine the prevalence of recent transmission controlling for demographic and clinical covariates at the individual and neighborhood level (at the level of the census block group).

Results: 310 (25%) of the 1,236 TB cases occurred among adults aged 65 years and older. Of those 310 cases, 22% resulted from recent transmission. Overall, those 65 years and older had a prevalence of transmission 50% lower than those aged 18–64 years—a finding that was unchanged with the addition of other individual- and neighborhood-level covariates. However, in a model of only those aged 65 years and older, the U.S.-born had a prevalence of transmission 2.64 times that of the foreign-born and Asians had a prevalence of transmission 2.90 times that of Whites.

Conclusions: Policies aimed at screening older populations for LTBI may be effective in reducing incidence overall among this population. However, increased efforts at reducing transmission are needed to address the racial disparities apparent among older Asian adults.

THE IMPACT OF TOOTH LOSS ON COGNITIVE DECLINE IN OLD AGE: A POPULATION-BASED LONGITUDINAL STUDY

C.S. Dintica, W. Xu, D. Rizzuto, *Department of Neurobiology, Care Science and Society, Karolinska Institute, Stockholm, Sweden*

Poor dental health has been associated with cognitive decline with some inconsistent result, and the role of cardiovascular disease (CVD) and chronic inflammation in such an association remains unclear. We aimed to examine the association between tooth loss and cognitive decline over time, and to explore whether CVD and inflammation may account for this association.

Within the population-based Swedish National study on Aging and Care-Kungsholmen, 2465 cognitively intact participants aged ≥ 60 were identified at baseline, and followed-up for 6 years. Cognitive function was assessed with the Mini-Mental State Examination (MMSE) at baseline and at follow-ups. Information on dental status (no tooth loss, partial and complete) and history of CVD was collected at baseline. C-reactive protein (CRP) was measured in blood samples and dichotomized (normal: 0–5 mmol/l and high: >6 mmol/l). Data were analysed using mixed-effects models with adjustment for potential confounders.

Of all participants, 472 participants (19.2%) had tooth loss including 339 (13.8%) with partial tooth loss and 133 (5.4%) with complete tooth loss. In mixed-effects models, both partial tooth loss (β : -0.8, 95% CI -1.40 to -0.2) and complete tooth loss (β : -2.89, 95% CI -3.89 to -0.51) were associated with greater MMSE decline compared to no tooth loss after adjustment for potential confounders including CVD and inflammation. In stratified analyses by CVD and CRP, the association between tooth loss and cognitive decline remained statistically significant.

In conclusion, both partial and complete tooth loss are associated with cognitive decline among the elderly people, independently of CVD and inflammation.

THE RELATIONSHIP BETWEEN ALCOHOL CONSUMPTION AND MORTALITY IN AN AGING COHORT OF U.S. ADULTS

K. Keyes, *Epidemiology, Columbia University, New York, New York*

Validity of the relation between moderate drinking and mortality has been a subject of substantial controversy. While epidemiological evidence has demonstrated a “J-shaped curve”, extant literature has been criticized for not separating recent abstainers from long-term abstainers and not characterizing the dynamic nature of consumption. We examined the relationship between drinking and mortality in a nationally-representative sample of aging adults. Data were drawn from 8,095 Health and Retirement Study respondents, surveyed 9 times between 1996–2012. Respondents were grouped into five categories: long-term abstainer, recent abstainer, occasional drinker, moderate drinker, and heavy drinker. We modeled mortality using Cox Proportional Hazards models with time-varying measures of alcohol consumption, wealth, depression, BMI, difficulties of daily living, chronic conditions, as well as time-invariant demographics. Overall, 27.66% of the sample died during follow-up. In unadjusted models, compared to long-term abstainers, moderate drinkers had a hazard ratio (HR) of 0.51 (95% CI 0.44–0.58); occasional drinkers had an HR of 0.71 (95% C.I. 0.62–0.82), and heavy drinkers had an HR of 0.74 (95% C.I. 0.61–0.91). In a fully adjusted model, moderate drinkers had an HR of 0.53 (95% C.I. 0.38–0.74). Interactions were observed by smoking status and race, and suggested that smokers and racial minorities do not demonstrate mortality benefits from moderate consumption. We observed that moderate drinkers have lower hazard of mortality than non-drinkers in a long-term follow-up study of older adults. However, there is substantial variation in the mortality benefit received, suggesting that social factors as well as biology shape physiological responses to drinking.

INFLUENCE OF EDUCATION ON ASSOCIATION BETWEEN MARRIAGE AND MORTALITY: A CROSS-NATIONAL STUDY

T. Saito-Kokusho¹, K. Shirai², T. Oksanen³, J. Pentti³, J. Vahtera⁴, 1. *Department of Social Science, Natl Center for Geriatrics and Gerontology (NCGG), Obu, Aichi, Japan*, 2. *University of the Ryukyus, Nishihara, Okinawa, Japan*, 3. *The Finnish Institute of Occupational Health, Turku, Finland*, 4. *University of Turku, Turku, Finland*

The association of marriage and mortality is well-established, however, the role of education on the excess mortality of the unmarried remains unclear. This study examined whether the effect of marriage on mortality differs by gender and education in older individuals in Japan and Finland.

Data were obtained from the Japan Gerontological Evaluation Study project (JAGES) and the Finnish Public Sector study (FPS). In JAGES, 4832 men and 4720 women aged 65–74 were followed for 5.7 years. In FPS, 3782 men and 14253 women aged 60–74 were followed for 4.4 years. A gender-wise Cox proportional hazards model estimated

the effect of marriage and interaction effect of education on the association of marriage and mortality in each country.

A total of 11.1% of men and 6.2% of women in JAGES and 4.4% of men and 2.6% of women in FPS died during the follow-up. A multivariate analysis showed that being unmarried was associated with excess mortality in both genders in Finland but not in Japan. A stratified analysis by gender and educational level showed that being unmarried with higher education was associated with a higher risk of mortality (HRs: 1.4–2.0) than with lower education compared to the married in both countries except for Japanese women whose marital status did not significantly affect mortality regardless of educational level.

The findings suggest that a higher education may expand marital health disparity rather than mitigate it. A support system beyond familial relationships should be considered for unmarried older individuals.

LOW NORMALIZED GRIP STRENGTH IS A BIOMARKER FOR DIABETES AND PHYSICAL DISABILITY IN AGING ADULTS

M. Peterson, K. Duchowny, *Physical Medicine and Rehabilitation, University of Michigan, Ann Arbor, Michigan*

Background: There is evidence to highlight the importance of muscular strength as a protective factor for metabolic health and function across populations.

Objective: To examine the extent to which low normalized grip strength (NGS) may serve as a biomarker for both diabetes and physical disability in a population-representative sample of U.S. adults age 50 and older.

Methods: A sample of 5,267 individuals, aged 50–85 years, was included from the combined 2011–2014 NHANES datasets. Strength was assessed using a hand-held dynamometer, and was normalized to body mass. A logistic regression model was used to assess the association between NGS and risk of diabetes (hemoglobin A1c (HbA1c) levels ($\geq 6.5\%$ [≥ 48 mmol/mol])), as well as physical disability status (self-reported restrictions in ADLs/IADLs), while controlling for age, sociodemographic characteristics, and daily television viewing time.

Results: Every 0.05 lower NGS was independently associated with a 1.49 times increased odds for diabetes in men and women; and a 1.45 times increased odds for disability. Women were at lower odds of having both diabetes (OR: 0.30; 95% CI: 0.21–0.42) and disability (OR: 0.74; 95% CI: 0.61–0.91), whereas only higher age (≥ 65 years vs 50–64.9 years; OR: 1.50; 95% CI: 1.18–1.91) and hours of television viewing time (OR: 1.16; 95% CI: 1.02–1.31) were associated with disability status.

Conclusions: NGS was robustly associated with both diabetes and physical disabilities in aging adults. This simple screen may serve as a valuable tool to identify adults that are at risk for negative health consequences, and that might benefit from lifestyle interventions to reduce risk.

LOW INCOME OLDER SNAP PARTICIPANTS DO NOT HAVE LARGER WAIST CIRCUMFERENCE THAN NONPARTICIPANTS

L. Samuel, S.L. Szanton, *Johns Hopkins University School of Nursing, Baltimore, Maryland*

Supplemental Nutrition Assistance Program (SNAP) participants have been shown to have higher obesity rates than their income-eligible nonparticipating peers. However, recent studies using causal inference in adolescent and young adult samples suggest that program self-selection may have biased those results. To obtain unbiased estimates in adults aged ≥ 65 years, we compared the average waist circumference of prior-year SNAP participants to the average in a propensity score matched group of nonparticipants, stratified by gender. Probability of SNAP participation was estimated based on age, race/ethnicity, socioeconomic status, household size, employment status, lack of money for food or other needs, and receipt of non-SNAP food assistance. Community dwelling participants of the National Health and Aging Trends Study with incomes $< 500\%$ of the poverty limit were included. Propensity score matching produced a matched subset of the sample comprising SNAP participant and nonparticipant groups that were similar on model covariates; Rubin's B, an estimate of standardized bias, reduced from 155 in the unmatched sample to 21 in the matched sample. In the unmatched sample, female SNAP participants had a larger average waist circumference than nonparticipants (40.7 vs. 38.3 inches, $t=5.49$, $n=1989$), but there was no statistically significant difference in the propensity score matched subset (40.5 vs. 39.5 inches, $t=1.38$, $n=1719$). Male SNAP participants did not differ from nonparticipants in this sample. These results suggest that economic and social factors may influence SNAP participation. Accounting for these factors, there is no evidence of greater waist circumference in low income older adults participating in SNAP.

USING GEOGRAPHICAL INFORMATION SYSTEMS (GIS) FOR TARGETING RECRUITMENT IN DEMENTIA STUDIES

D.L. Scerpella, K.A. Marx, K. Burke, L.N. Gitlin, *Center for Innovative Care in Aging, Johns Hopkins University, Baltimore, Maryland*

Recruiting sufficient numbers of individuals with dementia and/or their family caregivers is critical for advancing effective treatments and assuring generalizability and statistical power in randomized trials. Recruitment is one of the most expensive and time consuming aspects of dementia trials. A tool that may assist in recruitment is Geographic Information Systems (GIS). GIS applications provide a technology for connecting individual's data to their environment, allowing researchers to visually inspect the distribution of numerous variables across a location. Currently, there is no robust location data for people with dementia or their caregivers, yet existing data sets may be useful. This paper presents results of a post hoc analysis of families recruited for a randomized trial in the USA to demonstrate the power of GIS and effective use of existing data sets. Using US Census Bureau data, a grouping analysis of selected risk factors (age, education, gender, income) for dementia was performed in ArcGIS. Age alone was the most robust factor overlapping with 48% ($N=165$) of enrolled trial participants. However, the combination of risk factors predicted 52% of existing locations of participants. We found that by increasing the geographic area considered by one half-mile, we improved the reach to 76% of enrolled participants. By utilizing government survey data and identifying specific demographic

and health risk factors associated with dementia, GIS can be used to identify localized areas in a community where these attributes are concentrated. Using this information, a more targeted recruitment approach may be possible, prospectively resulting in potential cost savings.

DIFFERENT RISK PROFILES FOR INJURIOUS FALLS IN OLDER ADULTS OVER 60: A POPULATION-BASED STUDY

S. Ek¹, D. Rizzuto¹, L. Fratiglioni^{1,2}, K. Johnell¹, W. Xu^{1,3}, A. Welmer^{1,4}, 1. *Karolinska Institutet, Stockholm, Sweden*, 2. *Stockholm Gerontology Research Center, Stockholm, Sweden*, 3. *Tianjin Medical University, Tianjin, China*, 4. *Karolinska University Hospital, Stockholm, Sweden*

Although falls in older adults usually have multiple causes, falls risk factors have traditionally been studied one at the time. The aim of this study is to identify different risk profiles for injurious falls in people aged over 60 years by detecting different clusters of already established risk factors for falls and quantify their impact on fall risk. Participants were 2556 people (≥ 60 years) from the Swedish National Study on Aging and Care in Kungsholmen (SNAC-K) study. Cluster analysis was used to identify aggregation of possible risk factors. Associations between the clusters and injurious falls over 3, 5 and 10 years were analyzed by using flexible parametric survival models. The cluster analysis revealed five clusters. The first cluster included mainly healthy individuals and was used as the reference group. The second and third clusters included people with high physical function but high disease burden, FRIDs, depressive symptomology and unhealthy lifestyle. The last two clusters included mainly people with cognitive impairment, with or without FRIDs and physical impairment. The risk of injurious falls for all groups were significantly higher than for the comparison cluster. The hazard ratios ranged from 1.71 (95% confidence interval [CI]: 1.02–2.66) for the second cluster to 12.67 (95% CI 7.38–21.75) for the last cluster over 3 years of follow-up. Conclusion: The risk of experiencing an injurious fall varied largely between the different groups. Knowledge of the relationship between risk factors may help clinicians to tailor interventions by identifying people at different levels of risk of injurious falls.

SESSION 1010 (POSTER)

FALLS II

FEAR OF FALLING IN OLDER AFRICAN AMERICAN HEMODIALYSIS PATIENTS

C. Liu^{1,2}, D. Afezollu¹, S. Janet¹, A. Upadhyay¹, J. Bhatia¹, R.A. Fielding², 1. *Boston University, Boston, Massachusetts*, 2. *Jean Mayer Human Nutrition Research Center in Aging, Boston, Massachusetts*

Introduction: Older adults comprise the majority of incident hemodialysis patients. Falls are a tremendous threat for older hemodialysis patients. Over a one year period, approximately half of these patients will suffer a fall, twice the rate of falls among the general older adult population. Fear of falling is known to increase fall risk. Yet little is known about the fear of falling in this high risk population. Our objective was to determine the impact of fear of falling in older hemodialysis patients.

Methods: A convenience sample of 10 older hemodialysis patients followed at an urban hemodialysis facility affiliated with an academic medical center underwent key informant interviews in their homes between the period of June 1, 2015 through May 31, 2016. Inclusion criteria included: aged 65 years or older, English-speaking, and willing to allow interviewer into home. Questions included open-ended and Likert-style questions regarding attitudes regarding general physical function and falls; the Falls Efficacy Scale-International was administered. All interviews were audiotaped. Three research team members simultaneously reviewed transcripts of interviews and dominant themes determined by consensus discussion.

Results: Mean age of participants was 73.0 ± 5.0 years and 6 (60%) were women. All participants identified as African-American. Mean time on hemodialysis was 4.8 ± 4.5 years. Fifty percent of the sample agreed with the statement "I am afraid of falling." Mean Falls Efficacy Scale-International Score was 22.3 ± 9.0 points, which is consistent with a moderate fear of falling. Dominant themes about contributors to falls included hemodialysis side effects ("Hemodialysis just drains me out"); and lack of physical activity ("Don't like laying around, bed makes you weak").

Conclusion: In older African-American hemodialysis patients, fear of falling is a likely contributor to the occurrence of falls. Future studies should explore reducing the fear of falling as a preventive measure for falls in older hemodialysis patients.

DETERMINANT FACTORS IN THE RELATIONSHIP BETWEEN URINARY INCONTINENCE AND FALLS IN OLDER ADULTS

J. Rocha, L. Jorge, G. Guimaraes, B. Rauber, B.B. Neves, A. Bos, *Catholic University of Rio Grande do Sul, Porto Alegre, RS, Brazil*

Studies had shown a strong relationship between falls and urinary incontinence (UI) in the older-adult. However, this relationship is complex and might involve intrinsic (organic) and extrinsic factors. The aim of the study was to determine whether there was a significant relationship between the fall event and the presence of UI in the elderly, and what factors could influence this correlation. The dependent variable was reporting at least a fall in the last 6 months and the independent variables were UI, sex, marital status, age, health perception, cognition, and number of morbidities. A population-based survey interviewed 7315 older-adults (60 or older) residents in 59 cities of the State of Rio Grande do Sul, Brazil. Logistic regression models tested the odds of having a fall. Two hundred three participants (3.9%) reported. Prevalence of UI was statistically higher ($p < 0.001$) among those 693 older-adults reporting fall (14%). Urinary incontinence increased 7 times the risk of falling ($p < 0.001$) in the simple analysis and 3.5 when controlling for co-variables. Independent of UI, being male (confidence interval 0.63 to 0.91, $p < 0.05$) and not having cognitive impairment (CI 0.59 to 0.77, $p < 0.001$) were protective factors. Independent risk factors were being widowed compared to married (CI 1.22 to 1.84, $p < 0.001$), older (CI 1.04 to 1.06, $p < 0.001$), worst self-perceived health and number of morbidities (CI 1.16 to 1.28, $p < 0.001$). We concluded that the relationship between

the presence of UI and the history of falls is independent of intrinsic and extrinsic factors.

DEVELOPING A QUESTIONNAIRE TO ASSESS OLDER ADULTS' PERCEPTIONS ABOUT FALLING

P. Morsch¹, M. Myskiw², J. Myskiw¹, *1. Institute of Geriatrics and Gerontology, Pontifical Catholic University of Rio Grande do Sul, Porto Alegre, Rio Grande do Sul, Brazil, 2. Federal University of Rio Grande do Sul, Porto Alegre, Rio Grande do Sul, Brazil*

In Brazil, 28% to 35% of individuals over the age of 65 fall each year. Literature suggests that 30% to 40% of falls are preventable through management of risk factors. However, adherence in prevention programs depends on older adults' perceptions about falling. The objective of this study was to develop a questionnaire to assess older adults' perception about falls' risk factors. It was developed through qualitative and quantitative approach. Qualitative method was conducted through content analysis and quantitative through analysis of content validity. Sample of qualitative approach was 22 older adults, aged 60 or older, participants from senior groups in Porto Alegre (Brazil), and professors from two local universities. Mean age was 70.2 ± 7.1 years. Coding and interpretation of data resulted in two thematic categories: falls problematization and the perception of risk factors, which served as basis for the development of the questionnaire. The proposed research tool, with 36 questions was sent to content validity analysis through evaluation of "judges", in three aspects: clarity of language, importance and theoretical relevance. With these results, it was possible to calculate the Validity Coefficient (VC). All questions with $VC < 0,7$ were excluded. Final questionnaire consisted of 25 questions. According to preliminary results, the questionnaire seems quite relevant to identify how older adults perceive falling into a problem to be prevented and their perception of the risk factors. This knowledge will help to develop more effective methods considering for fall prevention.

FALLS IN BRAZILIAN OLDER PEOPLE: PREVALENCE, ASSOCIATED FACTORS, CONSEQUENCES

W. Teixeira Pimentel¹, S. Rizzato Stopa², V. Pagotto³, M.C. Hoffmann⁴, D. Carvalho Malta⁵, R.L. Menezes¹, *1. Universidade de Brasilia -UnB, Brasilia, Distrito Federal, Brazil, 2. Faculdade de Saude Pública da Universidade de São Paulo, Campinas, São Paulo, Brazil, 3. Faculdade de Enfermagem. Universidade Federal de Goiás, Goiânia, Goiás, Brazil, 4. Ministério da Saúde, Brasilia, Distrito Federal, Brazil, 5. Escola de Enfermagem da Universidade Federal de Minas Gerais, Belo Horizonte, Minas Gerais, Brazil*

Background: Falls are considered a public health problem because of their prevalence and consequences for health of older people.

Objective: To estimate the prevalence of falls, associated factors and consequences.

Methods: Data was obtained in the National Health Survey (PNS,2013) a cross-sectional population-based study with 23.815 older people (≥ 60 yrs), from all the States of Brazil. The fall, dependent variable, was evaluated by the question: "in the last 12 months, have you fallen and looked for health services?". The independent variables were age, sex, marital

status, self-rated health and femur fractures. It was estimated the prevalence of falls (IC95%). The statistic differences were estimated by the qui-squared test, considering $p < 0,01$.

Results: The prevalence of falls in the last 12 months was 7,8% (n=1825; IC95%: 7,3-8,4). It was observed a higher prevalence in women (9,6%), in people of 75 years old or more (11,6%). According to the health characteristics, the prevalence was higher in older with bad self-related health (14,8%). Among those who experienced falls, 8,3% had femur fractures as a consequence, these 13.4% made without surgery prosthesis placement.

Discussion/Conclusion: The prevalence of falls was low comparing to previous studies performed in Brazil and other countries. However, the associated factors and consequences are similar to the related in literature before: fractures, females, advanced age, bad self-related health, conditions that may make old people, more susceptible to this harm. Thus, one conclude that knowledge of these factors is important to support the planning of preventive measures and policies to prevent falls and their consequences.

FACTORS RELATED TO FALLS AND FEAR OF FALLING IN KOREAN OLDER ADULTS WITH CHRONIC DISEASE

J. Lee¹, M. Choi¹, C. Kim², 1. College of Nursing Yonsei University, Seoul, Korea (the Republic of), 2. College of Medicine Yonsei University, Seoul, Korea (the Republic of)

Elderly with previous fall experience perceives more fear of falling and lead sedentary life style. Fear of falling as well as falls in older adults are one of the most important health problems that healthcare providers should pay attention to. Nevertheless, there are limited evidence of falls and fear of falling. This study was conducted to identify factors influencing falls and fear of falling among older adults with chronic disease in Korea using a descriptive cross-sectional survey design. A convenience sample of 108 patients was recruited at a geriatric outpatient department of a tertiary hospital in Seoul, Korea. Demographic characteristics, comorbidities, medication use, falls history, level of physical activity, activities of daily living, mobility, muscular strength, and fear of falling were investigated. Student t-tests, Chi-square tests, and multiple linear regressions were utilized in statistical analysis. The mean age of the participants was 80.25 ± 5.1 years. Hypertension was the most prevalent disease (67.6%), followed by ophthalmologic disease (61.1%) and ischemic heart disease (59.3%). Thirty six participants (33.3%) reported that they had experienced one or more falls in the past year. Marital status and use of antipsychotics was associated with falls, while other factors did not show significant relationship with falls. The number of comorbidities, level of physical activity, activities of daily living, and mobility were predictors of fear of falling in the regression model. In conclusion, increase of physical activity, functional fitness, and physical independence is important to decrease fear of falling and encourage active and healthy life in older adults.

FALL RISK FACTORS IN MID-AGE WOMEN: RESULTS FROM THE AUSTRALIAN LONGITUDINAL STUDY ON WOMEN'S HEALTH

G. Peeters^{1,2}, A. White², L. Tooth², 1. School of Public Health and Preventive Medicine, Monash University,

Melbourne, Victoria, Australia, 2. The University of Queensland, Brisbane, Queensland, Australia

In contrast to older adults, little is known about risk factors of falls in adults aged 50–64 despite a high prevalence of falls in this age group. The aim was to identify risk factors of falls in mid-age women and explore how associations change with age. Data were from 11,226 participants in the Australian Longitudinal Study on Women's Health aged 50–55 years in 2001 (born 1946–51). A wide range of health and lifestyle predictors were measured in the 2001, 2004, 2007 and 2010 surveys. Falls in the past 12 months were measured in the 2004, 2007, 2010 and 2013 surveys. Associations between predictors and reported falls 3 years later were analysed using logistic regression. In surveys 2004–2013, 20.5%, 30.6%, 30.6% and 26.6% of women reported a fall in the previous 12 months, respectively. In the univariable models, most factors were associated with falls. In the multivariable models, higher odds of falling were found for overweight and obese women compared with healthy weight women at all time points (OR=1.16–1.43). Impaired vision (OR=1.24–1.35), poor physical functioning (OR=1.23–1.66) and frequent severe tiredness (OR=1.27–1.49) were associated with falls at three time points. Depression (OR=1.31–1.42), leaking urine (OR=1.46–1.49), stiff/painful joints (OR=1.34–1.63) and HRT use (OR=0.69–0.80) were associated with falls at two time points. There was no obvious age-related increase or decrease in the number of statistically significant associations. Identified fall risk factors varied over time, highlighting that falling involves a complex interplay of risk factors in mid-age women.

KAATUMISSEULA®: IMPLEMENTATION OF EVIDENCE-BASED FALL PREVENTION FOR COMMUNITIES

S. Karinkanta, T. Kulmala, P. Kannus, T. Vasankari, H. Sievänen, The UKK Institute for Health Promotion Research, Tampere, Finland

Compelling scientific evidence shows that every third fall can be prevented. Effective measures need to be based on knowledge of individual fall risk. This underscores importance of fall risk screening. In Finland, risk screening and preventive measures are not used systematically. Thus, implementation of evidence-based methods for communities is necessary. In the present economic situation, resources of the voluntary and non-profit sector (NGOs) should also be utilized.

The main objective of KaatumisSeula® project is to create local models for fall risk screening and implementing evidence-based preventive measures. The models are based on co-operation between local public sector and NGOs. Primary risk screening is offered for older people by public sector and NGOs. People with high fall risk are referred to comprehensive assessment of individual fall risk and tailored implementation of fall prevention measures by educated health care professional(s). This approach is based on the *multifactorial* Chaos Falls Clinic Study. NGOs play a central role in not only screening but also informing about fall prevention measures and offering accessible balance and strength training - the most effective *single intervention* in fall prevention.

The models are now in operation in 2 municipalities. NGOs are active and keen in their role. Two Falls Clinics

have started and almost 400 high risk older adults have found their ways to the multifactorial assessment. Public sector and NGOs have received education. New exercise groups have been established.

KaatumisSeula® is a feasible approach to screen the fall risk of older adults and implement preventive measures in community.

THE EFFECTS OF NUTRITION ASSESSMENT BY PREALBUMIN ON FIM SCORES IN PATIENTS WITH FALL AND FRACTURE

S. Niyati, *Nursing, University of Texas at Arlington, Allen, Texas*

Background: Fall is leading cause of injury in elderly persons. Nutritional status is an important aspect of elderly life that influences quality of life in patients with fall and fractures.

Objectives: To evaluate the effects of nutritional assessment by prealbumin level on Functional Independence Measures (FIM) and Length of Stay (LOS) in elderly population with fall and fracture in rehabilitation hospital.

Methods: This study design was a one group pretest-posttest without a control group. Seventy one patients (n=71) 65 years or older with a diagnosis of fall and fracture recruited. Nutritional status was evaluated using the pre-albumin levels. Nutritional intervention implemented for participants who had prealbumin level of 18>mg/dl. Outcomes measures were discharge FIM scores and LOS.

Results: Fifty four patients (76%) were required nutritional interventions. Prealbumin levels, FIM scores, and food intake were significantly improved from admission to the discharge, for Prealbumin levels, $t(71) = 7.53, p < 0.01$; $X = 14.97$ versus 19.42 , and for total FIM scores, $t(71) = 21.45, p < 0.01$; $X = 1.82$ versus 4.41 . There was no significant correlation found between prealbumin changes and improved total FIM scores. Improved total FIM scores and self-care has significant negative correlations with LOS ($r = -0.46, p < 0.01$) and ($r = -0.47, p < 0.01$) respectively. Fifty six patients (78.9%) gained prealbumin with a mean gain of 6.1 mg/dl. Prealbumin gain was associated with higher FIM scores and lower LOS.

Conclusions: In patients who suffered a fall with resulting fracture, improving nutritional status is associated with improvement of functional levels and a decreased length of stay in rehabilitation hospital.

STAFF RESPOND POSITIVELY WHEN OLDER PATIENTS ARE PROVIDED WITH FALLS PREVENTION EDUCATION

A. Hill¹, N. Waldron², J. Francis-Coad³, T.P. Haines⁶, C. Etherton-Bear⁴, L. Flicker⁴, K. Ingram², S. McPhail⁵,
1. *School of Physiotherapy and Exercise Science, Curtin University, Perth, Western Australia, Australia*, 2. *WA Department of Health, Perth, Western Australia, Australia*, 3. *The University of Notre Dame Australia, Fremantle, Western Australia, Australia*, 4. *University of Western Australia, Perth, Western Australia, Australia*, 5. *Queensland University of Technology, Brisbane, Queensland, Australia*, 6. *Monash University, Melbourne, Victoria, Australia*

Providing older patients with individualized falls prevention education was found to significantly reduce rates of falls

and injurious falls on hospital rehabilitation wards. The aim of this study was to understand how staff responded to the education and how they perceived the program impacted on falls prevention on their wards. Focus groups were conducted. Participants were clinical staff who were recruited from hospital aged care rehabilitation wards which had previously participated in a cluster randomized trial. During the trial trained health professionals provided individualized falls prevention education to (n=757) patients with good levels of cognition (Mini-Mental State Examination > 23/30). Staff were also provided with training to support the program. Staff feedback was sought after the trial concluded. Data were thematically analysed. Five focus groups were conducted at different hospitals with (n=30) multidisciplinary staff. Staff perceived that the education program generated a positive culture around falls prevention on the wards. The program facilitated a team approach, whereby patients and staff worked together to address falls prevention, with the educator viewed as a valued member of the team. Staff identified that providing patients with education increased their own knowledge and awareness about creating a safe ward environment. Patients being proactive and empowered to engage in falls prevention strategies was viewed as enhancing staff falls prevention efforts and motivation to change practice. Providing individualized patient education to patients with good levels of cognition can empower staff and patients to work as a team to address falls prevention on hospital rehabilitation wards

CHARACTERISTICS OF THE PATIENTS WITH FEAR OF FALLING SYNDROME IN MEXICAN ELDERLY

N. Sandoval^{1,2}, C. Moreno Cervantes^{1,2}, H. De la Vega Flores^{1,2}, J. Torres Gutiérrez^{1,2}, S. Saldana Cruz^{1,2}, M. Ramos Rojas^{1,2}, J. Viveros Garcia^{1,2}, 1. *Universidad de Guanajuato, Leon, Guanajuato, Mexico*, 2. *ISSSTE, León, Guanajuato, Mexico*

The Fear of Falling Syndrome (FoF) is the feeling that a person has to be in constant risk of falling, without necessarily be preceded by a fall. We conducted an analytical observational study, with patients ≥65 years old, from reference hospital of Institute of security and social services state workers. Who meet criteria for fall syndrome. As socio-demographic variables, anthropometric, clinical and biochemical data were collected. 114 patients were included, 39 of them met FoF criteria, the mean age was 82.5 years (SD + 7.46), and 78 (68.4%) were women. The main geriatric syndromes encountered were major depressive disorder 80 (70.2%), frailty 54 (47.4%), sensory dysfunctions 98 (85.9%), urinary incontinence 58 (50.9%), gait and balance disorder 86 (75.4%), polypharmacy 107 (93.9%). The functionality of activity of daily living scale was evaluated with the Katz scale, founding 41 patients (36.8%) A, 24 (21.9%) B, 10 (9.6%) C, and less functionality 36 (31.7%) patients. Instrumental activity of daily living was evaluated using Lawton scale founding > 5/8 18 (15.8%) patients. The FoF prevalence was 34%, and was associated to patients with lower albumin levels ($p = 0.04$), higher HbA1c levels ($p = 0.02$) and we identified urinary incontinence OR 1.32 (CI 95%: 1.01–1.72) $p = 0.03$ and orthostatic hypotension OR 10.56 (95% CI 9.97–11.17) $p < 0.01$. Declining functionality for FoF leads the elderly person to a loss of quality of life. Knowledge of this entity is

limited, the results of meta-analysis are inconclusive, knowing the associated factors could contribute to the prevention and management of this syndrome.

REDUCING FALL RISKS IN THE HOME USING SIMULATION EDUCATION FOR HOSPITALIZED GERIATRIC PATIENTS

K. Starhorsky, N. DeWalt, L. Drobnich Sulak, *Cleveland Clinic - Hillcrest Hospital, Mayfield Heights, Ohio*

Falls are the number one reason for hospital admissions and the leading cause of injuries among older adults. Each year, 2.5 million older individuals are treated in emergency departments for fall injuries and over 700,000 are hospitalized. As our population ages, the \$34 billion annual cost for US hospitals to treat falls will skyrocket. One out of three adults 65 and older and one out of two 80 years and older fall each year. Falls account for “25% of hospital admissions, 40% of nursing home admissions...40% admitted do not return to independent living and 25% die within a year” (CDC, 2012).

Hospital-based fall prevention strategies focus less on education and more on restricting movement to keep patients safe while in the hospital. These strategies should focus on applicability to the home setting and emphasize education, creating safer environments, and prioritizing fall-related research to reduce risk. Simulation-based education can provide a unique learning experience to maximize recall and retention, bridge the gap between hospital-based learning and post-discharge compliance, and stimulate a desire to make sustainable changes in the home to reduce injury risk. A minimal risk falls study launched in 2015 randomizes participants to an intervention group using a permuted-block randomization scheme to study the benefits of utilizing simulation versus traditional, written education. Preliminary results show significant advantages to using simulation education including, but not limited to, 54% fewer people experienced a fall and 38% fewer fell at least once after discharge, and 82% made sustainable changes to their home environment.

THE OTAGO EXERCISE PROGRAM—RESULTS FROM 5 YEARS OF DISSEMINATION IN THE UNITED STATES

T.E. Shubert^{1,2,3}, M. Smith⁴, M. Ory⁵, 1. *University of North Carolina, Chapel Hill, North Carolina*, 2. *Shubert Consulting, Chapel Hill, North Carolina*, 3. *South College, Knoxville, Tennessee*, 4. *University of Georgia, Athens, Georgia*, 5. *Texas A&M, College Station, Texas*

The Otago Exercise Program (OEP) is an evidence-based fall prevention program designed to be delivered by physical therapists and physical therapy assistants in 6 visits over a year period. Though highly effective, the program has been challenging to translate for implementation in the United States (US) due to a myriad of regulatory and reimbursement barriers. Innovative delivery models have been developed and tested in the US which have proven to be highly effective and lower cost than the traditional OEP. Three models will be compared in this paper: 1) The OEP delivered over an 8 week period; 2) the OEP delivered by non-PT; and 3) The OEP delivered virtually using a kinect camera and monitored remotely by a physical therapist. All three models have

demonstrated significant improvements in fall risk outcome measures. These innovative delivery models will be compared and contrasted for cost effectiveness and outcomes, and key characteristics of effective delivery sites will be presented.

ETHNICITY AND SOCIOECONOMIC STATUS AS PLAYERS IN COMMUNITY-DWELLING OLDER ADULTS' FALLS

T.V. Gonzalez-Cano^{1,2}, M. Chung¹, B. Flores¹, M. Martinez¹, A. Murray¹, J. Ross^{1,2}, S. Lee^{2,1}, L.C. Arevalo-Flechas^{2,1}, 1. *University of Texas Health Science Center at San Antonio, San Antonio, Texas*, 2. *South Texas Veterans Health Care System, San Antonio, Texas*

The United States is becoming older and increasingly diverse in cultures, languages and socioeconomic standing. However, providing culturally and linguistically adequate health promotion programs for ethnically diverse older adults remains a challenge. Research investigating the relationships between ethnicity, socioeconomic status and disease has been limited. This clinical demonstration project explored the relationship between falls and ethnicity and socioeconomic status in a group of community dwelling older adults in San Antonio, TX, using a culturally and linguistically adapted clinical video novela on fall prevention. The video, available in English and Spanish, was designed using quality indicators from the Assessing Care for Vulnerable Older Elders (ACOVE) criteria. Data were collected using pre and post surveys asking general demographic information, fall risk factors, general knowledge of falls and satisfaction with video. Zip codes were used as a proxy for socioeconomic status. Data were managed with REDCap and analyzed using the SAS V9.4 statistical software. 172 individuals attending different senior community centers and one clinic screened the video. 45.2% self-identified as Hispanic. 31 watched the video in Spanish. Significant relationships were found between mean household income and fear of falling ($\chi^2=11.92$, $df=3$, $p<0.05$), ethnicity and fall history ($\chi^2=8$, $df=1$, $p<0.005$), ethnicity and fall injury ($\chi^2=8$, $df=1$, $p<0.005$) and ethnicity and risk of falling ($\chi^2=11.15$, $df=1$, $p<0.001$). In conclusion, there are significant differences in attitude towards falling among Hispanic vs. non-Hispanic individuals and those from different socioeconomic levels. These differences must be considered when designing and implementing fall prevention education programs in the community.

IMPACT OF 25(OH)D AND FALLS ON OLDEST OLD SURVIVAL

T. de Pontes, P.F. Moreira, L.M. Araujo, C. de Mello Almada Filho, M.S. Cendoroglo, *Federal University of São Paulo, São Paulo, São Paulo, Brazil*

Introduction: Some factors that contribute to active aging can benefit the raising number of oldest old people. Vitamin D and life style have shown impact on functionality and mortality. Objective: Evaluating if 25(OH)D, outdoor activity time and falls are predictors of survival in independent oldest old. Methods: We selected 258 community-dwelling and independent elderly people with 80 years old or more. We evaluated the mortality through the death certificate or register in medical records from April 2010 to March 2016. During the survival analysis, we have used the models

of Kaplan-Meier and Cox. Results: Around 70.5% were women between 80 to 89 years old (80.2%), 38.8% had daily sunlight exposure superior to 15 minutes and 20.1% were chronic fallers. Regarding 25(OH)D, 9.3% had serum levels < 10 ng/mL, while 76.4% between 10–30 ng/mL and 14.3% showed values > 30 ng/mL. During the observational period, 65.9% of the old oldest have stayed independent, and 17.1% have deceased. The analysis of survival time have shown that men (HR=2.7, p=0.003), over 90 years old (HR= 4.12, p<0.001), with levels of 25(OH)VitD inferior to 10 ng/mL (HR=3.2, p=0.004) and chronic fallers (HR=1.97, p=0.042) have shown a lower survival in comparison to the other oldest old. Conclusion: This study has identified a profile of oldest old more susceptible to a higher risk of death.

SESSION 1015 (POSTER)

FAMILY AND INTERGENERATIONAL RELATIONSHIPS III

ENTERING OR EXITING GRANDCHILD CARE DURING THE ECONOMIC CRISIS IN THE U.S.

Y. Lee, *Syracuse University, Syracuse, New York*

Family members experience role-based household relationships as sets of resources and demands, including time, money, skills, and attention. Grandparents have resources; and family members have demands. Balance between resources and demands affect the care they are able to provide and the care that adult children and their grandchildren would need. However, less is known about the predictors of transitions entering into and exiting the roles as grandchild care during the economic downturns such as the Great Recession. Using the three waves from the Health and Retirement Study 2006~2010, data is drawn from 12,753 respondents in 2008 (Wave 9) with at least one living grandchild with a parent. Using the logistic regression, total 33,802 grandparent-parent relationships clustered within multigenerational families were examined in this study. Findings show that entering childcare occurs in hard times especially when adult-children's demands exceed grandparents' resources. At the economic recession, grandparents are most likely to enter the roles as grandchild caregivers because of adult children and their families' needs arise. Grandparents are valued resources for adult children who are in needs of childcare services and economic assistance.

CARING FOR AGEING PARENTS—GENDER INEQUALITIES IN A GENDER-EQUAL WELFARE STATE?

K. Herlofson, M. Veenstra, H. Vagen Nordbo, *Oslo & Akershus University College, NOVA, Oslo, Norway*

Norway, together with the rest of Scandinavia, is often seen as a vanguard with regard to changing gender roles. In the last decades, an important goal has been the dual earner/dual carer model. However, politics have been targeted couples with young children. Adult children's care for older parents has received limited attention, and recent Norwegian research has documented substantial gender differences in allocation of public help depending on both parents' and

their children's gender. Here, we address provision of care to parents among adult children in Norway, by taking account of both parents' and children's gender. We ask to what extent the degree of parental needs impact on sons' and daughters' care provision, and whether there are signs of more care involvement among more modern (gender equality oriented) men compared to more traditional men. The analyses are based on data from the Norwegian Life course, Ageing and Generation Study (N=14,884). The results show that sons are more inclined to help, but only as long as their parents are not in need of care. When parents, and mothers in particular, need help, daughters are more involved, and with increasing needs, gender differences become more and more marked. So far, there are no signs of a more caring son among modern men. The findings indicate that the gender equality debate needs to move beyond the early family years and care for children, and address division of care provision among adult children when ageing parents' become in need of help.

RECONCILING INTERGENERATIONAL AMBIVALENCE AND ONWARD TO INTIMATE JAPANESE AND KOREAN FATHERING

A. Kim, *Sociology, International Christian University, Tokyo, Japan*

This research analyzes the process by which intimate fathering is established among Japanese and Korean men. Due to globalization, new ideals of fatherhood are challenging traditional paternal roles in Japan and South Korea. Contemporary fathers striving to emulate more engaged parenting often wrestle with painful recollections of their own fathers' stern, distant, and patriarchal approach. How do men reconcile their aspirations for their own development as parents with their often-conflicted relationships with their fathers? Motivated by the concept of intergenerational ambivalence and social construction of masculinity, this study analyzes how Japanese and Korean participants of an international men's movement called Father School, craft a new fatherhood less tethered to breadwinning and distant patriarchy. With Father School guidance, men practice intimate fathering and adopt a life course frame that allows them to reconcile their mixed feelings toward their fathers. Based on the ethnographic study of multi-week seminars in the US, South Korea, and Japan, I illustrate the processual mechanisms that enable adult men to reconcile their ambivalence toward their adult fathers and practice a more contemporary fathering approach in their families. My analysis points to letter writing to adult fathers, affective family bonding practices, and small group confessional activities, as core processes that structure reconciliation and paternal change.

FORMAL CARE USE IN OLDER AGE: THE ROLE OF MARITAL TRANSITIONS

A. Ermer, C. Proulx, *University of Missouri, Columbia, Missouri*

When individuals need care, spouses are only second to adult children in care provided (AARP, 2015). Thus, marital transitions in later life may prompt changes in formal care use. But work that examines marital status and formal care uses cross sectional data without examining marital transitions as they unfold. We employed longitudinal data from

6 waves (2002–2012) of the HRS (N = 8,160) to examine whether changes in marital status (i.e., transitions to marriage, widowhood, or divorce) occurring in later life are associated with formal care use (i.e., home healthcare, hospital visits, doctor visits). Multilevel analyses were conducted in SAS. Level 1 variables (time-varying) included marital transitions, income, and outcome variables. Level 2 (time invariant) variables included race, gender, age, baseline marital status, and number of divorces, marriages, and times widowed at baseline. Only final models and primary IVs are presented. Transitions into divorce were not associated with immediate or long-term changes in outcomes. Respondents who married over the course of the study had a decreased likelihood of using home health care (OR = 0.74, $p = .049$) and reported more hospital visits ($\beta = 0.10$, $p = .049$) – these effects occurred in the wave immediately following marrying. Respondents who transitioned into widowhood experienced increases in number of doctor's visits ($\beta = 0.48$, $p = 0.002$) – this effect occurred over time, not immediately. These results emerged while considering marital status and marital histories at baseline and provide evidence of the impact of marital transitions on formal care use in later life.

WITHIN-FAMILY DIFFERENCES IN LIVING PROXIMITY AND INTERGENERATIONAL SUPPORT: IMPLICATIONS ON OLDER PARENTS' HEALTH IN CHINA

L. Bao, *California State University, Los Angeles, Los Angeles, California*

Research on the impact of living proximity on children's provision of support in Chinese families has been based on cross-family designs. Recent studies of western families have shown significant within-family differences in intergenerational support. Taking the within-family differences approach this paper uses data from the China Health and Retirement Longitudinal Study (CHARLS, 2013) to examine how children's relative living proximity to older parents compared to that of their siblings influences their support to parents. Results suggest that sibling children at different living distance to parents coordinate/cooperate in elderly support. Children who live relatively farther among siblings provide the highest level of economic support but have the least contact with parents. While living closer to parents among siblings is associated with the most frequency contact with parents and the lowest level of economic support. These patterns differ between rural and urban parent-noncoresident child dyads, and are also moderated by parents' living arrangement, the gendered division of elderly support, and the reciprocity between parents and children. The effect of non-coresident children's relative proximity on provision of economic support is less prominent if urban parents live with sons. Rural daughters' provision of economic support is less affected by their relative living proximity to parents than rural sons' and differences in intergenerational contact associated with children's relative living proximity to parents are smaller for all daughters than for sons. Furthermore, differences in children's provision of economic support associated with their relative living proximity are larger if rural parents have provided grandchild caregiving for children.

DOES LIVING WITH UNMARRIED ADULT CHILDREN THREATEN MARITAL RELATIONSHIPS OF ELDERLY KOREAN COUPLES?

S. Choi¹, M. Sung², Y. Choi³, J. Lee⁴, 1. *Home Economics Education, Korea National University of Education, Seoul, Korea (the Republic of)*, 2. *Korea National Open University, Seoul, Korea (the Republic of)*, 3. *Sangmyung University, Seoul, Korea (the Republic of)*, 4. *Seoul National University, Seoul, Korea (the Republic of)*

Coinciding with the global economic crisis, the age at first marriage in Korea has been delayed. Traditionally, the independence of adult children away from parents has been expectable mainly when they get married, thus, it would mean that for the elderly parents to live with their adult children will also be anticipated to extend. This study aims to investigate whether co-residence between adult children and older parents disrupts the quality of marital relationships for elderly parents in Korea. Using quota sampling in terms of living arrangements (living together vs. living apart), 500 elderly parents, having at least one unmarried child aged 35 years old or above, were selected in Seoul, Korea in June 2016. The quality of marital relationships as a dependent variable was measured with four concepts: marital satisfaction, marital intimacy, marital consensus, and marital conflict. Co-residence of parents with adult children as an independent variable was measured with a binary variable. Regular financial support for adult children and socio-demographic variables were controlled. Findings from a series of OLS regression models and the ordered logit model show that parents living with adult children were less likely to report satisfaction, intimacy, and consensus in their marital relationships than those who living apart from their adult children, holding financial dependency of the child fixed. However, co-residence with unmarried adult children was not positively associated with marital conflicts between the elderly couples. The present study has implications for the marital relationships of elderly Korean couples by boomer-ang and/or failure-to-launch families.

DOES CLOSENESS MATTER?: PARENTS' EXPERIENCES WITH CHILDREN SUFFERING PROBLEMS AND DAILY WELL-BEING

M. Huo¹, K. Kim², S. Zarit³, K.L. Fingerman¹, 1. *University of Texas at Austin, Austin, Texas*, 2. *University of Massachusetts Boston, Boston, Massachusetts*, 3. *The Pennsylvania State University, University Park, Pennsylvania*

Research has established associations between children's problems (e.g., divorce, major health problem, addiction) and parents' well-being. Yet, few studies have examined whether parents' closeness to a child with these problems accentuates the effects. The current study assessed aging parents' everyday experiences with grown children who were incurring life problems. We asked whether feelings of closeness to the child moderated effects of daily experiences on the aging parents' daily mood and physical symptoms. Data were from *The Family Exchanges Study* wave 2 conducted in 2013. The sample included 207 parents ($Mage = 79.86$) who reported during seven days on experiences including pleasant encounters, stressful encounters, and stressful thoughts about the adult children. Parents also reported their mood (positive and negative affect) and physical symptoms each day. Multilevel logistic regression models showed that

parents were more likely to have pleasant encounters and less likely to have stressful thoughts about problem children with high closeness than problem children with low closeness. Yet, parents' stressful encounters with problem children who were closer to parents did not differ significantly from the encounters with problem children who were less close. Further, multilevel regression models revealed that pleasant encounters and stressful thoughts about problem children with high rather than low closeness were associated with parents' better mood and fewer physical symptoms. Overall, findings suggest that lack of closeness may especially exacerbate the negative effects of offspring's problems on parents' well-being.

TRANSNATIONAL FAMILY SUPPORT EXCHANGES: AN EXAMINATION OF STRESS AND HEALTH STATUS

J.M. Kalavar, *Penn State New Kensington, New Kensington, Pennsylvania*

Increasing longevity and rapid globalization have spawned the emergence of transnational families. Over the past forty years, aging research has repeatedly demonstrated that caring for an older person may affect the health and well-being of the provider. While providing support long-distance within a country is itself stressful, transnational support involves the additional challenges of distance, visa, travel expenses, cultural expectations, different circumstances, and different types of resources.

The challenges of providing transnational support carry implications for the health and well-being of both the elderly parents and adult children residing in two different nations; however, migrants and their families are said to also experience care provision stress. Using data gathered from an online survey of 129 Asian Indian adults living in the USA who have an elderly mother living in India, a comparison between maternal health status and adult offspring health status as well as self-reported stress levels by the support provider was examined. The correlation between maternal health status and adult offspring was not statistically significant. However, findings show that marital stress was the highest ranked stressor, followed by guilt experiences, and time difference between the two nations. The risks to the physical and mental health of immigrants who provide transnational support to elders are varied and multifold. Results facilitate our understanding of how health care provision strategies are maintained, modified, and generated in transnational exchanges. Examining these transnational support experiences may help us generate policy to mitigate the health risks and stressors that these immigrant adults may face.

CORESIDENCE, GEOGRAPHIC PROXIMITY, AND SOCIALLY PRODUCTIVE ENGAGEMENT AMONG OLDER KOREANS

P. Ko, *National University of Singapore, Singapore, Singapore*

The study investigates the relationships between living arrangement of older Koreans and the engagement in socially productive activities (attending classes, social clubs, volunteering, joining NGOs and interest groups). Literature based on western contexts emphasizes that the individual resources, including education and socioeconomic status matter to the engagement. We argue that such a framework needs to add

the intergenerational solidarity into consideration in East Asia where older adults' social life is closely embedded with intergenerational relationships. Two hypotheses are tested: (1) Family norm hypothesis- older parents who live with their children would be more likely to engage in socially productive activities. The reason is that living with children is the late-life ideal and hence they would be more likely to develop their social circles in such living arrangement. (2) Assistance hypothesis- older parents who live with children are less likely to engage in socially productive activities than those who do not because it means that older parents need assistance due to health decline. The empirical examinations are based on two waves of Korean Longitudinal Study of Ageing (KLoSA) (n=7,869). The preliminary findings based on Wave 1 show that older adults whose children stay nearby are more likely to engage in activities than those who live with children while controlling for education, marital status, gender, mental health and disabilities, supporting the second hypothesis. The next step is to apply random effect estimations based on two waves in order to test whether when changes of living arrangement affect the engagement in activities.

THE CHANGING LANDSCAPE OF LATE-LIFE INTIMACY IN MODERN SWEDEN—A NATIONAL PORTRAIT

T.M. Bildtgård¹, P. Öberg², 1. *Social work, Stockholms Universitet, Stockholm, Sweden*, 2. *University of Gävle, Gävle, Sweden*

This paper focuses on union form in cross-gender relationships in later life, against the background of the transformation of intimacy in late modernity. Results are based on a survey to 60–90 year old Swedes (n=1225; response rate 42%) and European census data. Sweden seems to be the only country where there are more divorced than widowed people in this age group. Almost 1/3 of Swedes, aged 60–90, categorized as singles by official Swedish census data on civil status, are in fact living as LATs or cohabitants. In new romantic relationships initiated 60+ the dominant union form is LAT (70%) followed by cohabitation (26%), while marriage is rare (4%). Less than 2 in 10 singles think that is important to be married – and among marrieds less than 8 in 10. Relationship history data shows that although half of the respondents have been married only once, one third (33%) have had 2+ cohabiting unions (marital/non-marital), half (46%) 2+ established relationships, and a majority (66%) 3+ sexual partners. The results indicate that the transformation of intimacy includes older Swedes. Discussion: Should we see older people as a vanguard in the exploration of late modern intimacy, rather than carriers of cultural lag?

SESSION 1020 (POSTER)

GAIT

ANKLE STRENGTH AND GAIT DYSFUNCTION IN AGING PATIENTS

T.L. Kauffman^{1,2}, H. Jeffries³, 1. *Kauffman Physical Therapy, Lancaster, Pennsylvania*, 2. *Academy of Geriatric Physical Therapy, Madison, Wisconsin*, 3. *Curtin University, Perth, Western Australia, Australia*

Gait dysfunction in aging patients is often multi-factorial and unfortunately, ankle strength is infrequently measured. In our Balance Center we evaluated 13 females and 15 males, mean age 79.6 years, range 62–99. All had co-morbidities but primarily balance dysfunction, unsteady gait and some falls. Dismobility and loss of balance can occur in any direction. The ankle contacts the ground first and gives critical proprioceptive and kinesthetic sensory information. Dorsiflexion (DF), Plantar Flexion (PF), Eversion (EV) and Inversion (IN) muscle strength was measured with a hand-held dynamometer and calculated as a percentage of body weight.

The purpose of this study was to compare ankle strength in the patients with a control group without gait dysfunction which included 6 females and 4 males, mean age 75.3 years.

The percentage of DF/PF strength was statistically significantly less in the patients, 13.4% versus 28.7%. The percentage of EV/IN was also statistically significantly less in the patients 13.2% versus 4.5%. Our patients with gait dysfunction were slightly more than 2 times weaker for DF/PF and almost 3 times weaker in EV/IN compared to controls.

For EV/IN, 29% of the patients, but no control subjects, generated less than 5 pounds of force. Clinically, this medio-lateral weakness appeared to be a motor control problem because many of the patients did not know how to evert or invert the ankle and they lacked the kinesthesia.

In conclusion, our results indicate ankle weakness especially in the medio-lateral directions may be a factor in gait/balance dysfunction and falls.

GAIT SPEED AND MORTALITY IN OLDER ADULTS: WHY TIMING MATTERS

S. Karunanathan, C. Wolfson, *Epidemiology, Biostatistics and Occupational Health, McGill University, Montreal, Quebec, Canada*

Recently, an emerging body of literature has indicated a strong association between poor gait speed and mortality. However, these studies have several methodological limitations. Based on secondary analysis of data from existing longitudinal studies of aging, they generally measure gait speed at a single time point and use this time point as the time origin in assessing the association between gait speed and survival over several years. The objective of this study is to estimate the association between gait speed and mortality, using a meaningful time axis, and accounting for the time-varying effects of other health characteristics. The study is based on data from the Cardiovascular Health Study, a study of 5,201 individuals aged 65 years and over, with annual measurements of gait speed and several covariates over a period of 10 years. Using age rather than time-on-study as the time-axis, I apply a time-varying Cox model to estimate the independent effects of gait speed on mortality, while accounting for the effects of health characteristics, including depression, cognitive function, and chronic disease. For comparison, I provide estimates of models where variables are treated as time-fixed. Overall, I found that the time-varying measure of gait speed yields a stronger association with mortality compared to the time-fixed measure. Furthermore, the control for health and lifestyle factors attenuates the association in women, but not in men. Using time-varying measures of gait speed and controlling for health and lifestyle confounders

provides a more meaningful estimate of the association between gait speed and mortality.

CURVED-PATH WALKING: WHEN VARIABILITY IS GOOD

K. Bland¹, A. Dahlhauser¹, A. Krajek¹, E. Johnson², T. Woods³, W. Farrington¹, K.A. Lowry¹, 1. *Des Moines University, Des Moines, Iowa*, 2. *Iowa State University, Ames, Iowa*, 3. *Grand View University, Des Moines, Iowa*

The Figure-of-8 Walk test (F8W), a measure of walking skill, incorporates both straight and curved paths. While gait variability during straight-path walking is associated with adverse outcomes, variability during curved-path walking is critical for efficient turning. We examined variability of step length (SLV), step time (STV), and stride width (SWV) during F8W and expected greater variability in those with better motor skill.

Thirty-two older adults (mean age 72.1 ± 9.3 yrs) completed the F8W (walking a figure-of-8 around two cones 5 feet apart) on an instrumented walkway. Gait measures were: 1) variability, standard deviations of SLV, STV, and SWV, 2) F8W number of steps and time to complete, s. We examined differences in variability by skill group using ANOVAs (F8W time ≤ 8 seconds (F8H, high skill), F8W time > 8 seconds (F8L, low skill)). Correlations (*r*) adjusted for speed were used to examine associations between F8W and variability.

Motor skill groups differed for SLV (SLV: F8H = 22.2, F8L = 18.2, *p* = .024) and SWV (F8H = 23, F8L = 17.2, *p* < .001); no group differences for STV. Variability measures related to curved-path walking ability, F8W time (SLV, *r* = -.40, SWV *r* = -.70, STV *r* = -.51), and number of steps (SLV, *r* = -.42, SWV *r* = -.80, STV *r* = -.60).

Better motor skill in walking is associated with greater spatial variability. Individuals with better curved path walking ability (F8W time) are able to actively adjust spatial parameters for the walking task. Rehabilitation should include practice of curved paths and experience in active adjustments of step length and width.

LOW TEST-RETEST RELIABILITY OF GAIT VARIABILITY: AN INDICATOR OF POOR MOBILITY AND BALANCE?

M. Almarwani^{1,2}, J. Brach², 1. *King Saud University, Riyadh, Saudi Arabia*, 2. *University of Pittsburgh, Pittsburgh, Pennsylvania*

Test retest reliability of gait variability is less than ideal, i.e. ICC < 0.70. Low test-retest reliability or inconsistency of gait variability may be an indicator of impaired mobility, balance and overall health of the older adult. Our purpose was to examine the association of inconsistency of step time variability to mobility, balance and health in older adults. Participants included 46 community dwelling older adults who could ambulate independently (mean age = 78.09 years, SD = 6.2). Gait characteristics were measured twice, one week apart, using a computerized walkway. Step time variability (STV) was the standard deviation of the step times for all steps recorded during one session. Mobility, balance and health were measured during the first session using gait speed and global questions of mobility, balance, health and vigor. Using the difference of the STV measures from sessions 1 and 2 two groups were created: 1) inconsistent (IN, *n* = 14), STV

difference from session to session $> 0.013s$, 2) consistent (CN, $n=32$) STV difference from session to session $< 0.013s$. Differences between groups were determined by independent t-tests and Chi-square. IN compared to CN, walked slower (0.83 vs 1.01 m/s) and was less likely to report good or better mobility (36% vs 78%) and balance (21% vs 63%), all p 's < 0.05 . Overall health and vigor were similar between groups. Inconsistency in step time variability from week to week in older adults may not be due to measurement error, but may actually be an indicator of impaired mobility and balance.

INHIBITION, PROPRIOCEPTION AND STEPPING PERFORMANCE: IS THERE A SPECIFIC RELATION IN OLDER ADULTS?

J. Magnard¹, C. Cornu¹, G. Berrut², T. Deschamps¹, 1. Laboratory "Movement, Interactions, Performance" (E.A. 4334), University of Nantes, France, Nantes, France, 2. Investigation Clinical Center of Gerontology Department, Teaching Nantes Hospital, France, Nantes, France

The perceptual inhibitory process has been suggested to be specifically involved in the integration of proprioceptive information that is necessary for an efficient postural performance in older adults. This ongoing study aimed to investigate the perceptual and motor inhibition requirements of planning and executing a choice step initiation task in young and older adults following experimental perturbation of proprioceptive information using bilateral Achilles' tendon vibrations. Two groups ($n \sim 50$ each) of young adults (range age 18–30 years), and healthy older adults (>65 years of age) were asked to perform an inhibitory stepping reaction time (RT) task in which the participants had to step as quickly as possible in response to visual arrows that manipulated specific perceptual or motor inhibition, in two conditions: with or without vibrations. The preliminary results (up-to-date $n \sim 10$) showed that the vibrations induced higher RT performances irrespective of the perceptual or motor inhibition demands. Any specific role of the perceptual inhibition into the processing of proprioceptive inputs needs to be confirmed in healthy older adults. Compared to younger adults, older adults have greater variability in step behaviour, with longer total stepping time, when using localized vibrations in conditions requiring inhibition. More participants continue to be included to determine robustly whether modulating afferent proprioceptive inputs and inhibition are two processes that share, at least in part, the same cognitive resources in older adults, while executing a choice step. But the current results validate the view that inhibitory process is a core executive function of dynamic postural control.

NEUROMOTOR CONTROL, AGING AND EVERYDAY WALKING

K.A. Lowry¹, J.M. Van Swearingen², 1. *Physical Therapy, Des Moines University, Des Moines, Iowa*, 2. *University of Pittsburgh, Pittsburgh, Pennsylvania*

Neuromotor control and efficiency of walking is represented in the optimal relationship between step length and cadence (walk ratio, WR). Aging results in suboptimal WRs and inefficient walking. In older adults, we explored the neuromotor control of usual walking, WR, and motor skill in usual (gait variability) and curved path walking (Figure-of-8 walk, F8W). Older adults ($n=82$, mean age 74.9 yrs. \pm 7.5)

participated. Walking measures derived from an instrumented walkway: 1) WR, step length (m)/cadence (steps/min), 2) gait speed, cm/s, 3) gait variability, standard deviations of stance time (STV, s), step length (SLV, cm), and 4) F8W time, s, and number of steps to complete. WR categories were defined by distance from optimal range (WRo = optimal, WR1 = sub-optimal, WR2 = most suboptimal). ANOVAs were used to compare mean variability and F8W time and steps across WR categories, with test for trend (p_{trend}). The F8W time and steps increased, and usual speed decreased across WR categories (F8W time, s: WRo = 7.7, WR1 = 9.2, WR2 = 10.7; F8W steps: WRo = 13.7, WR1 = 15.2, WR2 = 18.1; speed, cm/s: WRo = 116, WR1 = 106, WR2 = 90; all $p_{\text{trend}} < .001$). Variability did not differ across WR categories (STV, s: WRo = 0.03, WR1 = 0.03, WR2 = .04; SLV: WRo = 3.4, WR1 = 3.0, WR2 = 3.6, $p_{\text{trend}} = .145$, $p_{\text{trend}} = .400$, respectively). Neuromotor control in walking is important for the adaptability needed to switch between straight- and curved-paths, typical of everyday walking.

INCREASED DIFFICULTY OF DUAL-MOTOR TASKS EFFECTS STEP LENGTH IN YOUNG AND OLDER HEALTHY ADULTS

K. Watson, J.A. Blaskewicz Boron, S. Myers, J. Yentes, *Biomechanics, University of Nebraska at Omaha, Omaha, Nebraska*

Many adults have difficulty doing two things at once, especially walking and completing another motor task. In older adults, this could lead to a fall. Further, falls during walking have been associated with changes in gait variability or the natural stride-to-stride fluctuations while walking. The aging process contributes to a more variable gait cycle, which contributes to falls, and has been used to predict falls occurrence. This project investigated the effect of task difficulty during dual-motor tasking on gait variability in young and older healthy adults. Fifteen young adults (20.6 ± 2 years, 167.4 ± 6.5 cm, 65.0 ± 5 kg), and five older adults (72 ± 3 years, 169.2 ± 13.3 cm, 68.7 ± 10.9 kg) completed a series of dual-task conditions, $3\frac{1}{2}$ minutes each, where the opaqueness of the tray and/or the amount of water in glasses on top of the tray (task difficulty) varied while walking on a self-paced treadmill. For each condition: sample entropy was calculated on step length, step time and step width. Older adults showed significantly less repetitive step length values than young adults ($p=0.04$). Step length was less repetitive during baseline walking as compared to conditions in which vision or task difficulty was altered (p 's=0.005, 0.021, 0.006, $<.001$ respectively). Larger sample size may help increase the significant differences between groups: trends suggest that a secondary motor task impacts step length in both populations. Older adults were impacted to a greater extent suggesting a more variable, less repetitive gait, consistent with previous literature in prediction of falls.

ROAD NETWORK HILLINESS AND DEVELOPMENT OF WALKING DIFFICULTIES AMONG COMMUNITY-DWELLING OLDER PEOPLE

K. Keskinen, M. Rantakokko, T. Rantanen, E. Portegijs, *Gerontology Research Center and Faculty of Sport and Health Sciences, University of Jyväskylä, Finland*

Aims: To study associations between objective road network hilliness and development of walking difficulties (WD) within two years, and to examine how hilliness as a perceived barrier and frequency of moving through the neighborhood affect to this.

Methods: Prospective analyses of community-dwelling 75-90-year-old people without any WD at baseline and living at the same address throughout the 2-year follow-up (n=546, 59% women). The average slope in the road network within 500m distance from home was defined using GIS (range 2.7–11.2%). Self-reports of hilliness as perceived barrier for outdoor mobility (yes/no) and frequency of moving through the neighborhood (0–3 / ≥ 4 times a week) were collected at baseline, and WD over 500m (yes/no) at baseline and follow-up. Logistic regression analyses were adjusted for age, gender, number of chronic conditions, years of education, years in current address, and length of road network.

Findings: Of the participants 18% perceived hilliness as a barrier, 15% moved through the neighborhood 0–3 times a week, and 15% developed WD over the 2-year follow-up. Higher road network slope increased the risk for developing WD (OR=1.22, CI 1.01–1.48). Hilliness perceived as a barrier (OR=1.51, CI 0.84–2.74) and frequency of moving through the neighborhood (OR=3.41, CI 1.94–6.02) attenuated the association between the road network slope and WD (OR=1.21, CI 0.995–1.47).

Conclusions: Hilliness perceived as a barrier and frequency of moving through the neighborhood partly mediate the association between objective road network slope and WD. Further study is needed to determine how hilliness affects behavior and consequently the development of WD.

EFFECTS OF VIRTUAL UPHILL WALKING ON ENERGY EXPENDITURE AND LOCOMOTOR-RESPIRATORY COUPLING

W. Denton, M. Mukherjee, N. Stergiou, J. Yentes, *Biomechanics, University of Nebraska at Omaha, Omaha, Nebraska*

Uphill walking becomes more difficult with age due to physiological changes. Aerobic respiration which increases to meet the increased energy demand becomes limited. The link between our movements and breathing that maximizes economy is termed locomotor-respiratory coupling (LRC). This project expands on previous LRC research using incline as the independent variable instead of walking speed. Virtual reality also provided level or uphill environments to see if vision could alter energy expenditure and LRC. Participants, 4 older adults (69 \pm 3.6 years, 160 \pm 12.4 cm, 61.3 \pm 11.6 kg) and 10 younger adults (22.5 \pm 1.2 years, 175.2 \pm 8.0 cm, 77.9 \pm 9.0 kg), walked on a treadmill that was either level (0%-grade) or inclined (10%-grade) while paired with level or inclined virtual reality. A baseline condition (level walking with no virtual reality) and an oscillating condition (level walking with sinusoidal level-uphill virtual reality) were also included. Average energy expenditure was used to quantify the energy requirement and cross recurrence quantification analysis (cRQA) was used to quantify LRC. Although not significant, energy expenditure decreased with the addition of virtual reality for the older group, while it increased for the younger group and while energy expenditure was similar

for all level conditions, the older group used less energy for inclined walking. Additionally, older adults always required a larger radius for cRQA ($p=0.032$) and cRQA's max line, mean line, and entropy may become significant with a larger sample size as they were always lower for the older group. Older adults exhibited less coupling, yet required less energy during uphill walking than younger adults.

EFFECT OF MOTOR-COGNITIVE TRAINING ON POSTURAL CONTROL OF ELDERLY: SYSTEMATIC REVIEW

E.M. Varise, J.R. Bacha, G. Gomes, J. Pompeu, *University of São Paulo, São Paulo, São Paulo, Brazil*

Objective: To analyze the effectiveness of motor-cognitive training on postural control of elderly people. **Methods:** We conducted a search in the databases PubMed and Web of Science, considering the period of 2011 to 2016, using the strategy: (“aged” OR “elderly” OR “older adult” OR “older people” OR “older person” OR “geriatric” AND “dual task” OR “dual-task” OR “dual task training” OR “dual tasking” OR “dual task elderly” OR “dual-task training” OR “cognitive engine” OR “cognitive-motor” OR “dual task cognitive engine” OR “motor cognitive dual task” OR “multi tasking” OR “multi-task”). We selected randomized clinical trials (RCTs) that used motor-cognitive training to improve postural control of elderly people. Papers not available in full in the collection of on-line journals USP Library, duplicates and studies that did not assess the static or dynamic postural control were excluded. **Results:** The search strategy result in 15 studies (122 in PubMed and 93 in the Web of Science). It was selected 12 studies. Most articles demonstrated superiority of different types of cognitive-motor training (CMT) compared to isolated training to improve postural balance and temporal gait parameters, with and without dual task. Training once a week demonstrated positive effects on the march, but long-term training attenuated the decline in physical function of older people in many ways. Adherence for cognitive training improves executive function, especially when management tasks. The incidence of falls and fractures reduced one year after training. **Conclusions:** The motor-cognitive training improves postural control, cognition, quality of life and reduces falls of elderly people.

SESSION 1025 (POSTER)

HEALTH AND SOCIAL SERVICE ASSESSMENTS AND INTERVENTIONS

PROMOTING THE HEALTH OF RURAL CAREGIVERS THROUGH THE CAREGIVER LITERACY SERIES

E.T. Jurkowski, *Southern Illinois University at Carbondale, Carbondale, Illinois*

Repeatedly as multidisciplinary professionals we are concerned about the individual patient we serve – especially as we consider their cognitive and neurological needs. The Caregiver Literacy Series, is a series of ten specific modules designed to enhance the coping of the caregiver and family members through scientific and educational resources. Four specific therapeutic workbooks and accompanying

CDs provides an overview of information about the specific neurological and biological aspects of the dementia disorder and how these aspects affect the individual's behavior. The series designed through the use of the Self Efficacy Model (Bandura, 1968) and Prochaska and DiClemente's Stages of Change (1988) theoretical frameworks has demonstrated some positive impact in improving one's understanding of the illness, decreasing caregiver burnout and improving depression levels for users. The efficacy of these educational tools was measured by various psychometric scales including the Care giving Burden scale, Compassion Fatigue and Satisfaction Scale and Center for Epidemiologic Study Depression Inventory. Some of the educational module topics include *Understanding the Care giving Role; Care giving and Depression; Care giving and People with Alzheimer's Disease; Care giving and People with Behavioral Issues*. This presentation will showcase the specific modules of the series related to Alzheimer's Disease, and showcase data on the efficacy of this intervention in a rural population of caregivers meeting the needs of their loved ones advancing in age. Qualitative and quantitative results suggest that these tools provide both information and respite to the potentially isolated caregiver and aids in the coping process.

FROM PASSIVE CARE TO ACTIVE CARE: PROMOTING SENIORS' HEALTH WITH HOME CARE AIDES

N. Muramatsu¹, L. Yin¹, M.L. Berbaum¹, D. Marquez¹, D.A. Jurivich², J.P. Zaroni¹, S.M. Walton¹, K.Y. Cruz Madrid¹, 1. *University of Illinois at Chicago, Chicago, Illinois*, 2. *University of North Dakota, Grand Forks, North Dakota*

As aging societies strive to strengthen home and community-based services systems, home care aides (HCAs), also called personal care assistants, play increasingly important roles for frail older adults. In the current home care paradigm of "passive care", HCAs provide prescribed help with daily activities, rather than actively stimulate older clients' reserves to maintain independence. To innovate home care practice, we piloted a safe, low-cost physical activity program delivered by HCAs for older adults in a Medicaid-funded home care setting in the United States. HCAs were trained to deliver a brief motivational enhancement and three chair-bound movements to motivate their clients to do physical activity daily and help maintain their independence. Mixed methods were used to evaluate the 4-month intervention. Survey data showed significant improvement in clients' function to perform daily activities targeted by the intervention ($p < .01$) as well as in clients' physical performance tests and other outcomes such as reduced interference with daily activities due to pain and fear of falling. The program was well-received by home care clients ($N=54$) and their HCAs ($N=46$) as indicated by the high retention rates and by remarks provided by clients and their HCAs. Building physical activity into the everyday care of older adults and the routine job of HCAs is feasible. The promising results urge a cultural shift in home care towards an active service model in which home care aides and their clients work together on a safe, simple physical activity program to maintain or improve function to remain in the community.

SCREENING OLDER ADULTS FOR FOOD INSECURITY DURING CHECK-UPS: WHAT DO HEALTH PROFESSIONALS THINK?

J. Pooler, V. Hoffman, F. Karva, *Health Services, IMPAQ International, Windham, Maine*

Food security screening is becoming increasingly common at well-child visits in the U.S. Systematic screening of older adults for food insecurity is much less common, despite increasing rates of food insecurity among seniors and the significant impact of food insecurity on health outcomes and chronic disease. Our study sought to understand health professionals' attitudes and beliefs about food security screening and referrals for older adults and barriers to implementation. We conducted 20-minute telephone interviews with a diverse group of health professionals ($n=16$) who are currently seeing older patients and do not currently screen for food insecurity in routine practice. Overall, those interviewed recognized the importance of good nutrition and food security for older patients and did not think a 2-item screener would be difficult to administer in routine practice. Three major challenges were identified: limited time available to meet with patients, a lack of resources available to address food insecurity when it is identified, and prioritizing food insecurity at both the health system and the patient levels, when competing interests such as billing and required screenings or chronic conditions and other social needs are present. Primary care practice may be one place where food insecurity among older adults can be identified and seniors referred to appropriate services and supports to enhance positive health outcomes and encourage management of chronic diseases. While community services are a critical piece in the referral process, health systems and insurers may consider ways to seamlessly integrate screening and discussions with patients around food insecurity.

EFFECTS OF EMPATHY CLUBS ON HEALTH CARE AMONG HIV-AFFECTED GRANDPARENT-HEADED HOUSEHOLDS IN VIETNAM

L.M. Harris¹, J. Wilfong¹, V. Schmidt¹, N. Thang², 1. *Kent School of Social Work, University of Louisville, Louisville, Kentucky*, 2. *Cooperation and Development (CESVI), Hai Phong, Viet Nam*

In areas of Vietnam with high rates of HIV/AIDS, Empathy Clubs (ECs) have become interventions for grandparents raising grandchildren. ECs offer psychosocial care and knowledge of community resources, such as healthcare events. This mixed methods study aimed to 1) explore the factors influencing health care for grandparents and grandchildren and 2) understand the differences in health care access between grandparents in ECs and those who are not. The research team interviewed 30 grandparents raising grandchildren in urban and rural areas of Hai Phong, Vietnam. Fifteen of the grandparents were involved in ECs and fifteen were not. The grandparents completed the Access to Healthcare Scale and a qualitative interview. The results showed a statistically significant difference between the two groups $t(2)=6.53$, $p=0.04$ and indicated that EC membership contributed to free healthcare for grandchildren. 73% of the EC group had free healthcare for their grandchildren compared to 26.6% of the non-EC group. The study found that ECs were most successful in terms of HIV testing for grandchildren. 100%

of the grandparents in the EC group had their grandchildren tested, whereas only 40% in the non-EC group had their grandchildren tested. Qualitative findings indicated that both groups of grandparents were not accessing healthcare services to address their significant health needs. The majority of the grandparents experienced barriers such as limited or no health insurance, physical health problems, poverty, and stress. Attributes that improved health among the grandparents included access to community health events, HIV testing, social support through ECs, resilience, and sacrifice.

COMMUNITY COMPREHENSIVE GERIATRICS ASSESSMENT WITH SERVICE DEVELOPMENT IN CAMBODIA

H.C. Cooper, S. Hean, B. Cordory, *Grace House Community Centre, Siem Reap, Cambodia*

Cambodia is a health poor country with health expenditure 5.68% of GDP in 2014 according to the WHO, with an ageing population. In the 2008 census, 6.34% of the population were over 60, rising to 11.1% predicted by 2030. At present there are no focused services existing in the country to care for the complex and specific health needs of older people and very little in terms of expertise.

A consultant geriatrician from the UK and a Cambodian social worker, undertook comprehensive geriatrics assessment (CGA) in the community, identifying and assessing older people for their health, financial and social needs. We studied 38 older people age 59 to 92 over a 4 month period in 3 semi-rural villages in Siem Reap province.

Many of the health needs in older people in Cambodia are very similar to those recognised in developed countries, such as cardiovascular disease, diabetes, incontinence, dementia and poor mobility. For example, of the 38 surveyed 29% suffered from severe incontinence affecting quality of life, 34% had difficulty using their squat toilet, 68% had problems with their vision and it was considered that 37% would benefit from a physiotherapist.

The service that was developed involved a trained social worker co-ordinating access and transport to health services that already exist, provision of equipment, expertise in physiotherapy, nutritional support and financial assistance when required.

We produced a simple, reproducible, cost-effective model to deliver basic health and social care support to older people in a developing country with an ageing population.

QUALITY ASSESSMENT OF ELDERLY LIFE OF COMMUNITY DWELLING PROJECT IN RIO DE JANEIRO, BRAZIL

C. Brasil¹, A. Brandão², C. Chaves², H.L. Furtado^{3,1}, 1. *Commission of the Elderly, Chamber of Deputies - Brazil, Brasilia - DF, Brazil*, 2. *Municipal Secretariat of Active Ageing, Resilience and Care, Rio de Janeiro, Brazil*, 3. *Castelo Branco University, Rio de Janeiro, Brazil*

Currently, Brazil has 23% of its population consisting of elderly. Seeking better health conditions and quality of life, the participation and social support networks are the focus of gerontology. The Community Dwelling Project for the Elderly of the Municipal Secretariat of Active Ageing, Resilience and Care (SEMEARC) of Rio de Janeiro City Government gives users a space of coexistence and social integration through

various activities. The objective was to evaluate the quality of life of elders in the program. We conducted an exploratory, transversal and descriptive quantitative research. The sample consisted of 113 women aged 73.05 ± 7.50 . To measure the quality of life, WHOQOL Bref and WHOQOL – Old were used. The results for the WHOQOL-BREF point to Global Life Quality with 71.8%, the highest score in the psychological domain with 74.7% and the lowest score in the environmental domain with 66.3%. As for the results of the WHOQOL-OLD, they indicate a total average score of 73.95%. The sensorimotor functioning facet had the highest average score 81.58%, showing good sensory performance. However, the death or die facet obtained the lowest average 67.48%, showing that there is a need to broaden the discussion on finitude. It is concluded that the Community Dwelling Program helps to raise self-esteem and improve the quality of life of elderly, demonstrating itself to be an efficient public policy for the elderly population of Rio de Janeiro.

MERGING HEALTH CARE WITH SENIOR HOUSING: A PROCESS EVALUATION

T. Barry, *Arcadia University, Glenside, Pennsylvania*

This paper reports the results of a case study on a successful partnership between a large health care organization and housing for seniors that resulted in lower emergency room visits and hospitalizations. The program provides on-site, primary care visits by a physician and a nurse in addition to intensive social services to residents in an affordable senior housing apartment building located in Pennsylvania. Using Avedis Donabedian's "Structure-Process-Outcome" model as a theoretical framework, this study sought to provide guidance for replication in similar settings.

With program structures in place and outcomes measured, this case study collected and analyzed qualitative information taken from program documents and key informant interviews on care processes involved in the program.

Qualitative analysis identified common processes across respondents; however, the nuanced processes that lead to successful outcomes suggest that defined structures and processes may not be sufficient to produce similar outcomes in other settings. Further research is needed to determine the program's replicability and policy implications.

HEALTH LITERACY AMONG KOREAN ADULTS AND KOREAN IMMIGRANTS IN THE U.S.

S. Chung¹, H. Lee², M. Lee¹, S. Chung¹, 1. *Ewha Womans University, Seoul, Seoul, Korea (the Republic of)*, 2. *University of Minnesota, Twin Cities, Minnesota*

Background: Health literacy is necessary to understand health information and make appropriate decisions regarding one's health. Largely influenced by cultural setting as well as age, to date no study has compared age-specific health literacy between immigrants and people from their home country.

Objective: This study aims to investigate (1) the health literacy level of Korean citizens and Korean immigrants in the United States (U.S.) and (2) factors that influence health literacy across three age groups (20–44, 45–64, and 65 and older).

Methods: A quota sampling method was used to collect cross-sectional survey data from 404 Korean participants

and 404 Korean immigrants. The Korean Participants' data were collected from February to March 2014 and data of Korean immigrants in U.S. were collected in 2009. Andersen's behavioral model, with its three components of predisposing, enabling, and need factors, was used as the theoretical framework for this study.

Results: Korean participants had a higher mean score on health literacy than did the Korean immigrants. Only one of predisposing (gender) and enabling factors (education) were significant variables influencing health literacy in Korean immigrants, while several predisposing (gender, employment, religion, and economic status), enabling (education and frequency of doctor visit) and need (frequency of doctor visit) factors were significantly associated with health literacy in Korean adults. These results were different from the three age groups.

Conclusion: Our findings indicate that Korean adults in both countries need to have a community-based health literacy educational program that is tailored to the needs of each age group. This age-specific and geographically competent intervention program will eventually reduce the health disparity disproportionately experienced by these at-risk populations with low health literacy.

“WHAT’S PAST IS PROLOGUE:” FINDINGS FROM WIGL PROJECT WAVE 1 ON BEING A WOMAN GERONTOLOGIST

D.B. Bradley¹, P.P. Brown², C. Bennett³, C.L. Estes⁴, 1. *Center for Gerontology, Western Kentucky University, Bowling Green, Kentucky*, 2. *Winston-Salem State University, Winston Salem, North Carolina*, 3. *University of Maryland Baltimore County, Baltimore, Maryland*, 4. *University of California San Francisco, San Francisco, California*

WIGL (Women in Gerontology Legacy) Project emanates from the Gerontological Society of America's Task Force (now Committee) on Women, and captures the life course trajectories of older female gerontologists via audio, video, and written interviews. Over 36 months, WIGL researchers interviewed 53 women gerontologists who have been active in research, education, and/or applied work for between 25–40 years. Professional association recognition of study participants' academic and applied achievements qualified them for study inclusion. One aspect of these interviews focused on examining how participants own experiences with aging influenced their professional growth and contributions. After qualitative analysis, two predominant themes emerged: *interconnectedness* and *personal gerontologist*, based on professional expertise. Within interconnectedness, interviewees demonstrated a great range in how their own aging experiences had impacted their research agendas. Brody (2010) who stated, “my future perspective is informed by my past and present perspectives”, best captures this interconnectedness between professional and personal lives. The second theme, *personal gerontologist*, revealed the myriad ways in which individuals responded to older women gerontologists. While family and friends who were dealing with aging-related issues accessed many for advice, a number of interviewees confirmed that this was not the case, despite their many years in the aging field. Since WIGL participants are well-known for their contributions to theoretical and

applied gerontology, their experiences as women gerontologists adds depth to our understanding of what it means to balance personal and professional identities, and roles.

IMPLEMENTING INTEGRATED SERVICES AT THE NATIONAL LEVEL: A VIEW OF 25 YEARS OF INNOVATIONS IN QUEBEC

Y. Couturier, *University of Sherbrooke, Sherbrooke, Quebec, Canada*

For 25 years, Quebec has been very innovative in the integration of services. Integrated service models are innovations involving various operational components (Case management, etc.), that can be implemented in various ways: “*let it happen, help it happen or make it happen*”, and applied to different essential works for change management. Cloutier and collaborators (2015), describe four of such works:

1. **A conceptual work**, which involves the creation and communication of stable representations, which are helpful in guiding the action of the various actors.

2. **A structural work**, which consists of the consolidation of the regulatory aspects of the system, that is, the redistribution of formal action capacities of actors involved in the intended change.

3. **An operational work**, which involves the creation of conditions such that the actors who are targeted by the innovation actually experiment new ways of doing things.

4. **A relational work**, which involves the accompanying of various actors with diverse roles and intentions.

This presentation summarizes the evolution of this movement of integration of services from the early 1990s until today through an analysis of the speech of 130 key witnesses of these transformations. Though we observe a strong conceptual continuity between successive reforms, it is clear that the movement seems to be moving on a conceptual standardization of the integration of services. Is the integration of services project inherently technocratic? Given the Quebec experience, it seems that yes, although this fact is less the result of conceptual models as of their empirical implementation.

GARMENTS AS TRANSITIONAL OBJECTS: NEW POSSIBILITIES IN RE-EVALUATING THE SUBORDINATE SENSE OF TOUCH

E. Mbonu, *University for the Creative Arts, Epsom, Surrey, United Kingdom*

Universally the hierarchy of the senses predicates visual dominance. Hearing is largely perceived as second in line, in the West, followed by, the “subordinate senses of touch, taste and smell” (Roque S L et al 2015). This paper will argue the efficacy found in the transitional object for persons living with dementia who have moved from their familiar home to the unfamiliar environment of a care-home is largely due to the surface of the object – the tactile quality, perhaps even more than the physicality and presence of the object itself. Using garments as transitional objects and focusing on the key component, cloth, this paper aims to explore new possibilities in how people living with dementia experience the world they live in.

This study gathered information from residents living with dementia (from moderate decline to moderately severe decline) in a care home setting. A variety of meaningful and

engaging sensory activities involving cloth, garments and accessories formed the basis of the study. Semi-structured interviews were also conducted to gather qualitative data.

The types and textures of fabrics that have elicited a measurable positive response amongst the participants will be described. The implications of their responses to these fabrics within the context of comfort, sensation, memory and familiarity will be discussed.

The sense of (meaningful) touch is under-rated and needs to be re-evaluated for the positive benefits that it can bring to persons living with dementia within a care-home setting.

HEALTH BEHAVIORS AND HEALTH OUTCOMES: COMPARISON AMONG THREE OLDER AGE COHORTS

Y. Su, H. Obhi, E. Beck, J.A. Margrett, *Iowa State University, Ames, Iowa*

Previous research found differences in social involvement, aging perception and health status among different older age cohorts (Field & Minkler, 1988; Garfein & Herzog, 1995; Seccombe & Ishii-Kuntz, 1991). In the current study, we aim to examine differences in both health-related behaviors and health outcomes among the three age groups: young old (65–74), the old (75–84), and the oldest old (85+). To investigate this, we collected data from older adults residing in one Midwest county ($N=433$), among which 76% were female and 28.2% were young-old ($n=122$), 42.3% were old ($n=183$) and 29.6% were the oldest old ($n=128$). A series of analysis of variance tests and chi-square tests were conducted. The results showed no significant difference in self-reported chronic diseases [$\chi^2(2, N=433) = 4.25, p = .12$], self-reported depression [$\chi^2(2, N=433) = 1.63, p = .44$], exercise duration every time they exercise [$F(2,430) = 1, p = .37$], nor in exercise frequency [$F(2,430) = 2.79, p = .06$]. However, the old had significantly higher social participation frequency than young old [$\chi^2(1, N=305) = 6.51, p = .01$] and the oldest old [$\chi^2(1, N=311) = 4.86, p = .03$]. Our results showed no significant differences in health outcomes but differences in health behaviors (social participation) were apparent. Thus, our study implied the compensatory effect of social participation in health and the fact that more attention may need to be paid to young-old.

“HOW CAN WE HELP?”: A BIO-PSYCHO-SOCIAL RISK SCREENER FOR COMMUNITY DETECTION OF VULNERABLE ELDERLY

Z.J. Hildon¹, C. Tan¹, F. Shiraz¹, W. Ng², X. Deng¹, G.C. Koh¹, K. Tan³, H.J. Vrijhoef¹, 1. *Saw Swee Hock School of Public Health, Singapore, Singapore*, 2. *Tsao Foundation, Singapore, Singapore*, 3. *Ministry of Health, Singapore, Singapore*

We examine additive effects of BioPsychoSocial (BPS) health to help identify vulnerable elders, and link them to appropriate care. Objectives are, to (1) outline a theoretical basis for measure (2) report BPS Risk Screener's items' and test its structure, and (3) discuss the tool's application to interventions, both as a stratified care-planning tool and as an outcome for evaluation. A quantitative cross-sectional, psychometric study was conducted using face-to-face survey

interviews with $n=1,325$ Singaporean elders, aged over 60 carried out in their homes. Standardized questionnaires (Easy-Care standard 2010 and Lubben Social network Scale) were included to help determine BPS domains using factor analysis. Three individual B(io),P(sycho) and S(ocial) domains were derived, then a combined BPS managing score was tested against: self-reported general health; number of falls; cognitive impairment; longstanding diseases; and linked data on utilisation of tertiary care. Results showed 52 questionnaire items were reduced to 35 (factor loadings over 0.5), which were in three distinct BPS clusters. These were independently associated with self-reported health: B: 1.99 (1.64 to 2.41), P: 1.59 (1.28 to 1.98), S: 1.33 (1.10 to 1.60), and the fit improved when combined into an additive BPS score 2.33 (1.92 to 2.83, <0.01). The score predicted mounting risk, particularly between lower and higher levels (score of 4 or over) for service usage outcomes. The BPS Risk screener's greatest attribute is that it renders the clients' domain needs transparent, and can inform future care planning for elders. The use of the tool will also depend on the intervention goals.

DEMENTIA CARE MAPPING (DCM): ODDS OF IT'S USE AS AN OBSERVATORY TOOL TO MEASURE QUALITY OF CARE

A. Dilara^{1,2}, A.J. Astell^{1,2,3}, 1. *Research and Academics, Ontario Shores Center for Mental Health, Whitby, Ontario, Canada*, 2. *University of Toronto, Toronto, Ontario, Canada*, 3. *University of Sheffield, Sheffield, United Kingdom*

A literature review was performed to present critique and to understand use of Dementia Care Mapping (DCM) in different patient situations. The review aimed to help in decision making for choosing DCM as an assessment tool to measure care-quality based on patients' optimal needs. Keywords and thesaurus searches were performed in Ovid interdisciplinary databases to find articles those specifically used DCM to measure quality and published between 1992 and 2016. Medical Subject Headings (MeSH) search terms “dementia care mapping” AND “quality of life” was used. Other keywords were “well-being”, “quality of care”, “wellbeing”, “quality-of-life”, “quality-of-care”, “QOL” and “DCM”. Out of sixty one yielded results, seventeen articles met inclusion criteria and were examined in this review. The critiques included inadequate sample size, sampling bias, short evaluation periods and a lack of consideration of the confounding variables commonly associated with dementia. Methods used to validate the use of DCM in different studies were highlighted. The review identified DCM has good validity and inter-rater reliability. However, content validity remains less convincing and it can only be considered as a moderately valid instrument for patients suffering from moderate to severe dementia. Although DCM is a very useful and one-of-a-kind tool for staffs who wish to improve the quality of their care, but it is a very time-consuming method and requires considerable training and attention of responders to complete the forms. It is recommended that this tool should be amended and used side-by-side of other tools to compare correlations of outcome measures.

DEVELOPMENT AND PILOT OF AN INDEPENDENT CARE ASSESSMENT FRAMEWORK IN SINGAPORE

R. Choo, D. Chia, P. Chow, I. Chung, W. Loong Mun, S. Ho, Z. Sum, *Care Integration Division, Agency for Integrated Care, Singapore, Singapore, Singapore*

In Singapore there is currently no consistent assessment tool or process which can identify a patient's cognitive, functional and social needs to determine what services would enable ageing in place. For this reason, Singapore has embarked on an Independent Care Assessment Framework (ICAF) pilot to standardise how patients are referred into long term care services and to build a consistent language of assessment for continuity of care.

The pilot encompasses (1) the development of an eligibility assessment tool to capture the essential parameters to determine a client's care needs and (2) the creation of an algorithm which can generate a hierarchical care needs level score to guide service recommendations.

The ICAF pilot began in January 2016 and will be carried out over two years in all public hospitals and selected long-term care services in Singapore. This process will be carried out in consultation with an appointed Clinical Advisory Panel. An iterative approach will be applied where continual enhancements to the algorithm and assessment will be made upon analysis of data collected. The agreement between care needs assigned by experienced assessors and the algorithm will be studied and used to inform improvements to the framework.

Based on the data collected thus far (N=200), 41% of clients are male while 58% are female. Their average age is 76 years old. Seventy-one percent are cognitively impaired, 63% have functional impairment and 42% are socially at-risk. These parameters will continue to be monitored during the on-going ICAF pilot study.

RECOMMENDATIONS FOR IMPLEMENTING A BIO-PSYCHO-SOCIAL RISK SCREENER FOR STRATIFIED CARE AT OLDER AGES

Z.Z. Lim^{1,2}, F. Shiraz², W. Ng¹, H.J. Vrijhoef^{2,3,4}, Z.J. Hildon^{2,5}, 1. *Tsao Foundation, Singapore, Singapore*, 2. *Saw Swee Hock School of Public Health, National University of Singapore, Singapore, Singapore*, 3. *National University Health System, Singapore, Singapore*, 4. *Department of Patient & Care, Maastricht University Medical Center, Maastricht, Netherlands*, 5. *London School of Hygiene and Tropical Medicine, London, United Kingdom*

Background: Successful translation of evidence-based innovations to real-world settings is dependent on innovation attributes, implementation context and strategies. This study was conducted to explore translational issues, at a pre-adoption phase, for a novel BioPsychoSocial (BPS) risk screener developed to inform stratified care at older ages. **Methods:** qualitative mixed methods were conducted with elders themselves, policy makers, community service providers and clinical referral teams: 1) administration of the screener to the elders (n=40) and 'managing scores'

generated; 2) in-depth interviews to explore the elders' views on suitability of survey and their scores; 3) researchers' reflections on the screener administration; 4) stakeholder focus groups (n=6) on strategies to improve implementation. **Results:** Three key translational approaches and two key strategies (i.e., adaptation and integration) were identified. First, screener attributes (in terms of its relevance, compatibility and simplicity) can be improved through cultural adaptation of the screener and integration of risk screening with interventions. Second, survey methodology can be adapted to better engage with the elders, who exhibited varying degrees of interest, ability and truthfulness. Third, existing workflow in home visits conducted by community workers can be adapted to incorporate the screener. New screener administrators should also be identified carefully and trained on both administration skills and cultural competency in engaging the elders. **Conclusion:** The BPS risk screener had demonstrated favourable attributes for its translation to a context of multiethnic community-dwelling elders. Adaptation strategies would connect the screener to the elders; whereas integration strategies would connect the screener to the existing delivery system.

DEVELOPMENT OF A PERSON-CENTRED COGNITIVE TOOL: HOW TO PROVIDE STRENGTH-BASED MEMORY CARE

M. D'Souza, L. Venturato, M. Gil, *University of Calgary, Calgary, Alberta, Canada*

As the aging population grows, there is an increasing focus on interventions that support person-centred and wellness-based approaches to care for older adults. This is particularly evident for those in supported living (SL) centres and the community, where the focus is on maximizing strengths, and reducing the need for admission to long-term or acute settings for more advanced care. Despite this, current cognitive assessment tools focus primarily on diagnosis or functional deficits in order to determine care needs, while there are limited strength-based and person-centered cognitive tools available.

Our research challenges this practice gap through understanding the 'gold standard' of person-centered care, in order to develop a tool that supports a wellness-focused approach to meet residents' everyday lifestyle goals and health support needs. This participatory action research study is a partnership between the Geriatric Research Unit at the University of Calgary and United Active Living, a SL facility in Calgary. In this study, researchers work alongside Memory Care staff and cognitive residents in developing an assessment approach that incorporates resident goals, memory care programming considerations, and cognitive support to maximize resident well-being.

This presentation will argue for critical engagement with a person-centred care philosophy that moves from the rhetoric of the approach to the application of the philosophy in relation to assessment. We will overview the process involved in developing the tool and present the draft assessment tool for discussion.

SESSION 1030 (POSTER)

HEALTH CARE NEEDS AND UTILIZATION

OLDEST-OLD PATIENTS IN ACUTE CARE HOSPITALS: A PORTUGUESE NATIONWIDE 15-YEAR RETROSPECTIVE STUDY

D. Brandao^{1,2,3}, A. Freitas^{2,3}, O. Ribeiro^{1,3}, M. Paul^{1,3},
1. UNIFAI / ICBAS.UP, Porto, Portugal, 2. Faculty of Medicine, University of Porto (FMUP), Porto, Portugal, 3. CINTESIS, Porto, Portugal

The oldest old is one of the fastest growing segments of the population in most developed countries. This exponential growth is expected to place a heavy demand on healthcare systems worldwide, since the oldest old are intensive users of healthcare services. This study aims to analyze inpatient hospitalizations by persons aged 80+ between 2000 and 2014 in Portugal. Administrative data from all public acute care hospitals in the Portuguese National Health Service was considered (national hospitalization database). Exploratory descriptive analyses regarding the number and nature of the episodes and discharge diagnoses were performed. A total of 1,837,613 inpatient episodes (number that doubled from 80590 in 2000 to 166210 in 2014) were analyzed. The majority were unplanned admissions (85.9%), of which 73% were medical (without any surgical intervention) and 12.9% were surgical. The most frequent diagnoses (classified in Major Diagnostic Categories) were Diseases and Disorders of the Respiratory System (22.2%), Diseases and Disorders of the Circulatory System (17.1%), and Diseases and Disorders of the Nervous System (10.8%). This study pointed to an increasing importance of oldest old patients in acute care hospitals, and provides insights into the clinical characteristics of these patients. The demand for hospital services by the oldest old should be a major concern for policy agents and healthcare professionals. Further studies should focus on variables associated with adverse outcomes, namely in-hospital mortality rates.

TRENDS IN HOSPITAL ADMISSIONS BY PORTUGUESE CENTENARIANS

D. Brandao^{2,1,3}, O. Ribeiro^{2,3}, A. Freitas^{1,3}, M. Paul^{2,3}, 1. Faculty of Medicine, University of Porto (FMUP), Porto, Portugal, 2. UNIFAI / ICBAS.UP, Porto, Portugal, 3. CINTESIS, Porto, Portugal

The number of centenarians worldwide is projected to increase rapidly from 441,000 in 2013 to 3.4 million in 2050. In Portugal, centenarians almost tripled over the last decade from 589 in 2001, to 1526 in 2011. The aim of this study is to examine hospitalisations between 2000 and 2014 by patients aged 100+ years using administrative data from all public hospitals in the Portuguese National Health Service located in the continent. ICD-9-CM codes associated to secondary diagnoses and the Charlson Comorbidity Index were considered to assess comorbidities. Exploratory descriptive analyses of data regarding the number of episodes, discharge diagnoses and comorbidities were performed. During the 15-years period, a total of 6,410 episodes of hospital admissions occurred, most of which were inpatient episodes (94.7%). The number of admissions more than doubled from 311 in 2000, to 688 in 2014. Most

frequent discharge diagnoses (grouped by CCS) were pneumonia (19.9%), fracture of neck of femur (hip) (7.8%), acute cerebrovascular disease (5.6%), and non-hypertensive congestive heart failure (4.7%). Most frequent comorbidities in inpatient episodes were congestive heart failure (16.4%) and renal disease (10.2%). Our findings document the importance of respiratory and cardiovascular diseases as reasons for hospitalization among extremely long-lived individuals, which is in line with the main causes of mortality in Portugal. Further studies should be conducted in order to identify the impacts of increased hospital admission rates among this population, in order to better manage their care needs and improve service delivery.

HEALTHCARE UTILIZATION AND BEHAVIORAL HEALTH IN OLDER ADULTS WITH OPIOID ABUSE

Y. Chang, S. Casucci, Y. Xue, S. Hewner, University at Buffalo, Buffalo, New York

Opioid abusers, particularly those that are middle-aged adults and older, often suffer from co-occurring mental health, chronic pain, and other substance use problems. Yet, little is known about the utilization of hospital and community based care services for this group. This study compared differences in healthcare utilization among middle-aged and older adults with opioid abuse to age-matched individuals without opioid abuse; and (2) identified predictors of healthcare utilization in older adults with opioid abuse diagnoses. Our study sample (N=58,934) included Western New York Medicaid recipients aged 50 and above during the June 2014-June 2015 period. Using data mining methods, risk factors influencing healthcare utilization were identified, and included mental health, chronic pain, smoking, and other substance abuse diagnoses. Healthcare utilization was categorized by the number of in-patient, out-patient, and emergency department encounters during the study period. Correlational statistics were used to compare utilization differences between opioid abusers and people without opioid abuse. A generalized linear model with Poisson error and log link was used to identify predictors of healthcare utilizations for opioid abusers. Results indicate that opioid abusers had significantly higher utilization across different types of healthcare services compared to their age-matched counterparts. Among older adults with opioid abuse, gender, mental health comorbidities, smoking, other substance use disorders, and chronic pain were significant predictors of healthcare utilization. These results will enable future opioid abuse treatment research to modify treatment plans based upon the unique care needs of this population.

HEALTH ECONOMIC EVALUATION OF CASE MANAGEMENT FOR FRAIL OLDER PEOPLE: EFFECTS OF AN RCT

M. Sandberg¹, U. Jakobsson², P. Midlöv², J. Kristensson¹,
1. Department of Health Sciences, Lund University, Lund, Sweden, 2. Department of Clinical Sciences Malmö, Lund University, Lund, Sweden

The aim of this study was to evaluate the effects of a case management intervention for frail older people (aged 65+ years) by cost and utility. In total 153 frail older people living at home were randomly assigned to either an intervention (n = 80) or a control group (n = 73). The 1-year intervention

was carried out by nurses and physiotherapists working as case managers, who undertook home visits at least once a month. Differences in costs, EQ-5D and EQ-VAS based quality-adjusted life years (QALYs), and incremental cost-effectiveness ratio were investigated. All analyses used the intention-to-treat principle. For the 1-year study, no significant differences between the intervention and control groups for total costs, EQ-5D-based QALY or EQ-VAS-based QALY were found. Incremental cost-effectiveness ratio analysis was not conducted because no significant differences were found for QALYs or total costs. However, the intervention group had significantly lower levels of informal care in terms of help with instrumental activities of daily living both as costs (€3,927 vs. €6,550, $p = 0.037$) and provided hours (200 vs. 333 hours per year, $p = 0.037$). The conclusions are that the intervention was cost neutral and does not seem to have affected health-related quality of life. One reason may be a too short follow-up period. The intervention reduced informal care in hours and cost of help with instrumental activities of daily living. This suggests that the intervention provides relief to informal caregivers.

IMPACT OF HEALTHY AGING ON MEDICAL AND LONG-TERM CARE EXPENDITURES IN THE LAST YEAR OF LIFE

H. Yoshida¹, T. Furuna², H. Makizako³, T. Akanuma⁴, K. Yokoyama⁴, T. Suzuki^{5,3}, 1. *Tohoku Bunka Gakuen University, Sendai, Japan*, 2. *Sapporo Medical University, Sapporo, Japan*, 3. *National Center for Geriatrics and Gerontology, Obu, Japan*, 4. *Bibai City Office, Bibai, Japan*, 5. *Institute for Aging and Development of J.F.Oberlin University, Machida, Japan*

This study examined the impact of healthy aging on medical and long-term care expenditures in the last year of life in Japanese older adults. The subjects were those aged ≥ 65 years ($n=326$) who died in fiscal 2013 in Bibai, Hokkaido, Japan and used public medical and long-term care insurance services at least one time in fiscal 2013. We classified the subjects into three groups: < 80 years old ($n=76$), 80–89 years old ($n=155$), and ≥ 90 years old ($n=95$). We compared the mean medical and long-term care expenditures per capita among the three groups during the last year, and determined whether aging affected these expenditures. The largest expenditure were that for those with < 80 years old (4.45 million yen), followed in turn by those with 80–89 years old (4.09 million yen) and those with ≥ 90 years old (3.78 million yen). Also only in women ($n=169$), the largest expenditure were that for those with < 80 years old (5.41 million yen), followed in turn by those with 80–89 years old (4.57 million yen) and those with ≥ 90 years old (3.84 million yen), and, in addition, using general linear models and post-hoc test, those with < 80 years old were significantly larger for those with ≥ 90 years old ($p=0.015$). In conclusion, healthy aging could reduce terminal care cost in Japanese older adults.

BEHAVIORAL HEALTH CARE NEEDS AMONG AGING VETERANS IN RURAL OUTPATIENT CLINICS: PROVIDERS' VIEWPOINTS

M.K. Luptak¹, B. Hicken², L. Greenberg³, M. Grant², R. Mabe³, K. Parry², R. Rupper^{4,1}, 1. *University of Utah, Salt Lake City, Utah*, 2. *Veterans Rural Health Resource*

Center - Western Region, Salt Lake City, Utah, 3. *George E. Wahlen Department of Veterans Affairs Medical Center, Salt Lake City, Utah*, 4. *VA Geriatric Research, Education, and Clinical Center, Salt Lake City, Utah*

Aging Veterans frequently have cognitive and behavioral health problems in addition to physical health issues. Meeting these complex needs is challenging, particularly in rural areas with scarce resources. This project utilized an exploratory qualitative data collection method to better understand and address these needs.

Focus groups (FG) of rural providers ($N = 62$) were conducted on site at eight VHA Community Based Outpatient Clinics (CBOCs) in three western states. Facilitators (2 per FG) used a semi-structured format with open-ended questions to prompt conversations among participants about patients' complex behavioral health and physical health issues, family/caregiver concerns, clinic workflow, internal/external referrals, and desired services/resources. FG sessions were digitally recorded and transcribed verbatim with participant consent. Observation notes were also completed. Analysis began with an a priori set of coding categories (FG questions). We employed team coding to identify and refine codes and categories as new themes and patterns surfaced. Three major themes (with multiple subthemes) emerged from the discussions: challenges working with this population, caregiver issues, and interventions to improve care. Subthemes include provider burden, remoteness from urban medical center, difficulties coordinating specialty services, barriers to providing family and caregiver support; and difficulty navigating resource networks.

Rural providers from VHA CBOCs in the western U.S. identified numerous challenges that complicate care for aging Veterans with co-morbid cognitive and behavioral health issues in rural settings and also offered practical suggestions to improve care. Findings are informing development of an evidence-informed intervention to improve access to specialty behavioral health care for these Veterans.

GENDER-SPECIFIC PREVALENCE OF COMORBIDITIES AND USE OF HEALTH CARE SERVICES IN GERMAN CENTENARIANS

D. Draeger¹, T. Zahn², P. v. Berenberg-Goßler¹, G. Paul¹, J. Neuwirth², A. Kuhlme¹, 1. *Charite - Universitätsmedizin Berlin, Berlin, Germany*, 2. *GeWINO Institut der AOK Nordost, Berlin, Germany*

Centenarians are the fastest growing segment of the population in many industrial nations; most of them are women. However, research on gender differences in terms of demographic characteristics, chronic conditions, and use of medical, pharmacological, and nursing care services is sparse.

To draw on to describe the socio-demographic characteristics of the centenarian population and patterns of use of medical, pharmacological, and nursing care services in this population separately for men and women.

This descriptive analysis will be based on master data from 1.8 million persons insured with a German statutory health insurance fund who were resident in Berlin or north eastern Germany. The study population comprises all those reaching the age of 100 or older on December 31, 2013 ($N=1,121$).

The number of centenarians increased between 2006 and 2013 by 25% in Berlin and by 59% in north eastern Germany. In terms of gender differences, the vast majority of centenarians are female (91%). Men accounted for only 9.2% of the 100+ year olds, and for none of those aged 107–109. The half of the centenarians were in long-term care. Women were more often in long-term care and less often without any care compared with men. Further findings on the gender-specific use of health care services will be discussed.

The study provides insights into health service use in centenarians against the background of their existing health conditions. The findings contribute to the gender-specific development of needs-based care structures for this population.

GERIATRIC CARE POST-MEGA EARTHQUAKE 2015 NEPAL

B. Pant^{1,2,3}, S. Banjade¹, 1. *Geriatric Society of Nepal, Kathmandu, Nepal*, 2. *POSSIBLE, Kathmandu, Nepal*, 3. *Grande International Hospital, Kathmandu, Nepal*

Nepal was hit by a devastating earthquake of 7.8 magnitudes on 25 April 2015 followed by a strong aftershock on 12 May. Over 8 million people are affected in 39 out of 75 districts, 11 of which are most critically hit. This caused over 8,670 deaths, injured 21,422. As a consequence 2.8 million people have been displaced. The most affected from this disaster are the Children and Geriatrics.

The consequences of earthquakes on elderly population are not limited to physical injuries but also results in an increase in adverse consequences of chronic illness because of lack of regular checkup-followup facilities and shortage of medicines. The affected people are neither able to travel for medical services nor can get access at their local levels. Lack of attention of the family members, absence of social security, non-availability of hospital care and financial dependency on children or relative are the prominent factors which worsen the life of Geriatrics.

Considering this fact, the Geriatric Society of Nepal (GSN) ran Health Camps with special focuses for Geriatrics to protect them from health issues and impact of earthquake. These GSN Health Camps concentrated on Health Check-up for earthquake affected patients, Psychosocial counseling for traumatized and stressed people, Referral and follow up services for elderly, Health care education for patients and their family members.

This type of targeted Health Camps post Disaster helps in understanding the needs of Geriatrics and solves them locally. The vulnerable group of elderly population should be taken well care post any disaster.

PREVENTION OF CATHETER-ASSOCIATED URINARY TRACT INFECTION IN A COMMUNITY HOSPITAL IN SINGAPORE

J. Koh, S. Agustinus, R. Bte Abu Hassan, Y. Phyu Thinn, B. Ng, *Ang Mo Kio-Thye Hua Kwan Hospital, Singapore, Singapore*

Background: Catheter-associated urinary tract infection (CAUTI) is a common hospital acquired infection which can lead to prolonged hospitalisation and mortality. Ang Mo

Kio-Thye Hua Kwan Hospital is a 360-bedded Community Hospital in Singapore, providing inpatient rehabilitation and subacute care. The majority of patients are geriatric and referred from tertiary hospitals.

A multidisciplinary Quality Improvement team was formed in March 2015 to reduce CAUTI.

Aim

The median CAUTI rate was 5.3 per 1000 catheter days in 2014. We aim to reduce CAUTI rate by 30% in 3 years.

Methods: Analysis of CAUTI cases showed majority had an indwelling catheter (IDC) on admission and developed CAUTI with the same IDC. The identified gaps were: Inefficient CAUTI data collection, lapses in IDC care and no IDC removal protocol.

Changes tested and implemented in stages at a pilot ward:

- Improved CAUTI data collection method
- IDC reminder system
- Nurse-led protocol to empower nurses to remove catheters
- Using S hook to lower urine bag during ambulation
- Daily audit of IDC care

Frontline staffs were engaged regularly for feedback. The changes were modified, tested and improved after PDSA cycles.

Results: CAUTI cases in the pilot ward reduced from 13 to 6 from 2014 to 2015, with 2 cases detected in the first 5 months of 2016. Results on compliance to IDC care have also been encouraging.

Conclusion: We plan to test and spread the changes to other wards to reduce CAUTI rate in the hospital. Getting feedback and buy-in from the ground helps in designing sustainable changes.

SESSION 1035 (POSTER)

LONG-TERM CARE AND ASSISTED LIVING I

BEDTIME: PARTNERED BABY BOOMERS' PRIVACY EXPECTATIONS IN RESIDENTIAL CARE

A. Rahn, *University of New England, Armidale, New South Wales, Australia*

Many couples in Australian residential care facilities experience institutional interference in their sexual relationships. Duty of care usually takes precedence over privacy. Some institutions separate couples, residents' doors may be kept open at all times, staff enter without knocking, ignore 'do not disturb' signs, or gossip about residents. In this presentation I report on findings of a phenomenological study using a self-administered online survey of partnered Baby Boomers (born 1946–65) conducted in 2016, which reveals their attitudes to these intrusions and their expectations of privacy. The majority of respondents expected to remain sexual throughout their lives, considered physical intimacy with their partners essential to their wellbeing, and required a high degree of privacy to maintain their relationships in care settings. Many expressed it was 'their business', and no-one else's, what happened in their rooms. Recommendations for providers include (1) clear written policies in relation to

residents' privacy; (2) individual privacy assessments of residents upon admission; (3) inclusion of privacy needs in resident care plans; and (4) creation of a culture that allows staff and residents to develop understanding and rapport with each other. Enabling new residents and their families to make informed decisions when choosing a facility has the potential to improve the experiences of both residents and staff.

PERCEIVED BARRIERS AND FACILITATORS TO HOME AND COMMUNITY-BASED PLACEMENT IN THE VETERANS HEALTH ADMINISTRATION

E.A. Miller^{2,4,6}, E. Gadbois^{4,6}, S. Gidmark⁶, O. Intrator^{3,4,5}, J.L. Rudolph^{4,6}, 2. *University of Massachusetts Boston, Boston, Massachusetts*, 3. *Canandaigua VA Medical Center, Canandaigua, New York*, 4. *Brown University, Providence, Rhode Island*, 5. *University of Rochester, Rochester, New York*, 6. *Providence VA Medical Center, Providence, Rhode Island*

The U.S. Department of Veterans Affairs (VA) administers the largest integrated health care system within the United States with more than 1,700 sites of care serving close to 8.8 million Veterans annually. The demand for VA funded long-term services and supports have risen concomitantly with the aging of the Veterans population. Because national VA policy has been to rebalance the provision of long-term care away from nursing homes and towards home- and community-based services (HCBS) options, lessons from the VA's experience in promoting greater use of non-institutional services and supports may prove informative for other initiatives seeking to shift the locus of care internationally. The purpose of this study is to identify factors that promote or impede the diversion of long-term care recipients from institutional nursing home care to non-institutional HCBS during the long-term care referral process, a heretofore limited area of study. Data derives from analysis of thirty-five semi-structured interviews performed with key informants from 12 VA Medical Centers (VAMCs). Results indicate that care teams recommend whether or not to refer Veterans for an HCBS or nursing home consult. Veterans' care needs and preferences and social and financial resources influence these recommendations; so too does the perspectives of care team members. Lack of staffing and failure to offer the specific types of services needed limits the use of HCBS. Distance and crime/safety concerns pose further barriers in rural and urban jurisdictions, respectively. Budgetary imperatives influence the relative availability of HCBS across VAMCs. Findings highlight the impact of provider-level practices and system-level constraints in impeding the successful diversion of long-term care recipients from nursing homes to alternative settings in the home and community.

THE RELATIONSHIP BETWEEN CHANGES IN HOME CARE EXPENDITURE AND USE OF INFORMAL CARE

D. Verbeek-Oudijk, I. Woittiez, *Labour and Public Services, Netherlands Institute for Social Research, The Hague, Netherlands*

In light of population ageing combined with cuts in government spending the financial sustainability of long-term care is high on the political agenda in many countries. In this paper we examine the relationship between rising home care expenditure and use of informal care among independent

community-dwelling persons aged over 50 in eight European countries. We use data from 2004 to 2013 – a period characterised by rising expenditure and investments in home care. The eight countries studied are Austria, Belgium, Denmark, France, Germany, the Netherlands, Spain and Switzerland. Unlike other studies we include expenditure on home care in our analysis as a characteristic of the care system next to individual factors such as need, predisposing factors and enabling factors. We analyse the effect of a change in home care expenditure using multinomial logistic regression with fixed effects on the longitudinal data from the *Survey of Health, Ageing and Retirement in Europe*, combined with national data on home care expenditure from the OECD (Organisation for Economic Co-operation and Development).

We find that, when home care expenditure in a country rises, fewer over-50s receive informal care. Consequently, the average informal care use in the European countries studied was lower in 2013 than nine years earlier. The changes in home care expenditure mainly affected people with milder care needs, who have several options open to them for meeting those needs.

CHALLENGES TO SUCCESSFUL TRANSITIONS FROM INSTITUTIONS TO LIVING IN THE COMMUNITY

N.A. Shugrue¹, M. Porter¹, D. Lambert², J.T. Robison¹, 1. *University of Connecticut, Farmington, Connecticut*, 2. *CT Department of Social Services, Hartford, Connecticut*

The Money Follows the Person Rebalancing Demonstration (MFP) is a U.S. initiative helping states transition people needing long-term services and supports from institutional settings to the community in order to honor individual preferences and rebalance Medicaid expenditures. In Connecticut, MFP transition coordinators complete a standardized checklist of transition challenges for each individual during the transition process. Twelve challenge categories are recorded cumulatively until the person transitions, or if not transitioning, until the case closes. Quality of life surveys are completed at baseline, 6, 12, and 24 months after transition. This study examined transition challenges as predictors of successful transitions, including length of time to transition, risk of post-transition reinstitutionalization, and post-transition community integration. Analysis of challenge checklists (n=7021) indicates that persons whose cases closed without transitioning had significantly greater challenges relating to physical (OR=1.2) or mental health (OR=1.3), consumer engagement (OR=1.8), other involved individuals (OR=1.7), and home and community-based services (HCBS) programs (OR=1.5). For persons who transitioned, five challenges significantly ($p < .05$) and independently predicted longer transition times: consumer engagement, housing, legal issues, HCBS programs, and other involved individuals. Challenges with mental health and engagement prior to transition significantly predicted reinstitutionalization twelve months following transition. Participants with mental health and nursing facility challenges had lower community engagement at 6 months after transition, while those with physical health and services challenges had less community engagement across all three follow-up times. Knowledge of pre-transition challenges enables program managers to make

policy and programmatic changes to enhance the probability of timely, successful transitions.

DEVELOPMENT OF A UNIVERSAL SATISFACTION SCORE FOR LONG-TERM CARE FACILITIES

N.G. Castle¹, L. Schwartz², 1. *University of Pittsburgh, Allison Park, Pennsylvania*, 2. *AHCA, Washington, District of Columbia*

Collecting satisfaction information from long-term care residents is important. We have seen a philosophical change in healthcare that now includes the patient and their preferences, as an integral part of the system of care. However, numerous satisfaction surveys exist and no uniform satisfaction measure or score can be used to compare facilities. This would be useful for both benchmarking and report cards. A parsimonious satisfaction measure was recently developed by the American Health Care Association (AHCA). This measure is the CoreQ. This research will detail the development and underlying basis of the CoreQ. The CoreQ consists of a limited number of satisfaction items that were used to create an overall satisfaction score. Information from more than 20,000 seniors was used to develop and test 5 CoreQ instruments. These CoreQ instruments include nursing home short-stay residents, long-stay residents, and family; and assisted living residents and family. The process of developing and choosing the items included in the CoreQ will be described. The testing of the CoreQ will be described (e.g., reliability, validity, exclusions, risk adjustment). The reliability of the measure at the data element level; the person/questionnaire level; and, at the measure (i.e., facility) level will be presented. The CoreQ is currently in use by over 1000 facilities. We will also present the experience and current uses of the information collected to date. This will include the distribution of scores and the correlation with other quality measures.

SERVICE USE AND HEALTH OUTCOMES AMONG LOW-INCOME OLDER ADULTS WITH UNMET NEEDS

R.H. Weaver², K.A. Roberto¹, 1. *Human Development, Virginia Polytechnic Institute & State University, Blacksburg, Virginia*, 2. *Washington State University, Pullman, Washington*

When older individuals fail to receive any or sufficient assistance for daily self-care and functional activities, a situation of unmet need is created. Prevalence of unmet need in the United States ranges from 20% to 58% of older adults with disabilities. Functional criteria for receiving assistance from federal and state programs vary. This study investigated patterns of service use among 1,040 low-income older Virginians seeking assistance from a Medicaid waiver program during the 2014 and 2015 fiscal year. Over the 2-year study duration, 660 clients met both financial and functional need eligibility requirement for Medicaid; 380 clients were not eligible because they did not meet Virginia's stringent functional need requirement (limitations in 4+ instrumental or basic activities of daily living). Of non-eligible clients, 222 received minimal and 158 received no Medicaid-supportive services. Non-eligible clients were more likely than eligible clients to live in rural areas ($X^2=23.139$, $p<0.001$) and access Older Americans Act funded services ($F=16.650$, $p<0.001$). Non-eligible clients receiving no services were significantly more

likely to have died ($F=11.686$, $p<0.001$), compared to non-eligible clients receiving minimal services ($p<0.001$) and eligible clients receiving waiver services ($p<0.001$). Hospitalizations were infrequent, but were more likely among non-eligible clients ($F=7.374$, $p=.007$). Trends suggest that individuals receiving 2 or fewer services ($F=1.948$, $p=.102$) had greater hospitalization risk. Based on these findings, policy provisions need to consider the long-term health implications experienced by older adults not eligible for waiver programs and develop targeted service delivery initiatives to reduce the likelihood of individuals living with unmet needs.

SYSTEMATIC REVIEW OF MEASUREMENT OF NURSING HOME CULTURE CHANGE

D. Sturdevant¹, C.A. Mueller², K.C. Buckwalter¹, 1. *College of Nursing, University of Oklahoma, McAlester, Oklahoma*, 2. *University of Minnesota, Minneapolis, Minnesota*

Nursing home culture change (NHCC) aims to change the way care is provided in nursing homes. Valid and reliable measures are needed to evaluate the impact of NHCC on outcomes. A systematic review of available instruments provides an overview of current instruments designed to measure NHCC and provide criteria for others to evaluate and choose instruments according to their own purpose. The purpose of this review is to identify instruments used to measure NHCC at the organizational level, describe the psychometric properties, and to examine to what extent the instruments have been used empirically to assess resident, staff, or organizational outcomes. Method: A systematic review was conducted using Medline, Embase, CINAHL, PsycINFO, ProQuest, and Web of Science databases, limited to articles published between January 1995 and December 2014. Citations were included if they reported: (1) the development and/or validation of an instrument; (2) evaluation of NHCC on an organizational level; and (3) quantitative results following administration of an instrument. Results: Ten instruments to measure NHCC on an organizational level were identified. A common limitation of the instruments reviewed was the lack of psychometric testing; thus, their validity and reliability needs further exploration. Three of the 10 instruments reported Cronbach's alpha and one reported construct validity. Implications: The systematic review demonstrated a number of tools available for measurement of NHCC on an organizational level. Lack of development description hindered their assessment and studies examining the relationship between NHCC and outcomes are rare. Further psychometric testing of the instruments is also needed.

NATIONAL TRENDS IN OMBUDSMAN RESIDENT ADVOCACY IN LONG-TERM CARE FACILITIES (2006–2015)

K. Nguyen², L. Ryan¹, E. White², S. Downie², 1. *US Department of Health and Human Services' Administration for Community Living, Washington, District of Columbia*, 2. *NORC at the University of Chicago, Bethesda, Maryland*

Since its inception in 1972, the Long-Term Care Ombudsman Program (LTCOP) has played a critical role in protecting and promoting the health, safety, welfare and rights of long-term care residents by maintaining a regular presence in facilities nationwide. Dramatic changes in

the long-term care landscape, however, including the rapid aging of the U.S. population and the tremendous growth of non-institutional residential options, have placed increasing demands on programs. Based on data from the National Ombudsman Reporting System, we describe national trends in ombudsman staffing and volunteer capacity in serving long-term care residents. While nursing homes and beds have been steadily declining as the field moves toward more board and care type facilities, the overall number of facilities and residents requiring ombudsman services has increased by nearly 11% from 2006 to 2014. During this period, the number of paid staff has remained fairly stable but the number of volunteer ombudsmen (who serve as key advocates for residents) has decreased by 11%. From 2006 to 2014, quarterly visits to nursing homes and board and care facilities have declined by 10% and 14%, respectively. While the increase in facilities overall presents challenges to maintaining regular visits, the loss of volunteers may have exasperated these challenges. As the elderly population and the number of long-term care facilities continue to grow, the LTCOP will increasingly be a vital resource for residents, particularly for vulnerable elders. Understanding the program's ability to advocate on their behalf is critical to ensure that all residents receive quality care.

CHANGING CHAIN OWNERSHIP IN THE NURSING HOME SECTOR AND ITS IMPACT ON SPECIALTY SERVICE PROVISION

J.C. Banaszak-Holl¹, Q. Zheng¹, O. Intrator², D.G. Stevenson³, D.C. Grabowski⁴, R. Hirth¹, J. Blackburn⁵,
 1. *University of Michigan, Ann Arbor, Michigan*, 2. *University of Rochester, Rochester, New York*, 3. *Vanderbilt University, Nashville, Tennessee*, 4. *Harvard University, Cambridge, Massachusetts*, 5. *University of Alabama-Birmingham, Birmingham, Alabama*

Nursing homes offer an array of specialty services, including the most prevalent types of dementia care, post-acute rehabilitative services, and hospice. Corporate ownership may support specialty care services in a number of ways, by making possible the sharing of costs across facilities or providing connections for sharing best practices. This paper explores whether changes in chain ownership of nursing homes impact provision of specialty care. The Online Survey Certification and Reporting (OSCAR) data were used to identify chain ownership and specialty care provision from 1993 to 2010. Nursing homes report the provision of nine types of specialty care, including care for those with Alzheimer's, AIDS, dialysis, head trauma, hospice, Huntington's, rehabilitative, ventilator, and disabled child services. Annual chain characteristics were coded from self-reported membership. Contemporaneous market and state data were added from other sources. We dropped the more rare forms of specialty care that did not change in prevalence over time. The remaining forms of specialty care, including Alzheimer's, rehabilitative, hospice and ventilator units, have shown dramatically different trends in prevalence although facilities change little in their reporting of all forms of specialty care. Most changes in prevalence occurred when nursing homes enter or exit the data. The availability of Alzheimer's beds peaked in 2004 despite continued growth since then in the prevalence of dementia among residents. Larger chains, with more than

30 facilities, acquired facilities with a higher prevalence of Alzheimers care but there is no evidence that these chains convert beds post acquisition. Overall, chains do not appear to convert beds to specialty care but do seek acquisition targets with services to fit with the chain strategy.

RESIDENTIAL CARE AIDES' EXPERIENCES OF PERSONHOOD IN DEMENTIA CARE SETTINGS

H. Cooke, *University of British Columbia, Vancouver, British Columbia, Canada*

Conceptually, person-centred care entails fostering the personhood of residents and the residential care aides (RCAs) who provide much of their hands-on care. Yet, to date, staff personhood has been overlooked in the empirical literature. Drawing on data from a larger ethnographic study examining the influence of the organizational and physical care environment on dementia care provision, this paper explores RCAs' experiences of personhood. In-depth interviews with 29 staff (21 RCAs, 3 LPNs and 5 managers), and more than 230 hours of participant observation, were conducted in two Canadian nursing homes with specialized dementia units. Two overarching themes, 'personhood undermined – management-staff relations' and 'personhood undermined – workplace policies and practices' illustrate how, despite exposure to features believed beneficial to their working environment (e.g., smaller staffing ratios, relatively good remuneration, manageable workloads), RCAs encountered repeated affronts to their personhood. The first theme encompasses the importance of being known (i.e., as persons and of their job demands) and valued (i.e., appreciated for their work in non-monetary terms). The second highlights the salience of work-life balance, full staffing coverage, supportive human resource practices, and information sharing. RCAs' experiences reveal how the ongoing search for cost-efficiencies, cost-containment, and cost-accountability overshadows their individuality, indicating a key disconnect between conceptual ideals and workplace realities. Organizations seeking to provide quality dementia care are encouraged to focus on the creation of person-centred management and workplace practices thereby providing tangible evidence that RCAs, and their work, matter.

DEPRESSION AMONG OLDER RESIDENTS IN LONG-TERM CARE: AN ILL UNDERSTOOD AND UNDERTREATED PROBLEM

A. Milne, *School of Social Policy, Sociology & Social Research, University of Kent, Chatham Maritime, Kent, United Kingdom*

420,000 older people live in care homes in the UK. Residents tend to be frail and many have dementia. Evidence suggests that between 4 and 25% have major depression and 29 to 82% have depressive symptoms. The factors that appear correlated with depression include: functional impairment, physical health problems, loneliness, loss and the depressogenic effects of living in an institutionalised environment. Depression is linked to increased mortality, suicide, and reduced quality of life. Barriers to recognition and treatment include: limited staff awareness of depressive symptomology, challenges in assessing its presence especially in people with dementia and variable access to health services. Antidepressants are the most common treatment

although they are often prescribed in sub-therapeutic doses. Behavioural and cognitive therapies are also effective although rarely available. In terms of management, in reach provision by primary care services appears effective. Improvements in the management and treatment of depression has a number of evidenced strands: supporting the older person's transition into the home; staff training to increase detection; a commitment to person centred care; education of GPs about the particular needs of residents; consistent access to health care; and an inspection regime committed to driving up quality. Clinical guidelines are also helpful. Although some research has been done in this area little is known about the nature and course of depression amongst care home residents nor their subjective experiences. Much more attention needs to be paid to this hidden issue as depression is common, profoundly undermining of well-being, and significantly under treated.

NURSING HOME SATISFACTION MEASURES: WHAT IS THEIR RELATIONSHIP TO QUALITY?

P. Nadash, J. Hefele, J. Wang, A. Barooah, *University of Massachusetts Boston, Boston, Massachusetts*

Consumers and their families need information to help choose nursing homes (NHs) that best suit them. Government, too, needs good information to perform its oversight and program management functions, incentivize better performance, and respond to consumers' information needs. Incorporating consumer perspectives could improve public reporting of NH quality. Little is known, however, about the relationship between resident/family satisfaction, and quality of life (QoL) and/or other quality measures and whether they supplement existing quality measures. This study investigates these relationships, and explores how different factors predict satisfaction. Using resident/family satisfaction survey data from 2887 NHs in all 50 states, along with data on NH characteristics and performance (using CASPER, LTCFocus, and NH Compare data), we found that, in 2013, overall satisfaction was high, averaging 3.3 for both residents and family members (on a scale of 1 to 4). Satisfaction was highest for families regarding nursing care quality, and for residents in feeling safe; it was lowest for families in staffing adequacy and for residents in meal quality. Overall satisfaction had near-zero or very low Pearson correlations with staffing variables. Nor was the link to quality measures strong: correlations with CMS NH star ratings were low (0.24 for residents and 0.31 for families), and with NH deficiencies near-zero. These results suggest that resident/family perspectives indeed add a unique component to the assessment of overall NH quality, and support the call to add satisfaction and experience ratings to public reports of NH quality.

QUALITY OF LIFE IN NURSING HOMES: ELEVATING THE STATUS OF RECORDING TO A RELATIONAL PRACTICE

K. Barrie, *Institute of Healthcare Policy and Practice, University of West of Scotlan, Edinburgh, United Kingdom*

Internationally, nursing home care provision demands radical change. Lack of honesty about the complexity of so-called 'basic care' together with performance cultures have created a more transactional and confused environment,

detracting from authentic care work grounded in human relationships. A personal outcomes approach, comprising three inter-related components of engaging, recording and using information, can result in more effective, inclusive, enabling and relational ways of working; but raises particular challenges in collective living settings for older people with complex and often fluctuating needs and priorities.

This session presents results from an action research study conducted in collaboration with multi-disciplinary staff from six nursing homes in Scotland to facilitate a focus on personal outcomes. Grounded in the philosophy of relationship-centred care, the study recognised the importance of everyday acts of noticing alongside scheduled care planning processes, including being attentive to, and properly valuing, the life stories and more embodied stories of people with communication or cognitive impairments. Building upon the ways staff already come to understand and negotiate what matters to a person and to family members, and thinking about how such insights might be used by others, the study facilitated a shift from recording as a bureaucratic task with a primarily retrospective orientation demonstrating compliance, to a practice foregrounding information useful for maintaining the identity of the older person, building relationships and shaping future care. It also highlighted the practical and ethical dilemmas encountered daily, and the necessity of successful negotiation amongst everyone involved in individual and collective decision making processes.

CHANGE OVER TIME IN THE USE OF CARE IN THE LAST 5 YEARS AMONG PEOPLE WITH DEMENTIA

M. Aaltonen^{1,2}, J. Raitanen^{2,3}, L. Forma², J. Pulkki², P. Rissanen², M.K. Jylha², 1. *Institute for Advanced Social Research, University of Tampere, Tampere, Finland*, 2. *Faculty of Social Sciences (Health Sciences) and Gerontology Research Center, University of Tampere, Tampere, Finland*, 3. *UKK-Institute for Health Promotion Research, Tampere, Finland, Tampere, Finland*

Advanced age and dementia are important contributors to care use, especially long-term care (LTC). We studied the impact of age on use of LTC and hospital care (HC) in last five years of life in those who died from dementia in three time periods.

Data were drawn from Finnish National Registers. The outcome variables, (1) use of LTC and (2) use of HC, were followed for the last five years of life for all those who died in 2001, 2007, or 2013 at the age of 70–79, 80–89, or 90+. Generalized Estimated Equations were used to estimate the impact of age and year of death, taking into account other major diagnoses and gender.

Between years 2001, 2007 and 2013, age at death and the use of LTC increased. Use of LTC was highest in the oldest old and HC in the youngest old, but the differences between age groups decreased during the study period. Among those aged 70–79, use of LTC increased. In the oldest age group, use of LTC increased until 2007 after which it decreased. Use of HC decreased among younger age groups. In the oldest, use of HC increased slightly.

Advanced age is an important driver of LTC in those with dementia. Longer lives and increased age at death likely lead to higher need for LTC. Yet the effect of age on use of LTC

and HC decreased between the study years. Causes behind the increase in LTC use in the youngest group should be studied further.

CONVINCING THE LEADERS: PERCEIVED BARRIERS TO THE IMPLEMENTATION OF NURSING HOME CULTURE CHANGE

N. Kusmaul, *Social Work, University of Maryland, Baltimore County, Baltimore, Maryland*

Nursing home culture change has been around since the emergence of the Eden Alternative in the early 1990's, yet few long term care communities use its practices. Culture change practices radically change nursing home operations and organizational structures in ways that flatten the organizational hierarchy and share decision making power with elders and direct care workers. Implementation studies have shown that organizational change is challenging and requires sustained engagement from leadership. The aim of this translational research study was to identify what keeps nursing home leaders from adopting culture change so that barriers could be addressed, resulting in more living communities adopting person-centered culture change practices.

The Maryland Culture Change Coalition conducted a culture change training series across the state in the Summer of 2015 aimed at nursing home administrators and assisted living managers. Exit surveys were given to all participants. Ninety eight participants completed the survey. The most common barriers identified were about regulations and their enforcement, and about the effectiveness of culture change practices.

Together these indicate ongoing concerns with regulations and the application thereof. If administrators are not convinced that culture change practices improve outcomes for older adults then they are less likely to consider making changes that they perceive as threatening to the health of the organization. This suggests a need for more outcomes research, clearer policies, and education for administrators and surveyors.

THE STATUS OF QUALITY CONTROL OF GERIATRIC CARE INSTITUTIONS IN SHANGHAI: A SURVEY

L. Gu¹, L. Zhang¹, Y. Weng¹, D. Li², *1. Department of Nursing, Changhai Hospital affiliated to Second Military Medical University, Durham, North Carolina, 2. Shanghai Donghai Geriatric Caring Hospital, Shanghai, China*

To investigate the situation of quality control in geriatric care institutions (GCI) and identify the existing problems and propose management strategies, a questionnaire survey and field survey was conducted in 270 GCIs in Shanghai in 2014, including facilities, human resources, characteristics of elder patients, distribution of adverse events and quality of geriatric care. Descriptive methods were used for data analysis. Totally 25 geriatric care hospitals (GCH) and 245 community health service centers (CHSC) responded to the survey. There were 6140 beds for elderly care in GCHs where mean length stay of elder patients were 140 days, while 10265 beds in CHSCs where mean length stay of elder patients were 119 days. The proportions of nursing assistants, nurses, medical physicians and technicians in GCHs were 37.91%,

29.11%, 19.62% and 13.35%, while those in CHSCs were 14.14%, 34.59%, 36.47% and 14.80%. The top five most frequent adverse events in GCHs were fall, medication, catheter, diet and transfusion related events, while those in CHSCs were medication, fall, catheter, transfusion and hurt related events. During field survey, public GCHs were found better in quality of elderly care than private ones after expert assessments. Our results indicate that administrators in GCIs should improve medical and nursing facilities, increase human resource, optimize geriatric nurse training system, implement risk analysis and quality management to promote quality of care for the elderly.

SELF-RATED HEALTH AND THE COMBINATIONS OF SELF-CARE DISABILITIES AMONG DISABLED ELDERS IN TAIWAN

H. Tung, H. Hsu, S. Chuang, S. Hsu, J. Wang, *Asia University --Taiwan, Taichung, Taiwan, Taiwan*

Introduction: Self-rated Health (SRH) is a commonly measured concept in gerontological studies. The single item measures people's subjective rating of their current health status. A great majority of Long-term Care users are physically disabled elders with a poorer rating of SRH. Yet, few studies have examined the associations between different combinations of self-care disabilities (e.g. Activity of Daily Living, ADL) and SRH. In this study, combinations of 6 ADL disabilities among a group of disabled elders were identified to correlate with their ratings of subjective global health.

Methods: Data were taken from a face-to-face interview survey (N=514) of disabled elders, aged 60 or over in 2008, who were users of long-term care services in central Taiwan. Self-rated Health was measured with a single item, "regarding your state of health, would you say it is excellent (=5), good, average, poor, or very poor (=1)." The 6 items in the ADL scale, tapping to the performance on 6 self-care tasks, were toileting, bathing, eating, dressing, transferring, and walking. The coding for each of the tasks was: "no difficulties" = 0, "somewhat difficult" =1, "very difficult" = 2, and "cannot do it at all" = 3. Both the total number of the 6 tasks with difficulties and the summing score of the 6 items were calculated.

Results: The correlation between the number of ADL disability items and SRH was $-.022$ ($p < .001$). "Walking" appeared in all of the frequently identified combinations of ADL disabilities, implying that it was often the first self-care disability a disabled elders would develop over the disablement process. The combination of ADL disabilities with highest mean SRH rating was not from the participants who were free of any ADL disabilities (N=57, mean SRH = 3.07), instead the participants with the combination of "walking" and "bathing" (N=37, mean SRH = 3.35) and the participants with the combination of "walking," "bathing," and "toileting" (N=26, mean SRH = 3.27) had the highest SRH ratings.

Conclusion: For the long-term care services users with ADL disabilities, some of them still show resilience and were able to find a way to interpret their health as adequate, as long as the provided services could meet some of their care needs.

SESSION 1040 (POSTER)

MENTAL AND COGNITIVE DISORDERS: ASSESSMENT AND INTERVENTION

OFF-LABEL USE OF ANTIPSYCHOTIC MEDICATIONS ACROSS LONG-TERM CARE SETTINGS IN KOREA

Y. Jung, H. Kim, *Graduate School of Public Health Seoul National University, Seoul, Korea (the Republic of)*

Introduction: Off-label use of antipsychotic medications refers to the utilization of drugs for an unapproved indication. Mitigating psychiatric conditions are often a reason for off-label use, which can cause unintended safety issues. The purpose of this study is to examine the prevalence and variations of off-label use of antipsychotics among older people with long-term care needs in nursing home (NH) and long-term care hospital (LTCH) settings.

Method: We conducted a nationally representative sample survey of 2,542 older people in 91 NHs (n=1,275) and 52 LTCHs (n=1,267) in South Korea in 2013, including comprehensive geriatric assessments and medication order reviews. Off-label use of antipsychotics was defined by applying the FDA's 2005 "black box warning." We calculated at the organizational level the prevalence of off-label use of antipsychotics and the interquartile range of the prevalence.

Results: The overall percentage of older people receiving antipsychotics for unapproved indications was 16.9%, and the prevalence was similar at NHs (16.4%) and LTCHs (17.3%). The variance in mean prevalence of off-label use of antipsychotics in both settings was large, and it was larger at NHs than LTCHs even after adjusting for individual characteristics.

Conclusion: Preliminary evidence suggests that organizational characteristics affect antipsychotic prescribing independent of resident case-mix. Additional research on off-label use of antipsychotics in LTC settings is needed.

REDUCING ANTIPSYCHOTIC USE IN NURSING HOME RESIDENTS WITH DEMENTIA

W.J. Spurlock¹, F. Epps², S.B. Anthony³, *1. Nursing, Southern University and A&M College, School of Nursing, Baton Rouge, Louisiana, 2. Georgia State University, Atlanta, Georgia, 3. SBAFA, Inc., St. Francisville, Louisiana*

Inappropriate use of antipsychotics in elderly nursing home (NH) residents with dementia has gained national attention. Adverse effects from the use of these drugs can result in poor health outcomes, as well as increased mortality rates. The overarching aim of this study was to determine the perception of NH employees of symptoms and situations that prompt the initiation or continuance of antipsychotics in dementia residents and to identify perceptions of major challenges to reduction in antipsychotic use. A survey was administered to 319 NH employees (i.e., directors of nursing, administrators, staff nurses, social service, and activity personnel) from Louisiana. Participants were asked to rank order their perception of the importance of the role that nine symptoms or situations have played in the initiation or use of antipsychotics in dementia residents. In conjunction with descriptive statistics to analyze survey results, content analysis of participants' comments from open-ended questions was

performed. Findings (ranked in the order from most to least important) were: combativeness; psychosis; resident placed on antipsychotic during treatment in acute care behavioral/mental health facility; agitation; admitted to NH on antipsychotic; severe sleep pattern disruption; wandering; resistance to care; and family requested. Responses overwhelmingly highlighted the need and interest for educational opportunities about evidence-based, non-pharmacological interventions and potential adverse effects of antipsychotics. Findings from this survey were used to tailor a statewide educational intervention targeting NH staff. Recommendations that emerged from survey findings can also be used by interested stakeholders from other geographical regions to reduce the use of antipsychotics.

THE RISE IN OCCURRENCE IN MENTAL HEALTH ISSUES AMONG LONG-TERM CARE RESIDENTS

A.E. Kris, C. Zembrzusi, *Fairfield University, Westport, Connecticut*

The purpose of this study is to document the trends in the incidence, prevalence and demography of long-term care residents with complex psychological needs over the previous decade. Admission records from residents at two U.S. long-term care institutions were selected for review. Data from 2016 were collected and compared with records from 2006. In addition to demographic characteristics, information was collected about a) the presence of mental illness b) the type mental health diagnosis, c) the presence, type and level of cognitive impairment and d) the number and types of medications used. Results indicated that between 2006 and 2016, there was a statistically significant rise in the number of residents with documented co-morbid mental health problems over time (n=250, p<0.05). This rise in the number of residents with diagnosed mental health issues upon admission was associated with a statistically significant rise in the use of both anxiolytic and anti-psychotic medications. In addition to the general trend towards increases in diagnosed mental health problems, there were also substantial increases in the number of residents dually diagnosed with both cognitive impairment and mental illness. This increase in both the prevalence and complexity of resident mental health problems has serious implications for both family members and healthcare providers. Increased education, staffing and services may be needed to address the complex medical and mental health needs of this vulnerable population.

SENSORY LOSS AND DEMENTIA: INSIGHTS INTO LONG-TERM CARE NURSES' EXPERIENCES OF CARE AND ASSESSMENT

F. Höbler^{1,2}, A. Escrig Pinol^{1,2}, M. Rodríguez Monforte³, X. Argueta-Warden², K. McGilton^{1,2}, *1. Toronto Rehabilitation Institute-University Health Network, Toronto, Ontario, Canada, 2. University of Toronto, Toronto, Ontario, Canada, 3. FCS Blanquerna-Universitat Ramon Llull, Barcelona, Spain*

More than half of long-term care (LTC) residents are reported to be living with dementia, affecting their ability to understand and express information, thereby having profound implications for effective interactions. This is further

compounded by hearing and vision loss which also affects two thirds of residents. Persons living with dementia have identified the assessment of such sensory impairment, along with its treatment and care, as a key research priority. As part of a larger project aiming to develop a package of effective sensory screening tools to identify LTC residents with dementia in need of specialist referral, an environmental scan was conducted to capture the tools and strategies currently being used by front line staff in this setting. A purposive sample of 20 registered nurses and registered practical nurses was interviewed across 2 facilities in Ontario, Canada, and asked about: their experiences of working with persons who have dementia and sensory loss; how they identify which residents have sensory impairment; ways in which current screening procedures could be improved; and, key elements to include in a sensory screening package. Using a strength-based analytical framework, we highlight “pockets of excellence” in nurses’ practices of care and assessment. Results from a two-step qualitative content analysis reveal diverging institutional frameworks of practice, along with shared barriers and enablers to the care and identification of sensory loss in this population. We also discuss examples of effective and creative strategies used by nurses to conduct informal assessments and enable communication with older adults who have dementia.

A NATIONAL APPROACH TO IMPROVING DEMENTIA CARE: THE DEMENTIA DYNAMICS TOOLKIT

S. Davis, A. Campbell, R. Capp, *Applied Gerontology, Flinders University, Bamaam, Victoria, Australia*

Under the Encouraging Better Practice Initiative, the Australian Commonwealth Department of Health and Aged Care funded a team from Flinders University to develop and disseminate the Dementia Dynamics Toolkit to all residential aged care homes in the country with the aim of building capacity in person-centred dementia care. The DD Toolkit comprises a manual, eLearning and micro-training DVDs, and a website which provides access to technical and implementation support. A national sample of aged care staff and management were surveyed pre/post the dissemination of the toolkit. Data was also collected during the project via workshop evaluations, pop-up surveys online, email surveys and telephone interviews. Of the 2768 residential aged care homes in Australia, 60% have staff and management completing the eLearning. This paper provides an overview of the project and presents data collected specific to examining staff-based measures of individualised care (ICI), work practices, person-centred leadership and responsive behaviour in relation to completion of the eLearning. Data analysis indicates that in care homes where a critical mass of staff have completed the eLearning the general institutional climate has shifted, with a consequential decrease in responsive behaviour expressed by residents with dementia. Overall, staff and management who have completed the eLearning have higher individualised care scores, report more person-centred work practices and feel more empowered in their workplace. The flexibility of the toolkit is highlighted through descriptions of the different ways care homes have made use of the resources.

COMMUNICATION LEADING TO SHARED MEANING IN THE NURSING HOME

A.S. Ashcraft, D.C. Owen, *School of Nursing, Texas Tech University Health Sciences Center, Lubbock, Texas*

Patterns of communication between nurses and physicians directly impact nursing home (NH) resident quality of care. Nurses not fully explaining clinical change and physicians not eliciting needed information has compromised effective communication. This qualitative study used a Sensemaking model of communication between NH nurse/physician to understand shared meaning informed by oral and written strategies.

Sample-19 nurses, 22 MDs. 33 communication events were the focus of 16 interviews, 17 nurse notes, 22 MD orders, and 16 MD notes. Using grounded theory and ethnographic interviewing (1st & 2nd cycle coding, constant comparative analysis, analytic memos) with a Sensemaking-based semi-structured interview guide and examination of related medical records, communication events were analyzed. Cases were created to illustrate communication processes. Trustworthiness was addressed through an audit trail of decision-making memos, triangulation of prolonged interviews with medical records, and using Sensemaking to guide interpreting codes and developing theory.

Nurses established relationships by intentionally approaching MDs at monthly NH visits, creating individualized communication exchange, contact lists, and MD information sharing. MDs noted nurses’ availability or phone contacts directed their coming to know the nurse and their capabilities. Case analysis yielded contrasting views by nurse and MD of the same event. Nurses described symptoms, and MD orders or transfer requests. MDs noted importance of crafting resident information for decision-making.

Nurses and physicians sought agreement about next steps or decisions. Education should emphasize how to reach shared meaning. Research should examine impact of nurse/MD communication on resident outcomes.

RELIABILITY AND VALIDITY OF THE RESISTIVENESS TO CARE SCALE AMONG COGNITIVELY IMPAIRED OLDER ADULTS

E. Galik¹, B. Resnick¹, S.D. Holmes², V. Nalls¹, 1. *University of Maryland School of Nursing, Ellicott City, Maryland,* 2. *University of Maryland Baltimore County, Catonsville, Maryland*

Resistiveness to care generally occurs when an individual with cognitive impairment interferes with caregivers’ attempts to provide care, and commonly occurs during personal care interactions such as bathing, toileting, and oral care. The purpose of this study was to test the reliability and validity of the Resistiveness to Care Scale (Mahoney et al., 1999) using a Rasch Measurement Model among a larger group of nursing home residents with moderate to severe dementia. This was a descriptive study using baseline data from 261 residents participating in an ongoing trial testing a Function and Behavior Focused Care intervention for cognitively impaired nursing home residents (FBFC). The average age of the residents was 84.64 (SD=9.60) and the majority were female (N=198, 74%), white (N=161, 61%), and not married (N=185, 69%). The mean MMSE was 7.23 (SD=5.10). There was sufficient evidence of internal consistency with findings similar to the

original scale development which was done with a non-independent sample of 68 residents younger residents (mean age of 72) providing 232 observations in which the alpha coefficient was .82. Psychometric testing using Rasch analysis supported the validity of the measure. The findings from this study provide new support for the reliability and validity of the Resistiveness to Care Scale for use with older adults with dementia in nursing home settings. Future work with the measure may benefit, however, from the addition of items that are easier to endorse or express with regard to resistiveness to care.

INTRODUCING MONTESSORI-BASED VISITING IN A CANADIAN LONG-TERM CARE HOME: RESULTS AND RECOMMENDATIONS

P.V. Hunter¹, L. Thorpe¹, W. Landen¹, L. Pickard¹, C. Hounjet², 1. *St. Thomas More College, University of Saskatchewan, Saskatoon, Saskatchewan, Canada*, 2. *University of British Columbia, Vancouver, British Columbia, Canada*

Enhancing quality of life for residents with advancing dementia remains one of the most significant problems of residential care. Nevertheless, there is growing recognition that when activities are appropriately adapted to individual interests and abilities, residents with dementia can enjoy sustained participation. One method that has seen considerable success in this regard is the Montessori method, introduced by Cameron Camp, and based on the work of Italian physician and educator Maria Montessori (1870 – 1952). We recruited and trained 18 community volunteers to use a Montessori-based approach to visit residents in a secure dementia care unit. In this presentation, we describe the design and implementation of this volunteer visiting program and provide brief data-driven summaries of resident, volunteer, family, and staff input. We offer specific recommendations from our experience to those interested in developing similar Montessori-based initiatives in dementia care settings.

COSTS OF A STAFF COMMUNICATION INTERVENTION TO REDUCE DEMENTIA BEHAVIORS IN NURSING HOME CARE

K.N. Williams¹, P. Ayyagari¹, Y. Perhounkova¹, M. Bott³, R. Herman², A.L. Bossen¹, 1. *The University of Iowa, Iowa City, Iowa*, 2. *University of Kansas, Lawrence, Kansas*, 3. *University of Kansas Medical Center, Kansas City, Kansas*

Background: Persons with Alzheimer's disease and other dementias experience behavioral symptoms that frequently result in nursing home (NH) placement. Managing behavioral symptoms in the NH increases time required to complete care, adds to staff stress and turnover, and increases costs of care. The Changing Talk (CHAT) intervention improves staff communication by reducing elderspeak and led to reduced resident resistiveness to care (RTC). We evaluated the cost effectiveness of CHAT in reducing elderpeak and RTC.

Methods: Costs to provide CHAT were determined for each NH (N=11) using process based costing.

Analysis: Based on the number and type of staff attending the CHAT training, and materials and interventionist time, an average cost per participant was calculated for each NH.

Regression estimates from the parent study were applied to determine costs per unit reductions in staff elderspeak and resident RTC.

Results: A one percentage point decrease in elderspeak was associated with an average 0.43 reduction in RTC. CHAT led to a 12.9% average drop in elderspeak use by NH staff. The average 12.9% reduction in staff elderspeak use predicted a 5.59% decrease in RTC per resident. Assuming that each staff cares for 2 residents with RTC, the cost effectiveness ratio for each 1% RTC reduction per resident is \$7.13.

Conclusions: Cost variations to reduce elderspeak and RTC were based on the number of factors such as baseline elderspeak and the number of residents with RTC. Overall, the 3-session CHAT program is a cost-effective intervention for reducing RTC in dementia care.

THE EFFECT OF AROMATHERAPY ON AGITATION AND CAREGIVER BURDEN IN PATIENTS WITH DEMENTIA

T. Turten Kaymaz, L. Ozdemir, *Hacettepe University, Ankara, Turkey*

Introduction: In dementia, psychiatric and behavioral symptoms develop over time. One of the most frequently observed behavioral symptoms is agitation. The caregivers of dementia patients with agitation have an increased burden. Therefore, studies are needed to examine the effect of aromatherapy on agitation in dementia. The aim of this study was to examine the effects of aromatherapy on agitation in patients with moderate to severe dementia and caregiver burden. **Method:** The study was carried out in patients with dementia and their caregivers at two university hospitals in Turkey. The study sample comprised a randomly selected aromatherapy (n=14) and control group (n=14). Patients in the study were stratified by dementia phase and taking antipsychotic medication. The intervention group was given aromatherapy via hand massage and inhalation for 4 weeks in their home. The control group received no intervention during the study. The data were collected using Neuropsychiatric Inventory (NPI), Cohen-Mansfield Agitation Inventory (CMAI) and Zarit Burden Interview (ZBI). **Results:** The NPI scores of intervention-group significantly decreased at weeks 2 and 4 compared with control patients ($p < 0.05$). In addition, CMAI and ZBI scores were significantly lower in the intervention group compared with the control group at week 4 ($p < 0.05$). **Conclusion:** After aromatherapy, agitation, neuropsychiatric symptoms and caregiver burden in the intervention group had significantly decreased compared with the control group.

THE EFFECTS OF WEB-BASED PHYSICAL RESTRAINT-REDUCTION EDUCATIONAL PROGRAM

E. Kong¹, S. Kim², M. Kim³, S. Yu⁴, D. Shin⁵, 1. *Gachon University, College of Nursing, Seongnam, Korea (the Republic of)*, 2. *Chungbuk National University, Department of Nursing, Cheongju-si, Korea (the Republic of)*, 3. *Sungshin Women's University, College of Nursing, Seoul, Korea (the Republic of)*, 4. *Sangji University, Department of Nursing, Wonju-si, Korea (the Republic of)*, 5. *Hallym University, Division of Nursing, Chuncheon, Korea (the Republic of)*

Physical restraints have been frequently used in Korean nursing homes. This study was conducted to evaluate the effects of web-based physical restraint-reduction educational programs on Korean nursing students. A randomized, single-blind, control-group pretest-posttest design was used to evaluate the effects of web-based physical restraint-reduction educational programs (six session-educations for 54.33 minutes). A total of 169 nursing students (85 in experimental group and 84 in control group) in four Korean nursing schools completed this study. The experimental group received the web-based physical restraint-reduction educational programs and the control group did not receive the program. Data were collected immediately before and after the intervention (between December in 2015 and January in 2016). Three instruments were used to measure nursing students' knowledge, perception, and attitudes regarding use of physical restraints in nursing homes. There were statistically significant effects of the web-based educational programs on nursing students' knowledge ($t = 5.97, p < .001$) and perception ($t = -9.67, p < .001$) regarding the use of physical restraints. There was no significant effects of the web-based educational program on nursing students' attitudes ($t = 1.72, p < .087$) regarding the use of physical restraints. The results show that web-based physical restraint-reduction educational program is an effective intervention to improve nursing students' knowledge and perception regarding the use of physical restraints in nursing homes. More intervention studies to improve students' attitudes toward physical restraint-reduction are required using more rigorous research methods. Also, restraint measurements targeting nursing students need to be developed and evaluated.

CLINICAL AUDIT: QUALITY OF PALLIATIVE CARE IN LONG TERM-CARE FACILITIES IN WESTERN FRANCE, 2015

J. Prudhomme^{1,2}, V. Morin-Chouarbi¹, M. Bechac¹, E. Menand^{1,2}, A. Corvol^{1,3}, D. Somme^{1,2,3}, 1. *Centre Hospitalier Universitaire CHU de Rennes, Rennes, France*, 2. *Université Rennes 1, Faculté de Médecine, Rennes, France*, 3. *Centre de recherche sur l'action politique en Europe, UMR 6051, Rennes, France*

Most of the elderly patients hospitalized in Long-term care (LTC) facilities are under palliative care. However, little is known about the quality of the care they receive in this setting. French health care Information system do not give precise information on their end-of-life. We conducted a study to assess families satisfaction with care after the death of their relative in LTC.

We asked 40 families of all patients deceased during one month (October 2015) in 13 LTC facilities of Western France, to respond the Family Perception of Care Scale. Respondents indicate their agreement with 25 items, rated on a seven-point Likert scale. Items are gathered in 4 sub-scales: resident care, family support, communication and rooming. Finally, respondents were invited to include written comments.

First results indicate the existence of a polarization of families satisfaction, without any nuances: either they consider the care received by their love one as perfect, either they consider it as clearly inadequate. Most of the commentaries concern resident care and communication with the

staff. The survey is still in process, complete results will be presented. The difficulties faced will be discussed.

Our study Palliative care; Long-term care; Long-term care facilities; Geriatric department

ASSOCIATION OF DIABETES AND ITS COMPLICATIONS WITH DEPRESSION IN OLDER PEOPLE OF INDIA

R. Bansal, H. Indani, P. Chatterjee, A. Chakrawarty, S. Dwivedi, A.B. Dey, *AIIMS, New Delhi, India*

Diabetes is a known risk factor for mental health disorders but studies on elderly diabetic in developing countries are limited. Each country should assess its own burden on mental health due to chronic diseases like diabetes. A cross sectional comparative study (180 diabetic cases, 180 age-sex matched non-diabetic controls; aged ≥ 60 years) were recruited from Geriatric Medicine OPD between November, 2014 to June, 2016. Depression was assessed using Geriatric depression scale (GDS). There was significantly higher prevalence of depression in diabetic (35.6%) as compared to non-diabetic (16.7%) (p -value < 0.01). On subgroup analysis, Diabetic neuropathy was more associated with depression (49.3%) than those without diabetic neuropathy (27%) (p -value 0.002) among diabetic group. Diabetes is associated with increased risk of depression, while diabetic neuropathy is associated with even more risk of depression. So, all diabetic patient (especially those with diabetic neuropathy) should be assessed for depression at each health care visit.

PREVALENCE OF MENTAL DISORDERS AND ITS ASSOCIATED FACTORS AMONG CHINESE ELDERLY PEOPLE

N. Li¹, Q. Zhou³, G. Xu², 1. *Peking University, Beijing, China*, 2. *Tianjin Mental Health Center, Tianjin, China*, 3. *University of International Business and Economics, Beijing, China*

Elderly people were at high risk for mental disorders. Most studies in China on geriatric mental health were focused on single mental disorder such as depression and dementia. Besides, screening scales on mental disorder symptoms were used and the results could be biased. In this study, using data with diagnosis information based on the Chinese version of the Structured Clinical Interview for Diagnostic and Statistical Manual (DSM-IV) Axis I disorders (SCID) by trained psychiatrists, we aimed to explore the prevalence rate of mental disorders and its associated factors among Chinese elderly people.

Data for this study was derived from the 2012 Tianjin Mental Health Survey, which employed a multistage stratified and probability proportionate to size sampling method. Participants were firstly screened with Chinese version General Health Questionnaire and 8 additional items that assessed other risk factors for mental disorders, and divided into 3 risk groups. All subjects from high risk group, 44.5% from moderate risk group, and 10.4% from low risk group were selected for diagnosis of mental disorders with SCID.

Of the 15,538 people selected for interview, 128,99 people were investigated and 3,450 aged 60 years or older. The adjusted 1-month prevalence rate of mental disorders among Chinese elderly people was 13.0%. Factors associated with

mental disorders included female gender, older age, being currently unmarried, and low educational attainment.

The results revealed a high prevalence rate of mental disorders among Chinese elderly people. Targeted intervention programs should be conducted to improve the mental health status among Chinese elderly people.

PROMOTING ACTIVE AGEING IN OLDER PEOPLE WITH MENTAL DISORDERS: DEVELOPMENT AND TESTING OF A TOOL

K. Kenbubpha, I. Higgins, S. Chan, A. Wilson, *The University of Newcastle, Newcastle, New South Wales, Australia*

This study was carried out in Thailand. A survey instrument was developed based on the mixed methods research. The first phase, a qualitative study with two focus groups was used to initially develop the instrument. The second phase, a quantitative study was used to develop and test a draft of the survey instrument which included two main steps. The instrument development consisted of item generation, content validity, face validity, and a pilot study. Then, a cross-sectional study of 575 primary care providers was surveyed with a response rate of 72%. Psychometric properties were tested for internal reliability using Cronbach's alpha, and construct validity using exploratory factor analysis. The survey instrument was categorised as; participants, education, health, leisure, and security for conceptual and theoretical meaningfulness. A 5 point Likert scale was used ranged from 0(never) to 4(always). The initial content validity index was 0.82 and the final of survey instrument was revised into 54 items. The total Cronbach's Alpha from the pilot study was 0.975. Three items were removed because corrected item-total correlation coefficient was lower than 0.30. Test-retest reliability was a significant correlation with total score 0.97($P < 0.01$). Factorability of all items was confirmed with correlations greater than 0.30. Significant results obtained on Barlett's test of sphericity [$c^2(1431) = 18737.05$, $P < 0.001$] and the Kaiser-Meyer-Olkin measure of sampling adequacy was 0.95. This paper reports preliminary evidence of the psychometric properties of a new survey instrument. Five factors identified assessment of promotion in active ageing for older people with mental disorders in communities.

CORRELATIONS OF NURSING PRACTICES FOR ELDERLY WITH COGNITIVE IMPAIRMENT AND COMPETENCE IN HOSPITALS

M. Suzuki¹, H. Yoshimura³, Y. Ito², M. Kanamori⁴, 1. *Faculty of Nursing, Hamamatsu University School of Medicine, Hamamatsu, Shizuoka, Japan*, 2. *Hamamatsu Rosai Hospital, Hamamatsu, Shizuoka, Japan*, 3. *Seirei Mikatabara Hospital, Hamamatsu, Shizuoka, Japan*, 4. *Ritsumeikan University, Shiga, Kusatsu, Japan*

In Japan, the proportion of elderly people in the population increased to 25% in 2013, and will increase to 38% by 2055. The number of elderly people with dementia in Japan has been increasing due to the increasing proportion of very old people among the elderly. In this context, many elderly people with dementia require physical treatment and admission to acute care hospitals. The Self-Assessment Scale of Nursing Practice for Elderly Patients with Cognitive Impairment (NPCI) was developed to

evaluate person-centered care practices for elderly people with dementia; the Clinical Nursing Competence self-Assessment Scale (CNCSS) was developed to evaluate clinical nursing competence. This study examined correlations between scores on the NPCI and CNCSS among 280 nurses working in two acute care hospitals; data were collected from March to July 2015. Participants self-administered the questionnaires. The NPCI has the following sub-scales: "creative care suited to the patient and their cognitive function," "care that emphasizes the patient's viewpoint," "care with a psychosocial approach that predicts potential problems," and "care that recognizes the will and worth of the patient." Six of the CNCSS' 13 sub-scales were used in this study. Correlation coefficients were calculated between scores on each questionnaire; NPCI and CNCSS sub-scale scores were significantly correlated. Multiple regression analysis indicated that the NPCI's "supportive human relationships" and "ethical practices" sub-scales were significantly correlated with all CNCSS sub-scales. These results indicate that clinical nursing competence training and accreditation should encourage nurses to use person-centered care practices to treat elderly people with dementia.

SESSION 1045 (POSTER)

NUTRITION AND DIET QUALITY II

NUTRITIONAL AND FUNCTIONAL STATUS OF OLDER PEOPLE LIVING IN YOGYAKARTA, INDONESIA

T. Arjuna^{1,2}, S. Soenen¹, R. Hasnawati², I. Chapman¹, K. Lange¹, N. Luscombe-Marsh^{1,3}, 1. *Discipline of Medicine and National Health and Medical Research Council (NHMRC) Centre of Research Excellence in Translating Nutritional Science to Good Health, The University of Adelaide, Adelaide, South Australia, Australia*, 2. *Department of Nutrition and Health, Faculty of Medicine, Universitas Gadjah Mada, Yogyakarta, Indonesia*, 3. *CSIRO Health and Biosecurity, Adelaide, South Australia, Australia*

Malnutrition is associated with poor health outcomes and places substantial burden on Indonesia's healthcare system. However, the prevalence, and impact, in community-residing Indonesians aged ≥ 65 years remains unknown. We conducted a cross-sectional study to determine the nutritional (using the 18-item Mini Nutritional Assessment (MNA) and serum albumin concentration) and functional (using grip strength and gait speed), status, of residents from the Yogyakarta region. Participants from two urban (City of Yogyakarta; $n=324$) and two rural (Kulonprogo Regency; $n=203$), districts, were assessed. According to the MNA, 5% were malnourished, 54% were at risk of malnutrition and 41% were well-nourished. Rural and urban participants were more likely either malnourished (3vs.6 %) or at risk of malnutrition (73vs.43 %) than well-nourished (24vs.51%). Rural compared with urban participants had lower body weight (mean \pm SD; 44 ± 9 vs. 52 ± 12 kg), body mass index (20 ± 3 vs. 23 ± 4 kg/m²) and albumin concentrations (3.9 ± 0.2 vs. 4.0 ± 0.2 g/dL) (all, $P < 0.001$). Although there was no difference in grip strength between rural and

urban participants (15.9 ± 6.2 vs. 16.8 ± 6.7 kg, $P > 0.05$), there was a tendency for gait speed to differ ($P = 0.057$); post-hoc analysis, indicated lower gait speed for participants from the rural district of Panjatan ($n = 125$, 0.51 ± 0.2 m/s) and the urban districts of Jetis ($n = 96$, 0.49 ± 0.2 m/s) and Gondokusuman ($n = 221$, 0.53 ± 0.2 m/s) compared with the rural district of Girimulyo ($n = 75$, 0.60 ± 0.2 m/s) ($P < 0.05$). In conclusion, 59% of Yogyakarta citizens were malnourished or at risk of malnutrition and, although the prevalence of poor nutrition was greatest for people from rural districts, functional status assessed by grip strength and gait speed was largely comparable.

FUNCTIONAL TOOTH UNIT COMPOSITION AND NUTRIENT INTAKES: THE CONCORD HEALTH AND AGEING IN MEN PROJECT

K.L. Milledge^{1,2,3}, R. Cumming^{1,3,4}, F. Wright¹, F. Blyth¹, V. Naganathan¹, D.G. Le Couteur⁵, V. Hirani^{1,2,3}, 1. *Centre for Education and Research on Ageing, Concord RG Hospital/University of Sydney, Sydney, New South Wales, Australia*, 2. *School of Life and Environmental Sciences, University of Sydney, Sydney, New South Wales, Australia*, 3. *ARC Centre of Excellence in Population Ageing Research (CEPAR), University of New South Wales, Sydney, New South Wales, Australia*, 4. *School of Public Health, University of Sydney, Sydney, New South Wales, Australia*, 5. *ANZAC Research Institute & Charles Perkins Centre, University of Sydney, Sydney, New South Wales, Australia*

Associations between inadequate nutrient intakes and poor dentition in older adults have been shown. The aims of this study are to investigate associations between nutrient intakes and composition of posterior functional tooth units (FTUs) in older men.

Preliminary analysis of a standardized validated diet history assessment and comprehensive oral health examination in 410 community dwelling men (mean age: 84 years) participating in Concord Health and Ageing in Men Project. FTUs were categorized as replaced and/or natural teeth and categorized by number of FTUs. Attainment of Nutrient Reference Values (NRVs) for total energy and key nutrients (protein, Fe, Zn, riboflavin, Ca and vitamin D) were incorporated into a 'key nutrients' variable dichotomised 'good' (≥ 5) or 'poor' (≤ 4).

43.2% ($n = 177$) had 'replaced' only FTUs, 31.7% ($n = 130$) had natural only FTUs and 36.8% ($n = 151$) had < 7 FTUs. Most men met their NRVs, however only 27% met their NRVs for fibre, 26% for potassium, 13% for calcium and $< 1\%$ for vitamin D. In adjusted logistic regression analysis, 'replaced' only FTUs, compared to 'natural only' FTUs, were associated with intakes below the recommendations for folate OR: 1.95 (95% CI: 1.16–3.29), riboflavin, 2.23 (1.03–4.83), magnesium 2.22 (1.32–3.74) and fibre 1.81 (1.06–3.10). Adjusted analysis also showed that men with < 7 FTUs, compared to complete FTUs OR: 2.28 (95% CI: 1.19, 4.41) and those with 'replaced' only FTUs, compared to 'natural' only FTUs 2.00 (1.09, 3.66) were more likely to have poor nutritional intake of key nutrients. Our study shows that composition of FTUs in older men is associated with inadequate intake of some nutrients.

WEIGHTED VEST USE FOR PRESERVING MUSCLE MASS DURING WEIGHT LOSS IN OLDER ADULTS

B.J. Nicklas¹, D. Yow¹, C. Crotts¹, J. Kiel², K. Beavers³, R. Henderson¹, 1. *Wake Forest School of Medicine, Winston-Salem, North Carolina*, 2. *Medifast Inc., Owings Mills, Maryland*, 3. *Wake Forest University, Winston Salem, North Carolina*

Muscle mass loss during weight loss is partially attributed to decreased gravitational load; thus, externally replacing lost body mass may be effective for reducing muscle loss during caloric restriction. To assess the feasibility of this approach, we randomized 37 older (65–80 yrs) adults with obesity (BMI = 30–40 kg/m²) to a 5-month intervention, with (Diet+Vest) or without (Diet only) use of a weighted vest during normal daily activities. The WL goal of 10% was achieved using the Medifast 4&2&1 Plan[®] (4 meal replacements, 2 self-prepared meals and 1 snack/day) and weekly group behavioral counseling meetings. Diet+Vest was asked to wear a weighted vest, progressing to 10 hours/day, with weight added weekly according to individual loss of body mass. At intervention end, vest wear time (mean \pm SD) was 6.7 ± 2.2 hours/day and vest weight was 13.8 ± 5.6 lbs. Both groups lost a similar amount of body mass (Diet = -11.2 ± 4.4 kg ($11.8 \pm 4.5\%$); Diet+Vest = -11.0 ± 6.3 kg ($10.7 \pm 5.9\%$)). Fat mass, lean mass, and % body fat decreased significantly ($p < 0.0001$), with no differences between groups; lean mass comprised $\sim 1/4^{\text{th}}$ of the total mass lost in both groups (Diet = $22 \pm 16\%$; Diet+Vest = $26 \pm 17\%$). Changes in lower-extremity physical function (gait speed, chair rise, stair climb) did not differ between groups; however, leg extensor strength, power and muscle quality tended to decrease in Diet (by 3–9%; $p = 0.03$ – 0.15), but were unchanged in Diet+Vest. These initial results indicate there may be a beneficial effect of weighted vest use for preserving muscle strength/quality independent of muscle mass retention.

DIET QUALITY AND COGNITIVE FUNCTION IN OLDER AUSTRALIAN MEN AND WOMEN

C. Milte, K. Ball, D. Crawford, S. McNaughton, *Deakin University, Geelong, Victoria, Australia*

Previous research into nutrition and cognitive function has focussed on individual nutrients or foods, with inconsistent results. The dietary pattern approach enables assessment of whole diet quality. The aim of this study is to examine associations between diet quality and cognitive function in men and women. Adults aged 55–65 years in the Wellbeing, Eating and Exercise for a Long Life (WELL) study ($n = 617$) completed an 111-item food frequency questionnaire in 2010 and 2014. The dietary guideline index (DGI), a measure of adherence to the Australian Dietary Guidelines assessed diet quality. The Telephone Interview of Cognitive Status modified (TICS-m) assessed cognitive function in 2014. Associations between previous (2010) and recent (2014) diet quality and cognitive function were assessed using linear regression. Key food groups (fruits, vegetables, protein, dairy, cereals) and dietary behaviours (diet variety, adding salt, low-fat, high-fibre) were also investigated. There was no association between 2010 DGI score and TICS-m. After adjustment for age, education, urban/rural area, depression, physical activity, BMI and cardiovascular conditions, a higher 2014 DGI score was associated with a higher TICS-m score

in men (coefficient=0.04, 95% CI 0.01, 0.07). Associations between high-fibre bread (coef=1.05, 95% CI 0.11, 1.99), added salt (coef=-1.79, 95% CI -2.90, -0.68) and TICS-m were also observed in men. Cross-sectionally, men who consumed a diet closer to the Australian dietary guidelines, with high-fibre breads and less added salt reported better cognitive function. Future studies should investigate trajectories of dietary change over time as determinants of cognitive function in older age.

CONCORDANCE OF ANTHROPOMETRIC, SELF-REPORTED AND BLOOD MEASURES OF NUTRITIONAL EVALUATION IN ELDERLY

L.P. Corona¹, A. Saron¹, D. Nunes², T. Alexandre³, T. Brito⁴, Y. Duarte⁴, M. Lebrao⁴, 1. *Faculty of Applied Sciences, University of Campinas, Limeira, Sao Paulo, Brazil*, 2. *Federal University of Tocantins, Palmas, Tocantins, Brazil*, 3. *Federal University of São Carlos, Sao Carlos, Sao Paulo, Brazil*, 4. *University of Sao Paulo, Sao Paulo, Sao Paulo, Brazil*

This study aimed to assess the concordance between some measures often used as nutritional status markers. We used data from elderly (n=1,256) evaluated in the third wave of SABE Study (Health, Well-being, and Aging) conducted in 2010 in Sao Paulo, Brazil. We evaluated nutritional status using the most common measures: Body Mass Index (BMI), hemoglobin and albumin concentrations, calf circumference, score in mini nutritional assessment (MNA) and self-perception of nutritional status (question: “do you consider yourself well-nourished?”). Differences between groups were estimated using χ^2 test with Rao-Scott correction, considering populational weights for estimates. The prevalence of Hypoalbuminemia (<3.5g/dL) was 7.9% of low body weight elderly (BMI<22kg/m²), proportion similar to normal weight elderly (6.8%; p=0.652). Anemia was more prevalent in low weight elderly, but the difference was not significant (12.2 and 7.2, respectively; p=0.078). Both anemia (15.9% and 7.5%, p=0.019) and hypoalbuminemia (15.9% and 7.5%, p=0.019; 20.1% and 7.5%, p<0.001) were more prevalent in elderly with calf circumference <31cm in relation to those with values ≥31cm. They were also more prevalent in those considered malnourished by MNA comparing with well-nourished (anemia: 14.4 and 5.9%, p=0.011; hypoalbuminemia: 21.6 and 6.0, p=0.002). Hypoalbuminemia was significantly higher in those who self-perceived malnourished (14.9% and 7.5%, p=0.019), but anemia and low calf circumference were not significantly. Thus, nutritional status is a complex part of geriatric evaluation and should count on several measures, including anthropometric, self-perception and blood indicators, to allow a complete understanding of nutritional status, once body weight alone may not reflect it correctly.

SALT CONSUMPTION AND OVERWEIGHT AMONG OLDER ADULTS: DATA FROM NUTRITION UP 65

P. Moreira^{1,2,3}, P. Padrao^{1,3}, A. Santos¹, N. Borges¹, C. Afonso¹, A. Sousa¹, R. Guerra¹, T. Amaral¹, 1. *Faculty of Nutrition and Food Sciences, University of Porto, Portugal, Porto, Portugal*, 2. *Research Center on Physical Activity and Leisure, University of Porto, Porto, Portugal*, 3. *EPIUnit - Institute of Public Health, University of Porto, Porto, Portugal*

A few studies suggested that salt consumption might be related with weight gain. We aimed to quantify salt consumption in a representative sample of Portuguese older adults and to evaluate the association between salt intake and overweight (including obesity).

A cluster sampling approach was used, representing Portuguese older adults (≥65 years) according to age, sex, education level and regional area within the Nutrition UP 65 study. This cross-sectional evaluation was conducted in 2015 and 2016. From a sample size of 1500 participants, 1312 were eligible for the present analysis, 57.3% were women, 23.5% were aged ≥80 years. Salt consumption was evaluated through one 24h urinary sodium excretion and excessive salt consumption was defined as ≥5g/day, according to the World Health Organization cut-offs. Overweight/obesity was defined as BMI>27kg/m², according to the Nutrition Screening Initiative criteria for older adults. A multivariable binary logistic regression model was conducted to evaluate the association between salt consumption and overweight/obesity, and Odds Ratios (OR) and respective 95% Confidence Intervals (95%CI) were calculated.

Salt consumption ≥5g/day was observed in 85.1% participants [median (interquartile range)=7.9(4.6) g/day], and the prevalence of overweight or obesity was 69.6%. After adjusting for potential confounders, excessive salt consumption (OR=1.48, 95%CI: 1.06–2.17) was associated with being overweight/obese.

These results emphasize the need for implementing nutritional strategies concerning the reduction of salt consumption among this age group, and particularly in the overweight or obese.

This project was granted by the Public Health Initiatives Programme (PT06), financed by EEA Grants Financial Mechanism 2009–2014.

ASSOCIATION OF BODY COMPOSITION AND PHYSICAL FUNCTION WITH VENTILATORY LIMITED OBESE OLDER ADULTS

M.D. Opina, T. Brinkley, M. Gordon, B.J. Nicklas, *Wake Forest School of Medicine, J Paul Sticht Center on Aging, Winston Salem, North Carolina*

We evaluated whether ventilatory limitation during peak cardiopulmonary exercise testing is associated with worse body composition and physical function in healthy older adults with obesity but without chronic pulmonary disease. 177 healthy adults, 65–80 years old, with obesity (BMI=30–45kg/m²) underwent cardiopulmonary exercise testing on a treadmill, body composition measurement using DXA, and physical function assessment. Participants were categorized into 4 groups based on the lower 95% confidence limit for mean VO₂peak (17.49ml/kg/min) and the median breathing reserve at peak exercise (BR_{peak}, 37.2). Those with low VO₂peak/low BR_{peak} were considered to have ventilatory limitation (VL,n=33), normal BR_{peak}/low VO₂peak had non-ventilatory limitation (NVL,n=48), low BR_{peak}/high VO₂peak were healthy obese (HOb,n=55), and normal BR_{peak}/high VO₂peak were fit obese (FOb,n=41). VO₂peak was lowest in VL (14.7±1.7ml/kg/min vs 15.5±1.7ml/kg/min vs 20.7±2.6ml/kg/min vs 19.9ml/kg/min) and was associated with lower oxygen pulse (10.3±1.5ml/HR vs 10.8±2.2ml/HR vs 13.3±2.5ml/HR vs 13.6±3.1ml/HR)

and higher VE/CO₂ (34.2 ± 5.2 vs 30.1 ± 3.1 vs 31.7 ± 2.5 vs 28.5 ± 3.1) compared to NVL, HOb, and FOb respectively ($p < 0.0001$ for all). While total body mass was similar across all groups, fat mass and percent body fat was highest in VL and lowest in FOb ($p < 0.0001$). Lean body mass was lowest in VL and highest in normal FOb ($p = 0.03$). Low VO₂peak groups had lower short physical performance battery scores ($p = 0.02$), slower gait speed ($p < 0.0001$) and 400-meter walk ($p < 0.0001$) compared to high VO₂peak groups, independent of BRpeak. In conclusion, ventilatory limitation at peak exercise capacity is associated with worse body composition in older obese adults without primary lung disease.

PROBLEMATIC DRINKING IS ASSOCIATED TO MUSCLE MASS AND MUSCLE FUNCTION IN ELDERLY MEN WITH DIABETES

N. Buchmann^{1,2}, D. Spira^{1,2}, I. Demuth^{1,2}, K. Norman^{1,2}, E. Steinhagen-Thiessen^{1,2}, 1. *Charite - Research Group on Geriatrics, Berlin (germany), Berlin, Germany*, 2. *Charite - Universitätsmedizin Berlin, Berlin, Berlin, Germany*

Background: Alcohol consumption is particular serious in diabetic subjects (T2D), as hypoglycemic states can occur due to an inhibition of hepatic glycolysis. Muscle is supplied with energy by the breakdown of glucose, frequent episodes of hypoglycemic conditions could result in muscle breakdown. Aim of the current analysis within the Berlin Aging Study II (BASE-II) was to analyze the association of problematic drinking behaviour to muscle mass and muscle function in diabetes.

Methods: Cross-sectional data of 1456 elderly BASE-II participants (50.8% women; 64 ± 4 years old) were analysed. Alcohol consumption and problematic drinking was assessed using the Alcohol Use Identification Test (AUDIT). Muscle mass was measured using dual energy X-ray absorptiometry (DXA), grip strength using a Smedley dynamometer. Adjusted regression models were calculated to assess the association of problematic drinking to muscle mass and grip strength.

Results: Problematic drinking was evident in 11.1% of BASE-II participants, 12.1% had diabetes. In adjusted models (adjustment for age, BMI, smoking status, morbidities, HOMA-IR, CRP, TSH, physical activity and antidiabetic medication) we found a statistically significant association between problematic drinking to muscle mass (Beta: -22.5 ; SE: 9.8 ; $p = 0.026$) and grip strength (Beta: -7.8 ; SE: 2.9 ; $p = 0.010$) in elderly diabetic men. These results were not evident in women and subjects without T2D.

Discussion: Alcohol consumption, particularly problematic drinking is associated with poorer muscle mass and grip strength in elderly men with diabetes. This topic should be addressed in these subjects as they could be at increased risk for early dependency.

ENERGY INTAKE AND FUNCTIONAL LIMITATIONS IN MALNOURISHED, GERIATRIC PATIENTS AT HOSPITAL DISCHARGE

K. Franz, L. Otten, L. Bahr, U. Müller-Werdan, K. Norman, *Charité - University Medicine Berlin, Research Group on Geriatrics, Berlin, Germany*

Inadequate dietary energy intake results in weight loss which is associated with functional limitations and frailty in geriatric individuals (1).

We investigated energy intake in malnourished patients at hospital discharge and its association with functional limitations, grip strength and risk of depression.

Malnutrition was assessed with the Mini-Nutritional Assessment (MNA) and dietary intake at discharge with a 24h-recall. Energy intake below 24 kcal/kg body weight/day was considered low (2). Frailty was identified with the Fried criteria (3). Restrictions in self-reported functional limitations (Longitudinal Aging Study Amsterdam questionnaire), activities of daily life (ADL), depression (Center for Epidemiologic Studies) and appetite (Council on Nutrition appetite questionnaire) were evaluated by validated questionnaires. Patients were questioned regarding fall frequency within the previous 12 months. Grip strength was measured with dynamometry.

115 patients (77.5 ± 6.9 years; 55.7% women) were included. 53.5% were malnourished ($MNA \leq 7$) and 46.5% were at risk ($MNA 8-11$). 55.7% had low energy intake (17 ± 4 kcal/kg body weight/day; 0.7 ± 0.3 g protein/kg body weight/day). 72.2% were pre-frail/frail. 98.2% had functional limitations. According to ADL, 67.9% were dependent. 52.1% were at risk of depression, 67.0% exhibited loss of appetite and 61.7% had fallen in the previous 12 months. Patients with low energy intake were more often functionally impaired (72.7% vs. 50.0% , $p = 0.018$). Energy intake at discharge correlated with grip strength ($r = 0.308$, $p = 0.001$).

In the majority of malnourished geriatric patients at hospital discharge, energy intake is still below reference values and is associated with functional limitations and reduced strength.

6-MONTH OUTCOMES OF A HOME-DELIVERED MEAL PROGRAM FOR ACUTE NUTRITIONAL RISK

R. Di Maria-Ghallili¹, K. Thoman¹, E. Albajri¹, N. Laverty², J. Nasser¹, 1. *Drexel University, Philadelphia, Pennsylvania*, 2. *MANNA, Philadelphia, Pennsylvania*

Purpose: To describe the changes in self-rated health status in individuals at acute nutritional risk who received medically-appropriate frozen meals delivered weekly by a community-based organization.

Methods: Individuals with an acute illness and at acute nutritional risk who were referred by a healthcare professional to receive medically-appropriate home-delivered meals for up to 6 months from the Metropolitan Area Neighborhood Nutrition Alliance (MANNA) in Philadelphia, PA were invited to participate in the program evaluation. Telephone interviews were conducted at baseline (within 2 weeks of receiving meals), 1 month, 3 month and 6 months. The following tools from the Performance Outcome Measurement Project (POMP) were administered at each time period: satisfaction with home-delivered meals, functional status, and social/emotional well-being.

Results: A total of 52 (Mean age 60.79 years ± 13.69) individuals agreed to participate in the program evaluation over a 3 month period. Participants were primarily female (61.5%), were Black (71.2%) and lived alone (55.8%). The primary diagnosis of participants included cancer (44.2%), renal disease (23.1%), diabetes (15.4%) and HIV/AIDS

(15.4%). At baseline 32.7% of participants had weight loss, 19.2% were at risk for malnutrition, and 13.5% had an impaired ability to prepare meals. Compared to baseline, at 6-months there was an overall increase in self-rated health status ($p=.006$), and increased satisfaction with social activity ($p=.01$).

Conclusions: Individuals with an acute illness and at acute nutritional risk reported an increase in self-rated health and social activity while receiving weekly medically-appropriate home-delivered meals for 6 months.

THE RELATIONSHIP BETWEEN SCHISANDRAE CHINENSIS SUPPLEMENTATION AND MUSCLE STRENGTH IN OLDER WOMEN

S. Lim⁵, H. Park^{2,3}, J. Park¹, J. Jang⁴, K. Kim¹, J. Ryu¹, 1. *Institute of Taekwondo for Health and Culture, Dong-A University, Busan, Korea (the Republic of)*, 2. *Department of Health Care and Science, Dong-A University, Busan, Korea (the Republic of)*, 3. *Department of Preventive Gerontology, National Center for Geriatrics and Gerontology, Nagoya, Japan*, 4. *Institute of Convergence Bio-Health, Dong-A University, Busan, Korea (the Republic of)*, 5. *Research Foundation for Industry-Academy Cooperation, Dong-A University, Busan, Korea (the Republic of)*

Background: Several studies reported that the direct relaxation effect of schizandra chinensis on animal smooth muscle was more dominant than the endothelium dependent NO pathway in corporal tissue and that activation of K⁺ channels and inhibition of TRPC6 channels could be one mechanism of schizandra chinensis induced relaxation of smooth muscles. The fruit of Schizandra chinensis (SC) is a well-known traditional herb used for pharmacological purposes in Asian countries (e.g., Korea, China and Japan), however, the association of SC suppl. and physical function in older population remains unclear.

Purpose: A controlled, randomized, double-blind trial to evaluate the effect of schizandra chinensis supplementation on skeletal muscle mass and muscle force in older women.

Subjects and Methods: Forty-eight female participants (intervention group, n=26; control group, n=22) were included in this study. The intervention group performed ingested two capsules containing either schizandra chinensis or cellulose with every day for 12 weeks breakfast and dinner. The schizandra chinensis capsule contained 250mg of schizandra chinensis, whereas the placebo capsule contained 250mg cellulose. Comparison of changes in body composition measured by DXA, muscles quadriceps strength by Biodex, and laboratory tests between the control and intervention groups during 12 weeks.

Results: After intervention, significant group \times time interactions for the strength of quadriceps muscle force were found. Also, significant group \times time interactions for appendicular skeletal muscle mass were found.

Conclusion: Schizandra chinensis supplementation may help to improve the age-related loss of skeletal muscle mass and muscle force in older women.

BIOIMPEDANCE-DERIVED PHASE ANGLE AND MORTALITY AMONG OLDER PEOPLE

L. Genton⁴, K. Norman², A. Spoerri³, C. Pichard⁴, V. Karsegard⁴, F.R. Herrmann⁵, C. Graf¹, 1. *Rehabilitation and palliative Care, University Hospitals of Geneva, Bernex,*

Geneva, Switzerland, 2. *Charite University Medicine Berlin, Berlin, Germany*, 3. *Social and Preventive Medicine, University of Bern, Bern, Switzerland*, 4. *Clinical Nutrition, University Hospitals of Geneva, Geneva, Switzerland*, 5. *Geriatrics, University Hospitals of Geneva, Geneva, Switzerland*

Phase angle measured by bioelectrical impedance analysis (BIA) may be a marker of health state. This study aims to investigate the link between phase angle and mortality in older persons, and to evaluate whether we can define a phase angle cut-off.

We included all adults over 65 years who underwent a BIA measurement at the Geneva University Hospitals between 1990 and 2011. We retrieved the phase angle and co-morbidities at the last BIA measurement and the mortality until December 2012. The analyses were performed with the Nutriguard ® device because they allow the calculation of sex-, age- and body mass index (BMI)- standardized phase angle using German reference values. Sex-specific and standardized phase angle were categorized into quartiles, where quartile 1 corresponds to the lowest phase angle values and is used as reference category. We evaluated the association of mortality with sex-specific or standardized phase angle through univariate and multivariate (age, sex, comorbidities, BMI categories and settings) Cox regression models, Kaplan-Meier curves and ROC curves.

1307 (38% women) underwent a measurement with the Nutriguard device. Death occurred in 628 persons (44% women). In a multivariate Cox regression model, the risk of mortality decreased progressively as the standardized phase angle quartile increased (HR 0.71 (95%CI 0.58, 0.86), 0.53 (95%CI 0.42, 0.67), 0.32 (95%CI 0.23, 0.43). The discriminative value of continuous phase angle, assessed as the area under the ROC curve, was 0.724 (95%CI 0.70, 0.75) not leading to define an acceptable phase angle cut-off to perform individual prediction of mortality.

This study shows the association of phase angle and mortality in elderly patients, independently of age, sex, comorbidities, BMI categories and settings (ambulatory vs hospitalized).

COMPARISON OF OLDER VS. YOUNGER HOSPITALIZED ADULTS WITH A MALNUTRITION DIAGNOSIS IN THE U.S., 2010

R. Di Maria-Ghalili¹, J. Slaughter¹, E.W. Gonzalez¹, P. Abeysekara¹, H. Resnick², P. Guenter³, 1. *Drexel University, Philadelphia, Pennsylvania*, 2. *Resnick Chodorow LLC, Silver Springs, Maryland*, 3. *American Society for Parenteral and Enteral Nutrition, Silver Springs, Maryland*

Purpose: To examine differences in demographic characteristics and comorbidities in a nationally representative sample of older (≥ 65 years) and younger (18–64 years) hospitalized patients with diagnosis of malnutrition (dxmal).

Methods: Data are from the 2010 Healthcare Cost and Utilization Project (HCUP), which contain patient-level data with ICD-9CM diagnosis codes on hospital inpatient stays. Data were weighted to generate nationally representative estimates of US hospitalizations. Characteristics of older and younger adults with a dxmal during their hospital stay were identified and compared.

Results: Among patients with a dxmal, those ≥ 65 years were 1.5 times more common than those <65 (727,858 vs 467, 378). Older dxmal patients were more likely to have chronic comorbidities than younger adults. However, among older dxmal patients, length of stay (11.6 vs 13.7 days, $p<.001$) and cost of care (\$80,191 vs 106, 535, $p<.001$) were lower and more older dxmal patients died during their hospital stay (10.7% vs 6.6%, $p<.001$). Older dxmal patients were three-times more likely to be admitted to the hospital from a skilled nursing facility (6.4% vs 2.0%, $p<.001$), and twice as likely to be discharged to an intermediate or skilled care facility (49.2% vs 25.0%, $p<.001$).

Conclusions: Older hospitalized dxmal patients appear to be more frail and have greater comorbidity than their younger counterparts. While their length of stay and cost of care is lower, their mortality is higher. It may be beneficial to carefully monitor nutritional status in hospitalized older adults with dxmal, especially those admitted from skilled nursing facilities.

IDENTIFICATION OF A MULTIDIMENSIONAL FOOD-AMINO ACID-DEFINED CIRCADIAN LONGEVITY ZONE

R.J. Martin¹, S.A. Raphaelson², H. Raphaelson³, W. Ashford⁴, A.D. Pruchnicki⁵, R. Schnoll⁶, 1. *Blueberry Health Study / MMT Corp, Sherman, Connecticut*, 2. *Midwife Services, Espanola, New Mexico*, 3. *Mansfield Senior Center, Mansfield, Connecticut*, 4. *Stanford/ Veterans Affairs Aging Research Ctr, Palo Alto, California*, 5. *Mount Sinai St. Luke's Hospital, New York, New York*, 6. *Brooklyn College City University of New York, New York, New York*

The amino acids cysteine, glycine, serine and tyrosine all increased steadily during evolution of primate to human milk, hinting that this combination may support the extraordinary human longevity which co-evolved. Methionine continued its long downward trend during primate evolution, so this amino acid declined steadily in heart tissue and then milk proteins from mice to man, spanning cat, dog, cow, horse and elephant evolution as well as rodent and primate. These amino acid changes are sufficiently precise to enable unbiased SIMCA multivariate analysis to predict primate/human lifespan with 99 percent accuracy, and to score and map all foods within the US Department of Agriculture Nutrition Database (Release 26) into zones comprised of proportions resembling short-lived species, or milk from the longest-lived primates. This presentation provides a tour of foods with longevity-correlated proportions, generally higher in serine and tyrosine and lower in methionine, which map together in 20-dimensional amino-acid-space near human milk, caviar and germ-line tissues that defy aging indefinitely. These carefully-evolved proportions are then linked to daily circadian peak periods of high methionine and genetic damage that by hypothesis represent a burst of daily aging that occurs unless we protect ourselves by carefully selecting nutrient proportions at each meal (either baboon-like proportions or non-aging-germ-line proportions). Longevity-linked ratios in burritos are then shown to predict surprisingly low rates of Alzheimer's, cancer, heart disease, stroke and other age-associated illnesses within Hispanic-Americans aged 80 and above, and the partial reversal of advanced kidney disease when cats are fed a specially-formulated kidney-support diet.

SARCOPENIC OBESITY INDUCED BY SHORT-TERM HIGH-FAT FEEDING IN AGED RAT

L. Wang^{1,2}, Q. Ruan^{1,2}, Y. Zhang³, Z. Bao^{1,2,3}, Z. Yu^{1,2}, 1. *Shanghai Institute of Geriatrics and Gerontology, Shanghai Key Laboratory of Clinical Geriatrics, Shanghai, China*, 2. *Department of Geriatrics, Huadong Hospital, and Research Center of Aging and Medicine, Shanghai Medical College, Fudan University, Shanghai 200040, China, Shanghai, China*, 3. *Department of Gastroenterology, Huadong Hospital, Shanghai Medical College, Fudan University, Shanghai, China*

Background: Sarcopenic obesity was defined as the combination of excess weight and reduced muscle mass or strength. Studies described the loss of muscle mass and strength in aged rat. And short-term high-fat feeding in rat increased the fat accumulation in multiple organs. The object of the study was to establish a rat model of sarcopenic obesity by short-term high-fat feeding.

Methods: Male SD young (2-month) and old (18-month) rats ($n = 30$ respectively) were fed a control diet (CD) ($n = 15$ respectively) or a high-fat diet (HFD) ($n = 15$ respectively) for 8 weeks. Body composition was measured by magnetic resonance techniques at the age of 4 and 20 months respectively ($n=59$). Grip strength normalized to lean body mass was measured in rats of each group ($n=59$). Muscle function were further examined by different stimulated protocols to determine the changes in contractile characteristics including the the maximum twitch force (Pt) and the maximum tetanic force (Po). The hindlimb muscles of 8 rats were collected for pathological experiments. Muscle lipid contents were reflected by Sudan black B staining and LAI (lipid accumulation index).

Results: In young rats, HFD consumption resulted in significant increases in body weight, fat mass, and muscle mass compared with control diet. In aged rats, however, muscle mass was slightly reduced in HFD-fed group compared with control group. Meanwhile, body weight and fat mass in HFD-fed old rats increased compared with old control rats. Muscle lipid content was increased in glycolytic tibialis anterior muscle but no changes in oxidative soleus muscle for the HFD-fed rats. Grip strength was significantly reduced in HFD-fed old rats compared with old control rats. However, no significant difference in grip strength between HFD-fed young rats and young control rats. The maximum twitch force (Pt) and the maximum tetanic force (Po) of hind-limb skeletal muscle were significantly decreased in HFD-fed old rats compared with rats of other groups.

Conclusions: These results showed that a rat model of sarcopenic obesity could be established in aged rats by short-term high-fat feeding.

DIETARY HABITS OF JAPANESE ELDERLY IN AREAS WITH HEAVY SNOWFALL

Y. Iiyoshi, C. Inoue, *Community Health Nursing, Niigata College of Nursing, Joetsu, Niigata, Japan*

[Purpose] This study examines the dietary habits of in the Japanese elderly individuals in areas with heavy snowfall.

[Methodology] Questionnaires were distributed to 1004 elderly in City B, Prefecture A; 494 responses were targeted for analysis. Survey items included attributes, food intake

conditions, dietary habits, impression of a balanced diet, height, weight, deglutition state, medical status, self-rated level of health, and measurement of psychological independence. Scores for dietary variety were calculated from food intake conditions. The scores were classified into three groups. Taking dietary variety as the criterion variable and attributes, dietary habits, BMI, deglutition state, medical examination status, and measurement of psychological independence, TMIG-IC as explanatory variables, an χ^2 test or correlation coefficient was calculated.

[Results] Average age was 75.7 (SD \pm 7.1) years, males were 45.5% and females were 54.5%, family composition was couples at 40.7% and those living alone at 10.5%. Average BMI was 22.8 (SD \pm 3.2). Individuals making food on their own were 47.6%. Means of shopping included shopping by car at 59.1%; 81.6% preferred supermarkets for shopping for perishables. The average dietary variety score was 3.4 (SD \pm 2.2). For dietary variety, gender, level of health, impression of a balanced diet, shopping means, meal preparation, and sharing side dishes were significantly related. Dietary variety and mental independence had a weak correlation. For females, Dietary variety and JST-IC subscale (information gathering) had a weak correlation.

[Discussion] This study suggests that self-rated level of health and level of mental independence are important indicators for dietary variety.

MODEL OF RELATIONS BETWEEN THE SOCIAL DETERMINANTS OF HEALTH ASSOCIATED WITH OBESITY IN THE ELDERLY

M.M. Stival, L.R. Lima, S.S. Funghetto, C.G. Volpe, W.S. Santos, M.V. Costa, M.G. Karnikowski, *Nursing, University of Brasilia, Taguatinga, Brazil*

Objective: To test the plausibility of the hypothetical model of relations between the social determinants of health (SDH) in a population of obese elderly. Design: Cross-sectional descriptive study conducted with the elderly population of a health family program of Distrito Federal, Brazil. Participants: 206 elderly classified as obese in the nutritional assessment performed by Mass Index and bioelectrical impedance. To research the SDH was used Household Survey. The Path Analysis was used AMOS, SPSS 20.0 to determine the relationships between variables. Results: the education explained 6.9% of the income variation ($\beta = 0.262$), income and gender explained 9.3% of the variation in alcohol consumption ($\beta = 0.255$), 6.4% of the smoking variable was explained by age ($\beta = -0.159$), gender ($\beta = -0.182$) and education ($\beta = -0.135$), 7.3% of physical activity was explained by alcohol consumption ($\beta = 0.124$) and for leisure ($\beta = 0.188$), 2.9% of the variation in the consumption of vegetables ($\beta = 0.170$) and 3.3% of fruit ($\beta = 0.182$) was explained by the presence of the diet, 2.7% of the diet variable variation was explained by income ($\beta = 0.164$), 3.5% of family functional life was explained directly by age ($\beta = 0.168$) and education ($\beta = 0.148$), 8.3% of community involvement is explained by gender ($\beta = 0.190$) and education ($\beta = 0.216$). Conclusion: SDH influence in obesity in the elderly in respect of how the elderly live and the conditions that have to live.

THE ADHERENCE OF ELDERLY WOMEN WITH METABOLIC SYNDROME TO A FOOD RESTRICTION PROGRAM

K. Medeiros¹, G.F. de Melo¹, F. Agostinho^{2,3}, 1. *Universidade Católica de Brasília, Brasília, Brazil*, 2. *Universidade de Rio Verde, Rio Verde, Brazil*, 3. *Faculdade Mineirense - FAMA, Mineiros, Brazil*

In this study, 40 elderly women with metabolic syndrome joined a food restriction and exercise program (EF) of 271 days divided into three phases: Phase I (21 days), Phase II (90 days) and phase III (160 days). In Phase I participants received a food plan (PA) prescribed with calorie restriction of 30%, attended lectures, workshops and an aerobic and anaerobic EF program. In the other phases they were instructed to proceed with the proposed protocol without direct monitoring of the nutritionist. Anthropometric, biochemical, food consumption and adherence to the PA data were collected before (pre) and after (post) each phase. At the end of phase I, II and III the study found a quantitative adherence to the program of 100%, 60% and 20% respectively. Significant statistical difference was found when comparing the averages of before and after phase I of the anthropometric data: Abdominal Circumference (pre: 100,36cm and post: 94,87cm ($p = 0.001$)); Body Mass (before: 72,07kg and post: 69,92kg ($p = 0,001$)); Percentage of body fat (pre: 40.07% and after: 38.62% ($p = 0.003$)); Body Mass Index (pre: 30,07Kg / m² and after: 29.17kg / m² ($p = 0.001$)). Weight loss and the individual monitoring with the professional nutritionist presented themselves as factors that contributed positively to the adherence of the elderly women to the program. The absence of a professional nutritionist in the second and final phase contributed to the discontinuance of the elderly.

SESSION 1050 (POSTER)

OSTEOPOROSIS

ETHNIC VARIATIONS IN VITAMIN D LEVELS AND BONE QUALITY IN BLACKS AND WHITES

R.O. Sakamoto¹, D. Thorpe², R. Knutsen², L. Beeson², S. Knutsen², 1. *California State University, Fullerton, Fullerton, California*, 2. *Loma Linda University, Loma Linda, California*

Studies have shown that vitamin D deficiency is common in Blacks, yet Blacks have lower prevalence of bone fragility fractures or osteoporosis than Whites. Broadband ultrasound attenuation (BUA) bone measurements have been used in studies to explore the association between vitamin D levels and bone quality in White and non-white populations. We investigated vitamin D status with corresponding BUA measurements assessed cross-sectionally in a bi-ethnic cohort: 232 Blacks and 260 Whites, aged 30–95 years. Subjects were part of the calibration sub-study of the large Adventist Health Study-2 (AHS-2) of about 96,000 participants. At enrollment, subjects completed a large baseline questionnaire including information on demographics, dietary practices, and medical history. At the calibration clinics, blood was drawn for later

serum 25(OH)D assessment and calcaneal BUA measured. In multivariable analyses, age was negatively associated with BUA, most strongly among females, but also among males (β -coefficient -0.69 and -0.28, respectively). Gender and race modified the relationship of serum vitamin D on BUA. In males, after adjusting for age, race, BMI, history of fractures, physical activity, smoking history and calcium intake, serum vitamin D was positively associated with BUA (β -coefficient 5.35 $p \leq .05$) and after also adjusting for serum vitamin D, BUA among Black men was significantly higher than among White men (β -coefficient 6.95 $p \leq .05$). However, for women, after also controlling for menopausal status and hormone therapy, there was no difference in BUA between Black and White females. Further studies are needed to understand how racial/ethnic differences in hypovitaminosis D influences bone health.

OSTEOPOROSIS TREATMENT AMONG OLDER WOMEN IN THE NATIONAL AMBULATORY MEDICAL CARE SURVEY (NAMCS)

L. Bozzi, P. Gaitonde, S. Tom, *University of Maryland School of Pharmacy, Baltimore, Maryland*

The safety of bisphosphonates has been called into question recently. While substitutes for osteoporosis management have become more common, profiles of those using substitute medications are not known. We hypothesized that older women (age ≥ 65 years) with chronic comorbidities would substitute other medications for bisphosphonates compared to younger women (age <65 years). We analyzed visit data of 2015 osteoporotic women from the 2005–2012 National Ambulatory Medical Care Survey (NAMCS). Osteoporosis-related treatments included bisphosphates, selective estrogen receptor modulators, denosumab, teriparatide, calcium, Vitamin D, and estrogen supplements. We used multivariable logistic regression to examine the relationship between age and comorbidities with prescription of bisphosphonates versus other osteoporosis medications, adjusting for potential confounders including race, physician specialty, and payer type. We weighted the estimates by drug mentions to account for the complex sampling frame. The majority of patients were White (79%), age ≥ 65 years (73%) with ≥ 3 comorbidities (59%). Of osteoporosis-related treatments, bisphosphonates comprised the majority of osteoporosis-treatment medications (68%). Women age ≥ 65 years had a similar distribution of substitute medications as younger women (30% versus 22%), and those with ≥ 3 comorbidities were similar to those with fewer comorbidities (31% versus 30%). Those with ≥ 3 comorbidities (Odds Ratio (OR): 1.12; 95% Confidence Interval (CI): 0.84–1.49) had a similar likelihood of receiving substitute medications compared to women with fewer comorbidities. In recent NAMCS data, the majority of osteoporosis-related treatments included bisphosphonate prescriptions. Age and comorbidities did not influence the type of osteoporosis medication prescribed.

ASSOCIATIONS BETWEEN TRABECULAR BONE SCORE AND VERTEBRAL FRACTURES ACCORDING TO SPINE T-SCORES

K. Kim^{1,2}, J. Lee^{1,2}, S. Lim^{1,2}, H. Jang^{1,2}, 1. *Internal Medicine, Seoul National University Bundang Hospital, Seongnam-si, Kyunggi-do, Korea (the Republic of)*, 2. *Seoul*

National University College of Medicine, Seongnam-si, Kyunggi-do, Seongnam-si, Kyunggi-do, Korea (the Republic of)

Trabecular bone score (TBS) has been shown to be significantly related to vertebral fractures. The study aimed to evaluate the associations between TBS and vertebral fractures according to BMD T-scores.

Areal BMD at the lumbar spine (L1-L4) was assessed in 957 women aged 45 years and older from Seoul National University Bundang Hospital from February 2015 to 2016 using dual x-ray absorptiometry (DXA) scan and TBS was further analyzed using iNsite software (Med-Imaps, Pessac, France). Vertebral fractures were identified on lateral X-ray films of the spine.

Mean age was 66.4 ± 10.5 years and vertebral fractures were observed in 93 (9.7%) subjects. Twenty-four percent of fractures were occurred in normal BMD, 44.1% in osteopenia and 32.3% in osteoporotic ranges. According to the TBS levels, 7.5% fractures were happened in higher TBS levels (>1.350), 55.9% in middle TBS (1.201–1.350), and 37.8% in lower TBS levels (≤ 1.200). Adjusted odds of lumbar spine T score for fractures was 0.40 (95% CI 0.32–0.51, $p < 0.001$). Odds of each increase of 1 SD in TBS was 0.75 (95% CI 0.57–0.98, $P < 0.05$). Adjusted ORs for lumbar spine T-score were only significant in osteoporotic or osteopenic subjects, whereas adjusted ORs for 1SD increases in TBS was only significant in women with normal T-scores.

In conclusion, both lumbar spine T-score and TBS were significantly associated with vertebral fractures. However, lumbar spine T-score predicts fractures well in women with osteopenia or osteoporosis, but TBS levels are better predictable in subjects with normal BMD.

PREVENTIVE EFFECTS OF TREATMENT FOR OSTEOPOROSIS ON AGE-RELATED WEIGHT LOSS IN POSTMENOPAUSAL WOMEN

T. Urano¹, M. Shiraki², T. Kuroda³, S. Tanaka⁴, F. Urano⁵, K. Uenishi⁶, S. Inoue⁷, 1. *Department of Geriatric Medicine, Faculty of Medicine, International University of Health and Welfare, Chiba, Japan*, 2. *Research Institute and Practice for Involutional Diseases, Nagano, Japan*, 3. *Public Health Research Foundation, Tokyo, Japan*, 4. *Kyoto University, Kyoto, Japan*, 5. *Washington University School of Medicine, St. Louis, Mississippi*, 6. *Kagawa Nutrition University, Saitama, Japan*, 7. *Tokyo Metropolitan Institute of Gerontology, Tokyo, Japan*

Decline of body weight with aging is a major risk factor for frailty, osteoporosis and fracture, suggesting that treatment for osteoporosis may affect body composition. However, the effects of treatment for osteoporosis on body composition are not well known. The present study aimed to identify the relationship between treatment for osteoporosis and body composition markers. We measured bone mineral density (BMD), body composition, and bone remodeling markers in 551 Japanese postmenopausal women with Selective estrogen receptor modulators (SERMs) (SERM treatment group; N = 143) treatment, with bisphosphonates treatment (BP treatment group; N = 193) and without treatment by any osteoporosis drug (No treatment group; N = 358) for 4 to 7 years (mean observation periods; 5.5 years) and analyzed the relationship of these with

BMD, body mass index (BMI), body weight, and biochemical markers. The mean (SD) age of the participants was in 68.9 (9.3) year SERM treatment group, 68.6 (9.8) year in BP treatment group and 63.7 (10.6) year in No treatment group. Percent-changes in body weight and BMI were significantly different between women taking SERMs or BPs and those not taking any osteoporosis drugs ($P < 0.01$ and < 0.01 , respectively). In multiple linear regression analysis, SERMs and BPs treatment was a significant independent determinant of body weight and BMI. Long-term use of SERMs and BPs may prevent reductions in BMI and body weight, usually observed in elderly women.

ESTABLISHING AN ANTI-OSTEOPOROSIS MEDICATION MONITORING AND MANAGEMENT SERVICE IN NORTHERN TAIWAN

D. Chan^{1,3}, C. Hong¹, I. Lee¹, L. Hung¹, C. Chang¹, J. Peng², K. Tsai¹, R. Yang¹, 1. *National Taiwan University Hospital, Taipei, Taiwan*, 2. *National Taiwan University Hospital, Bei-Hu Branch, Taipei, Taiwan*, 3. *National Taiwan University Hospital Chu-Tung Branch, Hsinchu County, Taiwan*

Background/Purpose: Recently data showed that adherence of oral anti-osteoporosis medications (AOMs) were only about 40% in 4 months and 20% in one year in Taiwan. We aimed to determine the effects of AOM management program on medication adherences in northern Taiwan.

Methods: Five hundred patients with osteopenia/osteoporosis and with/without fractures with one of the following criteria were referred to this program: newly prescribed with AOMs, recent change of AOMs, poor adherence to AOMs or participating physicians requests. Research coordinators conducted baseline assessments, which included osteoporosis/fracture diagnosis and risks, medical conditions, and life styles. Educational booklet on osteoporosis managements was provided and taught after assessments. The primary outcome was the osteoporosis medication adherence measured by medication possession ratio (MPR, at 4, 8, 12, and 18 months after enrollment. Bone mineral density (BMD) was measured by dual X-ray absorptiometry (DXA) at femoral neck, total hip, and lumbar spine (L1-L4) at baseline and when indicated by treating physicians. This report presented 4 month follow-up data.

Results: Mean age was 74.5 ± 10.4 years for the entire cohort (87.0% were women). The lowest mean T-score was -2.93 ± 0.81 . About 7/8 (87.4%) patients had at least one chronic medical condition. For the entire cohort, 49.8% were newly prescribed with AOMs, 11.0% were recent change of AOMs, 7.8% were poor adherence to AOMs, and 31.4% were requested from participating physicians. At baseline, 47.2% used Denosumab, 17.2% used Zoledronic acid, 15.4% used Alendronate, 10.8% used Raloxifene, 7.4% used Ibandronate, 1.8% used Teriparatide and 0.2% used Strontium ranelate. About 3/4 (73.4%) were reimbursed by National Health Insurance. Overall medication adherence at 4 months was 95.9%. Specifically, 100% for Denosumab and Zoledronic acid, 99.4% for Teriparatide, 98.8% for Ibandronate, 88.3% for Alendronate, 80.8% for Raloxifene, and 58.8% for Strontium ranelate.

Conclusion: Our preliminary data suggested that medication management program significantly improved adherence in 4 months with pending one year follow up data.

A DEMONSTRATION STUDY OF THE FRACTURE LIAISON SERVICE (FLS) MODEL OF CARE

A. Singer², D. Lee¹, D. Zeldow¹, 1. *National Bone Health Alliance (NBHA), Arlington, Virginia*, 2. *MedStar Georgetown Hospital, Washington, District of Columbia*

Although half of women and one-quarter of men over 50 sustain an acute osteoporotic fracture, less than a quarter receive appropriate secondary fracture prevention. The goal of this demonstration project was to examine the effectiveness of a cloud-based registry application to support the FLS model of care ("FLS App") for secondary fracture prevention at 3 academic medical centers.

Methods: The Bone Health Collaborative (National Bone Health Alliance, National Osteoporosis Foundation and CECity/Premier), developed a web-based registry application to deploy the FLS model of care to coordinate post-fracture care. The pre-post study design examined the number of men and women over age 50 years who received appropriate assessment (bone mineral density [BMD], vitamin D levels) and pharmacologic treatment within 6 months of an acute fragility fracture. A retrospective chart review was used to collect baseline data at each health care facility (N=344 patients). For the post evaluation (N= 148 patients), the FLS coordinator or champion examined these parameters during the 6 months following enrollment and collected pertinent data on the FLS App. Provider and data collection surveys were used to elicit provider satisfaction and barriers to collecting patient information prior to implementation of the project and at the conclusion of the study. Comparisons between pre-post FLS periods were done using chi-square tests.

FRACTURE PREDICTIVE VALUES OF FRAX® FOR SENILE MEN IN BEIJING

Z. Zhao, *Beijing Friendship Hospital Affiliated to Capital Medical University, Beijing, China*

Objective: To evaluate the fracture predictive applicability of FRAX® (Fracture Risk Assessment tool) for senile men in Beijing, and to discuss the effect of 25(OH)D on FRAX®. **Methods:** A total of 348 senile men were involved and the personal data were collected including the age, height, weight, parent brittle fracture history, oral steroid history, history of rheumatoid arthritis, drking history and smoking history. The serum concentrations of 25(OH)D were measured, and bone mineral density at lumbar spine₁₋₄ (L₁₋₄), left femoral neck, and total hip were measured by dual-energy X-ray absorptiometry. Each individual 10-year hip and major osteoporotic fracture probability was calculated by FRAX® Chinese model. Participants were divided into 4 groups by age and 4 groups according to serum 25(OH)D levels. The results of FRAX® in different groups were compared, and the effect of vitamin D status on FRAX® was investigated. **Results:** Only 4 participants achieved the diagnostic criteria of high risk of osteoporotic fracture. The 10-year probability of hip fracture was 0.96 ± 0.31 (0~4.2) and increased with age. The difference was statistically significant between

groups of all age ($P < 0.05$). The 10-year probability of major osteoporotic fracture was 3.57 ± 0.98 (1.3~7.6), and the difference was not statistically significant between groups of all age ($P < 0.05$). The 10-year probability of hip fracture increased with decreasing vitamin D levels, and the difference was statistically significant among all groups ($P < 0.05$). The 10-year probability of major osteoporotic fracture of vitamin D deficient group was higher than the probability of sufficient group ($P < 0.05$). **Conclusion:** FRAX[®] Chinese model may underestimate 10-year osteoporotic fracture probability of semile men in Beijing. Many factors such as vitamin D nutritional status maybe to improve the predictive value.

SIGNIFICANT GENE-GENE INTERACTION OF TNF- α AND VDR ON OSTEOPOROSIS COMMUNITY-DWELLING ELDERLS

L. Liao², C. Lin¹, T. Li², F. Wu², C. Yang¹, W. Lin¹, 1. *China Medical University Hospital, Taichung, Taiwan*, 2. *China Medical University, Taichung, Taiwan*

Osteoporosis (OST) is a complex multifactorial disease. Prior studies evaluated gene effects separately on OST. We evaluated gene-gene interactions of polymorphisms in tumor necrosis factor- α (TNF- α) and vitamin D receptor (VDR) genes on OST in elders.

A total of 472 elders were included from *Taichung Community Health Study for Elders*; polymorphisms (TNF- α : rs1799964, rs1800629, rs3093662; VDR: rs7975232, rs1544410, rs2239185, rs3782905) were genotyped. Bone mineral densities (BMD) of lumbar spine (LS), femoral neck (FN), and total hip (TH) were measured by DEXA. Overall and site-specific OSTs were defined as BMD T-score ≤ -2.5 standard deviations. Predictive models' ability to discriminate OST status was evaluated by areas under the receiver operating characteristics (AUROC) curve.

After considering age, BMI, physical activity, smoking, and drinking, significant interactions of TNF- α rs1799964 and VDR rs2239185, and TNF- α rs1800629 and VDR rs3782905 on overall and LS OST; interaction of TNF- α rs1799964 and VDR rs3782905 on LS OST in women were observed ($P < 0.05$). AUROC (95% CI) for Model1 (traditional factors), Model2 (Model1 + rs1800629 and rs3782905), and Model3 (Model2 + gene-gene interaction) for overall OST were 0.77 (0.70, 0.84), 0.79 (0.72, 0.86), and 0.81 (0.75, 0.88) in women, respectively. There were significant differences in AUROC between Models3 and Model1 ($P = 0.028$), and Models3 and Model2 ($P = 0.047$), indicating gene-gene interaction improved OST discrimination.

Adding gene-gene interaction into traditional factors model did improve OST risk prediction in Han Chinese elders, and help to identify high-risk individuals for OST appropriate management and intervention.

SERUM MAGNESIUM AND BONE HEALTH: A STUDY OF THE ELDERLY NUTRITION AND HEALTH SURVEY IN TAIWAN 1999

J. Gau^{1,4}, M. Bann¹, M. Nakazawa³, B.C. Clark^{1,4}, W. Pan², 1. *Ohio University, Athens, Ohio*, 2. *Institute of Biomedical Sciences, Academia Sinica, Taipei, Taiwan*, 3. *University of California at San Diego, San Diego, California*, 4. *Ohio Musculoskeletal & Neurological Institute, Athens, Ohio*

We analyzed data from the *Elderly Nutrition and Health Survey in Taiwan 1999*. We chose this dataset as it has data on both serum Mg levels and bone health. Among participants who had blood samples obtained (N=1,509), 210 older adults had reported fracture(s). Variables included in our linear regression models for BUA were age, sex, blood levels of hemoglobin, albumin, and creatinine. For logistic regression models for self-reported fracture, BUA measurement was included in addition to the above covariates. Our study revealed that self-reported fracture cases (N=210, female 56%, mean age 72.6 ± 6.2) and controls (N=1,352, female 47%, mean age 71.8 ± 5.2) had similar mean serum Mg levels (2.20 ± 0.19 vs. 2.18 ± 0.19 mg/dL). Fracture cases had significantly lower mean BUA compared to controls (54 ± 21 vs. 61 ± 19 , $p < 0.001$) as well as in T- and Z-scores. Serum Mg level and BUA was not significantly associated by univariate ($\beta = -0.87$, 95% CI: -4.73, 2.99) and by multivariate linear regression ($\beta = 0.29$, 95% CI: -2.94, 3.52). Adjusted odds ratio (OR) of serum Mg level for self-reported fracture was 1.74 (95% CI: 0.81, 3.77). We observed that increasing age, female gender, lower hemoglobin and lower creatinine levels were independent risk factors for lower BUA values. Participants with higher BUA had lower risk of self-report fracture (adjusted OR=0.985, 95% CI: 0.975, 0.995). Age and sex became insignificant with adjusting the above variables. *In conclusion*, our study of a population-based survey of Taiwanese elderly revealed that serum Mg level was not associated with bone density measurement by BUA nor with self-reported fractures.

ARE KNOWLEDGE AND LOCUS OF CONTROL IMPORTANT FACTORS IN REDUCING RACIAL INEQUITIES IN OSTEOPOROSIS?

N.C. Wright, M.E. Melton, N.V. Ivankova, S.L. Davies, E. Levitan, K.G. Saag, *University of Alabama at Birmingham, Birmingham, Alabama*

There are unexplained racial inequities in osteoporosis prevention activities. We recruited Black and White women with osteoporosis (T-score ≤ -2.5 at any skeletal site) to investigate the role that knowledge and locus of control play in the racial differences on osteoporosis prevention activities. We measured osteoporosis knowledge using the 10-item "Osteoporosis and You" scale. We measured locus of control using the Multidimensional Health Locus of Control (MHLOC) scale, which assesses three belief dimensions: internal, chance, and powerful others (e.g. doctors, family members, spiritual being). We used MHLOC Form A to assess overall health and Form C to assess bone health. Forty-five women (White: 36; Black: 9) completed scales. The mean (SD) age was 73.3 (9.5) years with no difference in age between the two groups. We observed higher osteoporosis knowledge among White women [8.5 (1.2) out of 10] compared to Black women [6.7 (3.1); p -value = 0.015]. We did not find racial differences in the MHLOC internal or chance belief subscales for overall health; however, Black women had significantly higher scores on the powerful others subscale [Black: 23.8 (6.4); White: 18.5 (4.6), p -value = 0.009]. We did not find any racial differences in any MHLOC subscales for bone health. To date, our study revealed that Black women have lower overall osteoporosis knowledge and higher dependence on others for their overall health. This

knowledge can be used to generate targeted educational interventions for Black women and provide guidance for healthcare providers to improve and emphasize osteoporosis prevention activities with Black women.

FRACTURE RISK AMONG TAIWANESE ELDERLY: A STUDY OF THE ELDERLY NUTRITION AND HEALTH SURVEY

M. Bann¹, J. Gau¹, M. Nakazawa², W. Pan³, 1. *Ohio University, Concord, Ohio*, 2. *University of California at San Diego, San Diego, California*, 3. *Institute of Biomedical Sciences, Academia Sinica, Taipei, Taiwan*

The *Elderly Nutrition and Health Survey in Taiwan 1999* dataset was used for analyzing risk factors of self-reported fracture. Patient survey data was available for 2038 patients, including: 290 self-reported fractures, demographic, smoking & alcohol use status, past medical history, current medication use, and dietary recall data. Variables, including dietary intakes, medication or supplement, were examined for a significant association with PUD. Association between PUD and fracture was used to build a multi-variable logistic regression model. Variables included in the logistic regression models were age, sex, use of supplements, PUD, GI medication use, total calorie intake, folic acid intake, magnesium intake, and phosphate intake. The results show PUD is associated with self-reported fracture with crude odds ratio (OR) of 1.71 (95% CI, 1.22–2.40, $p=0.0017$). Similarly, GI medication use is associated with self-reported fracture with crude OR=1.96 (95% CI, 1.41–2.72, $p<0.001$). Multivariate logistic regressions were created step-wise to demonstrate the relationship between PUD, GI medication use and fracture. Age, gender and supplement use remain significant at $p<0.05$; all dietary intake variable became insignificant. Adjusted OR for PUD becomes insignificant at 1.37, (95% CI: 0.934–2.004, $p=0.11$) while GI Medication use remains significant with adjusted OR=1.68 (95% CI: 1.163–2.424, $p=0.0057$). Overall, the model has a p -value=0.9206 for goodness of fit criteria. The step-wise approach for building the multivariate logistic regression model demonstrated that GI medication use is more heavily weighted as a covariate with PUD to explain the self-reported fracture in the Taiwanese Elderly Nutrition and Health Survey Data.

KNOWLEDGE OF OSTEOPOROSIS AMONG THE LAYPERSON

R. Burgess, A. Parker, J. Roberts, *William Carey University, Hattiesburg, Mississippi*

The purpose of this study was to determine the knowledge of laypeople about osteoporosis. Specifically, is there a generational or gender difference in knowledge of osteoporosis?

Osteoporosis and associated fractures are serious public health concerns. Millions of dollars are spent yearly to educate the public about prevention of and control of osteoporosis. A literature review revealed a sparse documentation of the general public's knowledge concerning osteoporosis.

A 23 item True/False survey to assess basic knowledge was developed by the researchers based on a review of the literature. Participants were recruited using an on-line survey platform along with pen and paper formats at onsite locations- college campus and senior citizen luncheons.

One hundred thirty-five completed surveys were returned (Age: 18–30: $n=41$; 50-older: $n=94$) (Gender: males: $n=41$; females: $n=94$).

Independent t-tests revealed a statistically significant difference in age and gender: older females (age 50 and older) demonstrated a greater knowledge base of osteoporosis than their male and younger (age 18–30) counterparts.

Chi square analyses were performed on the 6 most frequently missed items. Two questions were found to be statistically significant. A greater number of males than expected thought osteoporosis could be prevented. A greater number of younger participants than expected thought a family history of fractures was not a risk factor for osteoporosis. There were other frequently missed items that revealed a knowledge deficit regardless of age and gender. A greater understanding of these deficits are essential as educators equip physical therapy students to become effective health care practitioners.

CHARACTERISTICS OF ANTI-OSTEOPOROTIC MEDICATION UTILIZATION FOR OLDER ADULTS IN TAIWAN

S. Hwang^{1,2}, H. Chang^{1,2}, F. Chen^{1,2}, 1. *Department of Family Medicine, Taipei Veterans General Hospital, Taipei, Taiwan*, 2. *National Yang Ming University School of Medicine, Taipei, Taiwan*

Background: Osteoporosis is one of the major public health issue worldwide. In Taiwan, the prevalence of osteoporosis was about 11% for those who over 65 years old. Current status of utilization of anti-osteoporotic medications among older adults and characteristics of prescription pattern among health professionals in Taiwan was not well-explored.

Aim: The aim of this study was to examine the characteristics of anti-osteoporotic medication utilization and prescription pattern for older adults in Taiwan.

Methods: This study was a secondary data analysis by using the Taiwan National Health Insurance Research Database from 2001 to 2011. Older adults aged over 65 years old were included.

Results: During 2001 and 2011, 1,169,457 older adults aged over 65 years were identified. Of them, 1,169,457 (52.0%) were female. For age distribution, there were 642,548 (54.9%) aged between 65 to 74 years, 415,512 (35.5%) between 75 to 84 years, 110,743 (9.5%) between 85 to 99 years and 744 (0.1%) were centenarian. Of these older adults, 38,523 (3.20%) had ever been prescribed of anti-osteoporotic medications. Among available anti-osteoporotic medications in Taiwan, the most frequently prescribed medication was Fosamax 29,634 (76.9%), followed by Evista 6,439 (16.7%), Forteo 2,628 (6.8%), Calcitonin 1,525 (4.0%), Bonviva 1,161 (3.0%), and Aclasta 532 (1.4%). Top 5 health professionals prescribed anti-osteoporotic medications were orthopedic doctors (61.5%), neurosurgeon (14.2%), rheumatology doctor (4.8%), rehabilitation doctor (4.2%), family physician (3.3%).

Conclusion: The prescription of anti-osteoporotic medication is lower than the prevalence of osteoporosis. More attention should be paid for under treatment of osteoporosis in Taiwan.

APPLICATION OF HEALTHCARE INTEGRATION IN PERIOPERATIVE PERIOD MANAGEMENT OF AGED HIP ARTHROPLASTY

L. Yang^{1,2}, H. Zhou¹, Z. Sheng¹, C. Liu¹, D. Chen¹, J. Hu¹, Y. Chen¹, 1. *Department of Orthopaedic Surgery, the Affiliated Hospital of School of Medicine of Ningbo University, Ningbo, Zhejiang Province, China*, 2. *College of nursing, Zhejiang Chinese Medical University, Hangzhou, Zhejiang Province, China*

Objective: To assess the application effect of Healthcare integration in perioperative period management of aged Hip arthroplasty. **Methods:** 30 patients were randomly selected from 60 patients to implement Healthcare integration management model (the experimental group), traditional care service mode was given to the other 30 patients (the control group). On the 14th day after operation, patients' satisfaction degree, health education awareness and clinical nursing compliance were compared. **Results:** Compared with the control group, the patients' satisfaction degree, health education awareness rate, clinical nursing compliance of the experimental group were improved. **Conclusions:** Compared with ordinary care model, healthcare integration model can improve the patients' satisfaction and awareness rate, smooth the clinical nursing process, alleviate the pain of patients, and improve the quality of patients' life. So it is advised that healthcare integration model be widely applied in perioperative period management of aged Hip arthroplasty.

BONE MINERAL DENSITY TESTS AND THE RISK OF FRACTURES AND ADMISSION

B. Oh, *Family Medicine, SMG - SNU Boramae Medical Center, Seoul, Korea (the Republic of)*

Introduction: Korean National Health Screening Program for the Transitional Ages (NSPTA) underwent a bone mineral density test to target 66-year-old woman. By comparing the ratio diagnosed with osteoporosis between the examinees and non-examinees, outpatient care according to the diagnosis, and hospital admission by the fracture, the largest complication of osteoporosis, the effectiveness of screening will be determined.

Methods: Data from NSPTA was used, which offers basal health screening and bone mineral density results of women aged 66 years. Community-dwelling elderly were followed from 2007 to 2011 to determine the outcome measures of overall fractures, femoral fractures and admissions for femoral fractures. Also we compared drug-related osteoporosis cure rate, admission rate due to osteoporosis-related fractures.

Results: Participants comprised 909,869 women aged 66 years; non-Screening Group 334,267 (36.7%), Screening group was 575,602 (63.3%). Diagnosis rate of osteoporosis underwent a bone mineral density test subjects was 45.4%; by DEXA scan rate was 57.1%. Determining the odds ratio for prescription drugs based on examination status by logistic analysis, adjusted OR is 1.68 (95% C.I. 1.62–1.74), which means prescription rate increases in BMD Screening Group. As a result of comparing the admission rate for hip fracture, the major complications of osteoporosis, hospitalization

is reduced by approximately 17% in the Screening Group (adjusted hazard ratio 0.83).

Conclusions: Osteoporosis is a high prevalent disease from older women and is associated with a higher risk of hospitalization due to fractures. Therefore, it is advisable to screen the bone mineral density for drug therapy in prevention and early detection. This can significantly reduce hospitalizations due to hip fracture and therefore leads to cost-effectiveness.

SESSION 1055 (POSTER)

PREVENTION, HEALTH CARE AND HEALTH PROMOTION

A CLINICS-BASED SURVEY ON THE DETERMINANTS OF SUCCESSFUL SMOKING CESSATION IN OLDER ADULT SMOKERS

K. Wu¹, Y. Hou¹, K. Cheng¹, Y. Gu¹, L. Huang², 1. *Department of Family Medicine, Tainan Municipal Hospital, Tainan, Taiwan*, 2. *Health education Unit, Tainan Municipal Hospital, Tainan, Taiwan*

This study aims to identify determinants of successful smoking cessation after three months of treatment and six months of follow-up, and to investigate the differences smoking cessation behaviours in older adult smokers.

192 patients that aged 65 y/o and more all attended a smoking cessation clinic at a General Hospital in Taiwan from 2011 to 2014. These patients filled up a questionnaire which included demographic, morbid and smoking habits data. They were subjected to an interview at the clinics to determine their treatment for 3 months. 6 months and 3 years later, patients were contacted by telephone and were asked if they remained without smoking.

After 6 months and 3 years, 126 and 67 patients were contacted and 31.3% and 19.3% of patients responded that they were still without smoking. After 6 months of follow-up, on univariate analysis, successful 16-week clinics follow-up completion, successful smoking cessation at 3-month follow-up and medication use, appeared as a protective factor associated to abstinence. On multivariate analysis, only successful smoking cessation at 3-month follow-up appeared as a protective factor. However,

After 3 years, on univariate analysis, less cigarette smoking number and successful smoking cessation at 3-month follow-up appeared as a protective factor associated to abstinence. On multivariate analysis, still only successful smoking cessation at 3-month follow-up appeared as a protective factor.

In this clinics-based sample of older smokers, the use of medication including Nicotine patches and Varenicline was associated with better abstinence rates in initial half one year. Young-old adult smokers, more cigarette smoking number and not able to complete 16-week clinics follow-up appeared as a risk factor to continue smoking. Successfully smoking cessation at 3 month was a leading factor associated to abstinence.

PHYSICAL SIGN FOR DETECTING COGNITIVE DECLINE IN COMMUNITY-DWELLING OLDER ADULTS

T. Abe¹, Y. Soma³, N. Kitano⁴, T. Jindo⁴, A. Sato¹, K. Tsunoda⁵, T. Tsuji⁶, T. Okura¹, 1. *University of Tsukuba, Ibaraki, Japan*, 3. *Hirosaki University, Aomori, Japan*, 4. *Physical Fitness Research Institute, Meiji Yasuda Life Foundation of Health and Welfare, Tokyo, Japan*, 5. *Yamaguchi Prefectural University, Yamaguchi, Japan*, 6. *Chiba University, Chiba, Japan*

Previous cohort studies that investigated the association between physical and cognitive function conducted only either physical or cognitive assessment in their follow up survey. Therefore, the relationship between changes in physical and cognitive functions is unclear. The study aimed to investigate whether change in physical functions is associated with change in cognitive function. In this study, the data was obtained from the Kasama study, a cohort study in Japan; and the follow up period was 3 years. Only older adults without cognitive impairment at baseline were included and 131 participants (72.2±4.7 yrs.) were eligible. We used 6 physical performance tests: grip strength, one-leg standing balance, 5 times sit-to-stand, timed up and go, 5-m habitual walk, and peg moving task to measure physical function. To measure cognitive function, five tests were administered including tests of attention, memory, visuospatial function, verbal fluency, and reasoning. The total score was defined as cognitive function. Multiple regression analyses were conducted. We entered change in cognitive function as dependent variable and each of the change in physical function as independent variables, and age, sex, education, body mass index, medical history of hypertension and heart disease, depressive mood, intake medicine, knee pain, and upper-extremity pain as covariates. Changes in 5-m habitual walk ($\beta = -0.207$, $P = 0.026$) and peg moving task ($\beta = 0.178$, $P = 0.042$) showed significant association with change in cognitive function. These results suggest that deterioration of gait speed and hand dexterity is a useful sign for detecting cognitive decline.

AYUSH RASAYANA IMPROVES FITNESS AND QUALITY OF LIFE IN OLDER ADULTS

V. Gunasekaran¹, P. Mundada¹, P. Chatterjee¹, A. Chakrawarty¹, S. Sharma², B. Bharti², K. Dhiman², A.B. Dey¹, 1. *Geriatric Medicine, All India Institute of Medical Sciences, New Delhi, India*, 2. *Central Council for Research in Ayurvedic Sciences, New Delhi, New Delhi, India*

Introduction: Ayurvedic formulations have been used in India for thousands of years to promote health, physical fitness and endurance. This on-going clinical trial assesses the efficacy and safety of one such formulation Ayush Rasayana.

Methodology: Healthy volunteers between 60–75 years without any health issue with the exception of controlled hypertension were included. After systemic cleansing with Ayush Rasayana-'A' for initial 6 days, they were administered Ayush Rasayana-'B' twice daily for next 6 months. Detailed clinical and biochemical assessment done before entry and at 30, 90 and 180 days. Six-minute walk distance, quality of life using WHOQOL-BREF questionnaire were used as

parameters of efficacy. Any previous drugs and access to usual healthcare were allowed.

Results: A mid-term analysis was carried out in 27 subjects (17 males and 10 females; mean age 65.41 years) who completed the trial. Mean (\pm SD) six-minute walk distance at baseline, 3 months and 6 months was 419.41(\pm 76.93), 448.74(\pm 90.51) and 456.33(\pm 88.30). Improvement in walking distance was 29.33 metres at 3 months and 36.93 metres at 6 months ($p < 0.01$). WHOQOL-BREF (0–100) score at baseline, 3rd and 6th month in Physical health domain was 55.26(\pm 8.20), 61.07(\pm 6.32) and 59.93(\pm 7.56), [$p = 0.13$]; in psychological domain was 52.89(\pm 10.99), 59.33(\pm 10.42) and 61.22(\pm 7.56), [$p < 0.01$]; in social domain was 62.30(\pm 13.66), 68.85(\pm 6.97) and 71.07(\pm 7.97), [$p < 0.01$]; in environment domain was 70.41(\pm 11.37), 76.48(\pm 8.30) and 76.85(\pm 6.35), [$p < 0.01$]. No adverse effects were reported.

Conclusion: There is significant improvement in six-minute walk distance and quality of life. This drug seems to positively affect ageing process and further studies needed to relish its full potential.

EFFECTIVENESS OF COGNITIVE STIMULATION IN MAINTAINING COGNITIVE CAPACITY OF AN ELDERLY COHORT

A.M. Vicentin, A. Bonilha, L. Ramos, *Federal University of São Paulo, São Paulo, São Paulo, Brazil*

The study objective is to analyze the effectiveness of health promotion actions in the prevention of functional losses due to cognitive impairment of the elderly. It is a controlled intervention study, nestled within a cohort population resident in the neighborhood Vila Clementino, in São Paulo city, Brazil. From the application of the CDR (Clinical Dementia Rating), the elderly were classified as cognitively normal (CDR = 0) and with mild cognitive impairment (CDR = 0.5) and were randomly allocated in the intervention and control groups. The elderly had undergone a screening for depression, neuropsychological tests (MoCA, MEEM, list of words and naming animals) and an evaluation of independence in daily life. The intervention groups attended the "Memories Workshops" (MW) twice a week in a total of 34 meetings, 80-minute-long each (physical activity, computer activity and chat about the workshop experience). Preliminary results have shown that a non-pharmacological intervention such as the MW can have a positive impact in the functional capacity of a population sample of elderly with CDR <1, as it promotes the maintenance/improvement of cognitive functionality measured by the MoCA score when compared with controls, especially if the degree of improvement or worsening in the score is controlled in the analysis (among those who had greater improvement the majority was in the intervention group). The study is still including subjects to enlarge the sample and thus enable a more robust statistic of effectiveness of this kind of intervention in the primary health care level, as a protective factor against cognitive losses of this age-group.

REACH LIFESTYLE INTERVENTION: FEASIBILITY OF DELIVERING AN INSTRUCTOR TRAINING COURSE

L. Burnett², N. Cherneski², L. Fleig⁴, K. Milne⁵, L. Giangregorio⁶, L. Clemson⁷, M.C. Ashe^{1,2,3}, 1. *Family Practice, The University of British Columbia, Vancouver,*

British Columbia, Canada, 2. Centre for Hip Health and Mobility, Vancouver, British Columbia, Canada, 3. The University of Adelaide, Adelaide, South Australia, Australia, 4. Freie Universität Berlin, Berlin, Germany, 5. Cardea Health Consulting, Vancouver, British Columbia, Canada, 6. University of Waterloo, Waterloo, Ontario, Canada, 7. University of Sydney, Sydney, New South Wales, Australia

Return to Everyday Activities in the Community and Home (REACH) is a lifestyle intervention model for middle-aged and older adults. The goal of REACH is to reduce sedentary behaviour, increase physical activity, and increase adoption of strength and balance exercises. In this feasibility study we completed a formative evaluation to assess the effectiveness, impact and reception of the REACH instructor training course. Our aim was to summarise perceptions of the model and identify gaps in curriculum delivery. The REACH Instructor training course occurred over four sessions, each of two hour duration. The training methods included didactic and participatory elements, plus a comprehensive instructors' manual and handouts. The participants were provided with foundational knowledge, including principles of behaviour change theory. Participants also practiced teaching components of the program to their peers. We conducted semi-structured interviews at the end of the training session, and administered a Patient Education Materials Assessment Tool for Printable Materials (PEMAT-P) and session feedback forms. There were three participants who completed the study; all were community-based exercise physiologists with an average of 17 (8) years of experience. Emerging themes from participants' feedback included: credentials required, how to best prepare instructors for teaching REACH, the ideal learning setting and linking the instructor manual to presentation slides. The PEMAT-P scores for the instructor manual were 98 (0.03) % for understandability, and 100% for actionability. Each session was rated very good or excellent for presentation style and overall rating. We applied participant feedback to the existing instructor curriculum.

ASSOCIATION OF SELF-RATED HEALTH IN COMMUNITY-DWELLING ELDERLY PEOPLE OF JAPAN

A. Marui, Y. Ishikawa, S. Kaneko, Y. Kamiyama, N. Aizawa, *Dokkyo Medical University School of Nursing, Mibu, Tochigi, Japan*

Japan is known for its population longevity, however, people should be aware that longevity with health is better than a longer life in bad health. This study made analysis of socio-economic backgrounds, sleep, depression, chronic disease, long-term care and lifestyle factors related to self-rated health (SRH) in community-dwelling elderly people in Japan.

Cross-sectional research of community-dwelling elderly people was carried out in Mibu-town in Eastern Japan in 2015. 665 residents aged over 60 years old, participated in the study and completed a questionnaire. The results from SRH using a four-step scale were later categorized into two groups "Good and Poor" Health. Binary logistic regression was used to identify the factors associated with "Good" SRH.

The average age of the participants was 71.3 years old (SD 6.5, range 60–98). 50.2% of those were female and 84.5% of them answered that they were healthy. The characteristics of "Good" in SRH were non long-term care, a feeling

of satisfaction with life, nondepression, without cardiovascular or orthopedic disorders, without medication, having a regular exercise regime and keeping an active lifestyle.

People subjectively felt that "Good" for their SRH was closely related to doing regular exercise themselves and by being active. Further, we found no associations between socio-economic backgrounds, living alone and quality of sleep. It was indicated, by the end of this study, that it is important to keep the elderly active as this enables them to gain a feeling of satisfaction in regards to their own personal health.

LIFELONG MAINTENANCE AND INCREASES IN READING ENGAGEMENT IS ASSOCIATED WITH BETTER COGNITIVE HEALTH

T. Hammond, S. Bardach, X. Zhang, E. Abner, G. Jicha, *The University of Kentucky, Lexington, Kentucky*

Cognitive reserve theory proposes that early life cognitive experiences can reduce risk of late-life cognitive decline. Yet little information exists in the literature to describe whether increasing mid- and late- life cognitive engagement can have the same effect, bolstering cognitive reserve and potentially delaying the onset of late-life cognitive decline and dementia. In order to address this question, we analyzed self-report of reading engagement at ages 6, 12, 18, 40, and at present time in subjects spanning the cognitive continuum from normal to MCI to dementia in the Alzheimer's Disease Center cohort at the University of Kentucky using adjusted regression modeling (n=489). Reading engagement at ages 6, 12, and 18 was not significantly associated with lower CDR Sum scores. However, reading engagement at age 40 and current reading engagement was significantly associated with lower CDR Sum scores (p<0.05 and p<0.001, respectively). We also found that an increase in reading engagement over the lifetime was associated with lower CDR Sum scores (p<0.001), and that reading engagement increase after age 18 was more strongly associated with lower CDR Sum scores than reading engagement increase before age 18 (p<0.01 vs. p>0.05 respectively). These data suggest that lifelong maintenance and continued increases in reading engagement across the lifespan in mid- and late-life may be beneficial in delaying cognitive decline. Future intervention studies are needed to elucidate the role that reading engagement might play in avoiding or delaying cognitive decline.

THE EFFECT OF ADHERENCE TO DIABETES GUIDELINES ON NURSING HOME ENTRY AND HEALTH AT TIME OF ADMISSION

A.P. Yashkin, I. Akushevich, A.I. Yashin, *Boidemography of Aging Research Unit, Center for Population Health and Aging, Duke University, Morrisville, North Carolina*

Diabetes Mellitus (DM) is a chronic disease that is highly prevalent in the U.S. and is associated with multiple co-morbidities as well as reduced physical and cognitive function. When admitted to nursing homes, beneficiaries with DM are characterized by comparatively high levels of functional disability, the presence of many co-morbid conditions, and could represent a sub-population of residents requiring especially intensive care and representing a dis-proportional social and financial burden. Adherence to diabetes management guidelines such as those provided by the American Diabetes

Association (ADA) have been shown to be protective against many diabetes-related adverse health outcomes, but the role of adherence in reducing the risk of requiring nursing home care and/or improving the overall health status at time of admission has not been fully addressed. The purpose of this paper is to identify how adherence to ADA guidelines in U.S. Medicare beneficiaries age 65+ affects the risk of nursing home entry and functional, cognitive and co-morbidity status at the time of admission. Data from the Health and Retirement Study, linked to Medicare administrative claims was used to identify the presence of a new diagnosis of DM, the presence of co-morbidities and adherence to guidelines. Data on new nursing home admissions as well as detailed, professional in-person new resident assessments were drawn from the HRS-linked Minimum Dataset. The results of this study will aid in public health awareness efforts aimed at combating the diabetes pandemic and reducing the burden of DM to both the patient and society.

RATIONALE FOR MAINTAINING HIGH 25-HYDROXYVITAMIN D CONCENTRATIONS YEAR LONG

W.B. Grant, *Sunlight, Nutrition and Health Research Center, San Francisco, California*

Higher solar UVB exposure and vitamin D status have been found associated with reduced risk of many adverse health outcomes including autoimmune diseases, cancer, cardiovascular disease, cognitive dysfunction, dementia, diabetes mellitus, infectious diseases, etc., as well as lower mortality rates and increased life expectancy. The types of studies on which these findings are made include geographical and temporal ecological, observational, interventional, and laboratory studies. For a number of the outcomes, the roles of UVB and vitamin D are considered causally linked to better health outcomes based on the criteria for causality in a biological system outlined by A. Bradford Hill. Recently, it was also determined that the higher mortality rates in winter are due to lower UVB doses and 25-hydroxyvitamin D [25(OH)D] concentrations resulting in effect on gene expression associated with immunity and physiology. Globally, mean 25(OH)D concentrations are near 54 nmol/L, varying in midlatitudes from about 35–45 nmol/L in winter to 65–75 nmol/L in summer. The optimal 25(OH)D concentration is in the 90–110 nmol/L (36–44 ng/mL) range. To achieve the optimal range using supplements takes 1500–4000 IU/d vitamin D₃ depending on season and individual environment, genetics, and lifestyle. Based on 25(OH)D concentration-health outcome relations from observational studies, it is estimated that population mortality rates could be reduced by 15–20%, leading to increases in mean life expectancy by about two years. Increasing vitamin D supplementation and food fortification at the population level appears to be the most efficient way to increase healthy life expectancy.

SEX DIFFERENCES IN POSTURE AND PHYSICAL FUNCTION IN JAPANESE ELDERLY WITH EXERCISE HABITS

T. Ueda^{1,2}, Y. Shiba³, S. Watanabe^{2,4}, 1. *Sanno Rehabilitation Clinic, Ota-ku Tokyo, Japan*, 2. *Institute for Gerontology J.F. Oberlin University, Machida City, Tokyo, Japan*, 3. *Kitasato University, Sagami-hara City, Kanagawa Prefecture,*

Japan, 4. *J.F. Oberlin University Graduate School of Gerontology, Machida City, Tokyo, Japan*

A cross-sectional study described kyphosis to be related to decrease physical function and quality of life. However, few longitudinal studies have investigated changes due to kyphosis. We aimed to determine sex-related differences in postural changes and decreased physical function in Japanese community-dwelling elderly with exercise. The subjects participated in an interview and physical function measurement at baseline and follow-up 5 years later (19 men, 17 women; mean age, 72.5 ± 4.9 years). We used the Wilcoxon signed-rank test to analyze sex-related variables. After 5 years, we observed significant decreases in the 5 measurement items in the men as follows: kyphosis angle (KA; from 162.4° ± 4.7° to 160.2° ± 4.4°, *p* = .022), one-leg standing time (from 42.71 ± 23.4 to 38.1 ± 23.4 s, *p* = .012), grip strength (GS; from 37.7 ± 6.9 to 33.9 ± 6.8 kg, *p* < .01), the range of anteflexion in standing (ROA-ST; from 4.7 ± 6.9 to 1.0 ± 7.3 cm, *p* < .01), Fall Efficacy Scale International score (from 26.7 ± 10.1 to 30.7 ± 12.8, *p* = .031). In the women, 4 measurement items significantly decreased as follows: KA (from 166.1° ± 5.8° to 160.5° ± 5.4°, *p* < .01), GS (from 25.2 ± 2.6 to 23.7 ± 2.5 kg, *p* < .01), ROA-ST (from 13.6 ± 6.8 to 11.5 ± 7.7 cm, *p* < .01), weight-bearing index (from 61.2% ± 15.2% to 53.0% ± 12.7%, *p* < .01). The age-related changes in physical function differed according to sex. The decreases in the measurement values were related to balance ability in men and to muscle strength in women. Our subjects had higher levels of physical function than those in a previous study. In conclusion, exercise-related balance and muscle strength training from middle age are important for the physical functions of men and women, respectively.

SELF-REPORTED SLEEP, DEMOGRAPHICS, AND HEALTH IN SENIORS IN MIBU, JAPAN

Y. Ishikawa, A. Marui, S. Kaneko, Y. Kamiyama, N. Aizawa, *Dokkyo Medical University, Mibu, Tochigi, Japan*

Sleep disturbance is often reported by the elderly with 15% to 30% complaining of insomnia around the world. Poor sleep in later life represents a significant public health concern because of its association with cognitive decline, impaired social interaction, interfered daytime activities.

To understand sleep quality and its associated factors, a cross-sectional study was carried out in Mibu town in Eastern Japan in 2015. A questionnaire that included the Pittsburgh Sleep Quality Index, sociodemographic, comorbid health conditions and life styles was delivered to non-institutionalized elderly aged over 60, 805 subjects (75.8%) completed the questionnaire, which included an analysis.

The average age of the participants was 71.5 years (SD 6.6, range 60–98). 51.2% female, 30.9% were over 75, and 9.7% were living alone. 34.2% of the participants reported poor sleep quality. Logistic regression analysis revealed that overall sleep quality was strongly associated with stress, depressive symptoms and having more than one chronic medical condition. Having an eye or ear problem or orthopedic conditions were also associated with poor sleep. However, this study suggested that a low BMI, lack of daytime activity and taking naps were not associated with poor sleep quality.

Several factors may explain poor sleep in seniors and the study suggests stress and poor mental health management are considerable interventions for quality of sleep. As primary care providers we should be more concerned with our clients' sleep, and this can be achieved at the same time of managing their disease or conditions.

DEVELOPMENT OF THE HEALTHY AGING MODEL: A GROUNDED THEORY STUDY

L. Thiamwong¹, M. McManus², J. Suwanno³, 1. *College of Nursing, University of Central Florida, Orlando, Florida*, 2. *University of the Ozarks, Clarksville, Arkansas*, 3. *Walailak University, Tasala, Nakhon Si Thammarat, Thailand*

To develop a model of healthy aging from the perspective of Thais, a grounded theory approach, including in-depth interviews and focus groups, was used. A purposive sample of 39 community-dwelling adults aged 40–85 years old was interviewed. The Thai healthy aging model composed of three themes: normality, nature, and dharma. In Thai, they are called *tham-ma-da*, *tham-ma-chat*, and *tham-ma*, or “Thai 3Ts”. The theme of normality encompasses subthemes of staying physically active by being involved in plenty of physical activities, and being mentally active with creative and thoughtful hobbies and work. The theme of nature encompasses subthemes of living simply and being careful with money. The theme of dharma encompasses subthemes of enjoyment through helping family and participating in community activities, staying away from stress and worries by talking openly and honestly with someone, making merit, and helping other people without expecting anything in return. A greater understanding of healthy aging is a benefit for older adults and health care providers in an intervention-design process. Research can contribute valuable information to shape policy for healthy aging as well.

NEW SIMPLIFIED DIAGNOSTIC METHOD TO SCREENING FOR POSTPRANDIAL HYPOTENSION IN OLDER PEOPLE

M. Gaubert-Dahan¹, D. Bonnet-Zamponi^{2,3}, R. Abbas³, 1. *GHI Le Raincy-Montfermeil, Montfermeil, France*, 2. *OMEDIT (Observatoire des MEDicaments Dispositifs médicaux et Innovations Thérapeutiques) Ile de France, Paris, France*, 3. *Département d'épidémiologie et recherche clinique, CIC-EC 1425, Groupe Hospitalier Paris Nord Val de Seine, AP-HP, Hôpital Bichat, Paris, France*

Background: Postprandial hypotension (PPH) is a prevalent but not well diagnosed disorder in the older people. The reference PPH diagnostic method is too demanding, because blood pressure (BP) needs to be measured 8 times in 2 hours. Our primary objective was to define a new simplified PPH diagnostic method and to evaluate its performances.

Methods: Cross-sectional study of 104 patients (70 women, 34 men) with high risk of postprandial hypotension admitted to two geriatric rehabilitation units in France. BP was measured twice before the midday meal in seated position at the table, and every 15 minutes for 90 minutes after the end of the meal. Receiver Operating Characteristic curves were plotted for each postprandial BP measure to determine the best postprandial measure in terms of sensitivity and

specificity. The optimal diagnostic threshold was calculated with Youden's index according to BP difference before and after the meal.

Results: A new simplified diagnostic method is proposed: a decrease of at least 10 mmHg systolic BP between BP measures before the meal and 75 minutes after the end of the meal. This new method had a sensitivity of 82% (IC 95% 66 – 92) and a specificity of 91% (IC 95% 81 – 97).

Conclusion: This new diagnostic method is fast, efficient and suitable for everyday use. It could improve PPH diagnosis in older people. Larger studies are needed to validate it.

SESSION 1060 (POSTER)

RESIDENTIAL LIVING OPTIONS

BACCALAUREATE-EDUCATED REGISTERED NURSES IN NURSING HOMES: POSITIONING AND ROLE IMPLEMENTATION

R. Backhaus¹, H. Verbeek¹, E. van Rossum^{1,2}, E.A. Capezuti³, J. Hamers¹, 1. *Department of Health Services Research, CAPHRI School for Public Health and Primary Care, Maastricht University, Maastricht, Netherlands*, 2. *Research Centre on Autonomy and Participation, Zuyd University of Applied Sciences, Heerlen, Netherlands*, 3. *Hunter College, City University of New York, New York, New York*

In Dutch nursing homes, few registered nurses (RNs) work in direct resident care and baccalaureate-educated RNs (BRNs) are an especially scarce resource. It is unknown yet to which extent organizations make use of the BRNs' expertise and how their roles are differentiated from those of other staff members.

The aim of this qualitative study was to obtain insight into different roles that BRNs currently hold in institutional long-term care as well as explore the factors that impede their employment. In total, 26 semi-structured individual interviews (directors, ward managers, BRNs) and three group interviews (RNs, certified nurse assistants) were held in organizations that did or did not employ BRNs in nursing homes.

Directors not employing BRNs reported that low resident health acuity, disinterest of BRNs in the setting and the added costs of hiring BRNs hindered their employment. Directors that employ BRNs have a clear vision of how to utilize their role in the facility. Within and between organizations, there is variation regarding the positioning of BRNs. All BRNs fulfil ward- or location-transcending tasks that exceed direct resident care. For example, they coach direct care teams, supervise interns or have specific expertise areas (e.g., ‘physical restraints’ or ‘emotion-oriented care’).

This study found different possibilities how BRNs are working in nursing homes. Their added value is difficult to quantify, but positive effects for residents (e.g., less pain) and direct care teams (e.g., more confidence) were mentioned. The actual effectiveness of different ways to utilize BRNs should be tested in future studies.

DETERMINANTS OF LIVING ARRANGEMENTS FOR ELDERS TRANSITIONING FROM A NURSING HOME INTO THE COMMUNITY

C. Fabius, J.T. Robison, *University of Connecticut, Farmington, Connecticut*

The Money Follows the Person (MFP) Demonstration allows nursing facility residents to transition into community living arrangements. Research has shown racial differences in living arrangements – Blacks are more likely than Whites to live in multigenerational households. Transitioning into the community may also be accompanied by challenges (i.e. lack of housing). This study examines the influence of race, choice, and transition challenges on living arrangements in $N=659$ ($n=495$, 75% White, $n=164$, 25% Black) older (aged 65+) MFP participants in Connecticut. Multinomial and binomial regression models predicted living arrangements in unmarried and married participants. Findings show that among unmarried participants, Blacks are more likely to live alone or with family, and Whites are more likely to live with a live-in caregiver/supervised housing. White participants were also more likely to report having helped choose their home. Women and participants with more functional needs are more likely to live with family as well as with a live-in caregiver/supervised housing compared to those living alone. Having service challenges was a negative predictor of living with family, and having financial challenges was a negative predictor of living with a live-in caregiver/supervised housing compared to living alone. Among married participants, having more functional needs predicts living with a spouse, while those with housing challenges are less likely to live with a spouse. Research should further explore the impact of transition challenges on rebalancing programs. Findings can influence community housing plans and inform the field of gerontology with respect to cultural patterns in housing and service use.

MEDICAID BENEFICIARIES' ACCESS TO RESIDENTIAL CARE SETTINGS

M. Lepore, M. Knowles, K. Porter, J.M. Wiener, *RTI International, Washington, District of Columbia*

Residential care settings (RCSs) are community-based housing and supportive services providers. Many RCSs predominantly serve older adults and younger people with physical disabilities. Medicaid beneficiaries' access to these RCSs is of concern to policymakers and other stakeholders because providing community-based—rather than institutional—services is potentially less expensive and preferred by most people. To better understand Medicaid beneficiaries' access to RCSs that focus on older adults and young people with physical disabilities, we examined Medicaid policies in 50 states and the District of Columbia, interviewed subject matter experts ($n=7$), and conducted four state case studies informed by reviews of policies and interviews with stakeholders ($n=27$). Interviewees identified numerous factors influencing Medicaid beneficiaries' access to these RCSs, including the supply of Medicaid-certified RCSs relative to the older adult population, Medicaid reimbursement rates, initiatives that affect room and board costs for Medicaid beneficiaries, and policies that may incentivize RCSs to serve Medicaid beneficiaries. These factors can affect Medicaid beneficiaries' access to RCSs by limiting the number of RCSs

that participate in Medicaid, restricting the number of beds that RCSs allot to Medicaid beneficiaries, and by determining whether room and board rates will be affordable for Medicaid beneficiaries. The implications of these findings vis-à-vis implementation of federal Medicaid home and community-based services rules and continued implementation of managed long-term services and supports programs are discussed.

ANTIPSYCHOTIC AND RESTRAINT USE AMONG LONG-STAY NH RESIDENTS: IMPACT OF CMS REGULATORY CHANGES

J.A. Lucas¹, J.R. Bowblis², *1. Seton Hall University, South Orange, New Jersey, 2. Miami University, Oxford, Ohio*

APMs have potential for adverse effects and mortality risk for NH residents with dementia. CMS initiated its “National Partnership” (March 2012) to reduce APM use, implemented public reporting an APM quality measure (July 2012), and revised NH surveyor guidelines and training to identify unnecessary APMs and compliance with new dementia care standards (May 2013). We determine NH response to these initiatives, by examining change in APM and physical restraint utilization among long-stay NH residents and whether these vary with resident cognitive functioning. Using data from 2011–2013 Minimum Data Set, we examined long-stay residents in free-standing facilities that did not have CMS-approved indications for APM ($N\approx 8$ million). Linear probability models controlled for resident and facility characteristics and determined how restraint and APM rates change in response to each CMS initiative. Results were stratified into groups: no dementia/mental illness, dementia without symptoms (i.e., behavioral symptoms, delusions/hallucinations), dementia with symptoms, and severe mental illness consistent with APM utilization (e.g., bipolar, psychosis, and severe depression). Pre-initiative physical restraint use averaged 2.5%, with rates higher among those with dementia and severe mental illness. Among all groups, restraint use declined with each initiative. Pre-initiative APM use averaged 23.2%, though rates varied significantly with cognitive functioning (7.0%–66.2%). All groups saw declines in APM use with each CMS initiative; largest decline was among dementia residents without symptoms (27.8%), smallest among residents with mental illness (9.7%). Regulatory efforts to reduce APM prescribing had a significant impact, without an increase in physical restraint use; effectiveness varies with resident cognitive functioning.

DETERMINING HOME AND COMMUNITY-BASED SERVICE USE AMONG OLDER MONEY FOLLOWS THE PERSON PARTICIPANTS

C. Fabius, J.T. Robison, *University of Connecticut, Farmington, Connecticut*

The use of home and community-based services (HCBS) has been examined in research on community-dwelling elders. Research has not yet investigated the determinants of HCBS use among elders participating in a nursing facility transition program such as the Money Follows the Person (MFP) Rebalancing Demonstration. Further, race may be a factor in HCBS use – previous findings in community-dwelling populations have been mixed. The current study utilized The Andersen Behavioral Model of Health Service

Use to examine racial differences in determinants of HCBS use among $N = 240$ frail older MFP participants (aged 65+; 76%, $n = 182$ White, 24%, $n = 58$ Black). Binary logistic regression models predicted the use of three services: 24-hour care, per diem home health care, and functional care. Results showed that determinants vary for each outcome. Women and those with more ADL/IADL needs were more likely to have 24-hour care, while married participants and those reporting instrumental support were less likely to use this service. In contrast, being married and receiving instrumental support were determinants of per diem home health care, while those with more ADL/IADL needs were less likely to use home health care. Black race, ADL/IADL need, and financial inadequacy were all negative predictors of functional care. A negative interaction effect between race and gender (Black women) was also present in determining the use of functional care. Results from this study provide policymakers and providers with a better understand of the types of services MFP participants are using.

CAREGIVER STRESS AMONG FAMILY CAREGIVERS OF OLDER PERSONS IN JAPAN

K. Kageyama¹, Y. Sawada², M. Ono³, 1. *Health Science, Tokyo University of Technology, Tokyo, Japan*, 2. *Nihon Fukushi University, Nagoya, Japan*, 3. *Kansai University of Social Welfare, Aiko, Japan*

Family caregivers who provide care on a regular basis for their elderly loved ones at home often feel physically and emotionally overwhelmed. This study was conducted to investigate the physical and emotional stress of family caregivers in Japan.

A total of 123 caregivers were asked to freely describe their experiences, sentiments, emotions and opinions about providing elderly care at home. Of those, 64 caregivers (78.1% female, $\text{M age} = 65.52 \pm 9.93$, $r = 52\%$) provided responses in as much detail as desired. Their responses were grouped and analyzed according to content.

Results indicated that the caregivers reported emotional distress (37.5%) as well as positive attitude toward caring for their loved one (23.4%), feeling worried about their own or the loved one's health and life in the future (21.9%), their gratitude for those who share the responsibility of providing care for their loved one (17.2%) and/or for care services providers (12.5%), lack of time for self-care and/or social life (15.6%), thinking of placing the loved one in a long-term-care facility (9.4%), suicidal and/or murder-suicide thinking (4.7%).

Despite the wide range of home-care services available through the long-term care insurance system, family members still have to provide some forms of care. This study suggests that it is important to offer a variety of services and supports that help them to ward off or cope with their stress before they burnout.

AN INVESTIGATION ON NURSING SUPERVISORS' DILEMMA IN LONG-TERM CARE FACILITIES

S. Chang-Lee, M. Chung, *Asia University, Taichung, Taiwan*

This research aims for investigating the dilemma of nursing supervisors in long-term care facilities. Amongst researches on supervisor pressure, few focus on trials and tribulations of nursing supervisors in long-term care facilities.

Most of the related researches are quantitative studies aiming at nursing in acute health-care institutions, which makes further understanding of difficulties in working from nursing supervisors in long-term care facilities infeasible. This study adopts phenomenology and in-depth interviews with fifteen nursing supervisors in long-term care facilities to approach the perception and experience of nursing supervisors from long-term care facilities. The main results are as follow:

I. Attention to both administrative management and clinical practice

II. Insufficient human resources for heavy demands

III. Complex interpersonal interactions

IV. The grope for the even point with superiors

V. Mushy moral issues

VI. Exceptionals in disguise with no time to spare

This study finds nursing supervisors in long-term care facilities are multi-tasking. Their dilemma stems from the conflicts in correspondence, overloaded responsibilities in work and risks, and the lack of autonomy.

FAMILY MEMBERS' ROLE IN FACILITATING HEALTH CARE FOR RESIDENTS WITH DEMENTIA IN ASSISTED LIVING

T.J. Sharpp, *Nursing, California State University - Sacramento, Elk Grove, California*

The purpose of this presentation is to describe the results of an ethnographic study in two assisted living (AL) communities regarding the family members' role of facilitating health care for residents with dementia. AL communities were originally designed as a housing model; but it is now estimated that over 50% of the residents in AL have some form of dementia and may require more services. Registered nurses are not required to be employed in AL communities in California, thus health care is coordinated by unlicensed personnel and family members. The setting for this ethnographic study was two dementia-only AL communities in California. Participant observation was conducted over six months focusing on the interactions between residents, families, and employees. Open-ended interviews were conducted with twelve employees and nine family members. The data were analyzed for themes regarding how family members and employees communicated regarding the health care of the residents with dementia. Two qualitative themes: "Acknowledging Barriers" and "Assertive Advocacy" emerged from the qualitative data regarding how family members perceived the exchange of health care information regarding their loved ones with dementia. Family members and employees described the barriers regarding communication but acknowledged that family members who assertively advocated for their loved ones can overcome the barriers. The frustrations expressed by family members may lead to disruption in the continuity of care. Healthcare providers and gerontologists can provide education to families of older adults about how to advocate for smooth coordination of health care.

PEACEFUL DEATH VALUED AS A GAIN: INSIGHTS FROM FAMILY MEMBERS OF NURSING HOME RESIDENTS WITH CANCER

M.E. Bern-Klug, *Social Work, The University of Iowa, Iowa City, Iowa*

Knowing the type of medical care nursing home (NH) residents want at the end of life is important so that appropriate care can be pursued. Results of a qualitative study of 24 family caregivers of NH residents with a cancer diagnosis in the Midwest USA will be presented. Respondents' ages ranged from 25–75, 7 were men, 16 were adult children, all were white, and half had work experience in the medical field.

Interviews with family members were taped, transcribed, and analyzed using content analyses and key sensitizing concepts from Tversky and Kahneman's, "Prospect Theory of Decision-Making Under Risk" (1979, 2011).

Findings indicate that family members were more concerned about avoiding a painful protracted dying process for their loved one, than they were with trying to extend the time the resident remained alive. That perspective appeared to be related to the perception of the reference point (where the resident was in the continuum of death on one hand and perfect health on the other). "He said to me, 'Don't keep me alive just to keep me alive' and "We were beyond the point of trying to fix things and make things better." And "A few years ago she said she had a goal to make it to 90—she's done that and she has said she is ready to go anytime."

Findings suggest new avenues for research related to perceptions about the resident's reference point, consistency between residents and family about reference points, and how those perceptions can influence medical decision-making.

LONG-TERM CARE IN TURKEY: ARE WE READY TO MEET OLDER PEOPLE'S CARE NEEDS?

S. Oglak¹, A. Canatan², I. Tufan³, S. Acar⁴, N. Avci⁵, 1. *Labour Economics and Industrial Relationship, Adnan Menderes University, Aydin, Turkey*, 2. *Gazi University Department of Sociology, Ankara, Turkey*, 3. *Akdeniz University, Department of Gerontology, Antalya, Turkey*, 4. *Municipality of Dinar, Mayor of Dinar, Afyon, Turkey*, 5. *Adana Residential Care and Rehabilitation Center, Adana, Turkey*

Aging of population affects all aspects of the society ranging from the healthcare to welfare systems, public finances, family life and LTC issues, as well. Turkey's population is younger than that of European countries. However, the ageing population is growing rapidly in Turkey. As a result of the increase in the aging population, health expenditure and long-term care services needs have swiftly increased, and this increase, as well as becoming a noteworthy situation, has posed a serious threat to Turkey, including the ones having an extremely powerful social security system, for the future. In Turkey, currently there is no long-term care insurance system. The elderly are usually taken care of within their own family. Long-term care infrastructure are extremely scarce. At the same time, home care and social care are least developed in Turkey, with the scarce public supplies being rationed by quantity and treated as last resort options by families and private providers. Public and private support for long-term care for older persons still is not visible and at national level it is often a non-issue. However, in recent years, quite important steps are being taken for long-term care to innovative implementations has been witnessed. We will point out some good practices about long-term care for older people in Turkey.

MEASURING CARE OUTCOMES: THE AUSTRALIAN COMMUNITY CARE OUTCOMES MEASURE (ACCOM)

M.D. Fine, *Macquarie University, Sydney, New South Wales, Australia*

Measuring outcomes is essential for the success of aged care services delivered to people in their own home, yet to date, there has been no simple to use, practical methodology available for use in the community care field. This paper reports on the development and extensive field trial of the ACCOM, an Australian outcomes measurement tool that is based in part on a UK tool - the Adult Social Care Outcomes Toolkit (ASCOT), and is administered together with data on the demographics and capabilities of consumers. The research has been undertaken in partnership with a number of leading home care providers in NSW on measuring outcomes in case managed home care services. A key question addressed by the paper is whether it is necessary to develop a country specific approach. Can there be a universal measure of care outcomes?

SESSION 1065 (POSTER)

WORKFORCE AND CAREGIVING ISSUES IN LONG TERM CARE

EXPLORING THE IMPACT OF LEADERSHIP IN AGED CARE ON JOB STRAIN AND SOCIAL SUPPORT

A. Backman³, K. Sjögren³, H. Lövheim³, D. Edvardsson², 2. *School of Nursing and Midwifery, La Trobe University, Melbourne, Victoria, Australia*, 3. *Umeå University, Umeå, Sweden*, 3. *Department of Community Medicine and Rehabilitation, Umeå University, Umeå, Sweden*

It is well known that aged care staff experience high levels of job strain, and it is evident that aged care staff that experience job strain are exposed to increased risk for adverse health effects. Leadership is a factor that has been associated to job strain in the literature, however, the impact of managerial leadership on job strain and social support has not been clarified within this context. The aim of this study was to explore associations between leadership, job strain and social support among care staff in aged care. This study has a nation-wide, cross-sectional design, including staff in 188 residential aged care facilities throughout Sweden. Participating staff (n=3661) completed surveys which included questions about staff characteristics, valid and reliable measures of leadership behavior, job strain and social support. Statistical analyses of correlations and multiple regression analysis with interaction terms were conducted. The result revealed that leadership behaviors' among managers had a significant association with job strain and social support. Higher levels of leadership behaviour were related to lower level of job strain and higher level of social support. Further, levels of leadership moderated the impact of social support on job strain. The leadership behaviors' from aged care managers seem to contribute to supportive environment in terms of increased social support and thus, alleviate job strain among staff.

THE INFLUENCE OF TEAMWORK ON HEALTHCARE WORKERS' JOB SATISFACTION AND DESIRE TO PROVIDE QUALITY CARE

S. Dahlke, S. Stahlke, *Faculty of Nursing, University of Alberta, Edmonton, Alberta, Canada*

Background: Effective teamwork is widely regarded as a means of delivering safe, effective, and patient-centered care and improving patient outcomes, especially when it involves caring for populations with complex health challenges, such as the frail older adults, who often live in long term care institutions.

Objective: This aim of this study was to examine how healthcare workers working with older adults perceived teamwork and how teamwork affected care delivery and job satisfaction.

Method: Focused ethnographic methods were used to collect data in two residential care settings. Interviews were conducted with 22 healthcare providers who worked in a variety of roles.

Results: Characteristics of effective teamwork were: respect, listening, trust, and common goals. Barriers/facilitators of teamwork were: communication, commitment to the work, and familiarity. Perceptions about who was considered a team member varied with narrower views about team membership among healthcare workers providing direct care to older adults. There were expectations that leadership should create an environment that supports teamwork. Moreover, little things like scheduling, role clarification, and working with someone you knew impacted on teamwork experiences.

Conclusions: Healthcare workers identified that effective teamwork increased their job satisfaction and commitment to provide better care to older adults; yet, perceptions about who was on the team varied. More research is required to understand how to expand healthcare workers' perceptions about who they can include as part of the team and how leadership can foster teamwork.

EXPLORING THE ADAPTIVE AND TECHNICAL CHALLENGES NURSING STAFF EXPERIENCE IN USING NEW TECHNOLOGY

S. Kennerly¹, T. Yap², 1. *College of Nursing, East Carolina University, Chapel Hill, North Carolina*, 2. *Duke University, Durham, North Carolina*

The Pressure ulcer prevention (PrU) care standard for U.S. nursing home (NH) residents is repositioning every 2 hours to minimize pressure exposure; however, on-time repositioning nursing staff compliance is low. This study examined the adaptive and technical challenges nursing staff faced when using new technology to facilitate repositioning of NH residents. A 21-day trial with a convergent mixed methods pre/post-test design compared resident and staff outcomes at a southeastern US NH. The Leaf® Patient Monitoring System, a wireless system with sensor worn mid-sternum tracks (position, repositioning frequency; enabling percentage of on-time compliance calculation) resident movement 24-hours a day, cueing staff when repositioning is required. Web-based surveys completed by staff (RNs, LPNs, CNAs) pre/post intervention were the Nursing Culture Assessment Tool (NCAT), Perceived Organizational Support (POS), and Affective Organizational Commitment (AOC). During post-intervention focus groups (2, n=13), staff perspectives

were gathered. NH staff data and Leaf® monitoring data were quantitatively analyzed. Qualitative analyses using transcribed focus group sessions identified core concepts, applied satisfaction-based apriori codes, and allowed emergence of new themes. Staff on-time repositioning compliance improved from 59.8 to 77.3%. Staff responded positively to repositioning cues and described an enhanced sense of teamwork in order to achieve on-time repositioning, believing that usual care was provided faster. Adaptive and technical challenges will be discussed. Nursing culture's normative ranking percentage increased and communication, satisfaction, and professional commitment item scores positively corresponded with focus groups. Also, POS and AOC scale scores improved. Triangulated findings revealed nursing staff's enhanced experience by using new technology.

MEASUREMENT AND OUTCOMES OF PERSON-CENTERED CARE IN LONG-TERM CARE SETTINGS: A LITERATURE REVIEW

J. Lee, 1. *University of Alberta, Edmonton, Alberta, Canada*, 2. *CapitalCare, Edmonton, Alberta, Canada*

Person-centred care (PCC) is widely acknowledged among health care professionals as a best practice approach, but there is little available evidence on the impact of PCC in long-term care (LTC) settings. This literature review provides research-based evidence to describe the tools available and the examined outcomes of PCC in LTC settings for the resident, care staff, and family members. The inclusion criteria to select studies included peer-reviewed literature discussing measurement related to PCC in a LTC setting and/or tools that were adapted to measure PCC in a LTC setting. Thirty-one studies published from 2001 up to 2016 met the inclusion criteria and five categories of studies investigating PCC outcomes were established. Staff outcomes were most often investigated, followed by resident outcomes, and family outcomes were the least investigated. The various outcomes of PCC are mixed. Overall, PCC is correlated with positive outcomes, although some studies reported unchanged or negative outcomes after implementing PCC. A limited number of instruments exist designed to measure PCC and there is no consensus in the examined studies on the best instrument to use to measure outcomes of PCC. This investigation was to be completed during a year-long research internship, therefore the search did not require a large number of databases or a longer period of time to be examined. A more thorough investigation, including a larger number of databases searched as well as a longer time period for searching, is recommended to better determine the effectiveness of PCC.

EXAMINING THE IMPACT OF NURSING CULTURE ON TECHNOLOGY USE TO FACILITATE CARE PRACTICES

T. Yap¹, S. Kennerly², 1. *School of Nursing, Duke University, Durham, North Carolina*, 2. *East Carolina University, Greenville, North Carolina*

A positive cultural environment in nursing is vital to achieving quality outcomes. The Nursing Culture Assessment Tool (NCAT) captures general aspects of nursing's occupational subculture with results that can be used to advance care practices and outcomes. The subculture's influence was explored in this mixed methods study when

using new technology, the Leaf[®] resident activity monitoring system, in long-term care (LTC) as part of a pressure ulcer (PrU) prevention protocol and quality improvement processes. The LTC contracted with Leaf Healthcare[®] to train staff in system use. All nursing staff (RNs, LPNs, CNAs) were asked to complete a pre (n=34) and post-test (n=38) web-based electronic 19-item NCAT survey and demographics before and after a 21-day repositioning intervention. Repositioning activities of LTC residents at low, moderate, and high risk for developing a PrU were monitored 24-hours a day with Leaf's sensor worn mid-sternum. All residents (n=44) were monitored for time periods ranging from 2 to 21 days with the staff's on-time repositioning increasing. NCAT Cronbach's alpha was 0.93 (pre) and 0.94 (post). Communication subscale scores significantly ($F=4.605$, $p=.035$) improved pre ($m=8.79$) to post ($m=9.55$) intervention. Selected items for NCAT communication ($F=6.63$, $p=.012$) and satisfaction ($F=5.34$, $p=.024$) significantly increased posttest. The subculture's overall normative ranking percentage increased from 30.9 to 58.2%. The technology provided staff with new information which stimulated communication about repositioning and contributed to their satisfaction with the quality of care provided. The dynamic interaction between nursing culture and the use of new technology in the care environment merits further research.

A STAFF PERCEPTION OF RELATIONSHIP BETWEEN FAMILY AND STAFF IN LONG-TERM CARE FACILITIES IN KOREA

H. Jang¹, Y. Suh², 1. *Hanyang University, Seoul, Korea (the Republic of)*, 2. *Yonsei University, Seoul, Korea (the Republic of)*

Family and staff cooperative interaction in caring for older adults in long-term care facilities is recommended; however its importance and outcomes are poorly understood in Korea. The purpose of the study was to explore the staff's perception of his/her relationship with family caregivers of institutionalized elders with dementia in Korea. This qualitative study design was used. Data were collected through focused group interviews using an interview guide from May to June, 2016. Four focus group interviews were conducted with a total of 21 staffs in four long-term care facilities in Korea. The collected data were analyzed by qualitative content analysis using the MAXQDA12 program. Mean age of the participants was 50.1 (SD=8.1) years old, and the majorities were female (95.2%). Mean working period of the participants was 5.6 years with a range of 1.8 to 16 years. Four themes were emerged; 1) Disconnected relationships; 2) Monitored relationships; 3) Supportive relationships; and 4) Collaborative relationships. Staff who had developed a collaborative relationship with family caregivers was more likely to provide information about resident's care, to acknowledge the family caregivers' help to their relative, to use open communication, to share responsibility, and to let family caregivers involve in problem-solving. Findings of this study may help healthcare providers to establish collaborative care, to prevent any conflict between family caregivers and staff in long-term care facilities.

DEVELOPMENT OF THE STRAIN IN DEMENTIA CARE SCALE

A. Orrung Wallin¹, M. Bird², K. Anderson³, A. Edberg¹, 1. *Health and Society, Kristianstad University, Lund, Sweden*, 2. *Dementia Development Services Centre, Bangor University, Bangor, Gwynedd, United Kingdom*, 3. *Aged Care Evaluation Unit, Southern NSW Local Health District, Queanbeyan, New South Wales, Australia*

Many staff working in residential aged care facilities gain satisfaction from working with people with dementia, however, they also experience significant stress. High levels of stress among the staff can in turn affect the quality of the care provided to residents. There is thus a need for instruments to measure staff strain in the dementia-specific residential care environment. The aim of the study was to develop an instrument investigating strain among staff working in dementia care *i.e.* the "Strain in Dementia Care Scale". The instrument was initially developed through experiences of strenuous aspects of work identified in six focus group discussions with 35 nurses in Australia, Sweden and the United Kingdom. A preliminary 64-item scale was in the next phase reduced to a 29-item scale after being distributed to 927 staff working in dementia care in Australia and Sweden. In the final phase, a confirmatory factor analysis was made after distributing the 29-item scale to a new sample of 346 staff in Sweden. The final 27-item scale resulted in a five-factor solution: Frustrated empathy; difficulties understanding and interpreting; balancing competing needs; balancing emotional involvement; and lack of recognition. The Strain in Dementia Scale can be used (a) as an outcome measure of intervention studies in residential care; (b) to help identify interventions needed, based on high scores on different factors, to improve staff well-being in residential facilities and, in turn, those they care for; and (c) to generally highlight the importance of improving issues related to staff strain.

OLDER ADULT HOME HEALTH AIDES: A VIABLE OPTION

G. McGhan, D. McCaughey, R. Herald, *University of Alabama at Birmingham, Birmingham, Alabama*

The need for Home Health Aides (HHAs) continues to grow due to the aging of the population and older adults increasing preference to be cared for in their homes. Contributing to the shortage of qualified HHAs are the repetitive injuries, high job demands, poor benefits and lower pay they often experience. Suggestions have been made that older workers are more prone to workplace injuries and hence, are more costly to employee than younger workers. To address these perceptions, data from the 2007 National Home Health Aide Survey was used to examine the relationship between injuries and outcomes, as well as the frequency of injuries and sick days for HHAs. Post hoc analyses were conducted to identify differences by age groups ($n= 3,377$). Using OLS and multinomial logistic regression, injured employees were found to have lower job satisfaction ($\beta= -.119$, $p\text{-value} <.001$), higher turnover intentions ($\beta= .069$, $p\text{-value} <.001$), and be less likely to recommend their agency for care ($\beta= -.099$, $p\text{-value} <.001$) than non-injured employees. Older workers (over 55 years and 23.7% of sample) had significantly higher job satisfaction ($F=5.35$, $p<.001$), lower turnover intention ($F=8.15$, $p<.001$) but no significant

differences in injury rate or sick days taken. Older HHAs in this study had better outcomes and were neither injured nor sick more often than their younger counterparts. With an aging workforce and the need to fill existing vacancies, older workers offer a viable and accessible employee pool to help meet the growing demand for HHAs.

PROFESSIONAL DEVELOPMENT OPPORTUNITIES FOR PERSONAL CARE WORKERS: SEE THEM SHINE

S. Davis, A. Campbell, R. Capp, *Applied Gerontology, Flinders University, Bamaum, Victoria, Australia*

Under the Encouraging Better Practice Initiative, the Australian Commonwealth Department of Health and Aged Care funded a team from Flinders University to develop and disseminate the Dementia Dynamics Toolkit to all residential aged care homes in the country with the aim of building capacity in person-centred dementia care. In Australia, the largest percentage of the workforce in residential aged care comprises personal care workers, who are lowest paid and largely part-time. As such, opportunities to engage in professional development activities and build capacity in their role as the primary personal care-givers in an organisational setting are limited. To determine the feasibility of defined professional development opportunities for this important group of staff, a national, competitive fellowship program for personal care workers was offered as part of the Dementia Dynamics Toolkit project. The Dementia Dynamics Fellowship comprised fully funded attendance to an international dementia conference being held in Australia, a full day educational workshop and mentor support for 12 months to complete a small project in the aged care home in which they worked. Ten fellowships were awarded to personal carers from across the country. This paper presents a selection of the journeys these personal care workers embarked on during their fellowships, the impact it had on their personal and professional development and the outcomes for the care homes in which they worked. The personal care workers own views are presented through excerpts of short videos talking about their experiences going to a conference for the first time, developing and completing their project and their perspective of the impact of their projects.

THE PREVALENCE AND RISK FACTORS ASSOCIATED WITH ELDER ABUSE IN NURSING HOMES IN CHINA

F. Dai, L. Wang, R. Chen, L. Wang, *Henan Province People's Hospital, Zhengzhou, China*

Elder abuse is a serious problem in some areas but always to be hidden. However, abuse tendency is an important variable to predict abuse behavior. The purpose of this study is to investigate the prevalence and risk factors of caregiver abuse in nursing homes. A cluster sampling survey was conducted in Zhengzhou of China. 360 nursing staff in nursing homes were recruited. Data were collected with general information, the caregiver Abuse Screen (CASE), Workplace Social Capital (WSC), and Maslach Burnout Inventory General Survey (MBI-GS). The results showed that the rate of abuse tendency to professional caregivers is high in nursing homes. Working over 3 months in nursing homes, WSC, exhaustion, reasons of job-selecting, and ADL scores of the elderly

residents are correlated with abuse tendency. Therefore, abuse tendency of professional caregivers should be evaluated further continuously. It suggested that long-term care facilities should provide more humanistic environment to improve working conditions of the nursing staff, shorten their daily work time, increase the salary, aiming to make them more positive and delivery higher quality of care to the elderly residents with chronic illness.

THE DIFFERENT VIEWS OF RESIDENTS AND CARE STAFFS OF PERSON-CENTERED CLIMATE IN NURSING HOMES, CHINA

H. Feng¹, P. Mao¹, L. Xiao², X.Y. Yang¹, H.M. Xia¹, 1. *Xiangya Nursing School, Changsha, Hunan Province, China*, 2. *School of Nursing and Midwifery, Adelaide, South Australia, Australia*

Introduction: In China, the perspective of residents and care staff towards the climate of the nursing homes are unknown due to lack of studies in this area.

Methods: A cross-sectional study was conducted to explore residents' and staff's perspective of Person-Centered Climate in nursing homes, in Hunan Province. A stratified cluster sampling method was used to recruit 260 old people and 350 care staffs from 20 nursing homes using the Person-centered Climate Questionnaire-Patient version (PCQ-P) and Person-centered Climate Questionnaire-Staff version (PCQ-S).

Results: In total, 251 residents and 302 care staffs completed the questionnaires. The range of age was 70–89 years old. The range of age was 46–55 years old. The Cronbach's alpha values of PCQ-P and PCQ-S in Chinese version were the same 0.93. The mean score (SD) of the PCQ-P was 59.69 (11.49), and the mean score (SD) of PCQ-S was 66.3 (9.7). Correlation analysis showed that residents' age, the marital status, health condition were factors affecting their perspective of person-centered climate of nursing homes. Staff's age, education level and the attributes of nursing homes were the factors affecting staff's perspective of person-centered climate in nursing homes.

Conclusion: The residents perceived person-centered climates scores were lower than those of care staff. The findings have implications for staff education and training to improve resident-centred care in nursing homes in China.

SESSION LB1070 (POSTER)

LATE BREAKER POSTER SESSION 3

ACCESS TO HEALTH CARE IN RURAL CHINA: THE INFLUENCE OF TRAVEL DISTANCE ON HEALTHCARE DECISION-MAKING

H. Ruan, *Institute of Population Research, Peking University, Beijing, Beijing, China*

In 2009, China established several new schemes to provide social health care coverage for the vast majority of its 1.3 billion citizens. However, continued separated health-care system creates inequalities in access that disadvantage people in rural areas. Because public hospitals and clinics

are insufficient to meet their needs, older adults with serious health problems often must travel great distances to obtain care. This study draws on the Andersen Behavioral Model to examine this trade-off between accessing quality of care and travel distance in health care decision-making. Based on nationally representative data from the Study on Global Aging and Adult Health (SAGE) (N = 4,445), multinomial-logistic regression was used to examine the influence of distance traveled on health services utilization. Controlling for the effects of relevant predisposing, enabling and need factors, distance decreased older adults' use of private (OR=0.48, P<0.01) and public (OR=0.22, P<0.01) clinics, but it had the opposite effect on use of public hospitals (OR=1.52, P<0.001). Health status and availability of high quality medical care in their home province moderated this relationship; in cases of poor health, distance played a less significant role in choice of clinics, but a greater role in choosing a high-quality hospital regardless of distance (OR=2.09, p<0.01), while the availability of local medical resources lessened the impact of distance (OR=2.221, P<0.01). In sum, distance reduced the probability of older adults' clinic use, but not their decision to seek sophisticated hospital services, especially in cases of poor health and the absence of high-quality care locally. Feasible schemes must contend with this growing issue of distance to high-quality facilities in health care decision-making of older adults in rural China.

LEISURE CONSTRAINTS OF URBAN CHINESE OLDER ADULTS: A CASE STUDY OF SUZHOU

Y. Niu¹, D. Wang², H.J. Gibson¹, 1. *Tourism, Recreation and Sport Management, University of Florida, Gainesville, Florida*, 2. *Soochow University, Suzhou, Jiangsu, China*

As the Chinese population ages, concerns are raised over the wellbeing of its elderly. Leisure has been shown to play a significant role in the physical and psychological wellbeing of older adults (Broughton et al, 2016; Heo et al, 2010), yet not all older adults have access to leisure (Liechty & Genoe, 2013). This study explored the constraints that limit the leisure activities of Chinese older adults and analyzed the differences in perception of these constraints by demographic characteristics. Residents from three communities of Suzhou, China aged 55+ were surveyed (N = 285) during July 17–20, 2016. A questionnaire containing 18 constraints to leisure participation were assessed by the respondents using a 5 point Likert-type scale. A factor analysis of responses yielded four constraint factors (Cronbach's alpha=0.80, accumulated variance=81.24%): (1) subjective and social factor (6 items, leisure awareness, consumption habit, care giving and interpersonal relations with children and friends), (2) health (4 items, physical health, injury and health accident perception and health care), (3) support service (4 items, management, leisure education, guidance and information access) and (4) facilities (4 items, leisure space, environment, leisure facilities and community-level organizations). A one-way ANOVA revealed significant differences between living state, health, marriage, leisure expenditure, income with the four factors. Suggestions were proposed to address the problems: including the introduction of leisure education, the provision of facilities, the accessibility of affordable products, the

availability of health care, and the encouragement of leisure industry provision for older adults.

CHANGES IN DEPRESSIVE AND ANXIETY SYMPTOMS IN ADULTHOOD: FINDINGS FROM THE VA NORMATIVE AGING STUDY

H. Lee¹, C.M. Aldwin¹, S. Choun¹, R. Nath¹, A. Spiro², 1. *School of Social and Behavioral Health Sciences, Oregon State University, Corvallis, Oregon*, 2. *VA Boston Healthcare System & Schools of Public Health and Medicine, Boston University, Boston, Massachusetts*

Combat exposure influences posttraumatic stress disorder (PTSD) throughout the lifespan, including late life (Kang et al., 2016; Settersten, 2006). While PTSD is often comorbid with depression and anxiety (e.g., Stander et al., 2014), surprisingly few studies examine whether combat exposure influences the age-related trajectories of depressive and anxiety symptoms (Ginzburg et al., 2010). We examined whether these trajectories differed depending on combat exposure (combatant vs. non-combatant) and specifically whether killing someone had stronger effects than general combat exposure. We utilized survey data collected in 1985, 1988, and 1991 from men in the VA Normative Aging Study; response rates were >80%. The sample included 978 men (Mage=59.7 in 1985, SD = 7.2, range = 41–86), mainly WWII and Korea-era veterans, of whom 392 (40%) saw combat and 80 (8.2%) indicated that they had killed someone. Unconditional growth curve models showed that veterans had U-shaped trajectories of both depressive and anxiety symptoms, decreasing until ~60 and increasing again in the late 60's. In the conditional growth curve models, the interaction of combat and age² indicated that, for combat veterans compared to non-combat veterans, their levels of both depressive and anxiety symptoms increased sharply in late life. However, the indicator of killing experience did not add significant variance to the model, perhaps because relatively few veterans had this experience. Thus, combat intensified the age-related changes in anxiety and depressive symptoms, suggesting that combat veterans may need more mental health assistance in late life.

FAMILY, FAITH, AND FATALISM: AGENCY IN OLDER APPALACHIAN FAMILIES DEALING WITH GYNECOLOGICAL CANCER

E. Potter, K.R. Allen, K.A. Roberto, *Virginia Polytechnic Institute and State University, Blacksburg, Virginia*

Patient-centered cancer care promotes individualized care and engages patients in the decision-making process. This decision-making responsibility often involves family input, welcomed or not. Older women in rural Appalachia are reported to have low levels of agency and high levels of fatalism (i.e., viewing health as pre-determined) regarding cancer. In Fall 2016, we explored the consequences of patient-centered care among older Appalachian women with gynecological cancer and their family members. This qualitative study combined Elder's Life Course concepts of trajectories and agency with Johnson's Model of Cancer-Related Information Seeking to examine agentic processes among families and older Appalachian women with gynecological cancer before, during, and post-cancer treatment. Using thematic content analysis, we focused specifically on how

older women enacted agency through information seeking and avoidance. We conducted a total of 53 semi-structured interviews with 20 White women (aged 51–82; $M=67.1$) living in central Appalachia and 1 to 2 members of their family ($n=33$). Findings demonstrated three transitions throughout the cancer experience and resulted in the creation of four trajectories of information-seeking ranging from surrendering control, accepting death, caring for oneself, or advocating for others. Findings also highlighted the role and limits of family members in information-seeking, women's personal transformation in self-efficacy and passion for community empowerment, faith-informed fatalism, and the value of personal ownership during cancer experience. We recommend redefining fatalism and conceptualizing information-seeking as a mechanism of agency. Findings call for continued doctor-patient dialogue regarding desire and use of information, and further examination of rural expressions of agency.

DRIVING CESSATION AND DEPRESSIVE SYMPTOMS: GENDER AND CROSS-NATIONAL DIFFERENCES

E. Choi, S. Cho, S. Um, Y. Kim, *Kyung Hee University, Yongin-si, Gyeonggi-do, Korea (the Republic of)*

Background: Previous research showed that driving cessation is significantly related to depressive symptoms (Ragland et al., 2005). However, limited studies have considered gender and cross-national differences. This study aims to investigate (1) gender differences in the association between driving cessation and depressive symptoms, and (2) whether there is a cross-national variation between Korean and U.S. older adults.

Methods: Using data from the 2014 National Elderly Survey (KIHASA) in the Korea and the Health and Retirement Study (HRS) in the US, a total of 4,274 older adults (2,062 Korean citizens and 2,212 U.S. residents) aged ≥ 65 years were selected. Geriatric Depression Scale-15 and Center for Epidemiologic Studies Depression Scale-10 were used to measure depressive symptoms in Korean and U.S. sample, respectively. Demographic characteristics, disease burden, and cognitive functioning were included as covariates.

Results: Significant differences were found in the prevalence of driving cessation between nations. Korean elderly was more likely to stop driving than elderly in the U.S. (34% vs. 9.5%). Women were more likely to cease to drive in both countries. In the U.S., driving cessation was significantly related to higher levels of depressive symptoms in both gender. However, in Korean older adults, driving cessation was associated with higher levels of depressive symptoms only in men.

Conclusions: The results indicate that the relationship between driving cessation and depressive symptoms differs across gender and nations, suggesting that driving cessation may increase depressive symptoms, especially for the U.S. residents. Future research is more needed to examine underlying mechanisms.

DO MY PATIENTS NEED ALL THEIR MEDICINES? REGISTERED NURSES' VIEWS ON DEPRESCRIBING

N. Ailabouni¹, D. Mangin², J.M. Tordoff¹, P.S. Nishtala¹, *1. University of Otago, Dunedin, New Zealand, 2. McMaster University, Hamilton, Ontario, Canada*

Registered nurses are key players in caring for older people and are major influencers of prescribing and deprescribing

in residential aged care facilities (RACFs). However, studies investigating their opinions about these processes are limited. This study therefore aims to investigate nurses' views and perceptions on medicines' use and deprescribing in this setting. A cross-sectional survey was mailed to 307 nurse managers of a nationally representative sample of RACFs. A purpose-developed, pre-tested, 48-item structured questionnaire was used that included both open-ended and close-ended questions. Questions were grouped according to each stage of the medicine use process (prescribing, medicine charts, receiving dispensed medications, administration and monitoring). A dedicated section to explore nurses' views on deprescribing was included. We received 91 questionnaires in total; yielding a response rate of 29.6%. A descriptive analysis was conducted to analyse close-ended question responses, and a thematic analysis was carried out to analyse open-ended question responses. Nurses highlighted several challenges including achieving medicine reconciliation for new residents, access to physicians to admit patients in a timely fashion, and issues pertaining to lack of clear transcribing of medical information. Most respondents (67.4%) agreed that deprescribing implemented with the help of a clinical pharmacist, would be beneficial and could improve medication adherence (44%), benefit the resident's quality of life (50.5%) and reduce the length of time spent by nurses on medicines administration (35.2%). This study sheds light on important challenges faced by nurses, regarding medication management. The majority of nurses supported the idea of deprescribing; however a small proportion of them disagreed that it would be beneficial or had no opinion. Increased awareness regarding polypharmacy and potential deprescribing benefits, is necessary to help achieve optimisation of medicine use in older people.

SOCIOECONOMIC POSITION ACROSS THE LIFE-COURSE AND COGNITIVE ABILITY IN MIDLIFE

E. Foverskov^{1,2}, E. Mortensen^{1,2}, J. Pedersen^{1,2}, M. Osler^{1,2,3}, R. Lund^{1,2}, *1. Department of Public Health, University of Copenhagen, Copenhagen, Denmark, 2. Center for Healthy Aging, University of Copenhagen, Copenhagen, Denmark, 3. Research Centre for Prevention and Health, Glostrup Hospital, Glostrup, Denmark*

Cognitive ability is associated with morbidity and mortality in old age and has been proposed to be a marker of successful ageing. There is growing interest in understanding how socioeconomic position (SEP) across the life-course may influence the development of cognitive ability. However, few studies have been able to include measures of early life ability and separate the effect of life-course factors that adds variance to later ability from variance that has persisted throughout life. This study is based on 2481 men born in 1953 from the Danish Metropolit Cohort who have completed ability tests at age 12, 18 and 57. The data is unique because in addition to these three tests contains longitudinal prospective register information on childhood SEP, educational attainment and occupational skill levels throughout adulthood. Structural equation models were used to investigate how these indicators of SEP both directly and indirectly are associated with cognitive ability in midlife, when accounting for childhood ability. Estimating standardized coefficients, we found significant direct paths from childhood ability (0.86) and adult occupational skill levels (0.13) to midlife ability.

The association between childhood SEP and midlife ability was fully explained by the other study variables, and thus only the indirect effect was significant (0.35). Educational attainment was found to have a negligible effect on midlife ability. The results suggest that individual differences in midlife cognitive ability are mainly due to differences in early life ability, but that occupational skill levels in adulthood and SEP in early life may additionally have implications for cognitive development over the life-course.

CAREGIVER-CARE RECIPIENT RELATIONSHIPS ARE ASSOCIATED WITH NEUROPSYCHIATRIC SYMPTOMS IN DEMENTIA

E. Vernon¹, B. Cooley¹, W. Rozum¹, G. Rattinger², S. Behrens¹, J. Tschanz¹, 1. *Utah State University, Logan, Utah*, 2. *Binghamton University, Binghamton, New York*

Closer caregiver-care recipient (CG-CR) relationships have been associated with lower informal care costs and better cognitive and functional outcomes in persons with dementia. Considering difficulties in treating neuropsychiatric symptoms (NPS) and their significant detrimental effects on caregivers and care-recipients in dementia, we examined whether closer CG-CR relationships were associated with severity of overall NPS and specific subdomains in dementia. NPS were assessed by the Neuropsychiatric Inventory-12 (NPI-12) in 252 CG-CR dyads in the Dementia Progression Study a longitudinal-population based study in Cache County Utah. Caregivers reported on relationship closeness using the Whitlach Relationship Scale. Linear mixed models examined the association between NPI-12 total score and symptom subdomains with CG-CR closeness (time-varying) in separate models. When controlling for caregiver burden, kin relationship, and dementia severity, each increasing unit of closeness was associated with an approximate 3-point lower NPI-12 score ($b=-2.73$, $p=.002$), and an approximate 1-point slower increase in NPI total score per year ($b=-0.92$, $p=0.046$). In NPI subdomains, closer relationships were associated with lower affective domain scores ($b=-0.15$, $p<0.001$) and lower agitation/aggression scores ($b=-0.13$, $p<0.001$). These results suggest that closeness in CG-CR relationship, a modifiable factor, may help reduce severity or slow intensification of NPS in dementia patients, which may be clinically significant for challenging symptom management. Extending prior findings that higher CG-CR closeness also predicts better cognitive and functional outcomes and lower informal costs of care, enhancing the CG-CR relationship may improve quality of life in the care dyad and possibly avoid or delay costly outcomes such as institutionalization.

ORAL-HEALTH PROFESSIONALS AS A FIRST POINT OF CONTACT FOR ELDER ABUSE VICTIMS: A SCOPING REVIEW

B. MacDonald^{1,2}, A. Hussain^{1,2}, C. Aliman^{1,2}, J. Fujioka^{1,2}, K. David^{3,4}, R.M. Mirza^{1,2}, C. Klinger^{1,2}, L. McDonald^{1,2}, 1. *Factor-Inwentash Faculty of Social Work, University of Toronto, Toronto, Ontario, Canada*, 2. *National Initiative for the Care of the Elderly, Toronto, Ontario, Canada*, 3. *Lakehead University, Orillia, Ontario, Canada*, 4. *Lakehead University, Faculty of Social Work, Orillia, Ontario, Canada*

Oral-health professionals, which include dentists, orthodontists and dental hygienists, are often the first point of

contact for older adults experiencing various types of elder mistreatment (such as abuse and neglect). The scheduled and routine nature of the visit often provides an opportunity to recognize any indicators of mistreatment over a longer period of time. A 2017 technical report completed on support services for victims of elder mistreatment highlighted that oral-health professionals are an underutilized ally in identifying and intervening with abused or neglected older adults. However, training in the identification of elder mistreatment by oral-health professionals as well as protocols for reporting are not well established. In addition, entities such as the Public Health Agency of Canada have begun changing the scope from “dental professionals” to “oral-health professionals” to capture the important role this range of front-line professionals plays. A scoping review was completed to gain an in-depth understanding of the role of oral-health professionals with respect to elder mistreatment, and as crucial resources in community settings. Ten peer-reviewed and grey literature databases were searched for empirical studies published after 2000. This synthesis review analyzes approaches that oral-health professionals may utilize to identify different types of elder mistreatment and ensure their client’s safety moving forward (i.e., duty to report). Findings suggest that oral-health professionals equipped with appropriate education, training and awareness can be key in early detection of elder mistreatment. This merits further research, policy and practice attention to the role of oral-health professionals intervening in cases of elder mistreatment.

SES TRAJECTORIES, RECESSION HARDSHIPS, AND DAILY WELL-BEING AMONG ADULTS IN THE UNITED STATES

A. Surachman, D. Almeida, *The Pennsylvania State University, University Park, Pennsylvania*

Objectives. To examine how life-course trajectories of socioeconomic status (SES) and the experience of hardships during recession predict daily well-being across adulthood.

Methods. Data from the baseline survey and the daily diary study of the Midlife in the United States (MIDUS) Refresher study were combined, resulting in 782 participants (55.6% female, M age = 47.91 y.o.) who reported on 5,849 days of information including daily stressors and daily well-being. Participants’ childhood SES was combined with their formal educational attainment and adult SES, resulting in five SES trajectories: stable low, downwardly mobile, upwardly mobile, stable high, and mixed (no clear patterns). In addition, the recession hardships included job, home, and financial impacts of the economic downturn on individuals. The associations among SES trajectories, recession hardships, and daily well-being was analyzed using multilevel modeling.

Results. Participants in the stable low and downwardly mobile groups, but not in the upwardly mobile group, significantly reported a higher level of recession hardships, daily negative affect, and daily physical symptoms compared to participants in the stable high group. Higher levels of recession hardships were also associated with worse daily well-being. The impact of SES trajectories and recession hardships on daily physical symptoms was stronger among women, while their association with daily negative affect was stronger among older participants.

Discussion. Upward mobility, especially through the attainment of a better education, is the key to alleviating the negative impact of childhood socioeconomic disadvantage on later well-being, particularly during and post-recession.

MENTAL HEALTH PROFILES OF DEMENTIA SUBTYPES IN OLDER VETERANS

A.X. Lai^{1,2,3}, A.R. Kaup^{1,3}, A.L. Byers^{1,3}, 1. *R&D, San Francisco VA Medical Center, San Francisco, California*, 2. *University of California, Berkeley, Berkeley, California*, 3. *University of California, San Francisco, San Francisco, California*

Little is known about whether specific mental health issues are more prevalent in certain dementia subtypes. This study examined psychiatric disorders and suicidal behavior among older veterans with different dementia subtypes. The sample included 4,951,919 older veterans (≥ 50 years) who used Veterans Health Administration healthcare services. Data were from the National Patient Care Database and National Suicide Prevention and Application Network for fiscal years 2012–2013. International Classification of Diseases, 9th Edition codes were used to identify psychiatric diagnoses and dementia subtypes, and Pearson's chi-square tests were used to determine prevalence of mental health conditions among dementia subtypes. Among older veterans, 0.03% were diagnosed with frontotemporal, 0.52% with vascular, 0.66% with Alzheimer's, 0.08% with Lewy body, 0.30% with senile, and 3.45% with not otherwise specified dementia. Older veterans with any dementia had higher prevalence of mood and anxiety disorders and suicidal behavior than those without dementia ($p < .001$). Specifically, those with frontotemporal and vascular dementia had the highest rates of major depression (13.04%, 10.94%), post-traumatic stress disorder (15.11%, 13.17%), and suicidal behavior (0.36%, 0.21%), whereas those with Alzheimer's had the lowest rates of these disorders ($< 8\%$, $p < .001$) and suicidal behavior (0.07%, $p < .001$). Furthermore, older veterans with frontotemporal and vascular dementia had the highest prevalence of comorbid (11.05%, 10.10%), and ≥ 3 multiple (10.41%, 6.83%) mental health issues, while those with Alzheimer's had the lowest prevalence of these issues ($< 5\%$, $p < .001$). Specific mental health issues are more prevalent in certain dementia subtypes, and likely increase the complexity of treating patients with these subtypes.

THE ASSOCIATION BETWEEN COGNITIVE IMPAIRMENT AND CHANGES IN PATTERNS OF ACTIVITY ENGAGEMENT

T. Amano, S. Park, N.L. Morrow-Howell, *Washington University in St. Louis, St. Louis, Missouri*

Previous studies have shown that the overall pattern of engagement in various activities is associated with cognitive health in later life. To date, little evidence exists to what extent change in cognitive function may affect changes in activity engagement patterns over time. This study investigated the longitudinal patterns of social activities among older adults and examined whether, and to what extent, changes in cognitive function influence the transition patterns. Data from the 2008 and 2012 Health and Retirement Study were used. A total of 2,987 participants aged 65 or older were included in analyses. Latent transition analysis and multinomial

logistic regression analysis were used. Cross-sectional profile analysis identified High Active, Active Leisure, Passive Leisure, and Low Active groups in each wave of the study. Longitudinal profile analysis derived four transition patterns: three groups in three Stayer, remain high, remain moderate, and remain low and one Changer group: active to less active group. Multinomial logistic regression analysis showed that people who developed cognitive impairment were more likely to transition as Changer compared to remain high or remain moderate. This study adds to the extremely limited empirical evidence about stability and dynamics of later year social engagement: our findings showed that majority of the sample belonged to Stayers (87.4%) and subgroup (12.6%) belonged to Changer. Importantly, those who developed cognitive impairment were at risk of becoming disengaged in various activities, even in relatively short periods of time. These empirical findings add to the importance of identifying older adults with declining cognitive function.

EVALUATION OF A RELATIONSHIP-CENTRED MEALTIME EDUCATION INTERVENTION FOR CANADIAN LONG-TERM CARE

S. Wu¹, H.H. Keller^{1,2}, H. Dunn², S. Iuglio¹, V. Vucea¹, J.M. Morrison¹, 1. *Kinesiology, University of Waterloo, Waterloo, Ontario, Canada*, 2. *Schlegel-UW Research Institute for Aging, Waterloo, Ontario, Canada*

Mealtimes are an important aspect of quality of life for residents in long-term care (LTC), yet little attention has been directed to improving the quality of relationships between care staff and residents or the physical dining environment. C.H.O.I.C.E. is a multi-component (i.e., education, training, leadership, communication) intervention to improve relationship-centred care (RCC) and overall mealtime experience for residents. This study used the Mealtime Scan (MTS), a comprehensive and reliable tool, to evaluate the potential of C.H.O.I.C.E. to improve physical, social and RCC mealtime practices over time. C.H.O.I.C.E. was implemented (April–November 2016) within two units of a LTC home in Southern Ontario, Canada. Data were collected by two trained assessors (one per unit) at baseline, 8, 16, and 24 weeks (5 mealtime observations per assessor per time point). Linear regression analysis determined the association of time, unit, and time*unit interaction with 4 MTS summary scales (physical or social environment, RCC, overall atmosphere; 8-point scale). Units differed on number of residents in the dining room at meals (mean=22 \pm 2 vs. 26 \pm 2; $p < .01$), but not number of staff (mean=5 \pm 1). Each global assessment measure, with the exception of RCC, was found to improve with time: physical environment [$F(3,36)=3.7$, $p \leq 0.05$]; social environment [$F(3,36)=3.6$, $p \leq 0.05$]; atmosphere [$F(3,36)=4.8$, $p \leq 0.01$]. An interaction between time and unit was found for the association with social environment, and with overall atmosphere. C.H.O.I.C.E. improved several aspects of mealtime experience in LTC. Results highlight the potential for change, but also the varying response at unit level likely due to resident-staff mix and team dynamics.

THE RELATIONSHIP OF EMPLOYMENT AND HOUSEHOLD AND NON-HOUSEHOLD CAREGIVING

I. Sanidad¹, S. Vasireddy², L.H. Nitz³, 1. *University of Hawaii Manoa Sociology Department, Honolulu, Hawaii*,

2. *University of Hawaii Manoa Economics Department, Honolulu, Hawaii*, 3. *University of Hawaii Manoa Political Science Department, Honolulu, Hawaii*

This research examines the relationship between caregiving for elders, partitioned by place of residence, and being employed. Recent legislation in Hawaii (SB534 SD1) directed toward supporting working caregivers inspires this research project. Caregiving is an intensive activity that can affect not only physical and mental health but financial health as well. If caregiving activities lead to early retirement from the workforce then the financial effects go beyond immediate fiscal needs and can lead to the caregiver's own retirement funds and Social Security benefits to be reduced. Data (n=97,327) come from five years, 2011–2015, of the American Time Use Survey (ATUS), a U.S. national household survey conducted on a subset of the monthly Current Population Survey (CPS). The ATUS is sponsored by the Bureau of Labor Statistics and conducted by the U.S. Census Bureau. Employment is examined using logistic regression. Care time is examined by total time spent caregiving then partitioned into care time given to household members and care time given to non-household members. Care is further examined by count of elderly care receivers also partitioned by whether the care receivers live in the household of the caregiver. Results indicate that caregiving is associated with not being employed but there is a difference between caregiving for household members and non-household members. Caring for household members is more strongly related to unemployment than caring for non-household members.

THE PATTERN OF GENDER ROLE ATTITUDE AND MARITAL QUALITY AMONG MIDDLE-AGED KOREANS

H. Park, H. Jun, S. Joo, *Child and Family Studies, Yonsei University, Seoul, Korea (the Republic of)*

Although gender role attitude is a multidimensional phenomenon, only a limited number of studies has been directed at understanding its diversity stereoscopically in terms of family studies. Therefore, the aim of this study was to identify patterns of gender role attitude among middle-aged Koreans and to investigate the differences on marital quality between patterns. For the analysis, the Third National Survey of Korean Families was utilized and married individuals aged 40 to 59 were analyzed (N=3,704). Using Mplus 7.3, a latent profile analysis (LPA) was adopted to identify latent profiles of gender role attitude. Then, using SPSS 23, the analysis of covariance (ANCOVA) with post-hoc tests was used to analyze the differences on both marital satisfaction and marital conflict between patterns. A latent profile analysis of self-reported gender role attitudes identified three such patterns: the most egalitarian (33%), the modest egalitarian (48%), and the least egalitarian (19%). The classes resulting from the LPA were significantly related to marital satisfaction but not to marital conflict; those individuals with the most egalitarian gender role attitude pattern reported higher levels of marital satisfaction than those individuals with the least egalitarian gender role attitude pattern. The results of this study imply that more egalitarian gender role attitude contributes to increasing marital satisfaction but not decreasing marital conflict and that, its findings may be useful in the

field of marriage and family therapy to develop educational programs that seek to improve marital satisfaction in midlife.

INSIGHTS INTO IMPLEMENTING A RELATIONSHIP-CENTRED MEALTIME INTERVENTION FOR CANADIAN LONG-TERM CARE

S. Wu¹, H.H. Keller^{1,2}, H. Dunn², S. Iuglio¹, V. Vucea¹, J.M. Morrison¹, 1. *Kinesiology, University of Waterloo, Waterloo, Ontario, Canada*, 2. *Schlegel-UW Research Institute for Aging, Waterloo, Ontario, Canada*

Mealtimes are an important aspect of quality of life for residents in long-term care (LTC). Interventions aimed at improving mealtimes often give little attention to the quality of relationships between care staff and residents, and are designed with a single-strategy approach. C.H.O.I.C.E. is a multi-component (i.e., education, training, leadership, communication) intervention to improve relationship-centred care (RCC) and overall mealtime experience for residents in LTC. The current study evaluates the implementation of a proof-of-concept relationship-centred mealtime intervention through understanding the perspectives of participating LTC management and care staff. C.H.O.I.C.E. was implemented (April–November 2016) within two units of a LTC home in Southern Ontario, Canada. Data were collected post-intervention using staff and management key informant semi-structured interviews (n=9), which focused on mealtime changes, intervention components, implementation strategies, and program sustainability. Data was analyzed using thematic analysis. Preliminary findings provide several insights into the program and the implementation process: i) Knowing the context and culture to meet staff and resident needs; ii) Getting everyone on board, including management; iii) Keeping communication lines open throughout the process; iv) Sharing responsibility and accountability for mealtime goals and challenges; v) Empowering and supporting staff's creative mealtime initiatives. Participants identified multiple benefits from the program, most notably an enhanced appreciation for the importance of meals and an increase in meaningful socialization with residents. Our research illustrates the value of C.H.O.I.C.E. and its capacity to improve RCC and residents' mealtime experiences. Findings will inform the next phase of program development.

HOW STEREOTYPE THREAT MIGHT EXPLAIN STABILITY AND DEFICITS IN OLDER ADULTS' PROSPECTIVE MEMORY

S. Zuber¹, A. Ihle², A. Blum¹, O. Desrichard¹, M. Kliegel¹, 1. *Psychology, University of Geneva, Geneva, Geneva, Switzerland*, 2. *Center for the Interdisciplinary Study of Gerontology and Vulnerability, Geneva, Switzerland*

Prospective memory (PM; ones capacity to perform a planned action after a certain delay, e.g. taking ones medication at specific times) is an important proxy for autonomy and well-being in old age. The majority of previous studies observed age-deficits in PM which have so far largely been associated to the decline of cognitive resources in older adults. In the current study we suggest a novel, more social-psychological perspective on this topic. Specifically, sixty younger and sixty older adults performed two PM tasks. Half of the participants received instructions emphasizing the memory component of the tasks (i.e., high stereotype threat

for older adults) whereas the other half was instructed that the tasks evaluated their reading-ability (i.e., low stereotype threat). Results show (1) that older adults' PM performance was worse than younger adults' only in the stereotype condition ($U = 302.00$, $p < .05$, $d = .54$), and (2) that this effect was limited to the PM task that strongly relied on executive guided processes ($U = 225.50$, $p < .05$, $d = .60$).

In sum, the current findings illustrate for the first time that the PM deficits commonly observed in older adults might in fact be the result of age-related stereotypes which can – implicitly and involuntarily – be induced by practitioners. Thus, the present study has significant conceptual as well as practical implications, indicating potential age-stability of this crucial everyday function and highlighting the importance of carefully choosing their wording when practitioners assess older adults' abilities.

DOES COHABITATING FAMILIES' INVOLVEMENT AFFECT DEPRESSION AMONG COMMUNITY-DWELLING OLDER ADULTS?

S. Yamazaki¹, S. Yasumura², 1. *Bunkyo Gakuin University, Saitama, Japan*, 2. *Fukushima Medical University, Fukushima, Japan*

We used paired data of older adults and their cohabitating family members to examine whether daily involvement of and mental health of family members would affect emergence of depressive symptoms among community-dwelling older adults 1.5 years later. The initial survey was conducted with 1,229 people aged 70+ without ADL disability and their cohabitating family members. The questions for the older adults included their age, sex, education, depression (CES-D), being alone during the day, social support, ageist attitudes from family members, mobility, and IADL. The questions for families included their age, sex, ADL, relation to the older adult, and mental health. A follow-up survey was conducted 1.5 years later. The authors analyzed 460 pairs who had answered all the questions. Among the older respondents, 205 (59.2%) were female, and their mean age was 77.7 ± 5.8 . Regarding their families, 194 (56.1%) were female, their mean age was 59.6 ± 12.4 , and 244 (70.4%) were children. We defined emergence of depressive symptoms at the follow-up survey as the dependent variable, conducted logistic regression analysis, and found the following significant independent variables: depressive symptoms of the family (OR=2.48, 95%CI 1.01–6.28), ageist attitudes from the family (OR=1.16, 95%CI 1.00–7.23), emotional support from the family (OR=0.50, 95%CI 0.33–0.77), and being alone during the day (OR=2.87, 95%CI 1.14–7.23). This study found that cohabitating family members' ageist attitudes in daily living, being alone during the day despite cohabitation with families, and depressive symptoms of families affect emergence of depressive symptoms among older adults.

SPORTS GROUP PARTICIPATION REDUCES THE ONSET OF DEMENTIA AMONG HIGH-RISK OLDER ADULTS

T. Saito-Kokusho¹, T. Takeda², T. Ojima³, M. Saito⁴, C. Murata¹, H. Hirai⁵, K. Suzuki⁶, K. Kondo^{7,1}, 1. *Department of Social Science, Natl Center for Geriatrics and Gerontology (NCGG), Obu, Aichi, Japan*, 2. *Seijoh*

University, Tokai, Japan, 3. *Hamamatsu University School of Medicine, Hamamatsu, Japan*, 4. *Nihon Fukushi University, Nagoya, Japan*, 5. *University of Yamanashi, Kofu, Japan*, 6. *Aichi Gakuin University, Nisshin, Japan*, 7. *Chiba University, Chiba, Japan*

Social participation is known to protect cognitive function in older adults; however, it remains unclear whether it delays the onset of dementia, especially among those already at a high-risk. This study examined the association between the contents of group participation and onset of dementia among cognitively high-risk and healthy older adults.

Data were obtained from the Aichi Gerontological Evaluation Study project's 9.4 year cohort dataset. Respondents were functionally independent adults aged ≥ 65 years. High-risk and healthy groups were selected based on the 15-point risk score for dementia onset, which Takeda and colleagues (2016) developed and validated; 1018 people with scores ≥ 6 and 2395 people with scores of 0 or 1 were selected as the high-risk and healthy groups respectively. Eight types of community groups were assessed and examined in relation to the onset of dementia.

A multivariate Cox regression model revealed that those participating in a sports group were less prone to the onset of dementia (hazard ratio, HR: 0.53; 95% confidence intervals, 95% CI: 0.30, 0.94) in the high-risk group compared to the healthy group (HR: 0.93; 95% CI: 0.60, 1.43). Interaction terms of sports group participation by the risk score of the groups showed a marginal effect modification ($p < .098$), indicating that the effect of sports group participation was stronger in the high-risk group.

These findings suggest the importance of sports group participation on the onset of dementia, particularly in the high-risk group. Further studies should examine causal relationships among these variables.

DEVELOPING SUPPORT SERVICES FOR THE ELDERLY UNDER LONG-TERM CARE INSURANCE IN JAPAN

Y. Someya^{1,2}, 1. *Social Welfare, The Graduate School of Seirei Christopher University, Urayasu, Chiba, Japan*, 2. *Institute of Gerontology, University Putra Malaysia, Serdang, Serdang, Malaysia*

This research investigates daily life support and dependency prevention services for elderly people not covered by the Long-term Care Insurance (LTCI). As these services are essential for sustaining community living, many agencies try to develop them in the market.

The Min-kai-kyo agency, which enhances elderly care services, conducted this research starting in November 2016. Questionnaires were faxed to 1,927 service agencies, profit and non-profit, from November 14 to December 22, 2016. A total of 225 agencies (11.7%) replied and data analysis started soon after.

Daily life support services include the following: monitoring the needs of the elderly through home visits, delivering meals, shopping, providing transportation, senior housing, exercise classes, cafe salon, etc.

Major outcomes: (1) 9.2% of agencies provided one of these services before the year 2000 when the LTCI started; 36.9% of them started after 2012. (2) The reasons cited for providing these services include: meeting future service

needs by the LTCI (37.0%); developing services in the market (28.6%); supporting elderly in the community (22.8%). (3) The issues encountered in starting these services include: labor shortage (72.6%, M.A); difficulties in making a profit (67.3%); and challenges in securing adequate investment to expand (36.2%). (4) 29.6 % of agencies are successful businesses, but 32.3 % of them are in the red. However, 41.1 % of them will maintain services and 33.5 % will expand services.

In summary, many agencies try to provide these services to meet the needs of the communities and/or aiming for future business under LTCI.

FINANCIAL FRAUDS AND THE HEALTH OF MIDDLE-AGED AND OLDER ADULTS: THE CASE OF SPAIN

M. Zunzunegui^{1,2}, E. Belanger³, J. Ribera-Casado⁴, F. Zunzunegui², F.P. Bland¹, 1. *Universite de Montreal, Montreal, Quebec, Canada*, 2. *Finanzas y Salud, Madrid, Spain*, 3. *Brown University, Providence, Rhode Island*, 4. *Hospital Clinico de San Carlos, Madrid, Spain*

Background: Globally, financial frauds cause loss of lifetime savings to millions of small savers. Whether financial frauds have harmful effects on health has not yet been explored. Our objective was to examine whether fraudulent behaviors by financial institutions are associated with physical and mental health problems in affected populations, comparing with the health of the general population to which they belong.

Methods: Pilot study (n=188) conducted in 2015 in the central region of Spain by recruiting subjects affected by two major types of frauds (preferred shares and foreign currency mortgages) using venue-based sampling. Information about monetary value of fraud, dates for awareness of fraud, legal claim and financial compensation were collected. Comparisons of means and prevalence of physical and mental health indicators, sleep and quality of life were carried out between groups by type of fraud and the 2011–2012 National Health Survey.

Results: In this conventional sample, victims of financial fraud had worse health, more sleep problems and worse quality of life than comparable populations of similar age. Those who had received financial compensation for lost savings in preferred shares had significantly better health and quality of life than those who had not been compensated and those who contracted foreign currency mortgages.

Conclusion: This pilot research suggests harmful effects of financial frauds on the health of those affected. Further research could examine the mechanisms through which financial frauds impact public health. If these pilot results are confirmed, psychological and medical assistance should be provided, in addition to financial compensation.

MUSIC AND MEMORY: UPDATES FROM AN INNOVATIVE COMMUNITY-LEVEL INTERVENTION FOR PEOPLE WITH AD/DR

D.W. Coon¹, M. Cortes¹, M. McCarthy¹, R. Rio¹, V. Bontrager², M. Todd¹, R. Montague¹, M. Burlison¹, 1. *College of Nursing & Health Innovation, Arizona State University, Phoenix, Arizona*, 2. *Phoenix Symphony, Phoenix, Arizona*

This presentation expands upon initial findings (changes in quality of life indicators) from an innovative community-level, music-based intervention that holds policy implications for residents with dementia residing in long-term care communities. Teams of professional symphony musicians and music therapists delivered this interdisciplinary (music, music therapy, nursing, and behavioral science) intervention through 7 music-based events across 6 weeks. Nurse raters evaluated resident affect before and after each event while symphony musicians, facility staff, and family caregivers completed similar self-ratings. Participants also provided saliva samples to investigate the impact on biomarkers of stress (salivary alpha-amylase and cortisol). Results support the intervention in terms of significant changes in participant mood ratings and in behavioral activation, as measured by salivary alpha-amylase. A sub-study measuring salivary cortisol supported the ratings, suggesting that morning music events may have enabled residents to better regulate their stress responses around an afternoon stressor (bathing). Nurses also rated the following environmental factors significantly more positively on evenings when morning music events occurred versus those without music events: levels of verbal/physical disruption at change of shift and dinnertime; resident cooperation during evening care; overall mood of the unit; and, number of critical events including falls, acute illness, deaths, staff shortages. The intervention's acceptability and perceived benefit were also rated very highly. Results provided further evidence for the project's conceptual model that integrated three key parameters (receptive to active; observation to relationship; and planned to improvisation) by bridging science and practice and emphasizing the importance of community-level music-based interventions in long-term care.

COMPARISON OF PHYSICAL FUNCTION IN DAY CARE AND HOME CARE SETTINGS AMONG OLDER ADULTS WITH DEMENTIA

J. Chung¹, T. Lee², E. Yim³, H. Choi², 1. *University of New Mexico, Albuquerque, New Mexico*, 2. *Yonsei University College of Nursing, Seoul, Korea (the Republic of)*, 3. *Daegu Health College, Daegu, Korea (the Republic of)*

Despite increasing enrollment in long-term care (LTC) insurance in Korea, it is not known whether it has improved patient outcomes in different settings. The aim of this study was to compare physical function among older individuals with dementia in day care (DC) with those in home care (HC) settings. A retrospective, matched cohort study design was adopted using the LTC insurance data set from the National Health Insurance Service in Korea. A total of 7,822 older adults with dementia who received either DC or HC consistently for 1 year were identified. Higher scores of activities of daily living (ADLs) indicate a lower level of physical function. Paired samples t tests with a propensity-score-matched cohort were conducted to examine the relationship between changes in ADLs and LTC service type. The final matched sample included 416 individuals in each group. There was no significant difference in baseline ADLs between the two groups in the matched cohort ($p = .06$). ADL scores after 1 year were significantly lower for individuals in DC (22.4 ± 5.1) than for those in HC (23.3 ± 2.8) ($p < .05$). The score had increased by 1.61 for DC and 2.84 for

HC, indicating that there was less deterioration in physical function in the DC group than in the HC group ($p < .001$). Physical function of older adults with dementia could vary according to the LTC service type, and DC is more effective than HC for delaying the deterioration of ADLs.

SOCIAL CONNECTIONS MEDIATE THE ASSOCIATION BETWEEN FRAILTY AND MEANING IN LIFE FOR OLDER PEOPLE

A. Chau, Y. Fang, A. Wong, R. Yu, J. Woo, *CUHK Jockey Club Institute of Ageing, The Chinese University of Hong Kong, Hong Kong, Hong Kong*

Meaning in life (MIL) is important for psychological well-being, especially among older people. While much evidence showed that frailty has negative impacts on general adjustment and social functioning, little is known about the impact of frailty on MIL in particular. In this study, we examined the effect of frailty on MIL, and the mediating role of social connections in this association. A representative sample of 773 Hong Kong Chinese aged 60 and above was interviewed via a telephone survey. Frailty status and MIL were assessed using the FRAIL scale and the question “Do you feel your life is meaningful?” respectively. Social connections were assessed using frequency of social contact and loneliness. Compared to robust older people, frail and pre-frail older people had lower MIL after controlling for demographics (pre-frail: $\beta = -0.33$, $p < .001$; frail: $\beta = -0.58$, $p < .001$). These two groups also reported less frequent social contact and higher loneliness ($ps < .05$). Multiple mediation model revealed a significant indirect effect of frailty on MIL through social contact (pre-frail: -0.03 , 95% CI $[-0.07, -0.01]$; frail: -0.06 , 95% CI $[-0.12, -0.01]$) and loneliness (pre-frail: -0.11 , 95% CI $[-0.18, -0.07]$; frail: -0.22 , 95% CI $[-0.32, -0.14]$), indicating that frailty decreases MIL through reducing frequency of social contact and increasing loneliness among older people. These findings suggested that social contact and loneliness contribute to older people’s MIL and that interventions can target these two aspects of social connections to improve MIL in pre-frail and frail older people.

TRANSITIONS ACROSS COGNITIVE STATES AMONG OLDER ADULTS AND EDUCATION: A MULTI-STATE SURVIVAL MODEL

A. Robitaille¹, A. Van den Hout², R.J. Machado², I. Cukic³, A. Koval¹, J. Rijnhart⁴, J. Skoog⁵, G. Muniz³, 1. *University of Victoria, Markham, Ontario, Canada*, 2. *University College London, London, United Kingdom*, 3. *University of Edinburgh, Edinburgh, United Kingdom*, 4. *VU University Medical Center, Amsterdam, Netherlands*, 5. *University of Gothenburg, Gothenburg, Sweden*

This study examines the role of educational attainment on transitions in later life between cognitive states (i.e., normal cognitive functioning, mild cognitive impairment, dementia) and mortality and life-expectancies. Analysis of six international longitudinal studies was performed using a coordinated approach. Multistate survival models were used to estimate the transition patterns via different cognitive states taking conditional life expectancies into account for each transition pattern. Across most studies, a higher level of education was associated with a lower risk of transitioning from intact cognitive functioning to mild cognitive impairment,

but not with any other transition. Those with higher levels of education/socioeconomic status had longer non-cognitively impaired life expectancies. Inconsistent results were found for the role of education/socioeconomic status on overall life expectancies. This study highlights the sustained importance of education in later life and that early life circumstances can delay later compromised cognitive health. This study also demonstrates the feasibility and benefit in conducting coordinated analysis across multiple longitudinal studies to validate findings.

TRIGLYCERIDES AS A MODERATOR OF ACCELERATED COGNITIVE LOSS PRIOR TO DEATH AND DEMENTIA

V. Thorvaldsson, I. Skoog, B. Johansson, *Goteborgs Universitet, Gothenburg, Sweden*

Cognitive aging is frequently characterized by accelerated loss with an onset some years before death (terminal decline) or dementia diagnosis (pre-clinical dementia). Recent evidence suggest that an elevated level of serum triglycerides may contribute to accumulation of cerebral amyloids (A β) and potentially also cognitive decline. We evaluated this issue using data from the H70 study. The sample consisted of 392 individuals, systematically selected from the general population of 70 years-olds living in Gothenburg, Sweden, born in 1901–1902, and repeatedly measured on three cognitive outcomes (i.e., speed, spatial, verbal) at ages 70, 75, 79, 81, 85, 88, 90, 92, 95, 97, 99, and 100, or until death. Triglycerides levels were derived from blood samples taken at age 70 and complete date of death was retrieved from population register. Dementia diagnosis was made according to DSM-III-R. We fitted several random change point, and polynomial, quadratic mixed effects models to the data. Our findings revealed no evidence that triglycerides levels moderate the onset of the acceleration in either the terminal or the pre-clinical dementia models. Elevated levels of triglycerides were however consistently associated with poorer cognitive performance and, against expectation, also with less steep decline. When we compared the effect sizes to results using serum total cholesterol as moderator we found that the cognitive trajectory was more strongly associated with the levels of triglycerides than total cholesterol. These findings support the claim that triglycerides have a role in cognitive aging but not to the degree that it moderates the onset of the acceleration.

LONGITUDINAL RELATIONSHIP BETWEEN WORK-FAMILY EXPERIENCES AND HEALTH AMONG OLDER WORKERS

E. Cho², T. Chen¹, 1. *Duke-NUS Medical School, Singapore, Singapore*, 2. *Nanyang Technological University, Singapore, Singapore*

Although the workforce is aging rapidly, work-family experiences among older workers are under-studied. Using five waves of data from the Health and Retirement Study, we investigated the impact of work-family experiences – work-family conflict (WFC; a form of inter-role conflict that occurs when demands from the two domains are incompatible) and work-family enhancement (WFE; experiences in one domain are improved due to experiences in another domain) – on older workers’ health. Based

on the conservation of resources theory that posits losing resources leads to negative outcomes, whereas obtaining resources yields positive outcomes, we hypothesized that WFC and WFE relate to negative and positive health among older adults, respectively. WFC that occurs when an individual has insufficient resources to deal with work and family demands indicates loss of resources; WFE that occurs when experience in one domain improves another domain signals gain of resources. Data from 4509 workers aged 55 years and older at baseline were analyzed using growth curve modeling. As predicted, greater work-to-family conflict related to poor health, while work-to-family enhancement and family-to-work enhancement were associated with better health over time, even after known predictors of health were controlled for (sex, education, race, living arrangement, marital status, income). In sum, work-family experiences are an important predictor of older workers' health, and continued monitoring of work-family experiences among older workers is warranted. Because health promotes successful aging at work and work-family experiences are potentially modifiable, the current findings are informative for policy makers and organizations that are trying to retain older employees.

“IT’S LIKE A CYBER SECURITY BLANKET”: THE UTILITY OF REMOTE MONITORING IN FAMILY DEMENTIA CARE

J.E. Gaugler, L. Mitchell, C. Peterson, S.R. Rud, A. Cowl, S. Trost, *Center on Aging, School of Nursing, University of Minnesota, Minneapolis, Minnesota*

The prevalence and considerable challenges of dementia raise concerns as to the sustainability of the United States' reliance on families to provide care to cognitively impaired relatives in the community. Experts have proposed that various technologies could substitute for or supplement family caregiving. The objective of the current study was to examine whether one of these technological approaches, remote activity monitoring (RAM), was perceived as feasible and useful for family caregivers of persons with AD/DR living at home. As part of a larger, 5-year evaluation of the efficacy of RAM, the current study utilized a parallel convergent mixed methods design (QUAL + QUAN). Thirty family caregivers of persons with dementia who have used RAM for at least 6 months were included. Empirical and open-ended data on perceptions of system acceptability and utility were examined at 6, 12, and 18 months following enrollment; correlations, thematic analysis, and a case oriented merged analysis were utilized. Overall empirical ratings of RAM utility and acceptability were moderate at 6 months. Qualitative themes identified included fit, adjustment period, benefits, and drawbacks/recommendations. The case oriented merged analysis suggested considerable patterns of adaptation to RAM over time. The mixed methods findings imply that caregivers perceived RAM as moderately useful, but also that positive adaptation to the technology took place over time. For systems such as RAM to operate effectively in home settings, human guidance and support is necessary for adaptation to take place and allow such technology to successfully support persons with dementia and their family caregivers.

DO DEMOGRAPHICS AND HEALTH STATUS EXPLAIN OLDER ADULT FALL VARIATION BY STATE?

G. Bergen, E. Burns, M.R. Stevens, E. Parker, *Centers for Disease Control and Prevention, Atlanta, Georgia*

The percent of older adult falls in 2014 ranged from 21% in Hawaii to 34% in Arkansas and fall injuries from 7% in Hawaii to 13% in Missouri. It is unknown if demographics, health conditions or the urban rural/status of residence explain the variation. This study conducted multivariable analyses to understand variation in fall and fall injury risk by area of residence.

Data from the 2014 Behavioral Risk Factor Surveillance Summary for adults aged 65 and older were analyzed. State-specific crude and adjusted risk ratios were produced for dependent variables (falls, fall injuries), and by urban/rural status controlling for demographics (e.g. age, race/ethnicity) and health conditions (e.g. depression, diabetes). Urban/rural status was determined by dichotomizing the Rural-Urban Continuum Code for the subject's county of residence.

Older adults in rural areas had a significantly higher adjusted risk of falling (RR=1.09; 95%CI=1.05–1.12) compared with those in urban areas with no significant difference for fall injury. Older adults in Alaska, Arkansas, D.C., Michigan and Maryland had a significantly higher adjusted falls risk compared to the national average. In Florida, New Jersey, and West Virginia older adults had a significantly lower adjusted risk. Reporting depression was the strongest adjusted risk for a fall (RR=1.46; 95%CI=1.40–1.52) and a fall injury (RR=1.57; 95%CI=1.45–1.69).

Information on how older adult falls vary by residence can help guide prevention strategies. Rural adults may have less access to falls screening, assessment, and treatment; this study demonstrates the need for falls prevention in rural areas.

COLLABORATIVE CREATION OF CULTURALLY APPROPRIATE DEMENTIA EDUCATION MATERIALS FOR NATIVE PEOPLE

C. Carrico¹, T. Anastasia¹, C. McKibbin¹, J. Lewis², 1. *University of Wyoming, Laramie, Wyoming*, 2. *Alzheimer's Association, Cheyenne, Wyoming*

Little is known about the prevalence of dementia among American Indians and Alaska Natives (Jervis et al., 2006). Given that diabetes is a risk factor for dementia and this condition is highly prevalent among American Indian populations, it is believed that American Indian elders, like the general population, would benefit from education to increase recognition of cognitive loss. The Wind River Reservation, home to the Northern Arapahoe and Eastern Shoshone people, is located in the central-western portion of Wyoming. The Wyoming Center on Aging in collaboration with tribal health entities embarked on a multi-step process to create culturally appropriate education materials to increase the awareness and recognition of cognitive loss among American Indians.

Methodology: The methodology for this process included a review of available dementia education materials for native people, followed by multiple focus groups and interviews with key informants to develop a rich understanding of language used by native elders about cognitive loss and to identify appropriate images.

Results: Focus groups related the need for messages to be portrayed using native imagery (stories told with animals; use of specific shapes and colors), in keeping with oral history traditions, and the importance of brief text and easily understood words, rather than lengthy narratives. Specific images related to cognitive loss were identified.

This presentation will share the results of these focus groups, examples of the education products created, as well as detailed information about the methodology utilized, which has the potential to inform the work of many working with indigenous people.

HOW ELDERLY JAPANESE MAKE A DECISION ON WHAT CARE SERVICE TO CHOOSE

T. Taga^{1,2}, S. Matsubayashi³, 1. *Waseda Univ., Tokorozawa, Japan*, 2. *NPO Center for Dementia Prevention, Tokyo, Japan*, 3. *Fuji Care Management Center, Tsurugashima, Japan*

The long-term care insurance system formally requires clients to sign their care plans in person because they are contracts between a client and a care manager. But when elderly Japanese decide what care services to choose, many of them prefer to make agreements with the involvement of family members. The author therefore questions whether elderly Japanese prefer to make decisions with their family members, and asks how much family caregivers intervened in elderlies' care-service decision-making. Interviews were conducted from December 2016 to January 2017 in cities around Tokyo. Sixteen elderly people who were using long-term care insurance services at home and fifteen family caregivers were interviewed. Half of the interviewees were mothers and daughters. The others were married, half of whom were husbands in care.

Result show that most interviewees in care routinely got agreement with their family caregivers about service plans. When family caregivers intervened in their decision-making, it was because it restricted family members' daily lives. The intervention tended to be stronger if elderlies in care were more depended on caregivers. Care managers took an informal role, by mediating between elderlies in care and family members. Disability since childhood and the care profession were excepted.

The findings suggest that care plan formats should have signature blanks for both a client and family members involved. From the perspective of sociopsychology, such Japanese decision-making is consistent with the concept of the interdependent self (Markus & Kitayama, 1991). The concept may be applicable to east and south-east Asian elderlies in care.

DOES PHYSICAL FUNCTIONING DECLINE AFTER RETIREMENT? A LONGITUDINAL INVESTIGATION FROM 2006 TO 2016

A. Szabo, J. Allen, C. Stephens, F. Alpass, *School of Psychology, Massey University, Wellington, New Zealand*

The impact of retirement on physical health is an important focus of ageing research. However, research findings are inconclusive. To understand for whom and under what conditions retirement presents health benefits, the present study investigated physical functioning pre- and post-retirement. Using 10-year longitudinal data from the New

Zealand Health, Work, & Retirement Study, multiple linear trajectories of physical functioning were estimated. Growth mixture analysis indicated three distinct trajectory profiles. Profile 1 displayed good physical functioning at baseline, which steeply declined until retirement, and continued to decline post-retirement but at a slower rate. Profile 2 was characterized by poor and declining physical functioning pre-retirement. Post-retirement, however, this group reported improvements in physical functioning. Finally, profile 3 displayed good and stable physical functioning pre-retirement and a slow decline post-retirement. Significant differences were identified across profiles in socio-demographic variables. Participants in Profile 1 had the lowest qualification level, medium SES and the highest retirement age. Profile 2 consisted of physical labourers who had a very low SES and numerous chronic illnesses. Members of Profile 3 were highly educated individuals with high SES and a professional occupation prior to retiring. Economic living standards increased post-retirement in all groups. However, the increase in Profile 2 was twice as large compared to the other two groups - an effect that could be attributed to New Zealand's universal superannuation. In sum, findings indicate that retirement is beneficial for those with poor health and limited resources. For the wealthy and healthy, retirement does not necessarily present health advantages.

A LOW PROTEIN, HIGH CARBOHYDRATE DIET ATTENUATES BRAIN AGING AND IMPROVES SPATIAL MEMORY IN MICE

D. Wahl¹, V. Cogger¹, R. de Cabo², S. Biet¹, S. Simpson¹, D.G. Le Couteur¹, 1. *Charles Perkins Centre, University of Sydney, Sydney, New South Wales, Australia*, 2. *National Institute on Aging, Baltimore, Maryland*

Major discoveries in the understanding aging biology have been made, particularly by studying calorie restriction (CR) and intermittent fasting (IF), which remain the most robust non-genetic interventions to improve healthspan and lifespan in animal models. Additionally, CR and IF attenuate symptoms of brain aging in animal models. Recent studies have shown that low-protein, high-carbohydrate (LPHC) diets are optimal for lifespan in ad libitum fed animals. Furthermore, there is evidence that branch-chained amino acids (BCAA) mediate the effects between diet, longevity, and healthspan. While a clear link between macronutrient ratios and healthspan has been ascertained, little is known about their role in brain health. Therefore, 9 cohorts of male and female mice were placed on one of 9 diets differing in protein, BCAA, and carbohydrate ratios. Two cohorts of mice were also placed on a 20% CR diet or a 20% CR diet with added BCAA. Barnes maze and novel object recognition (NOR) tests were performed at 13 and 21 months of age on the same mice in order to determine spatial and visual memory performance. Preliminary results revealed that mice consuming a 10 percent protein diet performed significantly better on spatial memory tests than the other AL groups. Initial RNA sequencing data on hippocampus revealed clear genetic expression changes among diet groups. Future work will focus on protein expression levels, immunofluorescence, and biochemical enzyme assays in order to determine the effects of macronutrient ratios on hippocampus plasticity, vasculature, and inflammation.

RESTORING YOUTHFUL CELLULAR IMMUNITY BY REJUVENATION OF AGED HEMATOPOIETIC STEM CELLS

H. Leins^{1,2,3}, M. Denking^{2,5}, R. Schirmbeck³, H. Geiger^{1,4},
 1. *Institute for Molecular Medicine, Ulm, Germany*, 2. *AGAPLESION Bethesda Clinic, Geriatric Research Unit, Ulm, Germany*, 3. *Internal Medicine I, Ulm, Germany*, 4. *Experimental Hematology and Cancer Biology, Cincinnati Children's Hospital Medical Center, Cincinnati, Ohio*, 5. *Geriatric Center Ulm/Alb-Donau, Ulm, Germany*

Aging-associated remodeling of the immune system results in its decreased functionality. Most prominent in man and mice is a significant reduction of naïve CD8 T cells in old individuals, accompanied by a decreased responsiveness to infection or vaccination. Aging of hematopoietic stem cells (HSCs) could be a crucial factor in the age-associated immune remodeling, as old HSC inefficiently produce lymphoid progenitor cells. In vitro inhibition of the Cdc42 Rho-GTPase activity in aged HSCs with the pharmacological compound CASIN led to their sustained morphological rejuvenation.

In this study, we ask if and how old HSCs directly affect the remodeling of the old immune system and whether CASIN-mediated rejuvenation of aged HSCs contributes to restoring the functionality of an aged immune system. To analyze this, young, old and rejuvenated old HSCs (isolated from immune-competent young or old B6.SJL mice) were transplanted into T- and B- cell deficient young RAG1^{-/-} mice. Three months after transplantation, the immune system developed from young and CASIN-treated old HSCs was comparable to a youthful immune system, whereas old HSCs reconstituted an aged-like immune system as is indicated e.g., by appropriate proportions of naïve CD8⁺ T or regulatory Foxp3⁺ CD4⁺ Treg cells. Most interestingly, the immune system developed from CASIN-treated old, but not from old HSCs efficiently respond to vaccination, thus we could restore de novo priming of HBV-core-specific effector CD8⁺ T cell responses. Rejuvenation of old HSCs is therefore an attractive strategy to manipulate the age-associated remodeling of the immune system and to restore its immune competence.

EXACERBATED AGE-RELATED OBESITY IS TEMPERED BY RENIN ANGIOTENSIN SYSTEM

E. Bruce, C.S. Carter, Y. Sakarya, H.Z. Toklu, D. Morgan, P.J. Scarpace, N. Tumer, *University of Florida, Gainesville, Florida*

Diet-induced obesity is exacerbated in senescent compared with young rats in terms of both high-fat (HF) induced weight gain and increased food consumption resulting in metabolic abnormalities, contributing to multiple age-related diseases (diabetes, cardiovascular dysfunction, hypertension). We previously reported that activation of angiotensin converting enzyme-2 (ACE2), via diminazene aceturate (DIZE) reduces body weight in HF-fed young rats. We hypothesized that DIZE would temper or prevent the exacerbated diet-induced obesity observed in 24-month HF-fed F344xBN male rats. All senescent rats were HF-fed (60%) for 10 days, during which they consumed two-fold greater kcal and gained 48 ± 4g relative to baseline. Rats were then given 7.5 mg/kg/day DIZE s.c. or vehicle (n=6/group) for 26 days. DIZE reduced cumulative food consumption by 21% and

body weight by 41 ± 13 g compared to senescent controls over the treatment period. Adiposity (TDNMR and tissue weight) was diminished by 22%, whereas brown adipose and tibialis anterior (TA) tissue weights were unchanged. In summary, DIZE treatment resulted in a significant reduction in age-related diet-induced obesity in HF-fed senescent rats with no noticeable adverse effects. Our data suggest that DIZE has potential in the treatment of age-related diet-induced obesity without negatively impacting skeletal muscle mass, an additional important outcome for preserving metabolic function. Future studies may provide insight as to the mechanisms of these effects, potentially targeting ACE2-mediated increases in angiotensin (1–7) acting through the Mas receptor. This is a known pathway for reducing inflammation, oxidative damage, mitochondrial function, all essential elements that contribute to age-related metabolic diseases.

GENDER DIFFERENCES IN PHYTOESTROGEN INTAKE AND SPEED OF PROCESSING PERFORMANCE IN OLDER ADULTS

J. Alwerdt, M. Sliwinski, A.D. Patterson, *The Pennsylvania State University, University City, Pennsylvania*

Phytoestrogen consumption mimics estrogen in the body, albeit to a much smaller scale, and therefore represent a potential dietary intervention to supplement estrogen loss or hormonal changes. Additionally, studies have reported that phytoestrogens may benefit cognitive health, although this may differ among males and females in older adults due to differences in absorption, hormones, and age-related changes. In the current study, urinary phytoestrogen concentrations (covariate-adjusted standardized for urinary creatinine) and gender were used as predictors to examine differences in relation to speed of processing (SOP) measured by the Digit Symbol Substitution Test (DSS). Participants were drawn from The National Health and Nutrition Examination Survey (NHANES 1999–2002) and consisted of 354 individuals ranging from 65 to 85 years old. A multiple regression analysis included covariates; age, BMI, race, education, smoking, socioeconomic status, and urinary creatinine. Among the individual phytoestrogens, genistein demonstrated significant gender differences relating to SOP. Females scored higher on the DSS with increased amounts of genistein while demonstrating the opposite for males. Interestingly, for the overall lignan predictor, higher lignans were associated with better SOP performance in males but lower SOP performance in females. Overall, females scored higher on the DSS compared to males regardless of the number of phytoestrogens. Results suggest that there are significant gender differences in both the predictors of genistein and lignan consumption. Both yielded different associations demonstrating the potential impact that specific phytoestrogens may have on cognitive aging depending on gender. To become a viable intervention, further research on these gender differences are needed.

A NOVEL FOOD CONSTITUENT POTENTIALLY MITIGATES INFLAMMATION IN PHYSIOLOGICALLY AGED MICE

M. Maruyama^{1,2}, K. Jounai^{3,1,4}, A. Sakamoto¹, Y. Morita^{3,1}, T. Kirisako^{3,1}, T. Matsuda¹, D. Fujiwara³, 1. *National Center for Geriatrics and Gerontology, Obu, Japan*, 2. *Nagoya*

University Graduate School of Medicine, Nagoya, Japan, 3. Kirin Co. Ltd., Yokohama, Japan, 4. Koiwai Dairy Products Co. Ltd., Tokyo, Japan

Defective immune functions are key triggers of incidence and prevalence of age-related diseases, including infectious diseases and tumors. Previous works have reported that some food materials or constituents, for instance, prebiotics and probiotics, can improve immune defects; however, mechanistic linkages remain poorly understood. In this study, we demonstrate that our novel food constituent X may mitigate the age-related inflammatory phenotypes in various tissues, which is probably associated with the serum levels of pro-inflammatory cytokines. C57BL/6 mice at the ages of 16 (n = 45 mice) or 11 months (n = 20) were used as physiologically aged mice. The serum levels of pro-inflammatory cytokines, including interleukin-1 β and interleukin-6, in aged mice were higher than those in 1-month-old young mice (n = 30). Correspondingly, inflammatory phenotypes were observed in various peripheral tissues of aged mice. Interestingly, serum levels of these cytokines were reduced by oral administration of X into aged mice for 6 months, which was seemingly responsible for suppression of the age-related inflammatory phenotypes in peripheral tissues. These results suggest that some food materials or constituents may potentially mitigate the age-related physiological defects through regulation of pro-inflammatory cytokines.

4-HNE-INDUCED INNATE IMMUNE RESPONSES INFLUENCE ANTI-CARCINOGENESIS IN ROS-OVERPRODUCED MODEL MICE

T. Ishii^{1,5}, S. Asari¹, K. Sugita^{1,2}, K. Yasuda^{1,3}, Y. Yamamoto², P. Hartman⁴, N. Ishii¹, 1. Department of Molecular Life Science, Tokai University School of Medicine, Isehara, Kanagawa, Japan, 2. School of Bioscience and Biotechnology, Tokyo University of Technology, Hachioji, Tokyo, Japan, 3. Education and Research Support Center, Tokai University, Isehara, Kanagawa, Japan, 4. Department of Biology, Texas Christian University, Fort Worth, Texas, 5. Institute of Medical Sciences, Tokai University, Isehara, Kanagawa, Japan

Mitochondrial reactive oxygen species (ROS) which are mainly generated as an uncoupled consequence of electron transport cause the cellular and organismal oxidative stress. It has been previously demonstrated that the excessive mitochondrial ROS production caused by mitochondrial complex II SDHC mutation results in premature death in *C. elegans* mev-1 mutant (G71E) and *D. melanogaster* mev-1-mimic transgenic flies (I71E), and excessive apoptosis and tumorigenesis in mouse embryonic fibroblast SDHC E69 cells (V69E) (M. Tsuda, et al. BBRC 2007, T. Ishii, et al. Cancer Res. 2005, N. Ishii, et al. Nature 1998).

In humans, it has been reported that some mutations in SDHB, SDHC or SDHD often result in hereditary and/or sporadic paragangliomas, gastrointestinal stromal tumors and pheochromocytomas (T. Ishii, et al. BBA 2013). Recently, Tet-mev-1 conditional transgenic mice have been established using our uniquely developed Tet-On/Off system, which can induce the mutated SDHC (V69E) coding gene to be equally and competitively expressed compared to the endogenous wild-type SDHC gene. The Tet-mev-1 mice experienced intracellular oxidative stress by mitochondrial respiratory

chain dysfunction developed low birth weight, growth retardation, age-dependent corneal pathophysiological changes, low fertility, recurrent miscarriage and age-dependently disrupted memory consolidation with astrocyte defects (T. Ishii, et al. Mitochondrion 2011; H. Onouchi, et al. IOVS 2012; Y. Uchino, et al. PLoS ONE 2012; T. Ishii, et al. Redox Biology 2014; T. Ishii, et al. Aging Cell 2016)

Here, it has been demonstrated that lymphocyte accumulation which is chronically activated with age influences the anti-carcinogenesis of large-cell lung carcinoma with oxidative stress in Tet-mev-1 mice. In aged Tet-mev-1 mice, large-cell neoplastic cells were developed into the lymphocyte accumulation in lung. The lymphocytes which were associated with $\gamma\delta$ T cell activation leading to innate immune responses were initiated by ω -6 fatty acid peroxidation-derived 4-hydroxy-2-nonenal (4-HNE). We propose that the 4-HNE-induced innate immune responses which associate with $\gamma\delta$ T cells involved in intraepithelial lymphocytes (IELs) may initially prohibit the oxidative stress-developed carcinoma.

PHYLOGENETIC GROUPS OF ESCHERICHIA COLI TO DIAGNOSE URINARY TRACT INFECTION IN GERIATRIC POPULATION

R. Amarsy¹, D. Guéret^{2,3}, 1. *hopital Lariboisière, Paris, France*, 2. *Gériatrique Département, APHP Lariboisière Hospital, Paris, France*, 3. *IAME- UMR 1137 Faculté Médecine, Paris, France*

Discrimination between urinary tract infection and urinary colonization is a frequent and difficult problem in geriatric population. *E. coli* is the most frequently isolated pathogen in urine in this population. Of the 8 known phylogenetic groups in the species, groups B2 and D are the most virulent and more frequently responsible for extra-intestinal infections, particularly urinary tract infections. However, there is no data on the distribution of these phylo-groups in the geriatric population. We conducted a study that included clinical data from the host and the phylogenetic group of *E. coli* to find criteria to differentiate infection and colonization. All *E. coli*-positive urine analysis from patients over 75 years of age and hospitalized at the Lariboisière hospital from 15 February to 15 May 2016 were included. The virulent phylogenetic groups (B2 and D) of *E. coli* are significantly more frequent in infection than in colonization in geriatric population (Odds Ratio: 3.05 (1.44–6.86), P = 0.005). However, to the bacterial virulence is added factors of fragility of the host allowing the development of an infection, such as the presence of altered autonomy (P <0.001), falls (p <0.001), dementia (p = 0.005), malnutrition (p = 0.001) and urinary pathology (p = 0.002).

TRANSCRIPTIONAL PROFILING OF HUMAN FEMORAL MESENCHYMAL STEM CELLS IN OSTEOPOROSIS AND ADIPOGENESIS

Y. Chung, Y. Choi, *Endocrinology, Ajou University School of Medicine, Suwon, Korea (the Republic of)*

Genetic alterations are major contributing factors in the development of osteoporosis. Osteoblasts and adipocytes share a common origin, mesenchymal stem cells (MSCs), and their genetic determinants might be important in the relationship between osteoporosis and obesity. In the present study,

we aimed to isolate differentially expressed genes (DEGs) in osteoporosis and normal controls using human MSCs, and elucidate the common pathways and genes related to osteoporosis and adipogenesis. Human MSCs were obtained from the bone marrow of femurs from postmenopausal women during orthopedic surgeries. RNA sequencing (RNA-seq) was carried out using next-generation sequencing (NGS) technology. DEGs were identified using RNA-seq data. Ingenuity pathway analysis (IPA) was used to elucidate the common pathway related to osteoporosis and adipogenesis. Candidate genes for the common pathway were validated with other independent osteoporosis and obese subjects using RT-PCR (reverse transcription-polymerase chain reaction) analysis. Fifty-three DEGs were identified between postmenopausal osteoporosis patients and normal BMD controls. Most of the genetic changes were related to the differentiation of cells. The NR4A family was identified as possible common genes related to osteogenesis and adipogenesis. The expression level of the mRNA of NR4A1 was significantly higher in osteoporosis patients than in controls ($p=0.018$). The expression level of the mRNA of NR4A2 was significantly higher in obese patients than in controls ($p=0.041$). Some genetic changes in MSCs are involved in the pathophysiology of osteoporosis. The NR4A family might comprise common genes related to osteoporosis and obesity.

CHARACTERISTICS OF LATE-LIFE DEPRESSION RELATED WITH THE RISK OF INCIDENT DEMENTIA

J. Park^{1,2}, 1. *Psychiatry, Seoul National University School of Medicine, Seoul, Korea (the Republic of)*, 2. *Seoul National University Hospital, Seoul, Korea (the Republic of)*

Objectives: The incidence rates and risk factors of dementia and Alzheimer's dementia were examined, with special focus on the relationship between baseline depression and incident dementia.

Methods: The present study assessed elderly individuals who resided in a rural community in Korea. After the baseline assessment (2008), there were two schedules for the follow-up (2009 and 2013). Sociodemographics, lifestyle characteristics, and clinical factors were examined; depression was evaluated using the Geriatric Depression Scale, Short form and cognitive diagnoses were determined by a psychiatrist using the DSM-IV criteria. A Cox proportional hazard model was used to determine the risk factors for dementia and factor analysis was conducted to classify depressive symptoms.

Results: Among 751 subjects at the baseline, those who were not diagnosed with dementia at baseline ($N = 701$) were followed up with for a mean period of 5.5 years. A total of 483 subjects were assessed during this follow-up period and 40 new cases of incident dementia (16.2 per 1000 PY) were identified. Baseline depression was not related with the risk of 5-year incident dementia. However, regarding the characteristics of depression, higher persistence and severity increased the incident dementia. Also, depression accompanied with dysexecutive function and the low energy component which may imply frontal lobe dysfunction increased the incidence of dementia.

Conclusion: Different relationship between depression and dementia according to different quantitative and qualitative characteristics of late-life depression suggest that the

conversion process from depression to dementia may be the various ones, not the same one.

MODULATION OF HSF-1 LEVELS BY HIGH CHOLESTEROL AND ITS OXIDIZED PRODUCT 27-HYDROXYCHOLESTEROL

D.A. Jurivich, *University of North Dakota, GF, North Dakota*

Dietary intake may influence both aging and disease-related genes that increase Alzheimer's Disease risk. Some diets may improve cognition and people highly adherent to the Mediterranean diet experience less hippocampal atrophy over time than those less adherent. Conversely, diets rich in saturated free fatty acids (sFFA) may increase AD risk. The mechanism of fat induced neurodegeneration includes neuroinflammation blood-brain barrier (BBB) disruption, phosphorylated Tau, and proteotoxicity. Thus, diets may either promote or delay aging and AD.

We examined the expression of the longevity and stress factor, Heat shock transcription factor 1 (HSF1), in a cholesterol – fed rabbit model of AD. In this model, we found that both the mRNA levels and the protein distribution of HSF1 are significantly decreased in rabbit hippocampi relative to age matched controls. Because 27-OHC levels are elevated by hypercholesterolemia, aging and oxidative stress, we examined in vitro effects of 27-OHC on astrocytes and found dramatic reductions in HSF1 protein levels in the absence of cell death.

Collectively, our results suggest that high cholesterol diets and its oxidized metabolites such as 27-OHC negatively impact a key longevity and cell protection factor, HSF1. Dysregulation of HSF1 by cholesterol and/or its oxidative by-products appears to be at the mRNA or transcriptional level, suggesting a heretofore unknown mechanism of HSF1 regulation. Because disturbances in cholesterol metabolism, oxidative stress, and aging are all risk factors for AD, our results provide new information that disruption of HSF1 may be a key link by which these factors lead to AD progression.

ABUNDANT NON-PLEIOTROPIC AND PLEIOTROPIC ASSOCIATIONS WITH AGE-RELATED TRAITS IN A MODEST SAMPLE

Y. Loika, L. He, J. Huang, K. Arbeev, I. Culminkaya, A.I. Yashin, A. Kulminski, *Social Science Research Institute, Duke University, Durham, North Carolina*

Genome-wide association studies (GWAS) are traditionally based on principles of medical genetics. This strategy is well adapted for Mendelian disorders. Genetics of phenotypes that leave human organisms vulnerable to diseases in late life (called age-related phenotypes) is, however, more complex. The fundamental complicating factor is the elusive role of evolution in fixing molecular mechanism of these phenotypes. This complexity implies a special type of an inherent genetic heterogeneity reflecting sensitivity of genetic associations with age-related phenotypes to the life course of individuals in different environments. Here we follow a two-stage genome-wide approach that leverages this heterogeneity. This approach is demonstrated by examining non-pleiotropic and pleiotropic genetic predisposition to 24 age-related phenotypes (16 biomarkers, 7 diseases, and death) in a modest sample ($N=26,371$) from five studies (ARIC, FHS, MESA, CHS, and CARDIA) from the Candidate Gene Association

Resource. In Stage 1, we performed the traditional univariate GWAS for each of 24 phenotypes improved by leveraging information from longitudinal follow up in each study separately. In Stage 2, we used Fisher's and two omnibus tests to combine statistics from Stage 1 leveraging different types of heterogeneity. Our analyses replicated 212 SNPs in 49 loci at genome-wide level and identified 53 novel or firstly attained genome-wide significance non-pleiotropic SNPs in 49 loci and 202 pleiotropic SNPs in 154 loci in a modest sample (all loci exclude the Major Histocompatibility Complex). Our findings demonstrate benefits of more comprehensive approaches than the currently prevailing ones to gain insights into the genetics of healthspan and lifespan.

APATHY, NEUROCOGNITION AND FUNCTIONAL BRAIN CONNECTIVITY IN AMNESTIC MILD COGNITIVE IMPAIRMENT

A. Aleman, S. Tumati, T. Setiadi, F. Reesink, P. De Deyn, E. Opmeer, *University of Groningen, Groningen, Netherlands*

Amnesic mild cognitive impairment (aMCI) precedes Alzheimer's Disease (AD) and is associated with brain changes such as reduced gray matter of medial-temporal lobe areas and hypoperfusion in frontal and occipital areas. Apathy in MCI is a risk factor for more rapid conversion to AD. The cognitive and neural basis of apathy in MCI remain to be elucidated, however. Here, we investigated neurocognitive correlates using standard neuropsychological tests and functional brain connectivity using resting state BOLD fMRI.

Thirty-one patients with aMCI and 20 healthy controls (HC) were assessed with resting state fMRI. Apathy was assessed with the AES and neuropsychological assessment included memory, processing speed and executive functioning.

There were significant associations between AES and two neuropsychological measures: time to complete Stroop A ($r = .55$, $p = .002$) and performance on Digit symbol substitution ($r = -.40$, $p = .039$). There were no associations with the other cognitive measures. Moreover, apathy was related to decreased connectivity between the salience network (SN) and default mode (DMN) networks and increased connectivity between two SN components (one including mostly dorsal anterior cingulate cortex [dACC] and the other mostly the insula).

In conclusion, higher levels of apathy were associated with slower processing speed, but not with memory or executive functioning. Thus, reduced processing speed may specifically affect the ability to select, initiate and execute goal-directed behavior. The association of apathy with aberrant SN connectivity can be understood from the role of salience evaluation as an important component for goal-directed behavior.

LATE-LIFE ENALAPRIL ADMINISTRATION AFFECTS MITOCHONDRIAL BIOGENESIS IN THE HEART OF OLD RATS

A. Picca¹, V. Pesce², G. Sirago², R. Calvani¹, A. Lezza², E. Marzetti¹, *1. Department of Geriatrics, Neurosciences and Orthopedics, Catholic University of the Sacred Heart School of Medicine, Teaching Hospital "Agostino Gemelli", Rome, Italy, 2. Department of Biosciences, Biotechnologies and Biopharmaceutics, University of Bari, Bari, Italy*

Inhibition of the renin-angiotensin system has been shown to ameliorate age-related mitochondrial alterations in several rat tissues and to increase rodent lifespan. Here, we investigated the effect of late-life enalapril administration on mitochondria biogenesis, antioxidant enzymes content and mtDNA levels in rat hearts and sought to discern the effects of enalapril mediated by nitric oxide (NO) from those independent from NO signaling. Fischer 344xBrown Norway rats were randomly assigned to receive enalapril ($n=4$), the NO synthase (NOS) inhibitor NG-nitro-L-arginine methyl ester (L-NAME; $n=4$), enalapril + L-NAME ($n=4$), or placebo ($n=4$) from 24 to 27 months of age. Enalapril in combination or not with L-NAME induced a marked increase in mitochondrial DNA content. Accordingly, a higher content of mitochondrial biogenesis proteins [i.e., peroxisome proliferator-activated receptor gamma coactivator 1-alpha (PGC-1 α), and mitochondrial transcription factor A (TFAM)] and mitochondrial antioxidant enzyme superoxide dismutase 2 (SOD2) protein have been observed in the same two groups. Our data indicate that enalapril enhances mitochondrial biogenesis in the heart of aged rats as a result of a concerted modulation of NO and angiotensin II signaling. As both mtDNA content and mitochondrial biogenesis are crucial for preserving cellular respiratory capacity, and PGC-1 α is protective against ROS production and oxidative damage, our results support the hypothesis that the beneficial effect of enalapril on the heart is mediated at least partly by mitigation of oxidative stress.

INCREASED TRABECULAR AND CORTICAL BONE LOSS IN CURRENT OLDER ADULT SMOKERS: THE AGES-REYKJAVIK STUDY

E.A. Marques¹, M. Elbejjani¹, V. Gudnason², T. Lang³, G. Sigurdsson², L.J. Launer¹, G. Eiriksdottir², T. Harris¹, *1. Laboratory of Epidemiology and Population Sciences, National Institute on Aging - National Institute of Health, Bethesda, Maryland, 2. Icelandic Heart Association Research Institute, Kópavogur, Iceland, 3. Department of Radiology and Biomedical Imaging, University of California, San Francisco, California*

Previous studies have reported that smoking is associated with reduced bone mass in older adults, but no longitudinal studies have addressed the relationship of smoking behavior and compartmental measures of volumetric bone mineral density (vBMD).

This study aimed to explore the cross-sectional and longitudinal relationships of several indicators of cigarette smoking (smoking status, pack-years, age of onset and smoking cessation) with QCT-derived proximal femur bone measures (trabecular vBMD, integral vBMD and the ratio of cortical to total tissue volume (cvol/ivol)) and with subsequent change in these measures over the next five years, in a population-based cohort of 2633 older adults (55.9% women), aged 66–92 years.

In multiple linear regression adjusting for several potential confounders, current smoking was only associated with lower cvol/ivol at baseline, whereas former smoking was associated with lower trabecular vBMD, integral vBMD and cvol/ivol. Analyses of change in bone measures revealed that compared to never-smokers, current smokers had significantly greater loss of trabecular vBMD, integral vBMD and

cvol/ivol. Full-adjusted models included sex, age, education, BMI, Creatinine, high-sensitive C-Reactive Protein, coronary artery calcium score, % weight change from age 50, 25OHD, physical activity, diabetes, arthritis, and respiratory diseases. Among former smokers, longer duration since cessation was related to better bone health at baseline, especially for integral vBMD and cvol/ivol. Pack-years was associated with lower cvol/ivol.

In conclusion, smoking has a differential association with bone health assessed with QCT. Results suggest that, current smoking, but not former smoking, at older age may aggravate the rate of bone loss.

PATHWAYS ENRICHMENT AND AGE-RELATED PHENOTYPES: NON-PLEIOTROPIC SNPS VERSUS PLEIOTROPIC SNPS

I. Kulminskaya, Y. Loika, J. Huang, K. Arbeev, O. Bagley, A.I. Yashin, A. Kulminski, *Duke University, Durham, North Carolina*

Genetics of age-related diseases is complicated by the elusive role of evolution in fixing molecular mechanism of these phenotypes. This complexity implies an inherent genetic heterogeneity reflecting sensitivity of genetic associations to the life course. We used the results of a comprehensive analysis of genetic predisposition to 24 age-related phenotypes (16 biomarkers, 7 diseases, and death) in a modest sample (N=26,371) from five studies (ARIC, FHS, MESA, CHS, and CARDIA) from the Candidate Gene Association Resource, which leveraged this genetic heterogeneity. For bioinformatics analysis (IPA®) we selected 50 non-pleiotropic SNPs (mapped to 50 genes), which attained genome-wide significance with albumin in urine, and 122 pleiotropic SNPs (mapped to 99 genes), which attained genome-wide significance by combining statistics for 16 biomarkers. Five canonical pathways were genes enriched for non-pleiotropic SNPs at $pBH < 10^{-3}$ after Benjamini-Hochberg correction: Epithelial adherens junction signaling, Hepatic fibrosis, Colorectal cancer metastasis signaling, Molecular mechanisms of cancer, and STAT3 pathway. Top high-level disease categories for these genes ($pBH < 10^{-8}$) included cancer, organismal injury/abnormality, reproductive system disease, cardiovascular disease (CVD), and respiratory disease. All these categories except CVD included cancers at multiple sites. For the set of pleiotropic genes, we identified enrichment in two pathways at $pBH < 10^{-3}$: Leukocyte extravasation signaling and IL-8 signaling. Accordingly, the strongest gene enrichment ($pBH < 10^{-12}$) for the disease category was for inflammatory response. Our findings suggest that genes for highly pleiotropic SNPs are likely involved in fundamental pathways associated with regulation of inflammation as a risk factor for various chronic illnesses. Non-pleiotropic variants likely indicate disease-specific pathways.

UNDERSTANDING AGE-RELATED EFFECTS IN INTESTINAL EPITHELIUM

U.K. Kar, J. Laryea, W. Mustain, J. Mizell, M. Hauer-Jensen, D. Zhou, *Pharmaceutical Sciences, UAMS, Little Rock, Arkansas*

Ageing leads to a progressive deterioration of structure and function of all organs over the time. The progressive accumulation of senescent cells and impairment of Stem

Cells i.e. decline in their ability to maintain homeostasis is well known in aging. Intestinal homeostasis is regulated by proliferation and differentiation of cycling intestinal stem cells (ISCs). The ISCs are nested within a niche consisting of a wide variety of cell types including immune cells, mesenchymal fibroblasts & myofibroblasts, and endothelial cells. Niche-generated signals work in concert with intrinsic stem cell properties to regulate the stem cell behavior. Senescence of endothelial cells leading to impairment in vascular functionality and neo-angiogenic capability is well documented. In this study we investigated the biological changes to endothelial cells transformed to senescence by irradiation. HUVEC Cells were exposed to various doses of irradiation i.e. 2Gy to 10Gy. The induction of senescence was noted by BrdU incorporation and senescence-associated β galactosidase" (SA- β gal) staining. Induction of senescence led to upregulation of ROS level which was investigated by MitoSOX Red, peroxidized lipid sensor BODIPY and superoxide anion radicals (DHE MFI). Interestingly these senescent cells also displayed components of DNA damage response (DDR) which was revealed by γ H2AX detection assay. Our long-term goal is to investigate whether these senescent endothelial cells can affect the growth of ISCs using the Ex-Vivo 3D organoid culture and 2D co-culture methods.

INNOVATION IN PARKINSON'S DISEASE-ASSOCIATED DYSPHAGIA IN OLDER ADULTS: AN INTEGRATIVE REVIEW

C. Edwards, K. Rose, *Nursing, University of Oklahoma Health Science Center, Yukon, Oklahoma*

Parkinson's Disease (PD) is the second most common neurodegenerative disorder in the United States with aspiration pneumonia being a leading cause of hospital admission and death. Dysphagia is present in most individuals with PD and significantly increases risk of negative health outcomes, including death. The purpose of this review was to establish the state of the science regarding Parkinson's Disease-associated dysphagia (PD-D). PUBMED, MEDLINE, and CINAHL were searched through 2016 using MeSh terms "Parkinson(s)," "dysphagia," "swallowing," "deglutition," "elderly" "aged" "geriatric," "cancer," and "surgery." All primary articles written in English, involving individuals diagnosed with PD-D, and containing pathophysiology, frequency, diagnosis / assessment, treatments, or consequences were included. Articles pertaining to surgical-, medication-, intubation-, radiation-, or oncology-induced dysphagia were excluded, leaving 114 articles. Content were analyzed and divided into the following categories: dysphagia descriptive factors and pathophysiology, diagnosis and assessment, treatments, and consequences of PD-D. Within each category, findings were analyzed based on current knowledge and implications for future research. Pathophysiology of PD-D is not well understood and this limits targets for potential interventions. While the gold standard assessment of dysphagia is videofluoroscopy, no consensus regarding what the best practice assessment is available. Although there are many treatments available, skill retention and further innovation of treatments are warranted. It is generally accepted that PD-D has effects on one's physical and mental health, yet

lived experiences of those with PD-D and their caregivers are not fully understood.

GAINING INSIGHT TO THE UNDERLYING NEURAL MECHANISMS BY WHICH EXERCISE IMPROVES MOBILITY

C. Hsu^{1,3}, J. Best^{1,3}, S. Wang^{1,3}, M. Voss², R.G. Hsiung¹, M. Munkacsy³, T. Handy¹, T. Liu-Ambrose^{1,3}, 1. *Rehabilitation Science, University of British Columbia, Vancouver, British Columbia, Canada*, 2. *University of Iowa, Iowa City, Iowa*, 3. *Aging, Mobility, and Cognitive Neuroscience Lab, Vancouver, British Columbia, Canada*

Impaired mobility is a major concern for older adults and has significant consequences. While the widely accepted belief is that improved physical function underlies the effectiveness of targeted exercise training in improving mobility and reducing falls, recent evidence suggests cognitive and neural benefits gained through exercise may also play an important role in promoting mobility. However, the underlying neural mechanisms of this relationship are currently unclear. Thus, our main objective was to investigate whether six months of progressive aerobic exercise training alters frontoparietal network (FPN) connectivity during a motor task among older adults at risk for mobility disability – individuals with mild subcortical ischemic vascular cognitive impairment (SIVCI)—and whether exercise-induced changes in FPN connectivity correlate with concurrent changes in mobility. We focused on the FPN as it is involved in top-down attentional control as well as motor planning and motor execution. Participants were randomized either to usual-care (CON) or thrice-weekly aerobic training (AT). Functional magnetic resonance imaging was acquired at baseline and trial completion. At trial completion, compared with AT, CON showed significantly increased FPN connectivity strength during right finger tapping ($p < 0.05$). Across the participants, reduced FPN connectivity was associated with greater cardiovascular capacity ($p = 0.05$). In the AT group, reduced FPN connectivity was significantly associated with improved mobility performance, as measured by the Timed-Up-and-Go test ($r = 0.67$, $p = 0.02$). These results suggest progressive aerobic training may improve mobility in older adults with SIVCI via maintaining intra-network connectivity of the FPN.

PROFESSIONAL AND FAMILY CAREGIVERS' VIEWS ON INVOLUNTARY TREATMENT USE IN PEOPLE WITH DEMENTIA

A.M. Mengelers¹, M.H. Bleijlevens¹, H. Verbeek¹, E.A. Capezuti², J. Hamers¹, 1. *Maastricht University, Maastricht, Maastricht, Netherlands*, 2. *Hunter College of City University of New York, New York, New York*

The number of people with dementia (PwD) living at home is increasing rapidly and puts great emphasis on family caregivers, social support and professional home care. This can lead to situations in which caregivers provide care against the will of PwD, for example locking a door or forcing people to eat. Knowledge about attitudes towards involuntary treatment is scarce. This was the first study to investigate professional and family caregivers' attitudes towards involuntary treatment use in PwD. A cross-sectional study was conducted, in which 230 professional (physicians, nurses, case managers) and 77 family caregivers of PwD living at home completed

the Maastricht Attitude Questionnaire - Home Care. This questionnaire measures attitudes towards involuntary treatment (60 items) as well as perceptions of restrictiveness and discomfort (25 items). Involuntary treatment was divided in non-consensual care, psychotropic medication and physical restraints. Findings indicate that involuntary treatment is more accepted by family caregivers, as they held more positive attitudes towards involuntary treatment in general ($P < 0.001$), physical restraints ($P < 0.001$), psychotropic medication ($P = 0.005$) and non-consensual care ($P < 0.001$) compared with professional caregivers. Furthermore, family caregivers evaluated physical restraints and non-consensual care as less restrictive ($P < 0.001$ and $P < 0.001$ respectively) and experience less discomfort ($P < 0.001$ and $P = 0.002$ respectively) in applying these measures. Both professional and family caregivers considered physical restraints the most restrictive and experience most discomfort in applying physical restraints. Further research is needed to understand the discordant attitudes. Professional and family caregivers need to find common ground in order to reduce involuntary treatment use in home care.

GENDER DIFFERENCES IN AN IDEAL EXERCISE PARTNER FOR THE MENTAL HEALTH OF OLDER JAPANESE ADULTS

Y. Fujii¹, T. Jindo², N. Kitano², K. Fujii^{1,3}, J. Seol¹, K. Joho¹, T. Okura¹, 1. *University of Tsukuba, Tsukuba, Japan*, 2. *Physical Fitness Research Institute, Meiji Yasuda Life Foundation of Health and Welfare, Hachioji, Japan*, 3. *Ibaraki Prefectural University of Health Sciences, Ami, Japan*

Recent studies suggest an association between good mental health and exercise with others, as opposed to by oneself. However, it is unclear as to whether this association differs according to the type of exercise partner (e.g., spouse, friends, or experts).

This study aimed to investigate the relationship between the type of exercise partner and mental health in older adults.

This cross-sectional study was conducted through a mail survey on older adults living in Kasama City, Japan. Subjects were 1914 older adults (mean age: 74.2 ± 6.6 years; men: 48.4%). Depressive symptoms were assessed through the Kihon Checklist. Subjects were asked about their exercise habits (at least once a week) and the presence of an exercise partner, with the following options (multiple answers allowed) provided: by oneself, with a spouse, with same-gender friends, with opposite-gender friends, and with exercise experts. A logistic regression analysis adjusted for age, economic status, and household composition was conducted for each gender.

Exercise with opposite-gender friends (OR = 0.29) and a spouse (OR = 0.50) was significantly associated with a lower prevalence of depression among men ($P < 0.05$). For women, exercise with same-gender friends (OR = 0.55) and exercise experts (OR = 0.19) was significantly associated with a lower prevalence of depression ($P < 0.05$). Exercise by oneself was not associated with depression, regardless of gender.

These results suggest that exercise with others is related to good mental health among older adults. Moreover, there might be gender differences in terms of a preferred exercise partner.

EXAMINING PHYSICAL FUNCTIONING IN OLDER ADULTS: A COMPARISON OF TWO STRETCHING PRACTICE METHODS

K. Joho¹, T. Abe^{1,2}, J. Seol¹, Y. Fujii¹, K. Fujii^{1,3}, T. Okura¹,
1. *University of Tsukuba, Tsukuba, Japan*, 2. *Japan Society for the Promotion of Science, Tokyo, Japan*, 3. *Ibaraki Prefectural University of Health Sciences, Ami, Japan*

While the benefits of stretching are known, there remains controversy regarding the best methods of stretching practice for improving physical function in older adults. The aim of this study is to compare two stretching practices (instructed stretching practice vs. self-stretching practice using a guide at home) in terms of their effectiveness in improving physical function in older adults. Participants comprised 82 Japanese community-dwelling older adults (instructed group: n=46, 71.2±4.5 yrs; non-instructed group: n=36, 71.1±4.9 yrs). We provided a guide illustrating stretching exercises for both groups, and encouraged all participants to stretch at home. In the instructed group, we also provided a weekly 60-minute stretching class each week for nine weeks. We evaluated the following physical functions: upper and lower extremity muscle strength, static and dynamic balance, and normal and maximum walking speed and flexibility.

In our results, stretching was practiced significantly more frequently in daily life in the instructed group (6.1 days a week) than in the non-instructed group (1.1 days a week) (P<0.05). There was a significant group-by-time interaction for flexibility (P<0.05), with post-hoc analysis showing significant improvements only in the instructed group (P<0.05). We found a significant group-by-time interaction for maximum walking speed (P<0.05), with post-hoc analysis showing significant improvements in the instructed group only (P<0.05). These results suggest that it is necessary to stretch almost daily to achieve improvements in physical function over nine weeks. Additionally, we conclude that a visual demonstration with an instructor is an important addition to the stretching guide.

INPATIENT REFERRALS TO GERIATRIC CENTER: INDICATION AND OUTCOMES

J.M. Lubong, *Geriatric Center, St. Luke's Medical Center, Quezon City, Philippines*

This study aims to recognize the pattern of referrals to the Geriatric Medicine specialists. This is a descriptive cross-sectional study consisted of all admitted patients who were referred to Geriatric Medicine Specialists/geriatricians from other departments for a period of June 2013 to March 2015. The referrals were classified into geriatric co-management and geriatric evaluation. Details like socio-demographic profile, sources of referral, indication for referral and outcomes were recorded. The data was analyzed by using descriptive statistical methods. This is a descriptive cross-sectional study consisted of all admitted patients who were referred to Geriatric Medicine Specialists/geriatricians from other departments for a period of June 2013 to March 2015. The referrals were classified into geriatric co-management and geriatric evaluation. Details like socio-demographic profile, sources of referral, indication for referral and outcomes were recorded. The data was analyzed by using descriptive statistical methods. A total of 67 patients were referred to Geriatric

Medicine specialists in the Geriatric Center. The youngest referred was 67 years old while the oldest was 101 years old. 20% of the referrals were on the age of 81–85. Majority of the referrals were from the Pulmonary Department (21%) followed closely by the Cardiology Department (19.4%). The most common reason for referral was for geriatric co-management followed by geriatric evaluation using the comprehensive geriatric assessment. Majority of the conditions being managed were pneumonia followed by dementia. For the geriatric evaluation, most of the patients are being referred due to memory lapses. Almost all of the patients (94%) were discharged improved.

A NEW NON-INVASIVE AND BRIEF CVD RISK SCORE SYSTEM TO PREDICT COGNITIVE DECLINE

J. Heo, M. Tolea, J.E. Galvin, *Charles E. Schmidt College of Medicine at Florida Atlantic University, Boca Raton, Florida*

The main goal of our study was to assess the impact of a modified CAIDE risk score on cognitive performance in community-dwelling older adults. The study evaluated a multicultural population consisting of 314 participants enrolled in a cross-sectional aging study with valid measures on cognitive, physical, functional, and emotional health. The CAIDE risk score system was modified to: 1) reflect age and education levels specific to an older adult sample; 2) incorporate self-reported high cholesterol instead of total cholesterol level from blood test; and 3) use the Mini Physical Performance Test (mPPT) as a proxy measure of physical activity (mPPT:<12 inactive; ≥12 active). Using hierarchical linear regression models, 'risk' of cognitive impairment (MoCA<26) was assessed based on levels of CAIDE risk score (low, intermediate, high) using the equations reported by the authors of the CAIDE risk score. Higher modified CAIDE risk scores were significantly associated with lower MoCA score ($\beta=-0.447$, $p<0.001$) and with higher Framingham vascular risk scores ($r=0.673$, $p<0.001$). The association was robust remaining significant after controlling for significant risk factors ($\beta=-0.424$, $p=0.015$) and followed a dose-response pattern. Likelihood of cognitive impairment increased from 12.1% in the low risk group, to 35.8% in the intermediate, to 65.5% in the high-risk group. Findings suggest the utility of using the modified CAIDE risk score as an indicator of increased risk of cognitive impairment and highlight the need for brief, easy to administer, non-invasive cardiovascular risk batteries to estimate risk of future cognitive decline and dementia in later life.

IMPLEMENTATION OF MEDICAL ASSISTANCE IN DYING (MAID): SCOPING HEALTH CARE PROVIDERS' PERSPECTIVES

J. Fujioka^{1,2}, C. Klinger^{1,3}, R.M. Mirza^{1,3}, M. Sahar^{1,3}, A. Dillman^{1,3}, D. Akhtar⁵, L. Tamblin-Watts⁴, L. McDonald^{1,3}, 1. *Factor-Inwentash Faculty of Social Work, University of Toronto, Toronto, Ontario, Canada*, 2. *Dalla Lana School of Public Health, University of Toronto, Toronto, Ontario, Canada*, 3. *National Institute for the Care of the Elderly, Toronto, Ontario, Canada*, 4. *Canadian Centre for Elder Law, Toronto, Ontario, Canada*, 5. *University of British Columbia, Faculty of Medicine, Vancouver, British Columbia, Canada*

In tandem with increased life expectancy is a growing number of older adults living longer in discomfort and pain, with life-debilitating chronic or terminal illness and poor quality-of-life. With a focus on quality-of-dying and a ‘dignified death’ for older adults, medical assistance in dying (MAID) has gained widespread public and professional popularity as an end-of-life alternative, leading to legalization in several countries. However, continued debate about the necessity and limits of various healthcare professions’ involvement persists. Drawing on evidence from regions where MAID has been legalized, a scoping review was conducted to synthesize the literature on roles of diverse healthcare professionals in decision-making and implementation of MAID services for older adults. An exhaustive database search yielded 1,000+ articles. Abstracts were manually curated, with 35 studies fulfilling inclusion criteria and integrated in the final review. Synthesis and analysis of the literature led to five thematic conclusions being highlighted as relevant to older patients seeking MAID: Nurses are increasingly involved in MAID but lack role clarity in decision-making processes; mental health professionals should always be required to assess capacity and consent for MAID decision-making; physician involvement alone is insufficient to manage patient requests; conscientious objection by physicians leads to a de-medicalized framework for MAID; and guidelines/frameworks to clarify healthcare professionals’ roles in interprofessional collaboration. Findings from this review inform policy, practice and research and demonstrate urgency for a multidisciplinary approach to MAID for older adults that clearly defines scope of practice for diverse healthcare professionals to prevent legal, ethical and administrative hurdles.

COGNITIVE MEASURE MAY IDENTIFY ATROPHY IN BRAIN REGIONS ASSOCIATED WITH POSTERIOR CORTICAL ATROPHY

E. Couser¹, M. Albert², C. Pettigrew², A. Soldan², 1. *University of Maryland, Baltimore, Baltimore, Maryland*, 2. *Johns Hopkins Hospital - Department of Neurology, Baltimore, Maryland*

Posterior cortical atrophy (PCA) affects a small percentage of individuals with Alzheimer’s disease (AD) pathology and is characterized by significant visual-perceptual impairment. There are no consensus diagnostic criteria for PCA and misdiagnosis is common. This study tested whether a simple ratio score of visual-perceptual performance to memory performance was associated with MRI measures of visual association cortices in a subgroup of patients with suspected PCA. Analyses included 141 patients with AD dementia (M age = 74.4) from the Alzheimer’s Disease Neuroimaging Initiative. Ratio scores, reflecting constructional praxis performance (a measure of visual spatial ability) relative to immediate recall memory performance, were calculated for each patient using subscales of the ADAS-Cog. Atrophy was estimated using structural MRI measures (volume, thickness) of cortical regions involved in visual processing. Using ADAS-Cog ratio scores, 12 patients were classified as possible PCA subjects (M age = 69.9). Relative to the ‘typical’ AD group, the ‘PCA’ group had smaller volumes and lower thicknesses in several posterior cortical regions and a composite score of these brain regions ($p < .05$). Several MRI measures were significantly related to higher scores on the ADAS-cog

based ratio in the ‘PCA’ subgroup but not in the ‘typical’ AD group ($p < .05$). Additionally, logistic regressions showed that the degree of atrophy in several regions predicted ‘PCA’ group status ($p < .05$). The results suggest that the ADAS-Cog based ratio of constructional praxis to memory recall is associated with significant atrophy in posterior cortical regions. This measure may be useful for identifying individuals with suspected PCA.

FRAILITY PHENOTYPES, FALL, HIP FRACTURE, AND MORTALITY

O. Zaslavsky¹, S. Zelber-Sagi², N.F. Woods¹, 1. *Biobehavioral Nursing and Health Systems, University of Washington, Seattle, Washington*, 2. *University of Haifa, Haifa, Israel*

Background: We compared the simplified Women’s Health Initiative (WHI) and the standard Cardiovascular Health Study (CHS) frailty phenotypes in predicting falls, hip fracture, and death in older women.

Methods: Participants are from the WHI Clinical Trial. CHS frailty criteria included weight loss, exhaustion, weakness, slowness, and low physical activity. The WHI frailty score used two items from the RAND-36 physical function and vitality subscales, one item from the WHI physical activity scale plus the CHS weight loss criteria. Specifically, level of physical function was the capacity to walk one block and scored as severe (2-points), moderate (1-point), or no limitation (0). Vitality was based on feeling tired most or all of the time (1-point) versus less often (0). Low physical activity was walking outside less than twice a week (1-point) versus more often (0). A total score of 3 resulted in frailty classification, score of 1 or 2 defined pre-frailty, and 0 indicated non-frailty. Outcomes were modeled using Cox regression and Harrell C-statistics were used for comparisons.

Results: Approximately 5% of participants were frail based on the CHS or WHI phenotype. The WHI frailty phenotype was associated with higher rates of mortality (hazard ratio (HR)=2.36, $p < 0.001$) and falls (HR=1.36, $p = .03$). Comparable HRs in CHS-phenotype were 1.97 ($p < 0.001$) and 1.12 ($p = 0.44$), respectively. Neither phenotype predicted hip fracture. Harrell C-statistics revealed non-significant differences in HRs between the CHS and WHI frailty phenotypes.

Conclusion: The simplified WHI phenotype, which is self-reported and brief, might offer a practical advantage for epidemiological and clinical applications.

ADEQUACY OF MICRONUTRIENT INTAKE IN LONG-TERM CARE RESIDENTS: MAKING THE MOST OF MEALTIMES (M3)

H.H. Keller^{1,2}, N. Carrier⁴, C. Lengyel³, S. Slaughter⁵, L. Duizer⁶, C. Steele^{7,8}, J.M. Morrison¹, A.M. Duncan⁶, 1. *Kinesiology, University of Waterloo, Waterloo, Ontario, Canada*, 2. *Schlegel-University of Waterloo Research Institute for Aging, Waterloo, Ontario, Canada*, 3. *University of Manitoba, Winnipeg, Manitoba, Canada*, 4. *Universite de Moncton, Moncton, New Brunswick, Canada*, 5. *University of Alberta, Edmonton, Alberta, Canada*, 6. *University of Guelph, Guelph, Ontario, Canada*, 7. *University Health Network, Toronto, Ontario, Canada*, 8. *University of Toronto, Toronto, Ontario, Canada*

Food intake of residents living in long term care (LTC) is known to be poor. Yet, our understanding of which micronutrients are inadequately consumed is limited. The M3 prevalence study included an assessment of food intake from 639 residents (mean 86.8 ± 7.8 yrs old) in 32 nursing homes from four provinces (AB, ON, NB, MB) in Canada. Researchers rigorously collected weighed (main plate items) and estimated (snacks, beverages, side dishes) food and beverage intake from three non-consecutive days. Dietary records were analyzed for energy and micronutrient intakes using the Food Processor Nutrition Analysis Software (ESHA, version 10.14.1) and usual intakes were estimated by adjustment for intra-individual variation on all participants. Micronutrient intakes were compared with their estimated average requirement (EAR), when available, using the EAR cut-point method or with their Adequate Intake (AI) when an EAR was not available. Energy intake was 1715 ± 291 kcal and 1481 ± 261 (mean \pm SD) for males ($n=197$) and females ($n=435$), respectively. Nutrients where the prevalence of inadequacy was greater than 50% for males and females were: vitamin B6, D, E, folate, calcium, magnesium and zinc. More than 50% of participants were below the AI for vitamin K and Potassium. These results document a high prevalence (10 of 20 micronutrients assessed) of inadequate micronutrient intakes in residents living in LTC in Canada. Interventions to promote more nutrient dense foods in LTC menus are required. (Funded by Canadian Institutes of Health Research)

INDICATIONS OF GAMMA-GLUTAMYLTRANSFERASE (GGT) AS A MARKER OF COGNITIVE HEALTH IN LATE LIFE

M. Praetorius Bjork, B. Johansson, *University of Gothenburg, Gothenburg, Sweden*

A recently published study suggests an association between Gamma-Glutamyltransferase (GGT) in midlife and later risk of dementia. In the present study we explore the effects of serum GGT on cognitive decline and dementia also in more advanced ages. We tested the role of GGT in a sample of 452 non-demented individuals, aged 80 years and older at baseline, drawn from the OCTO-twin study. A battery of eight cognitive tests was administered at five occasions with measurements intervals of two years. We fitted hierarchical linear models by contrasting two models of overall cognitive change as a function of a) time in the study and b) time to death while controlling for baseline age, sex, education, stroke, cardiovascular disease, hypertension, diabetes, and incident dementia. In separate analyses, the potential association between GGT and dementia was tested. Our main finding was that higher levels of GGT were associated with an increased risk for cognitive decline and dementia in later life. Our study is the first longitudinal study to report on this association across a broad battery covering several cognitive domains and diagnoses of dementia. Further research is, however, needed to validate our findings and to evaluate the underlying mechanisms of the effects of GGT on age-related cognitive decline

DICHOTIC LISTENING IN THE ELDERLY: INTERFERENCE IN THE ADAPTATION OF BINAURAL PROSTHESIS

J. Martins, A. Ribas, C. Moretti, *Universidade Tuiuti do Paraná, Curitiba, Paraná, Brazil*

Introduction: Elderly individuals with bilateral hearing loss often do not use hearing aids in both ears. Because of this, dichotic tests to assess hearing in this group may help identify peculiar degenerative processes of aging and hearing aid selection. Objective: To evaluate dichotic hearing for a group of elderly hearing aid users who did not adapt to using binaural devices and to verify the correlation between ear dominance and the side chosen to use the device. Methods: A cross-sectional descriptive study involving 30 subjects from 60 to 81 years old, of both genders, with an indication for bilateral hearing aids for over 6 months, but using only a single device. Medical history, pure tone audiometry, and dichotic listening tests were all completed. Results: All subjects (100%) of the sample failed the dichotic digit test; 94% of the sample preferred to use the device in one ear because bilateral use bothered them and affected speech understanding. In 6%, the concern was aesthetics. In the dichotic digit test, there was significant predominance of the right ear over the left, and there was a significant correlation between the dominant side with the ear chosen by the participant for use of the hearing aid. Conclusion: In elderly subjects with bilateral hearing loss who have chosen to use only one hearing aid, there is dominance of the right ear over the left in dichotic listening tasks. There is a correlation between the dominant ear and the ear chosen for hearing aid fitting.

CAN DEPRESCRIBING GIVE WHAT POLYPHARMACY HAS TAKEN AWAY? FEASIBILITY TRIAL IN RESIDENTIAL AGED CARE

N. Ailabouni¹, D. Mangin², P.S. Nishtala¹, *1. School of Pharmacy, University of Otago, Timaru, New Zealand, 2. McMaster University, Hamilton, Ontario, Canada*

Polypharmacy, with its resulting negative health outcomes, is increasing worldwide alongside our ageing population. In specific, anticholinergic and sedative medicines contribute to the decline in cognitive and physical functioning of older people. The Drug Burden Index (DBI) measures the cumulative daily sedative and anticholinergic load. Our aim was to examine the feasibility of reducing the DBI of older people living in residential aged care facilities (RACFs). Residents aged ≥ 65 years prescribed one or more anticholinergic or sedative medicine, were recruited from three RACFs in New Zealand. A patient-centred approach was implemented; where a clinically trained pharmacist conducted a resident interview and a comprehensive medicine review for each participant. Deprescribing recommendations were put forward to the residents' general practitioner (GP). We recruited 37 participants with a mean age of 82.8 ± 8.2 . Residents were followed up three months after their GP deprescribed one or more of their medicine(s). A Wilcoxon Signed-Rank test indicated that post DBI test ranks, were statistically significantly less than pre DBI test ranks ($p=0.00016$) and post-Cognition Performance Score (CPS) test ranks were statistically significantly less than pre-CPS test ranks ($p=0.02$). In addition, a

one-sided paired t-test showed that potential adverse drug reactions (ADRs) decreased by a mean of 2.92 ($p=0.0001$). Therefore, the pharmacist's deprescribing intervention resulted in a statistically significant reduction in both residents' DBI and potential ADRs; as well as an improvement in residents' cognition. This supports existing research that deprescribing can reverse negative polypharmacy effects and result in several potential health benefits.

A CROSS-SECTIONAL STUDY—THE RELATIONSHIP OF MUSCLE MASS AND MUSCLE FUNCTION WITH AGE

J. Sun, H. Bai, M. Chen, D. Xue, J. Chen, *Huadong Hospital of Fudan University, Shanghai, China*

Sarcopenia is characterized by an age-related decline of skeletal muscle plus low muscle strength and/or physical performance, it is a strong predictor of falls, physical disability, morbidity and mortality. The aim of study is to investigate the relationship of muscle mass and muscle function with age in Chinese population. Methods: The study including 414 participants (212 men and 202 women, mean age 72.4 ± 8.0 years) in Shanghai. Upper (UMM) and lower (LMM) limbs muscle mass and whole body fat free mass (FFM) were measured by bioelectrical impedance analysis. The appendicular skeletal muscle mass (ASM) index ($ASM/height^2$) was calculated. Muscle function was assessed by measuring hand grip strength (HGS) and gait speed. Results: Low muscle mass using ASM index cutoff values was higher in women than men (33.5% vs. 23.6%, $p=0.025$). In the upper limb, HGS ($\beta=-0.809$) declined more rapidly with age than did UMM ($\beta = -0.592$) in men, but not in women ($\beta = -0.389$ and $\beta = -0.486$ respectively). In the lower limb, gait speed declined more rapidly than LMM in men ($\beta = -0.683$ vs. $\beta = -0.442$) and women ($\beta = -1.001$ vs. $\beta = -0.461$). The variance of UMM explained 28–29% of the variance of HGS, and LMM explained 7–8% of the variance of gait speed, in women and men respectively. In addition to the common predictors (BMI and age), the specific predictors were smoking, exercise and education for FFM and ASM, and smoking, drinking and exercise for HGS ($p<0.05$). Conclusions: Loss of muscle function was greater than the decline of muscle mass particularly in the upper limbs in men. However, women were more prone to have low muscle mass than the men. Exercise programs need to be designed gender specifically.

EARLY LIFE RISK FACTORS FOR DEMENTIA DEATH: THE HARVARD ALUMNI HEALTH STUDY

T. Russ¹, I. Lee^{2,4}, H.D. Sesso^{2,4}, D. Batty^{3,1}, 1. *Alzheimer Scotland Dementia Research Centre/ Centre for Dementia Prevention, University of Edinburgh, Edinburgh, United Kingdom*, 2. *University of Harvard, Boston, Massachusetts*, 3. *UCL, London, United Kingdom*, 4. *Brigham and Women's Hospital, Boston, Massachusetts*

Dementia is a growing public health crisis but its aetiology remains incompletely understood. Several risk factors measured in mid-life, including obesity and hypertension, have been linked with dementia risk, though the evidence is not uniform: overweight in mid-life might be protective against dementia. Neurodegenerative diseases develop over a long, initially asymptomatic, period. Thus, the possibility of

preclinical dementia affecting risk factors of interest (reverse causality) is important. The only solution is a cohort study recruited before the earliest stages of neurodegeneration are present.

33,319 male participants in the Harvard Alumni Health Study underwent an interview and physical examination at matriculation (<30 years) measuring/recording age, BMI (derived from height and weight), pulse rate, blood pressure, physical activity, smoking status, and alcohol consumption. Causes of death were extracted from death certificates (mean \pm SD follow up 53.1 ± 14.3 years). Dementia-related deaths were identified using ICD-7 codes 304–6 and 794. We constructed Cox proportional hazards models for the association between each baseline variable and dementia-related death (age included in every model).

We found no association between the risk factors measured in early life and subsequent dementia-related death, though the hazard ratio was raised for obesity (1.33, 95%CI 0.90–1.97) and reduced for alcohol consumption (0.60, 0.31–1.16). Expected risk factor-CVD death (ICD-7 330–334 and 400–446) associations were identified.

In a population free of the earliest stages of dementia, we found no association between early life cardiovascular risk factors and dementia-related death. The relationship between CVD and dementia is potentially more complex than hitherto considered and requires careful study.

SEX DIFFERENCES IN RESPONSE TO A TARGETED KYPHOSIS SPECIFIC EXERCISE PROGRAM

W.B. Katzman¹, N. Parimi², A. Schafer^{1,4}, R. Long¹, S. Wong¹, N. Lane³, 1. *University of California San Francisco, San Francisco, California*, 2. *San Francisco Coordinating Center, San Francisco, California*, 3. *University of California, Davis, Davis, California*, 4. *San Francisco Veterans Affairs Medical Center, San Francisco, California*

Hyperkyphosis, an excessive anterior curvature in the thoracic spine, is associated with reduced health status in older adults. Hyperkyphosis is highly prevalent, more common in older women than men. There is no standard intervention to reduce age-related hyperkyphosis. Sex differences in response to a targeted intervention are not known.

We conducted a waitlist design randomized controlled trial to determine if a targeted kyphosis specific exercise program improved Cobb angle of kyphosis, and whether the magnitude of change differed between men and women.

112 participants aged ≥ 60 years with kyphosis $\geq 40^\circ$ were randomized to exercise or waitlist control. Group intervention was delivered by a physical therapist, 1-hour, twice a week for 3-months. Controls received the intervention after 3-months. Primary outcome was change in Cobb angle measured from standing lateral spine radiographs. Secondary outcomes included change in kyphometer-measured kyphosis, physical function and quality of life. Groups were combined and ANOVA was used to test sex by time interaction to evaluate treatment effects in men and women.

Participants (67 women, 45 men) were 70.0 ± 6.2 years with baseline Cobb 55.6 ± 12.1 degrees. There were no between group differences at baseline, however men had higher kyphometer-measured kyphosis. There was no significant between group difference in change in Cobb after

intervention, $p=0.09$, but kyphometer-measured kyphosis differed by 4.8 degrees, $p<0.001$. There was no significant interaction between sex and change in Cobb after intervention, $p=0.67$.

A 3-month targeted exercise program reduced kyphometer, but not radiographic-measured kyphosis. Despite sex differences in baseline kyphosis, sex did not affect treatment response.

EFFECT OF FAMILY CAREGIVER SKILLS TRAINING ON PERCEIVED QUALITY OF CARE AND DEPRESSIVE SYMPTOMS

C. Van Houtven¹, J. Lindquist², V.A. Smith¹, J. Chapman², C.C. Hendrix¹, S.N. Hastings¹, E.Z. Oddone¹, M. Weinberger³, 1. *Durham VA and Duke University Medical Centers, Durham, North Carolina*, 2. *Durham VA Medical Center, Durham, North Carolina*, 3. *UNC Chapel Hill, Chapel Hill, North Carolina*

One national strategy to better support family caregivers in the U.S. is to increase effective training programs. We conducted a two-arm randomized controlled trial to evaluate the effectiveness of HI-FIVES, a skills training program for caregivers of community-dwelling Veterans recently referred to receive home and community-based services. Caregivers in the HI-FIVES group received five individually-tailored training phone calls and four weekly group training sessions delivered by a RN. Caregivers in usual care received information about VA Caregiver Support Program services. The perceived quality measure was: 0 is the worst, and 10 the best, possible VA healthcare received in the past 3 months. The CESD-10 assessed depressive symptoms (0–30). Linear models with an unstructured covariance matrix were estimated to test intervention effects on outcomes at 3, 6, and 12 months. Among the 242 dyads, caregivers' (patients') mean age was 61 (73) years, 54% (53%) were Black, and 89% (4%) were female. Model-estimated mean baseline caregiver perceived quality of VAHCS care was 8.34 (95% CI: 8.10, 8.57); the modeled mean difference between HI-FIVES and controls at 3 months was 0.28 ($p=.18$); 0.53 ($p<.001$) at 6 months; and 0.46 ($p=0.054$) at 12 months. Model-estimated mean baseline patient perceived quality of VAHCS care was 8.43 (95% CI 8.16, 8.70); the modeled mean difference between HI-FIVES and controls at 3 months was 0.29 ($p=.27$); 0.31 ($p=0.26$) at 6 months; and 0.48 ($p=0.03$) at 12 months. Model-estimated mean baseline caregiver CESD-10 was 8.96 (95% CI: 8.21, 9.72). No significant differences were observed in CESD-10 scores.

ASSOCIATION BETWEEN PROTEIN INTAKE AND CHANGE IN RENAL FUNCTION AMONG JAPANESE GENERAL OLD SUBJECTS

T. Sekiguchi^{1,2}, K. Kamide¹, K. Ikebe³, M. Kabayama¹, Y. Arai⁴, T. Ishizaki⁵, Y. Gondo⁶, H. Rakugi¹, 1. *Osaka University Graduate School of Medicine, Osaka, Japan*, 2. *Morinomiya University of Medical Sciences, Osaka, Japan*, 3. *Osaka University Graduate School of Dentistry, Osaka, Japan*, 4. *Keio University of Medical Sciences, Tokyo, Japan*, 5. *Tokyo Metropolitan Institute of Gerontology, Tokyo, Japan*, 6. *Osaka University Graduate School of Human Sciences, Osaka, Japan*

Objective: The aim of this study is to clarify the association between dietary protein intake and decline in estimated glomerular filtration rate (eGFR) among Japanese general old persons.

Method: We analyzed longitudinal data from 1246 participants (70 ± 1 years: 593, 80 ± 1 : 587, 90 ± 1 : 66, male: 48.5%, female: 51.5%) in the SONIC study, population based cohort study for old persons. Exclusion criteria were CKD stage G5 (eGFR<15) and dialysis reception in progress. The outcome variable, change in eGFR was estimated from serum creatinine measured at baseline and 3-year follow-up, and exposure variable, protein intake adjusted for total energy intake, sex and age, was calculated using brief-type self-administered diet history questionnaire (BDHQ) at baseline. Associations between eGFR change and protein intake were determined by multiple linear regression analysis. And we also carried out subgroup analyses for subjects with eGFR ≥ 60 and <60 , <45 , <30 .

Result: Mean eGFR change per year was -2.12 (eGFR at Baseline: 69.7, Follow-up: 64.7) mL/min/1.73m². Mean protein intake was 1.52g/kg/day. As results of multivariable analyses including almost all subgroup analyses, eGFR change was not associated with protein intake. However, only in the subgroup with eGFR<60, high protein intake was statistically associated with moderate eGFR change (β coefficient: 1.00, 95% CI: 0.11 – 1.89).

Conclusion: In general, old persons with eGFR<60, protein intake was positively associated with change in eGFR, and with eGFR<30 who are recommended restricting protein intake for chronic kidney disease in recent guidelines. Thus, dietary protein restriction might be reconsidered for old persons having reduced renal function as eGFR<30.

THE CORRELATION OF SERUM CATHEPSIN B WITH AGE-RELATED KIDNEY AND CARDIAC DIASTOLIC FUNCTION DECLINE

J.X. Bai¹, N. Wang¹, W. Han¹, F.X. Sun², M.X. Chen², 1. *Department of Gerontology and Geriatrics, Shengjing Hospital of China Medical University, Shenyang, China*, 2. *Department of Kidney, General Hospital of Chinese People's Liberation Army, Beijing, China*

Background: The purpose of this study was to longitudinally evaluate the association of serum Cathepsin B (CTSB) with age-related kidney and cardiac diastolic function decline in a healthy Chinese community-based population.

Methods: One hundred and ninety five healthy participants were evaluated at baseline and 3 years later. Serum CTSB was measured by enzyme-linked immunosorbent assay (ELISA). Rapid kidney function decline was defined as annual loss of estimated glomerular filtration rate (eGFR) > 3 ml/min/1.73m². Cardiac diastolic function was assessed by echocardiography based on mitral inflow patterns.

Results: Baseline serum CTSB concentration were significantly different among the four groups based on cardiac diastolic function. For the total participants, CTSB was significantly correlated with cardiac diastolic function. Compared to the individuals with high CTSB concentration, the individuals with low CTSB concentration had lower risk of cardiac diastolic dysfunction with the odds of 2.542 [(1.086–5.952), $P<0.05$]. However, this effect didn't exist after age adjustment. The incidence of diastolic function improvement of the

moderate CTSB concentration group was lower than that in the high concentration group. After adjusting for age and all other possible confounders, the association remained with the odds of 0.209 [(0.060–0.725), $P < 0.05$]. However, the association between serum CTSB and kidney function was not found.

Conclusions: Serum CTSB was correlated with age-related cardiac diastolic function decline in healthy people. Measurement of serum CTSB may provide valuable information for predicting the decline in age-related cardiac diastolic function in healthy people.

A ROLE OF MNA-SF AS A PREDICTOR FOR 30-MONTH MORTALITY IN A NURSING HOME IN JAPAN

J. Yasuda, Y. Watanabe, H. Hirano, A. Eda, M. Shirobe, K. Motokawa, S. Awata, *Tokyo Metropolitan Institute of Gerontology, Tokyo, Japan*

Background: Japan is a super-aged society. Along with the aging, the number of dependent elderly has increased. The Mini Nutritional Assessment-Short Form (MNA-SF) has been reported to be one of the useful questionnaires to assess nutritional status in older people. However, studies reporting with MNA-SF for the dependent elderly are lacking. Therefore, we observed residents in nursing homes in Japan for 30 months to examine whether MNA-SF is useful for assessment of nutritional status. Methods: A total of 423 residents (333 women; 84.2 ± 8.6 years) in nursing homes in Japan participated in this investigation. We investigated the following characteristics of the participants: age, sex, height, weight, medical history, Barthel index, clinical dementia rating, and MNA-SF. MNA-SF consists of 6 items: food intake decline, weight loss, mobility, suffering from psychological stress or acute disease, Neuropsychological problems, and BMI. We performed Cox proportional regression analysis to examine the association of MNA-SF score with 30-month mortality. Results: Mean MNA-SF score was 8.9 ± 2.2 . Among the participants, 104 (24.6%) were malnourished, 250 (59.1%) were at a risk of malnutrition, and 49 (11.6%) were in a normal nutritional status. After 30-month follow-up, 166 (39.2%) of the participants died. After adjustment for confounders, MNA-SF score was significantly associated with 30-month mortality (HR: 0.843, 95% CI: 0.770–0.922). Conclusion: MNA-SF score was significantly associated with 30-month mortality in Japanese nursing homes, even after adjustment for mortality-associated confounders. Therefore, the approach based on MNA-SF can be effective for nutritional assessment of dependent elderly.

YOUNG EFFORTS FOR OLDER INPATIENTS: DEVELOPMENT AND ASSESSMENT OF A CLINICAL POLYPHARMACY PATHWAY

L. Van der Linden, J. Hias, K. Walgraeve, E. Joosten, J. Flamaing, I. Spriet, J. Tournoy, *University of Leuven, Leuven, Belgium*

Background: Pharmacist-led medication reviews performed during hospital stay in very old adults have been shown to decrease emergency department visits and drug-related readmissions as well as downstream health care

utilization. Hence, a clinical pathway was developed and subsequently installed at the acute geriatric wards of a large referral University Hospital, Leuven, Belgium

Aims: To develop a structured and non-labor intensive data capture approach within the current framework, which allows for the following:

To establish the different tasks (i.e. the workload) of the assigned clinical pharmacists.

To identify the content of the provided recommendations.

To assess the acceptance rate of said recommendation.

Methods: A structured form was developed which was compatible with the hospital's software system and allowed for inclusive data registration: e.g. type of intervention, involved drug class and acceptance of the pharmaceutical recommendation by the treating physician. Structured data registration was done between April and December 2016.

Results: Medication reconciliation revealed a mean of 3.3 discrepancies per patient. Pharmacists provided at least 1 intervention for 785 (60%) of 1118 admissions. Medication review was performed in 50% of all patients resulting in 2159 recommendations. Drug discontinuation was mostly recommended (46%). Cardiovascular drugs (29%), followed by psychotropic drugs (17%) and gastro-intestinal drugs (12%) were the main subjects of the pharmaceutical recommendations; A majority of the recommendations (i.e. 76%), was accepted by the physicians.

Conclusion: Clinical pharmacists working in multidisciplinary geriatric teams provide a clear added value towards the pharmaceutical care and should be maximally integrated in geriatric care programs.

EARLY LIFE STRESS AND GENETIC RISK FOR NEUROTICISM PREDICTING HEALTH OUTCOMES IN OLDER SWEDISH TWINS

K. Lehto^{1,2}, I. Karlsson¹, C. Lundholm¹, N.L. Pedersen¹, 1. *Dept. Medical Epidemiology and Biostatistics, Karolinska Institutet, Solna, Sweden*, 2. *National Institute for Health Development, Tallinn, Estonia*

Better understanding of early risk factors for poor late-life health and low well-being is crucial for developing more efficient prevention strategies. This study explored how early life stress exposure (twins separated and adopted; mean age = 3) as well as novel polygenic risk scores for neuroticism (PRSn) influence psychosocial and health outcomes late in life. Data were collected over 7 waves of the Swedish Adoption/Twin Study of Aging (SATSA; 1984–2010). In total, 2174 individuals (older than 50 at baseline) were included in the analyses. Of those, 637 had genotype data available. Outcomes included psychosocial factors (socioeconomic status, life stress, family environment) as well as emotional health (neuroticism, depressiveness, anxiety symptoms, life satisfaction) and physical health (self-rated health, disease burden, functionality level). Early stress exposure predicted higher levels of neuroticism, disease burden and life stress, and lower life satisfaction and self-rated health in late-life. Out of seven PRSn created at various p-value thresholds, PRSn consisting of approximately 10 000 SNPs under p-value threshold of .01 was the most powerful predictor of measured neuroticism late in life. PRSn also predicted high depressiveness and

poor family environment. Interestingly, genetic effects were more evident in twins not exposed to early life stress, indicating underlying gene-environment interplays. Results suggest the importance of early life stress and genetic predisposition to emotional instability in shaping health and well-being in old age.

DIETARY PATTERNS AND SELF-REPORTED INCIDENT DISABILITY IN ELDERLY

P. Agarwal¹, Y. Wang^{1,2}, A. Buchman^{3,4}, D.A. Bennett^{3,4}, M.C. Morris¹, 1. *Department of Internal Medicine, Rush University Medical Center, Chicago, Illinois*, 2. *Department of Preventive Medicine, Rush University Medical Center, Chicago, Illinois*, 3. *Rush Alzheimer's Disease Center, Rush University Medical Center, Chicago, Illinois*, 4. *Department of Neurological Sciences, Rush University Medical Center, Chicago, Illinois*

Disability in older adults is associated with low quality of life and higher mortality. Diet may be a potentially important public health strategy for disability prevention. We examined the relations of the Mediterranean, DASH and MIND diets to functional disability in the Rush Memory and Aging Project. A total of 874 participants without functional disability at baseline were assessed annually over 12 years of follow-up using standardized measures for self-reported activities of daily living, instrumental activities of daily living and the Rosow-Breslau measure of mobility disability. The diet scores were computed based on a validated food frequency questionnaire administered at baseline. We examined relations between diet and disability using proportional hazard models adjusted for age, sex, education and total calories. Higher scores of the MIND (HR=0.88, 95% CI 0.83–0.94), Mediterranean (HR=0.96, 95% CI 0.94–0.98), and DASH (HR=0.88, 95% CI 0.82–0.95) diets were associated with decreased hazard of incident disability in activities of daily living. Only the MIND (HR=0.91, 95% CI 0.86–0.97) and Mediterranean (HR=0.97, 95% CI 0.94–0.99) diets were associated with reduced hazard of disability in instrumental activities of daily living. All three dietary patterns were associated with decreased hazard of mobility disability (MIND, HR=0.88 95% CI 0.83–0.94; Mediterranean, HR=0.88, 95% CI 0.83–0.94; DASH, HR=0.88, 95% CI 0.83–0.94). The findings did not change after further adjustment for BMI, depression, physical activity and vascular diseases, except for mobility disability, which became non-significant. These findings are encouraging that diet may be an effective strategy for the prevention of functional disability.

ONCE-DAILY MOUTH CARE REDUCES PLAQUE AND CHANGES ORAL MICROBIOME COMPOSITION IN NURSING HOME ELDERS

R.A. Jablonski-Jaudon, V. Winstead, C. Jones-Townsend, A. Azuero, M. Geisinger, C. Morrow, T. Ptacek, *The University of Alabama at Birmingham, Birmingham, Alabama*

Background: Persons with dementia usually receive mouth care from nursing assistants. Inadequate mouth care causes poor oral health, a risk for systemic diseases like pneumonia. Nursing assistants struggle with balancing optimal mouth care against triggering care-resistant behaviors.

Purpose: To evaluate the feasibility of a once-daily mouth care protocol on the outcomes of dental plaque and oral microbiome composition.

Sample: Six nursing home residents with documented mouth care-resistant behavior: mean age was 66.3 years, 50% were African-American, and 50% were female. They all had moderate dementia and significant dental plaque (mean surface covered=50.7%, sd=20.8%)

Methods: All subjects received 6 days of once-daily mouth care. Supragingival plaque and the anterior dorsum of the tongue were accessed for the microbiome samples, which were obtained before and after Day 1 and Day 6 mouth care activities. An intraoral camera (Soprocure™) was used to obtain video recorded images of all new plaque on all dentition before Day 1 mouth care and after Day 6 mouth care.

Data Analysis: Plaque scores were analyzed using an adaptation of the Planimetric plaque index for 5 participants (one person's decayed dentition precluded plaque measurements). Microbiome samples were descriptively analyzed at the genus level.

Results: Mean plaque scores fell from 50.7% to 24%. Changes in tongue and plaque of at least 6% of the microbiome at the genus level were observed for *Streptococcus*, *Veillonella*, *Prevotella*, *Haemophilus*, and *Rothia*.

Conclusion: Once-daily mouth care may be effective in reducing plaque and changing the oral microbiome composition.

ATROPHY OF THE ENTORHINAL CORTEX IS RELATED TO INCREASED DUAL-TASK GAIT COST AMONG MCI OLDER ADULTS

R. Sakurai^{1,2,3}, M. Montero Odasso^{2,3}, R. Bartha⁴, 1. *Tokyo Metropolitan Institute of Gerontology, Tokyo, Japan*, 2. *Gait and Brain Lab, Parkwood Institute, Lawson Health Research Institute, London, Ontario, Canada*, 3. *Schulich School of Medicine & Dentistry, Department of Medicine, Division of Geriatric Medicine, University of Western Ontario, London, Ontario, Canada*, 4. *Center for Functional and Metabolic Mapping, Robarts Research Institute, Department of Medical Biophysics, Schulich School of Medicine & Dentistry, Department of Medicine, Division of Geriatric Medicine, University of Western Ontario, London, Ontario, Canada*

Background: Lower dual-task gait performance (the slowing of gait speed while performing a cognitive demanding task) is associated with lower cognitive performance, particularly in MCI older adults. However, the neural mechanism of increased dual-task cost is still unclear. This study aimed to examine the relationship between dual-task cost and regional brain volume, focusing on prefrontal cortex, hippocampus, and entorhinal cortex, and whether these variables were associated with future onset of dementia among MCI older adults.

Methods: Forty-one older adults (mean age 74±6 years, 44% women) with MCI from the "Gait and Brain Study" were followed up for up to five years with biannual visits including cognitive, gait, and medical assessment. Gait velocity and stride time variability were recorded under simple and three separate dual-task gait conditions using an electronic walkway. Regional brain volumes were derived from automated segmentation using 3T-MRI scanning.

Results: Adjusted regression analyses showed that higher dual-task costs were associated with smaller volume in the entorhinal cortex but not with the prefrontal and hippocampal volumes. During the follow-up period (mean, 30 months), six participants converted to dementia. A logistic regression analysis showed that future onset of dementia was associated with smaller volume in the entorhinal cortex alone (OR = 1.005, $p = 0.034$).

Conclusions: Our results suggest that lower dual-task gait performance is a motor manifestation of entorhinal cortical atrophy which leads to progression to dementia. Our result provides an anatomical substrate to the concept that dual-task gait can be an early motor marker of progression to dementia.

ASSOCIATION BETWEEN INDIVIDUAL CHRONIC DISEASES AND POLYPHARMACY AMONG ELDERLY PATIENTS IN JAPAN

T. Ishizaki¹, S. Mitsutake¹, T. Yamaoka¹, C. Teramoto^{3,1}, S. Shimizu², H. Ito¹, 1. *Tokyo Metropolitan Geriatric Hospital and Institute of Gerontology, Tokyo, Japan*, 2. *Institute of Health Economics and Policy, Tokyo, Japan*, 3. *University of Tokyo, Tokyo, Japan*

The Japanese government is seeking to establish a community health program for the management of polypharmacy in elderly patients. To explore a community-based screening strategy for polypharmacy, this study examined the extent to which certain chronic diseases are strongly associated with polypharmacy among community-dwelling elderly adults in Japan. We used anonymized health insurance claims data from all beneficiaries aged 75 years and older in Tokyo, who received outpatient care between May 2014 and August 2014. We obtained the data from the Tokyo Metropolitan Association of Medical Care Services for Older Senior Citizens. The insurance program universally covers all citizens aged 75 years or older. The data included 134 categories of prescribed drugs and seven chronic diseases: hypertension, dyslipidemia, insomnia, osteoarthritis, diabetes, dementia, and depression. Polypharmacy was defined as the prescription of at least five drugs during a 4-month period. We estimated age- and sex-adjusted odds ratio (OR) for each chronic disease, using multivariate logistic regression analysis. The prevalence of polypharmacy among the beneficiaries ($n = 1,308,412$) was 34.4%. The prevalence was the highest among octogenarians (37.8%), followed by that among those aged 75–79 years (32.0%), nonagenarians (27.9%), and centenarians (10.9%). We found that the highest OR of having polypharmacy was 4.98 for diabetes ($p < 0.001$), followed by 4.75 for depression ($p < 0.001$); the lowest OR was 1.65 for dementia ($p < 0.001$). These findings emphasize the importance of identifying individual diseases to screen for polypharmacy among community-dwelling elderly patients.

THE CONTENT AND FOCUS OF THE SWEDISH NATIONAL INVENTORY OF HEALTH AND CARE (SWENIS)

A. Backman¹, S. Bjork¹, H. Lövheim¹, K. Sjögren¹, A. Skoldunger³, A. Wimo⁴, P. Sandman¹, D. Edvardsson^{2,1}, 1. *Umea University, Umea, Sweden*, 2. *School of nursing and midwifery, Melbourne, Victoria, Australia*, 3. *Umea*

University, Umea, Sweden, 4. *Division of neurogeriatrics, Stockholm, Sweden*

Sweden, like most countries worldwide, faces major challenges due to a rapidly aging population with increasing need to develop and ensure a high quality aged care for older people. The SWENIS study has a longitudinal design and contributes with nationally representative, valid and standardized prevalence measurements of models of care, organisation and person-centredness, staff working situation, and resident health such as cognitive impairment, neuropsychiatric symptoms, pain and P-ADL capacity in nursing homes. The SWENIS research group has developed a valid, reliable and internationally comparable Swedish nursing home survey, and baseline data were collected in 2014 from a randomised Swedish national sample of nursing homes; residents ($n = 4831$) staff ($n=3605$), and managers ($n =191$) in 188 nursing homes from 35 municipalities. The prevalence of cognitive impairment among residents was 67%, 56% of residents were P-ADL-dependent, 48% exhibited pain and 92% exhibited neuropsychiatric symptoms. Baseline measurements showed person-centred care mean 50.0 (SD 7.4), of a possible total score of 13–65, psychosocial climate mean 57.6 (SD 9.1), of a total score of 0–70, job strain mean 0.71 (SD 0.17), of a total score of 0.21–3.31, and also leadership mean 108.4 (SD 23.8) of a total score of 24–144. The SWENIS study is novel in several aspects, firstly; it provides nationally generalizable data that enables analyses of resident health well-being in relation to different care practices and organizational structures, and secondly: it enables international comparison and collaboration on the content and health outcomes of residents, in nursing home care.

PROSPECTIVE ANALYSES OF PAIN AND PHYSICAL FUNCTIONING IN THE ENGLISH LONGITUDINAL STUDY OF AGEING

V. Yiengprugsawan^{1,2}, A.P. Steptoe³, 1. *The Australian National University, Centre for Research on Ageing, Health, and Wellbeing, Canberra, Australian Capital Territory, Australia*, 2. *ARC Centre of Excellence on Population Ageing Research, Canberra, Australian Capital Territory, Australia*, 3. *University College London, Institute of Epidemiology and Health Care, London, United Kingdom*

Pain is often viewed as part of the ageing process and for many older persons, moderate or severe pain over a long period can result in lower levels of energy, higher levels of physical discomfort, and limited mobility. This study investigates the longitudinal impact of persistent overall and site-specific pain on physical performance and activities of daily living among older adults.

Data were analysed from the English Longitudinal Study of Ageing (ELSA), a representative sample of the population aged 50 years and older. Face-to-face interview and nurse records were used from Waves 2 to Waves 6 (2004–2012) for analyses. Overall pain and site-specific pain (back, hip, and knee) were measured biennially from 2004 to 2008 ($n=5010$). Activities of daily living and physical measures (chair rise and grip strength) were used as outcomes and were aggregated across assessments between 2008 and 2012. Multivariable multinomial logistic regressions were used for the former and linear regression for the latter, adjusting for potential covariates.

Overall pain (moderate to severe) was prevalent with close to a quarter of participants reporting pain on at least two occasions between 2004 and 2008. Multi-site pain was a strong predictor of subsequent limited activities of daily living, with more impairment in people who reported pain at least twice (Adjusted Odds Ratios range from 1.86 to 3.97 for back and hip 2.04 to 4.19 for back and knee, and 2.08 to 5.19 for hip and knee). Persistent pain was also strongly associated with worse physical performance outcomes.

By using longitudinal data, we are able to confirm the impacts of both overall and site-specific pain on physical functioning in older adults, with more pronounced effects for those reporting persistent pain over the years. These findings could be helpful for practitioners in the monitoring and management of pain in older adults.

OBESITY AND LONGITUDINAL CHANGES OF HANDGRIP STRENGTH IN OLDER ADULTS FROM DIFFERENT CONTEXTS

J. Barbosa¹, C. Gomes¹, T. Ahmed², N. Rosendaal³, R.O. Guerra¹, 1. *Federal University of Rio Grande do Norte, Natal, Brazil*, 2. *Université du Montreal, Montreal, Quebec, Canada*, 3. *University of Hawaii, Honolulu, Hawaii*

It has been suggested that the amount of fat tissue may contribute to accelerated loss strength with aging. However, little is known about longitudinal associations between obesity and low muscle strength. To examine the predictive value of abdominal obesity on longitudinal changes of handgrip strength (HGS) in older men and women. Data on 803 community-dwelling older adults, between 65–74 years, were collected in 2012, 2014, 2016 in Natal (Brazil) and Saint-Hyacinthe (Canada). Sociodemographic characteristics, height, weight, waist circumference (WC) and HGS were assessed. Sex-specific linear mixed models were fitted to examine the trajectory of HGS according to quartiles of baseline WC. Among men, mean four year HGS was 2.62kg (p-value < 0.01). There was a gradient between decline of HGS and WC, with increasing decline among those with greatest waist circumference values (6.15 kg, p-value <0.001) after adjustment for age, research site, height and weight. In women, four year decline in HGS was smaller 1.0kg (p-value < 0.01) and no association between baseline WC and decline in HGS was observed. Findings agree with previous cross-sectional research and emphasize the need for sex-specific analyses.

LONG-TERM CARE HOME, STAFF, AND DINING ROOM CHARACTERISTICS ASSOCIATED WITH RESIDENTS' FOOD INTAKE

N. Carrier¹, H.H. Keller², S.E. Slaughter³, C. Lengyel⁴, C. Steele⁶, L. Duizer⁵, A.M. Duncan⁵, 1. *Food sciences, nutrition and home economics, Université de Moncton, Shediac Cape, New Brunswick, Canada*, 2. *University of Waterloo, Waterloo, Ontario, Canada*, 3. *University of Alberta, Edmonton, Alberta, Canada*, 4. *University of Manitoba, Winnipeg, Manitoba, Canada*, 5. *University of Guelph, Guelph, Ontario, Canada*, 6. *University of Toronto, Toronto, Ontario, Canada*

The Making the Most of Mealtimes (M3) prevalence study recruited 639 residents from 32 homes in four

Canadian provinces (AB, ON, NB, MB) to determine factors associated with food intake (based on three days of weighed and estimated food records). Mealtime interactions with staff assessed with the Mealtime Relational Care Checklist (3 meals/resident), and the length of meals and assistance received (9 meals/resident) were recorded. Dining environments were assessed for physical features using the Dining Environment Audit Protocol, and the Mealtime Scan was used to record mealtime experience and ambiance. Staff (minimum of 10) in each home completed the Person-Directed Care questionnaire and home managers completed a survey describing home features and food services. Residents' mean energy and protein intakes were 1572 ± 412 kcal/day and 58.4 ± 18.0 g/day, respectively. Average mealtime length was 40.2 ± 13.0 minutes, and residents received more positive than negative staff interactions at mealtimes (ratio: 2.2 ± 1.3). Bivariate analysis showed a negative association (p < 0.01) for energy intake with number of residents to staff ratio during mealtimes and time since last menu revision (13–18 months). Protein intake was positively associated (p < 0.01) with dietitian time but negatively associated with the evening meal (supper) being the main meal of the day, having two food preparation systems (rethermalization and traditional) and a longer time (>18 months) since last menu revision. This is the first study to consider home, staff and dining room characteristics and resident food intake, providing new opportunities for interventions. (Funded by Canadian Institutes of Health Research)

HOW DOES SEX AFFECT THE CARE DEPENDENCY RISK ONE YEAR AFTER STROKE?

S. Schnitzer¹, J. Deutschbein¹, C. Nolte², M. Kohler³, A. Kuhlmeier¹, L. Schenk¹, 1. *Department of Medical Sociology, Charité Berlin, Berlin, Germany*, 2. *Center for Stroke Research, Charité Berlin, Berlin, Germany*, 3. *Central Research Institute of Ambulatory Health Care in Germany, Berlin, Germany*

The study explores the association between sex and care dependency risk one year after stroke. The study uses claims data from a German statutory health insurance fund. Patients were included if they received a diagnosis of ischemic or hemorrhagic stroke between 1 January and 31 December 2007 and if they survived for one year after stroke and were not dependent on care before the event (n=1,851). Data were collected over a one-year period. Care dependency was defined as needing substantial assistance in activities of daily living for a period of at least six months. Geriatric conditions covered ICD-10 symptom complexes that characterize geriatric patients (e.g. urinary incontinence, cognitive deficits, depression). Multivariate regression analyses were performed. One year after the stroke event, women required nursing care significantly more often than men (31.2% vs. 21.3%; odds ratio for need of assistance: 1.67; 95% CI: 1.36–2.07). Adjusted for age, the odds ratio decreased by 65.7% to 1.23 (n.s.). Adjusted for geriatric conditions, the odds ratio decreased further and did not remain significant (adjusted OR: 1.18 (CI: 0.90–1.53)). It may be assumed that women have a higher risk of becoming care-dependent after stroke than men because they are older and suffer more often from geriatric conditions such as urinary incontinence at onset of stroke. Preventive strategies should therefore focus

on geriatric conditions in order to reduce the post-stroke care dependency risk for women.

COGNITIVE STATUS IS ASSOCIATED WITH CCL11 IN OLDER RURAL DWELLERS: FINDINGS FROM THE FRAILOMIC STUDY

L. Butcher¹, K. Pérès², P. André², S. Walter³, J. Dartigues², L. Rodríguez-Mañas³, C. Feart², J.D. Erusalimsky¹, 1. *Cardiff Metropolitan University, Cardiff, United Kingdom*, 2. *University of Bordeaux, Bordeaux, France*, 3. *Hospital Universitario de Getafe, Madrid, Spain*

CCL11 (eotaxin-1) is a chemokine classically known to be involved in allergic responses. More recently, this mediator has been implicated in age-related cognitive decline. However, data available on the relationship between CCL11 and cognitive status in older adults living in the community is scarce. The aim of this study was to explore associations between CCL11 and cognitive status in two cohorts of community-based older adults recognised for their contrasting socio-demographic environments, which participated in the FRAILOMIC Initiative (www.frailomic.org/): The 3C-Bordeaux cohort, comprising city dwellers (n= 517), and the AMI cohort, comprising rural dwellers (n=320), both from South-Western France. Plasma CCL11 was measured at baseline by enzyme-linked immunoassay. Baseline Mini Mental Status Examination (MMSE) scores were used as a measure of global cognitive status. CCL11 concentration was significantly higher in AMI than in 3C [median (interquartile range): 146 (115–203) pg/ml vs 103 (85–129) pg/ml]. In AMI, individuals with cognitive impairment (MMSE≤23) had on average higher levels of CCL11 than the others (MMSE>23) [162 (128–219) pg/ml vs 142 (112–196) pg/ml, respectively; p=0.02]. In AMI, multivariate weighted logistic analyses confirmed that higher CCL11 concentrations (tertile 3) were significantly associated with a higher prevalence of cognitive impairment, independently of age, gender, education and frailty [OR=2.80, 95% Confidence Interval 1.65–4.75; p=0.0004]. In contrast, no differences were found in 3C. These results indicated that CCL11 could be a significant independent predictor of cognitive function in older adults residing in a rural environment. The factors that may account for this association will be discussed.

ENHANCING COMMUNICATION AND SHARED DECISION MAKING VIA ELECTRONIC HEALTH RECORDS

S. Dang^{2,3,1}, B. Thavalathil⁴, D. Ruiz², C. Gomez-Orozco⁴, P. Caralis², O. Gomez-Marin⁴, S. Levis^{2,3,1}, R. Rodriguez², 1. *University of Miami Miller School of Medicine, Miami, Florida*, 2. *Miami Veterans Affairs Healthcare System, Miami, Florida*, 3. *Miami VA Geriatric Research Education and Clinical Center, Miami, Florida*, 4. *South Florida Veterans Affairs Foundation for Research and Education, Miami, Florida*

Background: Shared decision-making (SDM), is a patient-provider collaborative process for making health decisions, accounting for both clinical evidence and patients' preferences. Women can benefit from improved SDM regarding menopause and associated conditions, which affect aging women.

Purpose: To assess impact of weekly materials related to women's health sent via secure messaging from an Electronic Health Record (EHR) on knowledge and SDM regarding menopause.

Methods: We implemented an educational intervention for women using the EHR, MyHealthVet. We enrolled 140 women, ages 45–60, from the Miami Veteran Affairs Healthcare System. After 6-months, participants were surveyed using a study-specific questionnaire and the validated SDM-Q-9.

Results: Post intervention survey respondents included 80 women, mean age 53 ± 4; 76% Non-Hispanic, 24% Hispanic; 44% White, 44% Black; 92% with a college education; and 8% who attended graduate school.

Post-intervention 88% of the women felt more knowledgeable regarding menopause treatment options; 87% recognized that a treatment decision was necessary, 89% felt more confident discussing menopause treatment with their provider, and 77% agreed their ability for SDM improved; 48% stated their doctor asked about their preferred decision-making involvement, 47% felt their doctors asked about their preferences, 51% weighed the options together, 48% agreed on treatment options; 27% planned to make an appointment with provider to discuss hormone therapy.

Conclusions: EHRs represent a novel and practical way to enhance women's knowledge of menopause and other age-related conditions, and promote SDM. EHRs promise to enhance SDM merits further exploration, as it may improve patient-centered care, adherence, and patient outcomes.

USABILITY TESTING OF A KINECT-BASED SENSOR SYSTEM TO AUTOMATE THE TIMED UP-AND-GO TEST

L.J. Phillips, I. Jahnke, M. Skubic, C. Abbott, B. Harris, F. Demir, *Nursing, University of Missouri, Columbia, Missouri*

Understanding older adults' preferences for technology is important for acceptance and adoption of future technologies. This study tested the operation of a Microsoft Kinect sensor system programmed to record the Timed Up-and-Go (TUG) test in sample of seven senior center attendees and three staff, and solicited their response to using the system and interpreting fall-risk graphics. Participants viewed PowerPoint slides containing information on falls and TUG instructions, then performed the TUG test under observation but without additional prompting. Participants were asked to Think Aloud to illuminate difficulties encountered during task performance and were video-recorded with Morae software. Following two TUG trials, we provided participants paper-based prototypes of the feedback interface with their age-normed TUG time and estimated fall risk, conducted interviews focused on user experience, and administered the System Usability Scale (SUS). Nine of 10 participants performed the test correctly although six had questions about the instructions. Eight individuals expressed interest in monthly testing. Eight participants comprehended the TUG results graphics, but offered suggestions to enhance clarity. Satisfaction, rated with the SUS was high at 83.4%. Because deviations from specified sitting and walking positions resulted in missing data, clear environmental landmarks will be required for older adults to perform the TUG independently. Findings from this user

experience study suggest that older adults may wish to self-monitor fall risk in a community setting and can interpret graphical fall-risk feedback. In addition, automating the system for senior center use will require precise configuration of the constituent equipment to each center's space.

AMYLOID AND TAU PET IN DIABETES-RELATED DEMENTIA

H. Hanyu¹, S. Shimizu¹, H. Sakurai¹, K. Ishii², 1. *Department of Geriatric Medicine, Tokyo Medical University, Tokyo, Japan*, 2. *Tokyo Metropolitan Institute, Tokyo, Japan*

Type 2 diabetes mellitus (DM) has been shown to increase the risk for cognitive decline and dementia, such as Alzheimer's disease (AD) and vascular dementia (VaD). In addition, there may be a dementia subgroup associated with specific DM-related metabolic abnormalities rather than with AD pathology or cerebrovascular diseases. This type of dementia, not showing hypoperfusion in the parietotemporal lobe on SPECT or cerebrovascular lesions on MRI, was characterized by old age, high hemoglobin A1c level, long duration of diabetes, high frequency of insulin therapy, low frequency of apolipoprotein E 4 carrier, less severe medial temporal lobe atrophy, impaired attention and executive function, less impaired word recall, and slow progression of cognitive impairment, and might be referred to as "diabetes-related dementia". We studied PiB (amyloid) and PBB3 (tau) PET imaging in 20 subjects with diabetes-related dementia to assess amyloid and tau accumulations in the brain. We found that only 40% of subjects showed positive PiB, whereas 91% showed positive PBB3. Some patients showed PBB3 accumulation restricted to the medial temporal lobe, while some showed PBB3 accumulation in the widespread cerebral cortices beyond the medial temporal lobe in the negative PiB, indicating tauopathy. We concluded that diabetes-related dementia may be more associated with tau pathology rather than amyloid pathology, and with non-specific neuronal injury due to DM-related metabolic abnormalities.

LONGITUDINAL CHANGES IN NUTRITIONAL STATUS; SARCOPENIA PROGRESSION IN COMMUNITY-DWELLING OLDER ADULTS

S.P. Yew¹, W. Lim^{1,4}, M. Chong^{1,2}, A. Yeo¹, C. Tan¹, N. Ismail⁵, L. Tay^{1,3}, 1. *IGA, Tan Tock Seng Hospital, Singapore, Singapore*, 2. *Ministry of Health, Singapore, Singapore*, 3. *Sengkang Health, Singapore, Singapore*, 4. *Geriatric Medicine, TTSH, Singapore, Singapore*, 5. *Continuing and Community Care, TTSH, Singapore, Singapore*

While cross-sectional studies have demonstrated the importance of nutritional status on sarcopenia, its impact on longitudinal progression of sarcopenia status remains unclear. This prospective cohort study sought to examine how longitudinal changes in nutritional status impact sarcopenia progression.

We studied 144 community-dwelling older adults who completed 2-year follow-up with repeat DEXA imaging using Asian cut-offs, participants were categorized as (i) no sarcopenia, (ii) pre-sarcopenia and (iii) sarcopenia. Sarcopenia

progressors were defined as participants who progressed from non-to pre-sarcopenia, non-or pre-sarcopenia to sarcopenia, or remained sarcopenic at year-2. We collected longitudinal data for cognitive, functional and physical performance; mood (Geriatric Depression Scale, GDS); physical activity level; and nutritional status (Mini Nutritional Assessment, MNA). We compared participants whose nutritional status improved or remained normal at 2 years, versus their counterparts whose nutritional status declined. Logistic regression was performed to examine the independent effect of change in nutritional status on sarcopenia progression.

Nutritional status declined in 15 (10.5%) participants. They were significantly older (72.30 ± 8.50 vs 67.50 ± 7.90 , $p=0.028$), more likely female (93.3% vs 63.6%, $p=0.021$), and exhibited an increase in GDS score over 2 years (0.016 ± 1.68 vs 1.80 ± 3.30 , $p=0.057$). Sarcopenia progressors were more likely to decline rather than improve/remain stable in nutritional status (93.3% vs 51.9%, $p=0.002$). In logistic regression adjusting for age, ethnicity and GDS scores, decline in nutritional status was an independent risk factor for sarcopenia progression in women (OR=12.2, 95% C.I 1.38–108.60, $p=0.025$).

Tracking changes in nutritional status is clinically relevant in identifying older adults at risk of sarcopenia progression, especially in women. Clinicians should pay attention to mood in patients with decline in nutritional status.

PROTECTIVE EFFECTS OF GLUCAGON-LIKE PEPTIDE-2 ON INTESTINAL MUCOSAL BARRIER FUNCTION IN AGED RATS

R. Ying, *Zhongsan Hospital, Fudan University, Shanghai, Shanghai, China*

Age-associated derangement of intestinal permeability could permit increased systemic absorption of lumen antigens and contribute to concomitant inflammatory status, closely associated with many age-related diseases. GLP-2 can improve the function of the intestinal barrier in patients with gastroenterological diseases and critical illnesses. However, the mechanism, by which GLP-2 influences intestinal barrier function during ageing, still remains unclear. In this study, twelve 26-month-old male Sprague-Dawley rats were randomized to old group and old+GLP-2 group. 3-month-old male SD rats were used as control group. Compared with young rats, the old rats had a significantly thinner intestinal mucosa and shorter, rare villi. The ileum villi of old rats were significantly thicker after GLP-2 treatment. By using fluorescein isothiocyanate (FITC)-labeled dextran, the intestinal permeability in GLP-2 treated old rats were decreased. The plasma GLP-2 levels were negatively correlated with the FITC levels ($r=-0.610$, $P<0.01$). The tight junction of intestinal epithelial cells, as detected by transmission electron microscopy, was clearer in the old+GLP-2 group than that in old rats. Moreover, GLP-2 treated rats showed the increased mRNA and protein expression of Zonula Occludens-1 (ZO-1) and Occludin. These results indicated GLP-2 improve the small intestinal epithelial barrier function in aged rats by alleviating an increasing permeability and morphological changes through up-regulation of the tight junction protein ZO-1 and Occludin.

DEPRESSION, SEX, AND GENDER ROLES IN AN OLDER BRAZILIAN POPULATION

A. Freire¹, A. Vafaei², C. Gomes¹, J. Barbosa¹, R.O. Guerra¹,
1. *Universidade Federal do Rio Grande do Norte, Natal, Brazil*, 2. *Queen's University, Kingston, Ontario, Canada*

Methods: Cross-sectional survey of a population of adults 65 years and older (n=256) in Natal (northeast of Brazil). Depression was defined in the Center for Epidemiologic Symptoms Depression Scale (CES-D \geq 16). We used a 12 items validated version of the Bem Sex Role Inventory (BSRI) to classify participants in four gender roles (Masculine, Feminine, Androgynous and Undifferentiated). Poisson regressions were fitted to estimate the prevalence ratios (PR) of depression for each gender role compared with the masculine role, and adjusting for sex, age, sufficiency of income, self-rated health and chronic conditions. Results: Almost all participants (n=237, 93%) were able to answer the questions in spite of low literacy. Gender roles were not associated with sex. 50% were classified as masculine, 19% as feminine, 32% as androgynous and 27% as undifferentiated. Depression prevalence was high (39.7%). Gender roles remained associated with depression prevalence after adjustment for covariates. Those endorsing the feminine role had a depression prevalence ratio (PR) of 2.2 (95% CI: 1.2–4.1) times higher relative to those endorsing the masculine role. Corresponding figures for those undifferentiated were 1.9 (95% CI: 1.0–3.5). Those endorsing androgyny were not different from masculinity PR=1.4 (95% CI: 0.75–2.7). Conclusions: Gender roles were associated with depression, independently from being a man or a woman, suggesting that certain aspects of gender as reinforced by society may contribute to the social production of depression.

THE USE OF WORKFLOW ANALYSIS TO CHARACTERIZE PATTERNS OF OLDER ADULTS' DAILY ACTIVITIES

J. Chung¹, M. Ozkaynak³, G. Demiris², 1. *University of New Mexico, Albuquerque, New Mexico*, 2. *University of Washington, Seattle, Washington*, 3. *University of Colorado Denver, Aurora, Colorado*

Aging is often associated with disruptions in the performance of daily activities. Despite considerable efforts to accurately assess older adults' functional abilities, there is a lack of methods to characterize the ordered tasks performed by individuals to achieve a particular goal within a home environment. Workflow analysis has the potential to examine procedural aspects of daily activities and detect early changes in activities that may indicate functional deterioration among older adults. We aimed to apply the workflow analysis to older adults' daily activity data to examine the patterns of and variability in their activities. Six community-dwelling older adults filled out an activity diary for 14 consecutive days on which they recorded the location and type of activities performed inside and outside the home every 30 minutes. The EventFlow, a novel visualization tool, was used to analyze daily routine based on 1453 events. The analysis revealed great variability in activity types, levels, and timing of performing certain activities across individuals. Normal day-to-day variation in the same individual was also detected, including sleep time, time to go to bed, and time to get up from bed. When applied to the spatial information

of activity, the analysis suggested variability related to individuals' mobility in different level of life spaces from home to community. Findings suggest that the workflow approach can allow researchers to observe lifestyle alterations and to detect changes indicating deteriorating health before these changes significantly affect older adults' quality of life.

APPLICATION OF ECHO TELEMEDICINE TO NURSING HOMES TO HELP STAFF ADDRESS PROBLEMATIC BEHAVIORS

B. Humel, M. Hasselberg, E. Enfield, J. Karuza, *Psychiatry, University of Rochester, Clarence Center, New York*

ECHO (Extension for Community Healthcare Outcomes) is a collaborative model of medical education and care management that uses telemedicine to empower clinicians. Interdisciplinary specialists mentor and share their expertise across a virtual network via case-based learning, enabling primary care clinicians to treat patients with complex conditions in their own communities. University of Rochester has developed and implemented an innovated an ECHO program for nursing homes. The mission of ECHO is to educate nursing home staff by presenting challenging patient cases along with educational sessions. Clinics occur two times a week and participants are given a baseline survey of their knowledge followed by a 6 month follow-up survey. 55 patient cases and 4 follow up cases have been presented. The ECHO project covers 13 rural and urban counties and enrolled 52 nursing homes. Over the past year 1,888 staff participated and 614 CME credits awarded within the past year. Since this is a new program, evaluation data is critical to fine-tuning the curriculum to ensure it meets the needs of the nursing homes. Preliminary evaluations indicate high staff satisfaction with ECHO. Post surveys found gaps in knowledge and use of non-pharmacological approaches (e.g., sensory rooms, music therapy, doll therapy) to treat difficult behaviors and lack of appropriate staff training on how to handle behavior problems. The initial evaluation data provide strong evidence for the feasibility of applying the ECHO model to nursing homes. Next steps include the development and dissemination of a novel curriculum on behavioral problems tailored to nursing homes.

PREDICTORS OF AND BARRIERS ASSOCIATED WITH HIV TESTING AMONG OLDER ADULTS IN THE UNITED STATES

O. Sims¹, Y. Guo², 1. *The University of Alabama at Birmingham, Birmingham, Alabama*, 2. *The University of Alabama, Tuscaloosa, Alabama*

Older adults are the fastest growing segment of people living with HIV and unfortunately many are unaware of their HIV status. Many providers are reluctant to ask older adults about their sexual histories, evaluate their risk factors, and test for HIV, and older adults have low perception of HIV risk. Using data from the 2013–2014 National Health and Nutrition Examination Survey, this study assessed the prevalence of recent HIV testing among older adults in the United States (n=1,056) and identified predictors and barriers to recent HIV testing. To achieve these objectives, the analysis was guided by the Systems Model of Clinical Preventive Care (SMCPC). A binominal logistic regression model was used to determine the odds of HIV testing uptake adjusting for

predisposing factors, enabling resources, reinforcing factors, and situational factors. The prevalence of recent HIV testing was 28%. Recent HIV testing was associated positively with male gender, education level, having public insurance, having same sex sexual behavior, African and Hispanic ethnicity; whereas, age, income-to-poverty ratio, and Asian ethnicity were associated negatively with recent HIV testing. Public health social workers are advised that targeted HIV testing for Asian, economically disadvantaged, female older adults is needed to increase HIV awareness and detection and to decrease late diagnosis of HIV. Provided public insurance was identified as a predictor of recent HIV testing, facilitating economically disadvantaged older adults' eligibility for public insurance will likely improve access to HIV testing services and increase HIV testing rates.

COMPARISON OF FOUR RISK SCORING SYSTEMS FOR OLD PATIENTS: A PROSPECTIVE MULTICENTER STUDY IN CHINA

F. Liu¹, J. Qin¹, X. Liang¹, J. Wang¹, P. Chan^{3,2,4}, 1. Department of Emergency, Xuanwu Hospital of Capital Medical University, Beijing, China, 2. Department of Neurobiology, Beijing Institute of Geriatrics, Xuanwu Hospital of Capital Medical University, Beijing, China, 3. Department of Geriatrics, Beijing Institute of Geriatrics, Xuanwu Hospital of Capital Medical University, Beijing, China, 4. Department of Neurology, Beijing Institute of Geriatrics, Xuanwu Hospital of Capital Medical University, Beijing, China

Objective: There are a few scoring systems in emergency departments (ED) to establish critically ill patients quickly and properly and to predict in-hospital death. We aim to compare the efficacy of National Early Warning Score (NEWS), Modified Early Warning Score (MEWS), Rapid Emergency Medicine Score (REMS) and quickSOFA (qSOFA) on in-hospital mortality in general older ED patients in different areas of China.

Methods: This is a prospective, multicenter and observational study. The study included general patients admitted to the EDs of nine teaching hospitals between 1st October, 2013 and 31 May, 2014. The primary outcome of the study is in-hospital mortality. Accuracy in predicting outcome measures was assessed by calculating the area under receiver operating characteristic curve (AUC).

Results: Total patients were 1528 (51.6% male, 48.4% female). The mean age was 75.86±8.46. Fifty-eight patients were dead in-hospital; the NEWS AUC for predicting in-hospital death was 0.834(0.778~0.890), the MEWS AUC was 0.753(0.679~0.827), the REMS AUC was 0.718(0.638~0.799) and the qSOFA AUC was 0.780(0.714~0.846). NEWS was found to have a better predictive strength than MEWS ($p<0.001$), REMS ($p=0.002$), qSOFA ($p=0.020$) in terms of predicting in-hospital mortality of patients presenting to ED, while the differences between MEWS, REMS and qSOFA were not significant.

Conclusions: The efficiency of NEWS was found to be superior to MEWS, REMS and qSOFA as a predictor of in-hospital mortality in older ED patients. The qSOFA, a score developed for predicting sepsis patients' in-hospital mortality, can also be used as a predictor of in-hospital mortality in older ED patients.

ASSOCIATION OF LIFELONG EXPOSURE TO COGNITIVE RESERVE-ENHANCING FACTORS WITH DEMENTIA RISK

H. Wang¹, S.W. MacDonald², S. Dekhtyar¹, L. Fratiglioni¹, 1. Karolinska Institutet, Stockholm, Sweden, 2. University of Victoria, Victoria, British Columbia, Canada

Background and aims: We examined the association of cognitive reserve-related factors over the lifespan with the risk of dementia in a community-based cohort of older adults.

Methods: Information on early-life education, socioeconomic status, work complexity at age 20; mid-life occupation attainment; and late-life leisure activities was collected in a cohort of non-demented community dwellers (n=602) aged 75+ residing in Stockholm, Sweden in 1987–1989. The cohort was followed up to 9 years (until 1996) to detect incident dementia cases. Participants who developed dementia three years after the baseline were excluded. Structural Equation Modelling was used to generate latent factors of cognitive reserve from early-, mid-, and late-life.

Results: A reduced risk of dementia was associated with early (RR: 0.6; 95% CI: 0.4–0.9), adult (RR: 0.6; 95% CI: 0.4–0.9), and late life (RR: 0.5; 95% CI: 0.4–0.7) reserve-enhancing latent factors in separate multivariable Cox models. Late life (RR: 0.7; 95% CI: 0.5–0.9) and partially, midlife factors (RR: 0.7; 95% CI: 0.5–1.06) preserved their association, but the effect of early life factor was attenuated (RR: 0.8; 95% CI: 0.5–1.2) in mutually adjusted model. The risk declined progressively with cumulative exposure to reserve-enhancing latent factors, and having high reserve scores in all three periods was associated with the lowest risk of dementia (RR: 0.40; 95% CI: 0.20–0.81). Similar associations were detected among APOE ε4 allele carriers and noncarriers.

Conclusions: Cumulative exposure to reserve-enhancing factors over the lifespan is associated with reduced risk of dementia in late life, even among individuals with genetic predisposition.

HEART DISEASE, DIABETES AND DEMENTIA'S ASSOCIATION WITH FUNCTIONAL TRAJECTORIES OVER 5 YEARS

J. MacNeil Vroomen¹, L. Han¹, J. Monin², H. Allore¹, 1. Yale School of Medicine, New Haven, Connecticut, 2. Yale School of Public Health, New Haven, Connecticut

Prevalence of functional disability related to chronic diseases are expected to increase as the population ages. Given that multimorbidity is common in older adults, we focus on heart disease, diabetes, both require complicated self-care, and dementia, which may make self-care more difficult, associations with functional disability over five years. Participants were a nationally representative sample of Medicare beneficiaries ages ≥65 years from 2011–2015 (N=7,609) from the National Health and Aging Trends Study. Annual in-person interviews included sociodemographic information, self-reported, physician-diagnosed chronic conditions, activities of daily living (ADL) and cognitive status. Trajectories of functional decline and attrition over 5 years were jointly estimated using group-based trajectory modeling and generalized to national estimates. Associations between ADL trajectory membership and diabetes, heart disease and dementia were examined using multinomial logistic regression, while

generalizing to national estimates and adjusting for patient characteristics. Three distinctive functional disability trajectories were identified in the overall sample and applied to national sample weights; 75.6% had no disability, while 14.7% had mild and increasing disability and 9.7% had severe and increasing disability. Persons with probable dementia had the highest odds ratios of functional disability. We found that approximately 25% of the US community-dwelling population ≥ 65 is likely to have functional disability over 5-years. Persons with dementia only had the highest odds of functional disability over a 5-years. Interventions targeting the dementia population are needed to prolong functional independence.

SARCOPENIA: PREVALENCE AND PROGNOSIS IN OLDER PATIENTS WITH CARDIOVASCULAR DISEASE

K. Kamiya¹, N. Hamazaki², R. Matsuzawa³, N. Kohei³, S. Tanaka², A. Matsunaga², T. Masuda², J. Ako¹, 1. *Kitasato University, Sagamihara, Kanagawa, Japan*, 2. *Kitasato University Graduate School of Medical Sciences, Sagamihara, Japan*, 3. *Kitasato University Hospital, Sagamihara, Japan*

To date, no study has systematically investigated the prevalence of sarcopenia in cardiovascular disease (CVD) according to the international consensus definition. The aim of this study was to investigate the prevalence and prognostic value of sarcopenia in older patients with CVD. The study population consisted of 1929 admitted patients aged 60 years and older (72.3 ± 7.3 years, 633 females) with CVD. Sarcopenia was defined according to the recommended diagnostic algorithm of the Asia Working Group for Sarcopenia (AWGS). Handgrip strength was measured with a handheld dynamometer, and gait speed was measured by a 10-m walking test. Using the cut-off points from the AWGS consensus, low hand grip strength was defined as <26 kg for men and <18 kg for women, and slow gait speed was defined as <0.8 m/sec. The muscle mass was estimated according to a previously validated anthropometric equation in Asian population. The endpoint was all-cause mortality. The prevalence of sarcopenia was 26.8% (male:17.6%, female:45.7%) and increased with age (<75 years: 16.5%, 75–84 years: 40.3%, ≥ 85 years: 62.6%, P for trend <0.001). During follow-up (2.3 ± 2.2 years), 203 deaths occurred. Patients with sarcopenia had a higher risk of all-cause death compared with non-sarcopenic patients (age-sex adjusted hazard ratio: 2.00, 95% confidence interval: 1.46 - 2.73, $P < 0.001$). The present study suggests that sarcopenia is highly prevalent among older patients with CVD and it is associated with increased mortality.

HIGH-DENSITY LIPOPROTEIN CHOLESTEROL LEVEL AND COGNITION IN OLD AGE: THE ROLE OF COGNITIVE RESERVE

A. Ihle¹, E.R. Gouveia², B.R. Gouveia³, D.L. Freitas², J. Jurema⁴, M.A. Tinôco⁵, M. Kliegel¹, 1. *Center for the Interdisciplinary Study of Gerontology and Vulnerability, University of Geneva, Carouge, Switzerland*, 2. *University of Madeira, Funchal, Portugal*, 3. *Saint Joseph of Cluny Higher School of Nursing, Funchal, Portugal*, 4. *Amazonas State University, Manaus, Brazil*, 5. *Federal Institute of*

Science and Technology Education of Amazonas, Manaus, Brazil

It remains unclear so far whether the negative relation of critically low high-density lipoprotein cholesterol (HDL-C) level to cognitive functioning in old age may be reduced in individuals with higher cognitive reserve accumulated during the life course. Therefore, the present study set out to investigate the relation of HDL-C level to cognitive performance and its interplay with key markers of cognitive reserve (education, cognitive level of job, and cognitive leisure activity) in a large sample of older adults. We assessed tests of working, short-term, and long-term memory in 701 older adults (mean age = 70.4 years) from Fonte Boa, Apuí, and Manaus, Brazil. HDL-C level was derived from fasting blood samples. In addition, we interviewed individuals on their education, past occupation, and cognitive leisure activity. Results showed that critically low HDL-C level (< 40 mg/dl) was significantly related to lower performance in working memory ($r = -.28$, $p < .001$), short-term memory ($r = -.24$, $p < .001$), and long-term memory ($r = -.24$, $p < .001$). These relations were significantly moderated by education, cognitive level of job, and cognitive leisure activity (β s $\geq .08$, $ps < .05$). Subsequent analyses revealed that the relation of HDL-C level to cognitive performance was negligible in individuals with longer education, higher cognitive level of job, and greater engaging in cognitive leisure activity (β s $< .07$, $ps > .05$). In conclusion, cognitive reserve accumulated during the life course may reduce the detrimental influences of a low HDL-C level on cognitive functioning in old age.

ALTERNATIVES TO ACUTE HOSPITAL CARE FOR THE OVER 65S AT RISK OF UNPLANNED ADMISSION

A. Huntley¹, M. Chalder¹, A. Heawood¹, C. Metcalfe¹, W. Hollingworth¹, J. Benger², S. Purdy¹, 1. *University of Bristol, Bristol, United Kingdom*, 2. *University of the West of England, Bristol, United Kingdom*

Some older patients are deemed to be 'at the decision margin' at the time of potential hospital admission. We conducted a systematic review to understand:

- what are the defining characteristics of those individuals for whom the decision to admit to acute hospital may be unclear?
- what alternatives to admission exist?
- how acceptable, safe, effective and cost-effective are each of these options?

Any controlled studies and systematic reviews of people >65 years who were at risk of an unplanned admission and offered an alternative care pathway which were published between April 2005 and December 2016 were included in our systematic review. Our outcomes of interest were reduction in secondary care use, safety, patient preferences and costs. All eligible studies were assessed using the Cochrane risk of bias tool whilst relevant reviews were assessed using the AMSTAR checklist. The results were presented narratively and discussed.

A total of 19 studies and 7 reviews were identified. These recruited patients with both specific and mixed chronic or acute conditions. Alternatives to acute admission fell into four distinct categories: paramedic/emergency care practitioners ($n=3$), emergency department-based interventions ($n=3$), community hospitals ($n=2$), and hospital-at-home

services (n=11). The factors underpinning uncertainty around the decision to admit were age >75 years, co- and multi-morbidities, dementia, home situation, availability of social support and individual coping abilities.

Data suggest that alternatives to acute hospital admission appear safe and effective, with potential to reduce secondary care use, length of time that care is needed and reliance on community resources. However, there is a lack of available information about the patient-related outcomes and costs of such interventions.

FOSTERING NURSES WHO CAN TAKE ON THE CHALLENGE OF A SUPER-AGING SOCIETY IN URBAN AREAS

Y. Yokoi, H. Fujino, M. Mitou, M. Murata, *Toho University, Tokyo, Japan*

We established an instructional lab (IELABO) in Tokyo, and then creating an environment in which nurses, nursing students and caregivers can actually put themselves in the shoes of a (fictional) elderly resident, and always being aware that the recipients of nursing care are individuals with their own lives. In this educational program, nurses and caregivers learned together. As they progressed through the program, they learned each other's strengths, thereby building the framework for collaboration. We shared the IELABO learning outcomes with residents in Tokyo. We place great stock in the motivational value of such civic pride in work.

Major points of outcome are summarized as follows:

1. By learning in a home setting, learners could place themselves next to the elderly persons in their care and their family members, and devise and implement a realistic care plan centered on the daily lives of said persons.

2. By enabling communication in a daily-life setting (i.e., the home), care providers could discuss daily life-oriented care with care providers working in other care provision settings, leading to mutual understanding.

The IELABO became the hub of this program. In the presentation, the outline of the IELABO project as well as its details is presented with special emphasis on the collaboration framework among the nurses, caregivers, and local communities. This will provide a new perspective to the practical and conceptual studies of comprehensive care for elderly citizens.

USING MAINTENANCE OF CERTIFICATION TO PROMOTE ADVANCE DIRECTIVE DISCUSSIONS IN PRIMARY CARE

E. Duthie¹, J. Myers¹, D. Simpson², K. Denson¹, S. Denson¹,
1. *Medical College of Wisconsin, Milwaukee, Wisconsin*, 2. *Aurora UW Medical Group, Milwaukee, Wisconsin*

Background: Physicians and patients agree that primary care visits are the appropriate place to discuss advance directives (AD) with geriatric patients as it normalizes the discussion. Yet barriers are known to keep AD completion rates low.

Methods: An interprofessional team designed and implemented a three-health care system approved AD focused Maintenance of Certification (MOC) Part IV activity for primary care physicians (PCPs) to meet American Board of Medical Specialists (ABMS) requirements. The activity focuses on PCPs initiation of brief (2–3 min) AD conversations

with geriatric patients. The activity was launched at a state-wide PCP meeting using a workshop that employed interactive educational strategies (quiz, video analysis, role play). Retrospective “post-post” evaluation focused on workshop processes and outcomes.

Results: Eight PCPs completed the session reporting that at baseline the modal number of conversations PCPs initiated each week about ADs was < 1/week (range 0 to > 10). All participants targeted a minimum 25% increase in AD conversations as the improvement goal. Post workshop evaluation analysis found: 1) improvement among four literature-based barriers to AD discussions in the aggregate of responses; 2) all participants were more likely to initiate conversations with patients about ADs; and 3) 88% (7/8) were “very likely” to recommend the session to a colleague.

Conclusion: Experienced PCPs perceive AD discussions as fraught with barriers. This brief (90 min) interactive AD discussion focused MOC activity minimized perceived barriers and increased primary care physician commitment to increase AD discussions with geriatric patients.

COGNITIVE RESERVE AND COGNITION IN OLD AGE: THE MEDIATING ROLE OF CHRONIC DISEASES

A. Ihle, M. Oris, D. Fagot, C. Chicherio, B.W. van der Linden, J. Sauter, M. Kliegel, *Center for the Interdisciplinary Study of Gerontology and Vulnerability, University of Geneva, Carouge, Switzerland*

The present study is the first so far in empirically testing the recent conceptual view that the number of chronic diseases may mediate between the build-up of cognitive reserve (e.g., by educational attainment and cognitive level of job) on the one hand and cognitive performance on the other. We assessed Psychometric tests on processing speed and verbal ability in 2812 older adults (mean age = 77.9 years) from Switzerland. Individuals were interviewed regarding their education, occupation, and chronic diseases. Results showed that higher educational attainment and higher cognitive level of job were significantly related to better performance in processing speed ($r_s \geq .15$, $p_s < .001$) and verbal ability ($r_s \geq .27$, $p_s < .001$). These relations were significantly mediated via the number of chronic diseases. Mediation effects of the relation of educational attainment to cognitive performance were 5.3% exerted indirectly ($\beta = .01$, $p = .007$) for processing speed and 1.5% exerted indirectly ($\beta = .01$, $p = .014$) for verbal ability. Mediation effects of the relation of cognitive level of job to cognitive performance were 7.3% exerted indirectly ($\beta = .01$, $p = .004$) for processing speed and 1.8% exerted indirectly ($\beta = .01$, $p = .015$) for verbal ability. In conclusion, individuals with higher educational attainment and higher cognitive level of job in early and midlife may suffer from fewer chronic diseases later in life. This may finally preserve their performance in verbal ability and processing speed in old age.

ASSOCIATION BETWEEN FRAILTY AND POSTOPERATIVE COMPLICATIONS IN PATIENTS UNDERGOING ABDOMINAL SURGERY

M. Smietniansky, E. Gonzalez Zalazar, B. Boietti, V. Ardiles, M. Cal, E. Riggi, L. Camera, E. De Santibañes, *Internal Medicine - Geriatrics, Hospital Italiano de Buenos Aires, Buenos Aires, Ciudad Autonoma de Buenos Aires, Argentina*

Background: Although several studies relate frailty with poor postoperative outcomes, trials with specific intraabdominal surgery cohorts are scarce.

Objetives: To evaluate the association between frailty and 1 month postoperative complications, and 3 months mortality

Materials and Methods: Observational, descriptive and analytical study of a prospective cohort. Patients older than 70 years who underwent elective surgery were evaluated in the preoperative area of Italian Hospital from Buenos Aires, with the Edmonton Frail Scale. Data were collected between June 4, 2014 and February 1, 2017. We estimated mortality risk and complication risk with a logistic regression. We reported OR and 95% confidence intervals. A multivariate logistic regression analysis was performed to control confounding

Results: We included 85 patients, 18% (15) were frail, mean age 80.3 years old (SD 7.1). The non frail group was younger 76.4 (SD 5.5). Overall 3 months mortality was 20% (3) for frail and 1.4% (1) for non frail patients, OR 17.2 (IC95% 1.65–179.9, p 0.02). After adjusting for sex, age, comorbidity and oncologic surgery this association persisted statistically significant, OR 36.8 (IC95% 2.4–543.9, p 0.01). 53.3% (8) of frail patients and 17.1% (12) of non frail patients had complications within 1 month postoperatively, OR 5.5 (IC95% 1.6–18, p 0.01) and after adjusting for confounders this association persisted statistically significant OR 5.71 (1.43–22.7, p 0.01).

Conclusion: In this population, the presence of frailty was associated with a significant increase in overall postoperative complications and death.

COMPARISON SURVEY ON FAMILY CAREGIVERS OF ELDERLY PEOPLE IN THAILAND AND JAPAN

C. Greiner¹, D. Tamdee², N. Okamoto³, P. Tamdee², T. Isowa⁴, W. Boonchiang², H. Ryuno¹, A. Kitagawa⁴, 1. *Kobe University, Kobe, Japan*, 2. *Chiang Mai University, Chiang Mai, Thailand*, 3. *Sophia University, Chiyoda-ku, Japan*, 4. *Mie University, Tsu, Japan*

Purpose: The purpose of this study was to clarify the situations of and differences between family caregivers of elderly people in Thailand and Japan, and obtain basic data that can be used for constructing family support systems in both countries through collaboration and the applying of each country's strengths.

Methods: A cross-sectional exploratory descriptive research design was employed. Participants were family members taking care of elderly people at home. Data were collected in the Kanto, Kinki, and Tokai areas of Japan, and three districts in Chiang Mai in Thailand. This research was approved by the first presenter's Institutional Review Board.

Results: Of a total of 114 family caregivers in Japan, 82 (71.9%) were female and mean age was 64.8 ± 11.1 years. In Thailand, 76 (73.8%) of 103 family caregivers were female and mean age was 49.1 ± 13.3 years. Family caregivers in Thailand felt more healthy both mentally and physically ($p = .000$, $p = .000$). Specifically, they felt a lighter care burden and less loneliness ($p = .000$, $p = .000$) compared to those in Japan, which relate to family caregivers in Thailand having more social connections and informal support than those in Japan ($p = .000$, $p = .000$).

Conclusion: Despite there being a long-term care insurance system in Japan and not Thailand, the condition of family caregivers was better in Thailand than in Japan. We conclude that social connection and informal support are important factors of well-being for family caregivers.

CONTRIBUTING FACTORS FOR AVOIDABLE HOSPITALIZATION IN SWISS NURSING HOMES

F. Zuniga¹, T. Brunkert¹, M. Giger¹, M. Simon^{1,2}, 1. *Basel University, Basel, Switzerland*, 2. *Nursing Research Unit, Inselspital University Hospital Bern, Bern, Switzerland*

The reduction of avoidable hospitalizations from nursing homes (NHs) is a high priority because of the high human and financial costs. Common hindering factors range from the lacking diagnostic services and trained personnel in the NH to patient and family wishes and the lack of individual advanced care plans or do-not-hospitalize orders. This study reports the systematic assessment of barriers and facilitators of avoidable hospitalizations in a group of 20 private NHs in Switzerland. The results are embedded in the ProQuaS study, an implementation science project guided by the Consolidated Framework for Implementation Research (CFIR).

In a cross-sectional questionnaire survey in summer 2016, 20 NH directors, 34 ward supervisors and 61 registered nurses (RNs) assessed the current situation. Over 70.6% (95%-confidence intervals (CI): 0.52- 0.84) of the ward supervisors considered it important to implement changes to reduce hospitalizations, and 29.4% (CI: 0.16- 0.48) reported to never or seldom have do-not-hospitalize orders discussed with admitted residents. Moreover, 70.6% (CI: 0.52- 0.84) agreed that emergency physicians' lack of familiarity with the resident at night or weekends is a central factor for hospitalizations. Similarly, only 67.8% (CI: 0.54- 0.79) of RNs state that the assigned physician can be reached in time in emergency situations. Overall, critical factors related to avoidable hospitalizations include the clarification of residents' wishes, do-not-hospitalize orders and the availability of physicians. Insights from this survey will guide the development of a locally adapted intervention to reduce hospitalizations.

CURRENT STATUS OF DENTAL INTERVENTION AND SAFETY MANAGEMENT IN THE DEMENTIA WARD

A. Yamaguchi, S. Nozue, Y. Maruoka, T. Tsuneoka, S. Hironaka, Y. Sato, K. Takahashi, *Showa University, Tokyo, Japan*

Safety management in psychiatric medical care includes issues of suicide, self-injurious behavior, accidents, medication errors, escape from the hospital, and unauthorized overnight stays. Additionally, preventing asphyxia is a challenge in the dementia ward of our hospital. Dentists have conducted intraoral examinations and evaluation of ingestion/swallowing function in patients, and have performed dental interventions. As a result of the safety management by the team medical care, the ward maintains 0 asphyxia. Therefore, the oral function and dental intervention of recent patients for higher safety management will be present. The subjects were 229 hospitalized patients in the dementia ward between April 2014 and December 2016. Using the medical records, age, sex, primary disease, oral function, and details

of dental intervention were extracted. The subjects were aged 59–99 years, and the ratio of men to women was 10:13. Alzheimer type dementia was the most common disease, accounting for 60% of the total. There were 66% of the all patient who needed oral hygiene control and were able to intervene. The patients who did not have occlusal support in molars accounted for 47% of the total. Seventeen of the 80 patients who needed dental treatment were difficult to be treated. The types of dental treatment were denture adjustment / repair, denture construction, conservative treatment, and teeth extraction under intravenous sedation. Extraction was performed for prevention of accidental biting, ingestion, and aspiration. The examining the background of patients who experienced difficulties with dental intervention may lead to improved safety management in future.

FACET JOINT OSTEOARTHRITIS INCIDENCE IS ASSOCIATED WITH BACK PAIN IN OLDER ADULTS: FRAMINGHAM STUDY

L.J. Samelson¹, M. Jarraya², D.P. Kiel¹, M.S. Yau³, T. Trivison¹, P. Suri⁴, A. Guermazi⁵, 1. *Harvard Medical School/Inst for Aging Research, Hebrew Rehab Ctr, Boston, Massachusetts*, 2. *Mercy Hospital, Philadelphia, Pennsylvania*, 3. *Hebrew SeniorLife, Boston, Massachusetts*, 4. *University of Washington, Seattle, Washington*, 5. *Boston University Medical Center, Boston, Massachusetts*

Back pain in older adults is a major public health problem, and facet joint osteoarthritis (FJOA) is commonly treated as the source of this pain. Despite the clinical importance, little is known about the relation between longitudinal changes in FJOA and pain symptoms. The purpose of this study was to determine the association between incidence of FJOA over 6yr, evaluated by CT, and self-reported back pain in a community-based cohort. Participants included 885 cohort members of the Framingham Study: 491 women, 394 men, 40–85 yr (mean=63 yr, SD=+8 yr). FJOA was graded by a musculoskeletal radiologist (MJ) bilaterally from T4/T5 to L4/L5 on baseline and follow-up CT images as: grade 0=normal, 1=mild, 2=moderate, or 3=severe. Incidence of moderate/severe FJOA was defined as an increase at any spinal level from grade 0 or 1 at baseline to grades 2 or 3 at follow-up. During the follow-up period, participants reported frequency of back pain (no, some, most, or all days/month in the past year). 6-year incidence was 33% for moderate/severe FJOA. 23% of participants reported having back pain on some days/month, 7% on most days/month, and 13% on all days/month. Incidence of moderate/severe FJOA increased with frequency of back pain: OR=1.00 (no back pain), OR=1.06, 0.74–1.51 (some days/month), OR=1.24, CI=0.72–2.14 (most days/month), OR=1.64, CI=1.07–2.50 (all days/month); trend, $p=0.03$. Our results suggest that CT based findings of incident moderate/severe FJOA may have clinical importance for prevention and treatment of back pain in older adults.

A NEW APPROACH TO BENCHMARK CARE PRACTICE BASED ON COSTS AND QUALITY OF CARE: THE IBENC METHOD

H.G. van der Roest¹, L. van Lier¹, G. Onder³, V. Garms-Homolova⁴, H. Finne-Soveri⁵, P.V. Jonsson⁶, J. Bosmans², H. van Hout¹, 1. *VU University Medical Center, Amsterdam, Netherlands*, 2. *VU Amsterdam, Amsterdam,*

Netherlands, 3. *Università Cattolica del Sacro Cuore, Rome, Italy*, 4. *Hochschule für Technik und Wirtschaft, Berlin, Germany*, 5. *National Institute for Health and Welfare, Helsinki, Finland*, 6. *Landspítali, Reykjavik, Iceland*

To achieve sustainability of our health care system, care should be delivered more efficiently in the future to serve the rapidly ageing population. Evidence-based restructuring of systems should build on reliable benchmarks of the combination of quality and costs of care. These currently lack. A novel benchmark method on organizational efficiency in home care was developed.

Longitudinal data were collected in the European IBenC project among 2884 home care clients from 38 home care organizations (six countries). Data-collection capitalized on the comprehensive geriatric assessment instrument interRAI-HC. Quality was expressed by the 11-point Independence Quality scale (IQS) and Clinical Balance Quality scale (CBQS), respectively reflecting quality of care aimed at functional independence and engagement, and on functional improvement. Higher scores indicating better quality. Cost of care over six months were estimated by valuing resource utilization with Dutch standard costs. Case-mix adjustments were applied.

Quality varied between poor to good: IQS scores varied between 2 and 7, CBQS between 4 and 8. Mean adjusted costs were €21,004 (range €14,300–€24,209). Per organization outcomes were combined in the IQS-index and CBQS-index. Index values of 1 indicate average quality against average costs, higher values reflect better organizational efficiency. IQS-index ranged between 0.49 to 1.74 and CBQS-index between 1.00 and 1.66. The indexes had high face-validity compared to the plotted costs and quality, and discriminated between organizational efficiency.

The indexes permit for a new way of benchmarking, opening up possibilities for unexplored areas of research and knowledge in organizational performance and restructuring care systems.

QUALITY INDICATORS RELATED TO MEAL SATISFACTION AND ADEQUATE NUTRITIONAL STATUS IN ELDERLY CARE

M. Skinnars Josefsson¹, M. Nydahl¹, I. Persson², Y. Mattsson Sydner¹, 1. *Department of Food, Nutrition and Dietetics, Uppsala University, Uppsala, Sweden*, 2. *Department of Statistics, Uppsala University, Uppsala, Sweden*

Studies of organizational prerequisites for nutritional care practice and their effect on meal satisfaction and nutritional status of older adults in residential care homes are scarce. Guided by Donabedians' model of quality of care, the aim was to explore structure and process quality indicators of nutritional care practice that predict residents' meal satisfaction and adequate nutritional status according to MNA-SF, in Swedish elderly care. Data at municipal level from i) a national questionnaire, ii) records from a quality registry and iii) a benchmarking survey, were merged. Logistic and multiple regression analyses included 117 municipalities (of 290 in Sweden). Residence in rural and urban municipalities predicted meal satisfaction over city municipalities. Independent structure indicators of meal satisfaction were local food policy, cooking on-site and private meal providers, and independent process indicators were choice of meals

and residents' possibility to influence the menu. Adequate nutritional status was positively predicted by the structure indicator availability of clinical/community dietitian and the process indicator calculation of nutritional content of meals. To conclude, a locally adapted organization adjusted to residents' choices, and availability of dietitians, benefit meal satisfaction and nutritional status among older adults in residential care homes. The results from this study can benefit future interventions aiming to improve nutritional care practice and serve as guidance for leaders in elderly care organizations.

NEIGHBORHOOD FACTORS RELATED TO FUNCTIONAL LIMITATIONS AMONG OLDER ADULTS IN MEDICARE ADVANTAGE

D.H. Jung¹, E. DuGoff¹, W. Buckingham³, A.J. Kind², 1. *Department of Population Health Sciences, School of Medicine and Public Health, University of Wisconsin, Madison, Wisconsin*, 2. *Department of Medicine, School of Medicine and Public Health, University of Wisconsin, Madison, Wisconsin*, 3. *Applied Population Laboratory, Department of Community and Environmental Sociology, University of Wisconsin, Madison, Wisconsin*

Over 90% of older adults in the US report that they wish to age in place. Preventing and mitigating functional limitations is important for maintaining independence, but identifying those who needs services and supports to remain independent is challenging for health plans. The Area Deprivation Index (ADI) is a validated neighborhood-level measure of socioeconomic disadvantage that has been associated with mortality and hospital readmissions. The ADI could potentially be harnessed to target those at risk for functional limitations, yet the relationship between the ADI and functional limitations has not previously been examined. This study includes 182,796 Medicare Advantage beneficiaries aged 65 or older who participated in the Medicare Health Outcome Survey in 2013. We used a multivariate linear probability model accounting for the complex survey design to examine the association of high neighborhood-level disadvantage (defined as ADI \geq 85th percentile) and any functional limitations (1 or more difficulty with an activity of daily living (ADL) or an instrumental ADL). We also examined whether health, measured by number of chronic conditions, mediated this relationship. In 2013, 1.3 million Medicare Advantage beneficiaries were living in a high-disadvantaged neighborhood, and these individuals were significantly more likely to report any functional limitation compared to individuals living in a less-disadvantaged neighborhood. Among individuals in high-disadvantaged neighborhoods, the probability of reporting a functional limitation was significantly greater in individuals with multiple chronic conditions, but the neighborhood-level affect attenuated somewhat as the number of reported chronic conditions increased. Health plans should consider using a neighborhood-level measure of disadvantage to target independent living interventions.

SPATIAL POLYGAMY IN LATER LIFE: THE MANY GEOGRAPHIES OF AGING

J. Finlay, *University of Minnesota, Minneapolis, Minnesota*

Older adults' lives are increasingly negotiated in, transformed by, and informed through a broad range of physical,

social, and emotional settings. Seated and mobile interviews with community-dwelling older adults (n=125, mean age 71 years) explored everyday contexts of aging in three distinct case studies of the Minneapolis (USA) metropolitan area. Qualitative thematic analysis revealed that participants inhabited overlapping past and present contexts. They exhibited 'spatial polygamy' by being attached and exposed to multiple contexts across space and time. Nested contexts operated at the scale of the body, dwelling, surveillance zone (watchful spaces visible and/or audible from the home), neighborhood, and beyond spaces (meaningful distal locations such as past employment sites and travel destinations). These dynamic, multi-scalar spaces provided both change and stability over time. Temporal context importantly shaped participant experiences of aging, such as diurnal, seasonal, and longitudinal factors. For instance, participants demonstrated differing perceptions of neighborhood safety in the day versus night; climactic variation posed seasonal challenges and vulnerabilities; and objects around the home evoked rich imaginative connections to the past. Participants' everyday lives were bimodal in time and space, with clusters of activity spent in distinct locales at specific times. The findings enrich environmental gerontology by attending to overlapping socio-physical contexts that range from the intimate scale of the body to broader community settings. Analyses integrate often-overlooked temporal elements that frame and calibrate spatial experiences of aging. The observations illustrate aging as a complex geographic process that evolves dynamically through time and space.

PROVIDING CARE TO PARENTS IN KOREA: FILIAL PIETY, RECIPROCITY, AND PARENT-CHILD RELATIONSHIP QUALITY

K. Ko, A. Chapman, *University of Missouri-Columbia, Columbia, Missouri*

Adult children's attitudes towards caring for aging parents are important to predict their caregiving behavior. Using 2006 EASS (East Asian Social Survey), this study examined how caregiving activities in South Korea can be explained by three major factors: filial piety, reciprocity, and parent-child relationship quality. The result of multiple logistic regression showed that adult children who were given more support from parents and who had better relationship quality with parents were more likely to provide caregiving. However, filial piety representing traditional value of supporting parents was not significantly related to adult children's caregiving behaviors. These results have great implications for contemporary South Koreans. First, emphasizing the importance of filial piety may not be ineffective for adult children to care for their parents. This can imply that the traditional norm of piety has weakened as South Korea has experienced rapid social changes under the influences of economic growth and globalization. Second, reciprocity, a concept rooted in social exchange theory, may be more popular rationale of exchanging inter-generational support between parents and adult children, which can be regarded as westernization. Third, parents should be encouraged to develop and maintain good relationships with their adult children, which can increase the possibility to get supported too.

CHARACTERISTICS OF OPINION LEADERS AND BOUNDARY SPANNERS IN LONG-TERM CARE

W.B. Berta¹, J. Keefe², L. Cranley¹, D. Taylor³, E. McAfee², G. Thompson⁴, J. Baumbusch⁵, J. Profetto-McGrath⁶, 1. *University of Toronto, Toronto, Ontario, Canada*, 2. *Mount Saint Vincent University, Halifax, Nova Scotia, Canada*, 3. *Interior Health, Kelowna, British Columbia, Canada*, 4. *University of Manitoba, Winnipeg, Manitoba, Canada*, 5. *University of British Columbia, Vancouver, British Columbia, Canada*, 6. *University of Alberta, Edmonton, Alberta, Canada*

The Advice Seeking Networks in Long Term Care Study used social network analysis to understand the informal advice networks of senior leaders in Canadian long term care (LTC), with the goal of using this knowledge to inform future efforts to more effectively disseminate quality improvement innovations. In this abstract we describe one main component of the study, a qualitative analysis of interviews conducted with 39 opinion leaders, boundary spanners, and advice seekers identified in interpersonal advice networks in the sector. At each of the 958 LTC facilities spanning 11 of Canada's 13 provinces and territories, we asked one senior leader to complete a survey identifying individuals who were informal sources of advice about quality improvement. The survey data from 482 respondents was then used to identify and interview network advice seekers by their out-degree scores, opinion leaders by their in-degree scores, and boundary spanners by their betweenness centrality scores. Results from thematic analysis of the interviews indicated that advice seekers tend to seek advice from those with whom they deem trustworthy and knowledgeable and with whom they share similar professional backgrounds and care philosophies. Opinion leaders possess an appetite for change and a strong sense of responsibility for improving care throughout the LTC system. They often have career trajectories that move them from clinical to administrative or oversight roles. Advice seeking relationships often endure over many years, transcending roles and even care sectors, and can evolve into reciprocal relationships.

BARRIERS OF CREATING AGE FRIENDLY ENVIRONMENTS

E. Hwang¹, S. Lee², S. Koh², 1. *Virginia Tech, Blacksburg, Virginia*, 2. *Jeju Development Institute, Jeju, Korea (the Republic of)*

The purpose of this study was to understand barriers and supporters of creating age friendly environments. WHO's Age Friendly Cities (AFC) initiative has highlighted the importance of eight aspects including three built environmental features (i.e., housing, outdoor spaces and buildings, and transportation); five social environmental features (i.e., social participation, respect and social inclusion, and civic participation and employment, communication and health services, and community support and health services).

To understand how these AFC aspects affect seniors' wellbeing in Jeju, South Korea, we used a mixed method approach and collected both quantitative data on seniors' perception on AFC (n = 500) and qualitative data asking barriers creating AFC. In our quantitative data analysis, seniors perceived that "respect and social inclusion," "social participation," and "outdoor space and buildings" as the most

important aspects. After quantitative data collection, we conducted six focus group interviews (n=43) in four urban and two rural communities in Jeju to collect qualitative data. The qualitative data showed that the most frequently stated barriers of creating AFC were related to the built environmental aspects both in urban and rural communities. The emergent themes based on qualitative data analysis were involved with sidewalk design, pedestrian safety, traffic lights, bus driver's attitude and bathroom design. Our findings are integrated to explain supporters and barriers in creating AFC.

THINKING GLOBALLY, ACTING LOCALLY FOR AGE-FRIENDLINESS: THE AGE-FRIENDLY DC INITIATIVE

M. Rosenberg¹, G. Kohn², N. Kushner², 1. *Centre for Health Development, World Health Organization, Kobe, Hyogo, Japan*, 2. *District of Columbia Office of the Deputy Mayor for Health and Human Services, Washington, District of Columbia*

Ageing and urbanization are among the most transformative demographic dynamics of the 21st century. In order to ensure that urban environments are responsive to the needs of residents across their life course, the World Health Organization (WHO) promotes the creation of Age-Friendly Cities and Communities. During 2012–2015, WHO conducted research to develop a set of core indicators of age-friendliness which measure the physical and social environment, quality of life, and equity. As part of this project, a study was conducted to measure these indicators in 15 communities worldwide. Washington, DC was one of the test sites. Some of the key findings from the indicator assessment, which was led by Age-Friendly DC staff with the cooperation of the Mayor-appointed Task Force and several government agencies, were that when inequities could be analysed there were profound differences across race and income. Importantly, this focus on equity revealed the need for more disaggregated data by age and geography at the local level. Subsequently, the WHO core indicators informed the development of the Age-Friendly DC Livability Survey, which was conducted in 2016 to track progress in implementing the Age-Friendly DC Strategic Plan. The survey found that progress was being made in home internet access while improvement is still necessary in the wheelchair accessibility of homes. The Age-Friendly DC initiative is exemplary of how the outcomes of the global project to develop metrics for age-friendliness were translated into local strategic plans and actions to create an age-friendly urban environment in the nation's capital.

WORK OR WALK? A NATIONAL MIXED-METHOD STUDY OF MATURE AGE WORKERS AND RETIREES

J. Irving, C. Kulik, *School of Business, University of South Australia, Stirling, South Australia, Australia*

The economic challenges of an aging population have led to many countries introducing policies intended to reduce older people's dependency upon the state and the age pension, through accumulation of superannuation (and other assets) and encouragement to remain in the labor force longer. The Work, Care, Health and Retirement project is a three year government and industry funded mixed-method study that explores the implications of these policies, while identifying how men and women can be supported to remain in paid

work while enjoying high levels of health and wellbeing. Selected findings from the national cross-sectional survey (n=2,100) and qualitative interviews (n=100) with Australian men and women age 45 years and over will be presented. This poster will describe the main ‘triggers’ to initiating voluntary retirement, factors associated with retirement age (such as gender, health, assets, industry and occupation) and what conditions may have delayed the decision to withdraw permanently from paid employment. This poster will also discuss dominant characteristics of older workers (65 years and over) including the type of work they undertake, how they work, and why they continue to participate in paid work past the traditional retirement age.

CONTRIBUTION OF WISDOM TO CHINESE ELDERLY WELL-BEING

E.O. Chow, J. Cheung, *City University of Hong Kong, Hong Kong, Hong Kong*

Wisdom is an important asset of elders and has been shown to be related to wellbeing, but it is not clear whether wisdom affects wellbeing or wellbeing affects wisdom. The relationship between wisdom and wellbeing has not been largely researched in an Asian cultural context and this study is the first of its kind. To clarify the relationships, this study utilized baseline data from a questionnaire of 142 Chinese community dwelling older adults aged 60 and above, invited in all the 18 districts in Hong Kong. The analysis controlled for the elder’s mastery, social support received, and a number of background characteristics. Results show that wisdom derived from inspirational engagement – social relations can contribute to older adults’ self-esteem; whilst wisdom derived from emotional management – dealing with life situations can contribute to life satisfaction. Social support continued to play an important role in Chinese older adults’ wellbeing, the primary caregiver’s support contributed to the elder’s life satisfaction unconditionally, whilst non-caregivers’ support indicated a contribution to life satisfaction contingent on the elder’s instrumental dysfunction. The results thus imply that helping older adults to make social contributions and manage life situations can improve wellbeing in later life

THE AGE-FRIENDLY NEIGHBORHOOD STRATEGY APPLIED IN MOOCA (SÃO PAULO, BRAZIL)

B. Graeff, M. Bestetti, M.A. Domingues, *University of São Paulo, São Paulo, Brazil*

In São Paulo, Mooca is a traditional Italian immigration neighborhood where 19% of the inhabitants are 60+ years, a high percentage compared to the Brazilian population. This qualitative research was intended to mobilize workers and elderly inhabitants from Mooca, and to analyze their perceptions about the neighborhood through Age-friendly cities program method proposed by the World Health Organization (2007). A committee composed by researchers, representatives of the public administration, and civil society followed the implementation of the project, and assisted in the organization of 8 focal groups: 2 groups of elderly aged 60–75 years, 2 groups of elderly aged 76+ years, 2 groups with professionals, and 2 groups of elderly people of varying ages, totaling 44 participants (29 women and 15 men). About living in Mooca being an older person, the participants highlight as positive aspects the identity and tradition

of the neighborhood, where people still know each other. As negative points, they mention: irregular sidewalks, flooding areas, the presence of homeless people, lack of green areas and non-adaptation of residential buildings for the needs of the elderly. Difficulties in obtaining participants aged 76+ years suggest that older adults have more difficulty participating in activities outside their homes. Many of them revealed they were caring for other elderly or grandchildren. Elderly participants demonstrated satisfaction in collaborating with the research, proposing that meetings should be permanent, revealing a demand for greater social interaction.

FINDING RABBIT HOLES WITHOUT FALLING IN: NAVIGATING PALLIATIVE CARE POLICY IN CANADIAN LONG-TERM CARE

D. Taylor^{1,2}, J. Keefe², L. Tay², B. Parker¹, K. Delaney², H. Cook¹, 1. *Research, Interior Health Authority, Kelowna, British Columbia, Canada*, 2. *Mount Saint Vincent University, Halifax, Nova Scotia, Canada*

Canada has one of the most regulated policy-laden long-term care (LTC) systems in the world. While there is noble intent, the high volume of policies creates ambiguity for knowledge users on how to provide quality end of life care for residents. More importantly, the desires of residents and/or their families for quality of life often get lost in the jungle of rules and regulations. Our research team titled SALTY (Seniors: Adding Life to Years) is assessing the complex interplay of LTC policies that influence palliative care. To date, we have collected 275 LTC related policies and influencing documents in four Canadian provinces and by using a policy analysis framework from NCCHPP (National Collaborating Centre for Healthy Public Policy), we plot each in a logic model (NCCHPP) according to policy function, sphere of influence (e.g., health authority, provincial, federal) and geography. Using a hermeneutics content analysis approach, each policy is examined using Kane’s (2006) 11 domains for measuring quality of life. This iterative process reveals both the extent to which policies have resident’s quality of life at the forefront and its intended and unintended effects on other factors in the logic model. In this poster, we describe the dual framework used to structure the policy analysis aimed at adding ‘life to years’ within a palliative approach. We present our preliminary results of palliative care exemplary policies, gaps, and tensions between what should be done (system) and what is preferred (resident choice) depending on the circumstances and geography.

OLDER PERSONS AND MEDICAL CANNABIS USE

J. Bobitt¹, B.P. Kaskie², K. Arora², K. Shannon², G. Milavetz², 1. *Interdisciplinary Health Sciences, University of Illinois at Urbana-Champaign, Champaign, Illinois*, 2. *The University of Iowa, Iowa City, Iowa*

While researchers have begun to illuminate critical public health issues concerning the increasing availability of cannabis, there have been few glimpses into the use of medical cannabis among older persons. The extent to which persons over 65 take medical cannabis has not been documented, nor have any of the associated outcomes. Do older adults who take medical cannabis for managing pain substitute cannabis for prescription opioids? Do older adults who take medical cannabis experience any negative side effects? This

research sought to close the gap in what is known about the use of medical cannabis among older persons and learn more about how cannabis impacts quality of life. In analyzing information provided by 80 purposively selected focus group participants across 4 Midwestern states, we found that approximately 3.7% reported taking recreational cannabis, 12.5% reported taking medical cannabis, and 18.7% reported taking cannabis for both medical and recreational purposes. While the majority of respondents, 65%, reported no cannabis use in the past year, most indicated they would consider taking cannabis for medical purposes, especially if other means of controlling pain or other medical conditions were not effective. Additional information provided by the focus group participants highlighted the critical role that health care professionals play in providing information about the use of medical cannabis.

INTEGRATIVE GROUP MOVEMENT FOR PEOPLE WITH DEMENTIA AND CARE PARTNERS: INITIAL QUALITATIVE FEEDBACK

J.J. Casey¹, K.L. Harrison^{1,2}, W. Mehling^{1,2}, D.E. Barnes^{1,2},
1. *Mental Health, San Francisco VA Medical Center, San Francisco, California*, 2. *University of California, San Francisco, San Francisco, California*

Paired PLIÉ (Preventing Loss of Independence through Exercise) is a behavioral intervention that integrates physical, mental and social activities into a multi-modal, group movement program for pairs of people with dementia and care partners. This process evaluation aimed to examine care partners' observations and reactions to the Paired PLIE Program as part of a larger RCT. Three pairs completed up to 24 in-person classes and home practice (weekly handouts with themes for reflection and practice). Data included care partners' daily written logs, weekly responses to home practice handouts, and emails received after program completion. Themes were categorized as physical, cognitive, and social/emotional based on prior work, and sub-themes were identified through an iterative, collaborative process. Physical functioning: care partners observed functional improvement and less symptomatic discomfort in both partners (e.g., dyad 3, week 9: "He could get up even without optimal chair and cushion.") Cognitive functioning: care partners observed heightened engagement and focus in affected individuals (e.g., dyad 2, week 4: "He finished two crosswords completely (this was never done prior).") Social/emotional functioning: care partners observed greater connection to the affected individual and lower stress in both partners (e.g., dyad 1, week 2: "...helped me relax and feel less stress.") Two care partners noted that the PLIE program, especially the home practice component, added burden (e.g., dyad 3, week 9: "Neither of us was into doing more than [a] short time.") For future groups, the home program will be revised and de-emphasized to maximize benefits and minimize burdens.

LONELINESS AND THE HEALTH AND WELL-BEING OF LGBT SENIORS

M. Hughes, *School of Arts and Social Sciences, Southern Cross University, Coolangatta, New South Wales, Australia*

Recent research has identified higher rates of loneliness among older lesbian, gay, bisexual, and transgender (LGBT) people than one would usually expect to find in the general population. In an Australian survey of the health and

wellbeing of 312 LGBT people aged 50 and over, loneliness was associated with living alone, not being in a relationship, higher psychological distress, and lower mental health. Those who experienced the greatest degree of loneliness were much more likely than those who were less lonely to want to participate in social and health promoting activities with other LGBT people. This poster presents the most recent detailed analysis of a subset of 18 people in this study who reported the highest degree of loneliness, and explores their qualitative responses to questions on their connections with friends and family, participation in community groups, and interest in participating in future social and health promoting activities. While facing many challenges, most of these participants reported that they have a friend they can rely on in a crisis and that they are engaged in some social activities, as well as activities to promote their health and wellbeing. Nonetheless, many wanted to socialise more, have more companionship, experience an intimate relationship, develop their spirituality and exercise more. Barriers to engaging in these activities included anxiety, depression, not knowing how to connect with LGBT people, adjustment to recent 'coming out', and physical health issues.

IMPACT OF INFORMAL CARE, TRAVEL DISTANCE, AND STRESS ON RETIREMENT DECISION MAKING

S. Vasireddy², I. Sanidad³, L.H. Nitz¹, 1. *University of Hawaii at Manoa Department of Political Science, Honolulu, Hawaii*, 2. *University of Hawaii Department of Economics, Honolulu, Hawaii*, 3. *University of Hawaii Department of Sociology, Honolulu, Hawaii*

Established literature informs us that caring for the elderly living over a distance can be a stressful for the caregivers. We add to this literature by showing the impact of distance on reported physical, emotional and financial stress levels, and further show that this distance can have a negative impact on the retirement decision-making of care providers. Using data from the Caregiving in the United States, 2015 survey conducted by the National Alliance for Caregiving and AARP Public Policy Institute, we find that increased distance between the care-giver and the recipient living outside the household significantly increased the burden of care-giving stress on the provider. This is especially significant for those over fifty years of age and providing care. However, those who are caring for elderly inside their household also report high stress levels.

Our findings indicate that among women, those with parents residing within 20 minutes of travel are least likely to be stressed out emotionally and financially, and are less likely to report care-giving as a reason for retirement than those with parents living further away. The likelihood of early retirement among women seems to increase substantially with an increase in their travel-time to elderly care recipients and is negatively related to income levels, possibly due to improved access to transport and paid-care services.

INTERGENERATIONAL FORUM TO ENHANCE STUDENTS' ENGAGEMENT AND ELDERS' LEARNING OUTCOMES

O. Lee, *University of North Carolina Charlotte, Charlotte, North Carolina*

The Intergenerational Forum (IF) was an innovative intervention that engages college students in conducting community-based participatory research (CBPR). This set of guided learning opportunities was designed to improve college students' understanding of aging and health issues in their communities. In this study, a total of 252 mentoring hours were provided in kind by 78 students. The majority of these youth volunteers were aspiring health professionals who had received intensive academic and field training to strengthen their interpersonal skills and ability to build meaningful one-on-one relationships. Fifty five low-income older adults (with mean age of 73) participated in the six-session IF tutorials.

Findings revealed that as a result of IF, students were able to improve their knowledge and attitudes toward working with older people measured by Facts on Aging Quiz. ($t=8.28, p<.001$). Students were able to combine ideas from courses when completing this IF assignment. Particularly, levels of active and collaborative learning were enriched by engagement with people representing different economic backgrounds ($t=4.46, p<.001$) and religious beliefs ($t=3.91, p<.001$). Major themes emerged in students' narrative data revealed their learning outcomes in the areas of self-awareness, empathy, empowerment, and new perspectives about ageism.

Older adults presented significant improvement between pretest and posttest in various outcomes such as ehealth literacy ($t=-4.61, p<.001$), anxiety about technology ($t=2.37, p<.01$), self-efficacy ($t=-7.52, p<.001$), self-confidence ($t=-3.11, p<.001$), and social connections ($t=7.53, p<.01$). Hence, the IF produced synergistic effect by improving older adults' utilization of health information and strengthening cultural competency among youths.

AGING IN THE ERA OF AIR TRAVEL: IMPROVING THE ACCESSIBILITY OF AIRPORTS FOR TRAVELERS WITH DEMENTIA

M.T. O'Reilly^{1,2}, N. Shepherd^{2,3}, H. Edwards³, J. Franz³, L. Willmott³, E. Fielding^{2,3}, E.R. Beattie^{2,3}, 1. *Occupational Therapy, CQUniversity, Bundaberg, Queensland, Australia*, 2. *Dementia Collaborative Research Centre: Carers & Consumers, Brisbane, Queensland, Australia*, 3. *Queensland University of Technology, Brisbane, Queensland, Australia*

Many older people enjoy travelling for leisure, air travel included. To increase the self-determination and independence of people living with dementia we need to reduce the barriers to participation in all areas of life, including leisure. We used an exploratory, mixed method research design to learn about the experiences of people with dementia when they travel. This included online surveys with 82 people (7 people with dementia, 41 travel companions, 21 flight crew and 13 security staff). Ten of the companions who completed the survey volunteered to participate in a qualitative telephone interview. This was followed by an assessment of the physical environment of an airport in a major Australian city using the Dementia Friendly Communities Environmental Assessment Tool (DFC-EAT) (Fleming & Bennett, 2015).

The survey results showed that people with dementia and their travelling companions found navigating airport processes and designs the most challenging part of air travel, in particular security and immigration procedures. Using the DFC-EAT we identified problematic design features such

as poor signage and blurred boundaries between retail and travel spaces that contributed to confusion at the airport.

Efforts have been made to modify built environments to promote accessibility for people with physical disability, yet there has been comparatively little done for those with cognitive impairments. People with dementia need to have access to physical spaces that allow them to participate in a wide range of social activities. Improving the accessibility of transport hubs, such as airports, is an important way to facilitate social inclusion.

WHO AGE-FRIENDLY CITIES AND COMMUNITIES: THE KOREAN EXPERIENCE

J. Woo, M. Choi, *Korea Advanced Institute of Science and Technology (KAIST), Daejeon, Korea (the Republic of)*

In 2010, the World Health Organization (WHO) created the WHO Global Network of Age-Friendly Cities and Communities, a global network of cities that are committed to using the WHO guidelines to make their community more age-friendly. For the last seven years, the Network has grown to include 380 cities in 37 countries; however, little has been known about how the guidelines have been adopted and implemented in Asian countries given that the majority of cities and communities in the Network are in the Western world. This study aims to explore the social, political, and cultural forces that have led the cities in South Korea, the fastest aging country and also one of few developed countries in Asia, to join the Network. A series of interviews with stakeholders such as the public administrators of the four cities in the Network—Seoul, Jeongeup, Suwon, and Busan—have been conducted and subjected to a content analysis in January/February 2017. The primary findings are threefold: (1) Among the three factors analyzed, political motivation held the greatest sway; (2) the driving force behind the political motivations took several forms, from election year platforms to a new local government department needing to find work projects for itself; (3) Finally, implementation patterns showed great variability between the metropolitan cities and the self-governing cities. This study contributes to closing the knowledge gap in age-friendly initiatives in Asia, and future research needs to compare factors affecting the participation in the Network between countries within and across continents.

AGING IN CUBA AND PUBLIC POLICY RESPONSES: ANALYZING NEWLY RELEASED SURVEY MATERIALS

B. Destremau, *CNRS/ Iris / EHESS, Paris, France*

Quantitative data recently released on various facets of Cuba's aging process allows to draw new analyses on several demographic and socioeconomic dimensions of the phenomenon, as well as policy responses and their effects. This new data will be put in relation with results of sociological / ethnographic qualitative surveys conducted in Cuba (mainly, but not exclusively Habana) since 2009 and until 2016.

With a view on gender gaps, the poster will thus articulate new quantitative and qualitative data concerning:

- The extent and facets of Cuba's aging process, namely life expectancy, fertility, epidemiology/morbidity, demographic growth and population structure.

- The sociodemographic profile of the care issue, especially aging persons' household composition, migration, caregivers'

aging, elders' isolation, public care supply, and the socioeconomic biases of the incipient care market.

-The components of the elderly's socioeconomic condition public problem, contrasting a high level of access to public health and social services and informal community and family support, on the one hand, and a widespread monetary and material destitution, and its public policy responses, on the other.

These innovative results will demonstrate the specificity of the challenges posed to public policies by Cuba's aging process, and assess the responses brought by institutions and social / community organisations. The poster will finally discuss research results in terms of public policy options and models.

SESSION 1075 (SYMPOSIUM)

PREDICTORS OF HEALTH EXPECTANCY ACROSS MULTIPLE COHORTS FROM THE U.S. AND EUROPE

Chair: S. Stenholm, *University of Turku, Turku, Finland*

Discussant: J. Robine, *Inserm*

Health expectancy is a useful summary measure that captures both the "quantity" and "quality" of life. This concept takes into account both morbidity and mortality and is therefore useful in comparing the health of different populations and population sub-groups. The objective of this symposium is to discuss the predictors of health expectancy using data from large cohort studies from Europe and the US. The cohorts included are the English Longitudinal Study of Ageing, Finnish Public Sector Study, French GAZEL cohort, Swedish Longitudinal Occupational Survey of Health and the US Health and Retirement Study. Partial health expectancy from ages 50 to 75 is estimated in each cohort by using multiple repeat measures of self-rated health and chronic diseases. Dr. Head will open the symposium by introducing the methodology used in estimating health expectancy, namely multistate life tables and micro-simulation. She will also present results related to social inequalities in health expectancy across cohorts. Dr. Zaninotto will show associations of health expectancy with lifetime socio-economic status. Dr. Stenholm will present the independent and combined effect of health behaviors on health expectancy. Finally, Dr. Platts will describe differences in health expectancy in relation to physical and psychosocial work exposures. Taken together, this symposium demonstrates the importance of socio-economic status, health behaviors and work exposures in midlife on health development in advancing age.

SOCIOECONOMIC DIFFERENCES IN HEALTHY LIFE EXPECTANCY: EVIDENCE FROM FOUR PROSPECTIVE COHORT STUDIES

J. Head¹, H. Chungkham², M. Hyde³, P. Zaninotto¹, S. Stenholm⁴, M. Zins⁵, J. Vahtera⁴, H. Westerlund⁶, 1. *UCL, London, United Kingdom*, 2. *Indian Statistical Institute, Tezpur, India*, 3. *University of Manchester, Manchester, United Kingdom*, 4. *University of Turku, Turku, Finland*, 5. *INSERM, Paris, France*, 6. *University of Stockholm, Stockholm, Sweden*

There are striking socioeconomic differences in life expectancy, but less is known about inequalities in health

expectancies. We estimated differences in healthy life expectancy and chronic disease-free life expectancy using data from four European longitudinal studies for two health indicators: (i) sub-optimal self-rated health and (ii) having a chronic disease. Socioeconomic position was measured by occupational position and grouped into high, medium and low grade occupations. Multistate life table models were used to estimate healthy life expectancy and chronic disease-free life expectancy from ages 50 to 75 by occupational position and sex. In all four cohorts, we found inequalities in healthy life expectancy between ages 50 to 75 according to occupational position such that men and women in the higher occupational positions had higher healthy life expectancy compared to those in low occupational positions. Similarly, there were occupational differences in chronic disease-free life expectancy in all four cohorts.

SOCIOECONOMIC INEQUALITIES IN HEALTHY LIFE EXPECTANCY AT OLDER AGES: COMPARING ENGLAND WITH THE U.S.

P. Zaninotto¹, D. Batty¹, H. Westerlund², M. Goldberg³, J. Vahtera⁴, S. Stenholm⁴, J. Head¹, 1. *Epidemiology and Public Health, UCL, London, United Kingdom*, 2. *Stockholm University, Stockholm, Sweden*, 3. *Inserm, Paris, France*, 4. *University of Turku, Turku, Finland*

This study uses data from the Health and Retirement Study (HRS) in the US and the English Longitudinal Study of Ageing (ELSA) in England, to describe health life expectancy by lifetime socioeconomic status. Multistate life table models were used to estimate sex-specific health expectancy from ages 50 and over using longitudinal data from 2002 to 2012 and mortality up to early 2013. Three measures of health life expectancy are used: healthy life expectancy defined as excellent, very good and good health; disability-free life expectancy defined using no limitations with activity of daily living and instrumental activity of daily living and chronic disease-free life expectancy. We used father's socioeconomic position in childhood and wealth, income and social class at older age to construct a measure of life-time socio-economic status. We also explore which of the socio-economic measure is more strongly associated with health life expectancy in the UK and US.

SMOKING, PHYSICAL INACTIVITY, AND OBESITY AS PREDICTORS OF HEALTH EXPECTANCY: A MULTICOHORT STUDY

S. Stenholm¹, J. Head², M. Kivimaki^{2,7}, I. Kawachi³, V. Aalto⁴, M. Goldberg⁵, H. Westerlund⁶, J. Vahtera¹, 1. *University of Turku, Turku, Finland*, 2. *University College London, London, United Kingdom*, 3. *Harvard T.H. Chan School of Public Health, Boston, Massachusetts*, 4. *Finnish Institute of Occupational Health, Turku, Finland*, 5. *Inserm, Villejuif, France*, 6. *Stockholm University, Stockholm, Sweden*, 7. *University of Helsinki, Helsinki, Finland*

This study examined the extent to which smoking, physical inactivity and obesity individually and in combination predict health expectancy in four European cohort studies. Data were drawn from repeated waves of the Finnish Public Sector Study, GAZEL (France), Swedish Longitudinal Occupational Survey of Health, and Whitehall II (UK). Multistate life table models were used to estimate sex-specific

healthy life expectancy and chronic disease-free life expectancy from ages 50 to 75 years. Compared to men and women with at least two behavior-related risk factors, those with no behavior-related risk factors could expect to live on average eight years longer in good health and six years longer free of chronic diseases between ages 50 and 75. Having any singly risk factor was also associated with reduction in healthy years. Of the individual behavior-related risk factors, physical inactivity was associated with the greatest reduction in healthy years and obesity with greatest reduction in chronic disease free years.

HEALTH EXPECTANCY BETWEEN AGES 50–75 IN RELATION TO PHYSICAL AND PSYCHOSOCIAL OCCUPATIONAL EXPOSURES

L.G. Platts¹, L.L. Magnusson Hanson¹, J. Head², S. Stenholm^{3,4}, H. Singh Chungkham⁵, M. Zins^{6,7}, 1. *Stress Research Institute, Stockholm University, Stockholm, Sweden*, 2. *University College London, London, United Kingdom*, 3. *University of Turku, Turku, Finland*, 4. *Turku University Hospital, Turku, Finland*, 5. *Indian Statistical Institute, North-East Centre, Tezpur, India*, 6. *Inserm, Villejuif, France*, 7. *Versailles St-Quentin University, UMS 011, Villejuif, France*

While poor working conditions increase morbidity, no studies have quantified how much poor psychosocial and physical working conditions reduce health expectancy. We examined this using four cohorts: Finnish Public Sector Study (Finland), GAZEL (France), Swedish Longitudinal Occupational Survey of Health (Sweden), and Whitehall II (UK). Data on job strain (high demands combined with low control) were available for 64,533 individuals across the cohorts. Physical occupational exposure data (ergonomic strain, physical danger, night work, company records of workplace accidents and a job-exposure matrix of chemical exposures) were obtained for 13,393 male GAZEL cohort members. Partial health expectancies (age 50–75) relating to 1) self-rated health and 2) chronic health conditions were estimated using multistate life tables. Job strain was related to shorter healthy life expectancy and less consistently with shorter chronic disease-free life expectancy. Physical occupational exposures apart from night working were associated with shorter healthy and chronic disease-free life expectancy.

SESSION 1080 (SYMPOSIUM)

GERONTOLOGICAL SOCIETY OF AMERICA'S COGNITIVE IMPAIRMENT DETECTION AND EARLIER DIAGNOSIS INITIATIVE

Chair: R.H. Fortinsky, *University of Connecticut, Old Lyme, Connecticut*

Discussant: J. Simmons, *Eli Lilly and Company, Indianapolis, Indiana*

In January, 2015, the Gerontological Society of America (GSA) released a report by an expert Workgroup aimed at increasing detection and diagnosis of cognitive impairment in older adults by primary care practitioners. This report included recommendations in the form of a 4-step process to help improve the detection and diagnosis rate and spur referrals of older adults and their families to dementia-capable

community resources that are widely available but little known to primary care practitioners. The process, known as KAER, includes: Kick-starting brain health conversation, even among asymptomatic older patients; Assessing for cognitive impairment using tools that are brief, validated, no cost, and easily available; Evaluating for dementia diagnosis by referring to clinical specialists or following clinical practice guidelines; and Referring diagnosed patients and families to community resources for further education and support. The report also recommended a national Summit of primary care practitioners and health system representatives to develop action plans for disseminating and implementing the KAER process in primary care practices. This national Summit is scheduled for August, 2016. In the proposed Symposium, Fortinsky will provide greater detail about the GSA report and Summit, Maslow will discuss the KAER toolkit developed for use and dissemination at the Summit, and Kobylarz will present on the usefulness and impact of the Summit and KAER materials on Summit attendees based on surveys they will complete before and after the Summit. Discussant Simmons will place this GSA KAER initiative within the broader context of efforts to improve dementia care for older adults.

OVERVIEW OF THE GSA KAER REPORT, RECOMMENDATIONS, AND NATIONAL SUMMIT

R.H. Fortinsky, *UConn Center on Aging, University of Connecticut, Old Lyme, Connecticut*

This presentation will provide a synopsis of the Gerontological Society of America (GSA) report and recommendations to promote cognitive impairment detection and earlier diagnosis of dementia in the primary care setting in the United States. The health policy context for this report in the form of the Medicare Annual Wellness Visit (AWV) will be explained, along with a summary of the Workgroup's activities to gather evidence about cognitive impairment assessment tools to recommend in the report. The report's recommended 4-step KAER framework will be explained as a guide for primary care practitioners as they navigate the challenging process of discussing and clinically evaluating cognitive health and impairment with older patients and their families. Finally, proceedings from and action plans developed at the national Summit of health care providers and health to help implement the KAER framework will be summarized.

TOOLKIT TO ASSIST PRIMARY CARE PRACTITIONERS WITH THE RECOMMENDED 4-STEP KAER PROCESS

K. Maslow, *Gerontological Society of America, Washington, District of Columbia*

The GSA Workgroup created a compendium of tools and procedures to help PCPs implement the 4 steps in the KAER process: Kick-start the conversation about brain health; Assess for cognitive impairment, Evaluate for dementia, and Refer for community resources. The toolkit includes a selection of tools and procedures so that PCPs in single-person offices, multi-physician practices, and health care systems will be able to choose the tools and procedures that fit best with their existing primary care practices. This presentation will discuss the structure and content of the toolkit,

the topics for which appropriate tools were more and less difficult to find, and responses to the toolkit from PCPs and administrators of health plans and health care systems who participated in the GSA KAER Summit.

RESULTS OF THE KAER SUMMIT SURVEY: CHALLENGES AND SUCCESSES

F. Kobylarz, *Rutgers Robert Wood Johnson Medical School, New Brunswick, New Jersey*

The detection of cognitive impairment is a required element of the Medicare Annual Wellness Visit (AWV). Limited data is available regarding the operationalization of the detection of cognitive impairment in the primary care setting. Nevertheless, efforts to evaluate this have not been described. A pre and post survey of participants attending the KEAR Summit will examine features of the program at baseline and various intervals for one year. This qualitative study will focus on responses to survey questions to ascertain individual practices and understand processes of care for brain health. A particular focus of the survey will be on attitudes towards the KAER process, how pertinent and useful was the materials presented during the program, and challenges and barriers to implementing action plans. The KAER process can facilitate practice change and guide a quality improvement process for the detection of cognitive impairment.

COGNITIVE IMPAIRMENT DETECTION AND EARLIER DEMENTIA DIAGNOSIS: THE KAER PROCESS APPLIED TO PRACTICE

J. Chodosh, *NYU School of Medicine, Langone Medical Center, New York, New York*

Physicians frequently do not recognize cognitive impairment in their older adult patients and do not conduct an evaluation to diagnose dementia. This presentation will provide case examples of older persons with cognitive impairment, emphasizing the unique characteristics and situation of each case and the need for primary care providers to individualize procedures for detection and assessment of cognitive impairment and dementia to match the individual's situation and needs. It will provide information, insights, and tips to achieve earlier detection, improve diagnosis, and build and maintain a strong, trusting relationship between the older person and the primary care provider.

SESSION 1085 (SYMPOSIUM)

CONSENSUS IN MEASURES OF GAIT AND COGNITION: FROM THE CANADIAN CONSORTIUM IN NEURODEGENERATION AND AGING

Chair: M. MonteroOdasso, *University of Western Ontario, London, Ontario, Canada*

Co-Chair: L. Middleton, *University of Waterloo, Waterloo, Ontario, Canada*

Discussant: L. Bherer, *University of Montreal, Montréal, Quebec, Canada*

Extensive epidemiological evidence supports interrelationships between mobility and cognition in aging. However, until recently, clinicians and researchers have evaluated and treated cognitive and mobility dysfunction in older

individuals as separate problems. This approach has led to gaps in our understanding of the cognitive-motor interactions and of the potential underlying mechanisms that can affect pathways to disability in aging. Thinking and moving share behavioral and etiological factors that can drive new insights into prevention and treatment. Mechanistically, brain networks, which control movement, overlap with networks involved in cognitive performance.

Therefore, there is a need of a common framework among clinician and researchers to i) better characterize the relationship between cognitive and motor changes with aging, comorbidities and neurodegeneration, ii) standardize clinical and research methodologies to measure and assess mobility and cognition in older adults iii) agree upon a "core of set" of measures to assess cognitive-mobility interaction.

The Canadian Consortium on Neurodegeneration and Aging is a Pan-Canadian Initiative funded by Canadian Institute of Health and Research (CIHR), which aims to better understand neurodegenerative process in aging. As part of this initiative, the "Gait and Cognition team" has established by consensus a set of common measurements to assess motor-cognitive interactions. Results of the Delphi process carried on in during 2015 and the consensus meeting which involved 15 researchers from eight lead centers in Canada will be presented with the "core-set" and "minimum set" of measures selected. Having common and standardized measures will positively contribute to the prevention, management, and rehabilitation of the cognitive and mobility disability in older adults.

EPIDEMIOLOGICAL EVIDENCE OF THE BIDIRECTIONAL RELATIONSHIP BETWEEN MOBILITY AND COGNITION

R. Camicioli, *University of Alberta, Edmonton, Alberta, Canada*

An update on the evidence regarding the role of central nervous systems (CNS) in mobility in addition with established multifactorial causes connected to age related changes in the cardiopulmonary, musculoskeletal, and central and peripheral nervous systems will be presented. Research done on patients with neurological diseases consistently demonstrates that the CNS is a key contributor to gait and motor function. Stronger associations have been detected for information processing and executive functions, which are important for rapid and efficient planning of goal-oriented mobility. Emerging evidence shows changes in gait that precede and predict cognitive decline and Alzheimer's disease dementia, and other dementias. Similarly, cognitive changes also adversely affect gait and cognitive deficits paired with slowed gait in those without dementia may represent a distinct clinical syndrome.

TEMPORAL AND SPATIAL MEASURES OF GAIT AND DUAL-TASK GAIT IN AGING AND NEURODEGENERATIVE DISEASES

Q. Almeida, *Wilfrid Laurier University, Waterloo, Ontario, Canada*

This presentation will review the evidence linking spatial and temporal characteristics of gait including gait speed, pace, rhythm and variability, with global cognitive

ability, executive function, verbal fluency and memory in non-demented older adults and in neurodegenerative conditions including Parkinson Disease and dementia syndromes. The influence of neurological medications will also be considered. The value of dual-task gait, a divided attention task that requires individuals to walk (motor component) while simultaneously performing a cognitively demanding task (reciting words, mental calculations, etc.) will be reviewed as a potential brain stress test to unmask latent gait disturbances and for detecting impending functional and cognitive decline. Results from longitudinal studies showing that dual-task gait can help identify older adults at a higher risk of developing cognitive and mobility decline, and, potentially, progression to dementia will also be presented. Finally, the role of the dual-task cost will be evaluated.

COGNITIVE MEASURES SENSITIVE TO MOBILITY DECLINE, GAIT IMPAIRMENTS AND FALLS

K.Z. Li, *Concordia University, Montreal, Quebec, Canada*

This presentation will highlight recent findings on cognitive measures shown to be associated with indices of gait, mobility, and risk of falling in older adults. These associations are based upon the theoretical principle of neural overlap, i.e., the common brain regions or networks that underpin cognitive processes and motor behaviors such as walking and balancing. Evidence will be presented involving standardized neuropsychological measures of executive functioning that are suitable for the assessment of healthy and frail elderly adults. The use of experimental methods such as cognitive-motor dual-task designs will also be presented.

ON-LINE ASSESSMENTS OF MOTOR-COGNITIVE INTERACTIONS, WHAT CAN NEUROIMAGING WITH FNIRS TELL US?

S. Fraser, *University of Ottawa, Ottawa, Ontario, Canada*

FNIRS or functional near infra-red spectroscopy is an emerging neuroimaging technique that can be applied to situations that involve movement (i.e., walking/exercise). Recent technological advances have allowed for the development of portable devices which measure cerebral oxygenation changes of over ground walking in “real-life” ecological conditions. Advantages and disadvantages of this technique are discussed and their sensitivity to detect motor-cognitive interaction will be summarized. In conclusion, future applications of this technique to clinical settings will be presented.

A PROPOSED CORE SET OF MOBILITY AND COGNITIVE MEASURES

M. MonteroOdasso, *University of Western Ontario, London, Ontario, Canada*

A “core-set” of measures based on their clinical utility, feasibility, and evidence for sensitivity to mobility-cognitive interactions will be presented. Advantages and disadvantages of each measure evaluated and their sensitivity to detect motor-cognitive interaction will be summarized. A “minimum set” of measures to be used in large epidemiological or population studies will be also presented including four candidate measures, which can be performed in 15 minutes.

SESSION 1090 (SYMPOSIUM)

PRESIDENTIAL SYMPOSIUM: EVALUATION AND IMPLEMENTATION OF GERIATRIC CO-MANAGEMENT MODELS FOR HOSPITALIZED FRAIL OLDER PATIENTS

Chair: M. Deschodt, *Leuven, Belgium*

Discussant: H. Javedan, *Brigham and Women's Hospital*

Geriatric co-management has been described as “the most far-reaching model of shared care between a general treating physician and a geriatrician since they manage the patient together from admission until discharge and are both responsible for the process and outcome of provided care”. (*Kammerlander, 2010*) A key difference with consultation models is that patient care is co-managed together with an acute medical care discipline instead of solely making non-mandatory recommendations based on a consultation request. (*Deschodt et al. 2015*) This approach is now considered the standard for managing older hip fracture patients, but might also be beneficial in other frail populations. In this symposium we will discuss 1) the development and evaluation of two European geriatric co-management programs, i.e. a program for cardiology patients in Belgium and a program for surgical and internal patients in the Netherlands, and 2) the implementation of two North-American geriatric co-management models, i.e. a ward-based model in Highland Hospital, Rochester NY and a team-based model in Rhode Island hospitals.

GERIATRIC CO-MANAGEMENT FOR CARDIOLOGY PATIENTS IN THE HOSPITAL (G-COACH) IN BELGIUM

B. Van Grootven, *KU Leuven, Leuven, Belgium*

G-COACH aims to develop and evaluate an in-hospital cardio-geriatric co-management model using a mixed-methods multi-phase methodology. First, a systematic review and meta-analysis determined the intervention components and potential value of geriatric co-management on patient and system outcomes. Next, a two-round international Delphi study determined appropriate and feasible structure, process and outcome indicators for the evaluation of geriatric co-management programs. We integrated this data in a first program theory that details how the G-COACH intervention will affect the desired change in outcomes. Focus groups, interviews and participant observations were then used to translate this theoretical framework to a consensus-based stakeholder-developed care model. This model will be implemented on two cardiology units of the University Hospitals Leuven. A before-and-after study (September 2016 – 2017) including patients aged 75 years or older will evaluate the effectiveness, process and participants' experiences. Data will be used to refine the program theory and scaling-up of co-management programs.

INNOVATIVE TEAM-BASED GERIATRIC CO-MANAGEMENT FOR FRAIL OLDER PATIENTS IN THE NETHERLANDS

H. Habets, *1. Zuyderland Medical Center, Sittard-Geleen, Netherlands, 2. Zuyd University, Faculty of Health, Heerlen, Netherlands*

In Zuyderland Medical Center we conducted a study aiming to prevent complications and functional decline during hospital stay. Main conclusion: comprehensive geriatric assessment at admission and delivery of advices by a geriatric consultation team was not sufficient: the recommended interventions were often not executed. This led to a new model: co-management for frail elderly at risk for functional loss. This model is currently being implemented and evaluated in a surgical, internal medicine and pulmonary ward. Main components of the program are: Comprehensive Geriatric Assessment, systematic medication review, a personalised nutrition and mobility program, specific role of the geriatric resource nurse, a physiotherapist (specialization Geriatrics), daily rounds of the geriatric team and participation in multidisciplinary rounds, the Transitional Care Bridge Program and continuity of care after discharge and follow up at the polyclinic geriatric medicine. In this presentation structure, process and first results of this approach will be presented.

GERIATRIC CO-MANAGEMENT AS A SERVICE LINE: SPREADING CO-MANAGEMENT WITHIN AN INSTITUTION

L. McNicoll, *Alpert Medical School of Brown University, Providence, Rhode Island*

The Alpert Medical School model of co-management focuses on creating co-management service line working with multiple groups within an organization which include fracture, elective joint replacement, trauma, colorectal, and urology. Geriatricians are aligned with one surgical specialty for 50–85% of their time assisting with high risk patients within that group. In addition to providing patient care aligned with co-management principles, co-managers also lead teams within the groups to discuss and agree upon protocols of care for geriatric patients, such as delirium assessment and management, pain protocols, bowel regimen protocols, and ERAS (Early Recovery After Surgery) protocols. Education is also a major part of each program as well as data collection in order to document improvement in outcomes for patients with the addition of the co-management program. At the symposium, we will be able to share our process as well as outcomes for this model of co-management.

GERIATRICS ORTHOPAEDICS CO-MANAGEMENT OF FRAGILITY FRACTURES IN ROCHESTER, NEW YORK, AND THE USA

D. Mendelson, 1. *University of Rochester School of Medicine & Dentistry, Rochester, New York*, 2. *Highland Hospital, Rochester, New York*

The Geriatrics Fracture Center (GFC) at Highland Hospital developed an innovative co-management model for fragility fracture care in 2004. Each patient is assigned both an orthopaedics surgeon and a geriatrician who share responsibility for insuring high quality care throughout the patient's entire hospitalization. Standardized protocols and consult notes are used to decrease unwarranted variability. Lean process and continuous quality and performance improvement techniques are used to maintain or improve person-centered and system-based outcomes. The center is a model for value-added geriatrics. The GFC has sustained improvements in mortality, complications, length of stay, readmission rates,

and cost. The GFC, in collaboration with Brown University and the American Geriatrics Society, is working on a dissemination program to spread the model with generous funding from the John A. Hartford Foundation. In this presentation, the structure of the GFC and outcomes will be discussed as well as the potential to replicate the program.

SESSION 1095 (PAPER)

GERONTOLOGY AND GERIATRICS EDUCATION TO IMPROVE OUTCOMES

HEALTH PROMOTION OF UNDERSERVED OLDER ADULTS USING AN ACADEMIC-COMMUNITY PARTNERSHIP MODEL

L. White, J. Styron, C. Gubler, *University of South Alabama, Mobile, Alabama*

Interprofessional collaborative practice has been shown to improve healthcare and reduce care-related costs in older adult populations. While many health profession programs have adopted formalized interprofessional education (IPE) curriculum delivered in a didactic setting, models of IPE in which students engage in interprofessional collaborative practice are needed to ensure health professions' graduates are prepared to deliver team-based care when entering the geriatric healthcare workforce. Community-based models of interprofessional collaborative practice may be particularly advantageous because faculty and students can address the vast need for health and wellness services in underserved older adult populations. This presentation will provide a framework for designing interprofessional collaborative practice experiences using an academic-community partnership model. The University of South Alabama Colleges of Nursing, Allied Health, and Medicine developed a three-year initiative in which health and wellness services were delivered by faculty-supervised health profession students to older adults living in an urban low-income senior residential community in Mobile, Alabama. First- and second-year students in medicine, nursing, physician assistant studies, and physical therapy participated in the project. The authors will explain how the interprofessional initiative was developed, including goals of the team, strengths, and limitations of the project. Academic outcomes assessed included interprofessional core competency attainment, readiness for interprofessional learning, and student perceptions of interprofessional clinical education. Community-based outcomes included the number and type of health and wellness activities designed to engage, educate, and evaluate participants and improve health conditions of individuals. Processes for establishing, maintaining, and evaluating academic-community partnerships will also be discussed.

URINARY INCONTINENCE AMONG OLDER INDIANS: ASSESSMENT AND IMPACT ON QUALITY OF LIFE

N.N. Prem, P. Chatterjee, A. Chakrawarty, A.B. Dey, *Geriatric Medicine, All India Institute of Medical Sciences, New Delhi, Delhi, India*

Urinary incontinence is a common problem in old age. Little research has been carried on this genito-urinary health issue in India as the symptom goes often under-reported. Urinary incontinence is associated with significant impact on the individual, their carers and the wider healthcare system. Management of urinary incontinence is often difficult.

In this cross sectional observational study, 608 patients were recruited from Geriatric Medicine OPD and Ward. They were subjected to a predesigned semi quantitative questionnaire to determine the frequency of urinary incontinence in older people and its impact on various aspects of their life.

Stress incontinence was most common in females and urge incontinence was common in males. Certain patients also had mixed incontinence. There was significant impact on quality of life due to incontinence and this was measured with the help of the Incontinence quality of life. Majority had Indian type of toilets. Stress type had maximum patients with severe IQOL and urge type had maximum with mild IQOL. ($p < 0.0001$). Incontinence had a significant correlation with age type, sex, social status, depression and number of drugs. Diaper use was acceptable for (>90%) of the elderly.

Urinary incontinence detection is essential, as it can lead to increased dependence. It can be treated with appropriate interventions varying from exercises, modifying medications, altering fluid intake and interdepartmental interventions. The interventions vary according to the type. Urinary incontinence is an important geriatric syndrome. Early detection and intervention can help in improving quality of life of the elderly

PERIOPERATIVE CARE OF THE ELDERLY: A EUROPEAN ANSWER TO EDUCATIONAL NEEDS IN THE FIELD

G. Bettelli, D. Cucinotta, G. Ghironzi, C. Renzini,
G. Zuliani, *2nd Level Master in Geriatric Medicine,
University of San Marino and Ferrara, San Marino, Italy*

Appropriate care in geriatric surgery requires multidisciplinary approach combining geriatric, surgical, anesthesiological and nursing knowledge, resulting in ability of the team to manage complex situations in coordinated ways.

To provide knowledge, skills, values and attitudes in the professional spheres of the surgical care of older patients, a multidisciplinary University Master on "Perioperative Care of the Elderly" is implemented at the San Marino and Ferrara University (Italy). Its aim is creating an inter-professional culture.

To reach this goal, the following Entrustable Professional Activities (EPAs) of geriatric medicine become common assets for the whole team:

- provide patient-centered care by optimizing function and well-being, in accordance with patient's functional status and needs, as evaluated by CGA

- manage the surgical care by integrating the patient's goals and values with comorbidities and reasonably expectable prognosis

- assist patients and families in decision-making

- provide thoughtful medication reconciliation

- prevent and manage postoperative delirium and other geriatric syndromes

- coordinate post-discharge care transition.

Allthesame, geriatricians will be educated in perioperative medicine and made familiar with some surgical and anesthesiological issues such as:

- pre-habilitation as a strategy to increase functional reserves preoperatively

- the endocrine-metabolic reaction to surgical aggression, its consequences on the surgical course, and ways to minimize it

- context-sensitive and multimodal postoperative pain management

- techniques of Enhanced Recovery After Surgery (ERAS).

Both acquisition of competencies and capacity to perform the tasks involved in the daily work are implemented in the educational plan.

DO PHOTOGRAPHS AND OLDER ADULTS' NARRATIVES FOSTER ANTICIPATORY REFLECTION IN MEDICAL STUDENTS?

C. Etherton-Beer^{1,2}, G. Brand², *1. Royal Perth Hospital,
Perth, Western Australia, Australia, 2. University of Western
Australia, Perth, Western Australia, Australia*

In changing higher education environments, medical educators are increasingly challenged to prepare health workers to care for ageing populations. We have developed the "Depth of Field: Exploring Ageing" reflective learning resource that uses photographs, reflective questioning prompts, older adults' narratives and collaborative dialogue to foster anticipatory reflection or 'prelection' among diverse learners. Using mixed method evaluations, we now have data from Australian medical students comprising attitudes (pre and post responses) and qualitative analysis of individual written reflections of 128 second year medical students, exploring their perceptions toward older adults. Quantitative data reveal students self-report positive perceptions towards older adults, and the intervention is associated with positive shifts in attitudes. However the written reflections expose some negative attitudes and unexplored assumptions. The qualitative reflections were captured in four main themes: Prelecting on older adults; Creating Tension; Deconstructing Assumptions, and Seeing the Person. These findings support the use of visual and narrative methodologies to foster 'prelection' that surfaces and challenges medical students' perceptions and assumptions around ageing and how these may influence their care of older adults.

DEMENTIA WORKFORCE EDUCATION: DOES IT CHANGE PRACTICE?

S. Hirst¹, S. Gordon², *1. University of Calgary, Calgary,
Alberta, Canada, 2. Mt Royal University, Calgary, Alberta,
Canada*

Health-care professionals are well positioned to recognize dementia in older adults. However, barriers to implementing quality care include their limited knowledge. Consequently educational programs have been designed to promote the knowledge and skills of the dementia workforce. The question that emerged is *whether or not education changes health care practice?* A systematic review of the literature was conducted to identify approaches to providing dementia workforce education. The review was conducted using databases searched from 2000 to 2015. Two researchers screened each title and abstract for inclusion. Discrepancies between them

were resolved by a third team member. A matrix was used for analysis including: type of research, participants, study design, type of education activity, outcome measures, and perceived effectiveness.

The review included 144 studies, from an initial list of 3432, which met the inclusion criteria. Descriptive data was obtained from the matrix. In addition, thematic analysis was conducted to answer the original research question. Results identify that educational activities are primarily face to face, evaluated by participants' satisfaction with the activity or changes in their knowledge levels, and usually conducted with facility staff. The exception to facility staff is physician education. Limited examination of the effect of the activity on practice have been conducted. In addition, there is no long term evaluation (> than 1 year) of the outcomes of the educational activity.

There is limited evaluation of the effectiveness of educational activities on the quality of care provided to older adults living with dementia.

SESSION 2000 (PAPER)

PALLIATIVE CARE FOR OLDER ADULTS

WISHFUL THINKING: AN EXAMINATION OF PALLIATIVE HOME CARE CLIENTS WHO EXPRESSED A WISH TO DIE NOW

S. Freeman¹, E. Neufeld², T. Frise Smith³, K. Fisher⁴, S. Ebihara⁵, 1. *School of Nursing, University of Northern British Columbia, Prince George, British Columbia, Canada*, 2. *Laurentian University, Sudbury, Ontario, Canada*, 3. *Nipissing University, North Bay, Ontario, Canada*, 4. *McMaster University, Hamilton, Ontario, Canada*, 5. *Toho University Faculty of Medicine, Tokyo, Japan*

PURPOSE: To provide the highest quality of person centered palliative care clinicians should prioritize understanding of client needs and preferences at end of life to inform tailored care planning. During clinical assessments, clients may voluntarily express a 'wish to die' either directly to the clinician or it may be indirectly reported second-hand to the clinician through an informal caregiver or family member.

METHODS: This study examined 4,840 interRAI Palliative Care assessments from community dwelling palliative home care clients in Ontario, Canada (2006–2011). The interRAI PC gathers a wide range of information on physical, cognitive, and social domains, as well as demographic, health service utilization, and care preferences which is then used by the clinician to inform the care planning process

RESULTS: 308 palliative home care clients (6.7 %) voluntarily expressed a 'wish to die now'. In multivariate analyses predicting expression of a 'wish to die' strong independent variables included not being married/widowed, a shorter estimated prognosis, depressive symptoms, functional impairment, excessive amount of sleep, feeling completion regarding financial/legal matters, and struggling with the meaning of life. Of clients who expressed a 'wish to die now', clients who exhibited depressive symptoms (23.8 %)

were also more likely to exhibit cognitive impairment and recent cognitive decline, weight loss, psychological distress.

DISCUSSION: Not all clients who expressed a 'wish to die' exhibited depression, pain and psychological distress. Findings promote the need for an individualized approach to care management. Clinicians should strive to embrace not fear discussing with the client their preferences for death.

INTERPROFESSIONAL PALLIATIVE CARE WORKFORCE: A SURVEY OF TOMORROW'S HEALTHCARE TEAMS

J.M. Sautter¹, N. Boucher², A. Franzione³, 1. *Behavioral & Social Sciences, University of the Sciences in Philadelphia, Philadelphia, Pennsylvania*, 2. *Duke Center for the Study of Aging & Human Development, Durham, North Carolina*, 3. *Rutgers University, New Brunswick, New Jersey*

Recent assessments of the current palliative care workforce recommend increased training and exposure for all health care providers to manage symptoms and improve quality of life during serious illness. To assess the future workforce in palliative care, a multi-institution team conducted an online survey of students pursuing professional degrees in medicine, nursing, occupational therapy, pharmacy, physical therapy, physician assistant, and public health.

Preliminary results from 360 advanced professional students at five institutions describe the healthcare workforce currently in training. Approximately 80% of students reported personal or professional experience with people who are seriously ill and 68% reported some educational experience with death and dying. More than 90% of students reported that people in their profession can play an important role in patients' end-of-life care; 25% of students reported a desire to provide patient care for end-of-life issues and 41% were neutral. Medicine and physician assistant students reported stronger recognition of their profession's importance in end-of-life care and stronger interest in working in end-of-life care compared to other professions. Across professions, students with professional and/or personal experience reported stronger interest in providing palliative care.

These results are useful to inform professional curricula and public health planning. As need grows, it is important to expose students to palliative and end-of-life care through interprofessional experiential learning. These experiences can influence future leaders in medicine and public health to emphasize prevention and palliation of suffering, especially among older adults with serious life-limiting illness.

EFFECT OF A PERSON-CENTERED INTERVENTION ON PATIENT EXPERIENCE WITH CARE IN SERIOUS CHRONIC ILLNESS

N. Shippee¹, T.P. Shippee¹, P. Mobley², K. Fernstrom², H. Britt², 1. *University of Minnesota, Minneapolis, Minnesota*, 2. *Allina Health, Minneapolis, Minnesota*

Patients with serious chronic illness face multiple challenges in managing conditions to reduce ongoing risk, while increasingly moving toward issues and decisions surrounding end of life. Meanwhile, broad overmedicalization leaves patients at risk for overly invasive treatment and self-management routines and a depersonalized experience of care. However, most studies of patient experience and tools designed to measure it are not well suited to addressing

patients with serious illness in late life. This study evaluates a new patient-centered approach to care for patients with serious chronic illness. LifeCourse is focused on understanding the whole person and ongoing, cross-setting assistance by layperson care guides, supported by a clinical team. We test whether participation in LifeCourse improves patient experience compared to usual care (n=110 intervention and 93 comparison patients). The outcome variable is 6-month change the LifeCourse experience tool, a multi-item self-report experience tool designed specifically to emphasize key domains of the intervention, including listening, access and time, trust, frustration, and patient goals. In multivariate analyses, LifeCourse had a significant positive effect on change in patient experience versus usual care. Domain-specific analyses indicated that the primary driver of this effect was time/access for patients. Overall, our findings show that LifeCourse has a positive impact on QOL when compared to usual care patients. These trends indicate that whole-person, supportive care approaches like LifeCourse may offer modest benefits in improving experience with care as patients require more services for chronic illness in later life.

CHRONIC AND INCURABLE DISEASE IN ETHIOPIA: AN ASSESSMENT OF OUTPATIENT PALLIATIVE CARE NEEDS

R. Anderson^{1,2}, E. Gudina⁴, N. Ayers³, W. Tigineh^{5,6}, Y. Mamo Azmera³, 1. *Emergency Medicine, Yale University School of Medicine, New Haven, Connecticut*, 2. *London School of Hygiene and Tropical Medicine, London, United Kingdom*, 3. *Ethiopian Ministry of Health, Addis Ababa, Ethiopia*, 4. *Jima University College of Health Sciences, Jimma, Ethiopia*, 5. *Addis Ababa University College of Health Sciences, Addis Ababa, Ethiopia*, 6. *Tikur Anbessa Hospital Department of Oncology, Addis Ababa, Ethiopia*

Palliative care reduces physical suffering and the emotional, spiritual and psychosocial distress of life-threatening illness. It can be offered at any time, including concurrently with life-prolonging therapies. Palliative care is a human right, yet there are significant disparities in its provision: of the 40 million people globally in need of palliative care, just 14% receive it, largely in high-income countries. There is a particular paucity of data on palliative care needs in the African context.

We recruited 98 adults (mean age: 43.7±14 yrs, 64% female) at three outpatient clinics (Oncology, HIV, Non-Communicable Disease) and hospice patient homes in Ethiopia. Four internationally validated survey tools assessed physical symptoms, psychosocial distress and disability. In-depth interviews gauged poverty level, costs of care, and end-of-life preferences. Qualitative data was analyzed by thematic content, quantitative data by standard descriptive and frequency analyses.

In Oncology, 95.5% of the population endorsed moderate-to-severe pain and 100% were unaware of their terminal diagnoses. Across sites, there was an inverse relationship between pain and peace, while anxiety and depression mirrored pain. Widespread, enormous costs for medical care and transportation were reported. To cope, livestock, homes, and gold were sold, and children pulled from school. Oncology withstanding, the majority of subjects wished to die at home.

Oncology patients cited pain control as the top reason they preferred to die in hospital.

These results reveal extensive unmet palliative care needs. In addition to untreated pain, costs of illness are the major contributor to psychosocial distress in this Ethiopian population.

SESSION 2005 (SYMPOSIUM)

A FINANCIALLY SUSTAINABLE APPROACH TO OPTIMAL OUTCOMES IN A COMPREHENSIVE GERIATRIC SPECIALTY CLINIC

Chair: P.S. Reed, *University of Nevada, Reno, Reno, Nevada*

Twenty years ago, Zeiss and Steffen (1996) described “interdisciplinary healthcare teams” as the “basic unit of geriatric care.” Despite long-standing recognition that the complexity of elder needs extends far beyond basic medical requirements and warrants the involvement of multiple perspectives, many barriers persist to successful integration of care and services. In November 2015, the Sanford Center for Aging at the University of Nevada Reno launched a comprehensive, community-based, interdisciplinary geriatric specialty clinic to serve elders across Northern Nevada. This launch followed an 18-month needs assessment, planning and development process to identify the most appropriate clinical model for filling the geriatric service gaps of the region. This collaborative planning process, including representatives from more than 15 disciplines within the University Health Sciences Division and community members, determined a need for integrated assessment, planning and care coordination services, including the following: 1) comprehensive geriatric assessment; 2) psychosocial assessment; 3) medication therapy management; 4) advance care planning; and 5) chronic care management. Further, these clinic-based services are being extended via telemedicine to support primary care providers and their patients in rural communities. This symposium, intended for geriatric clinical providers of any discipline, will highlight each dimension of the new integrated clinical approach, detail the financial structure for this viable model, and report on the patient status and follow-up data. The various talks will walk audience members through the development and delivery of this new approach, as well as use financial and quality metrics to demonstrate the clinic’s viability and impact.

COLLABORATIVE PLANNING TO FACILITATE INTERDISCIPLINARY GERIATRIC CLINICAL APPROACHES

P.S. Reed, Z. Gibb, S. Phillips, K.R. Macmillan, *University of Nevada, Reno, Reno, Nevada*

This presentation will provide an overview of the collaborative planning process used to engage multiple health disciplines and community members in developing and launching a new community-based comprehensive geriatric specialty clinic. It will outline results of the key elements of the process, such as the national environmental scan of clinical geriatric models, the regional needs assessments, the collaborative committee structure and disciplinary engagement

strategies. It will conclude with an overview of the final clinic model that was implemented.

LEADING A COMPREHENSIVE GERIATRIC ASSESSMENT IN AN INTERDISCIPLINARY TEAM-BASED CLINICAL MODEL

S. Phillips, K.R. Macmillan, Z. Gibb, P.S. Reed, *University of Nevada, Reno, Reno, Nevada*

This presentation will describe the details of the comprehensive geriatric assessment being conducted by the geriatrician on the clinic's inter-disciplinary team. It will highlight the key dimensions of the assessment, with particular focus on how these elements can be successfully integrated into a collaborative care plan along with the results of the assessments being conducted by providers in other disciplines. It will also highlight innovative uses of the clinic's EMR system to maximize care planning and reimbursement.

COMPREHENSIVE PSYCHOSOCIAL ASSESSMENT TO IDENTIFY CLIENT SOCIAL NEEDS AND AVAILABLE RESOURCES

K.R. Macmillan, Z. Gibb, S. Phillips, P.S. Reed, *University of Nevada, Reno, Reno, Nevada*

This presentation will describe the key elements of the comprehensive geriatric psychosocial assessment and life-story review being offered in the clinic. By conducting this in-depth assessment, the inter-disciplinary team is able to identify potential social risk factors that may compromise the clients' abilities to effectively manage chronic conditions and receive needed care in the most efficient / cost-effective manner. This presentation will further describe the importance of the social work perspective as a key element of the clinic's inter-disciplinary approach.

CLIENT OVERVIEW: BASELINE STATUS AND 1-YEAR OUTCOMES OF COMPREHENSIVE GERIATRIC SPECIALTY CARE

Z. Gibb, S. Phillips, K.R. Macmillan, P.S. Reed, *University of Nevada, Reno, Reno, Nevada*

This presentation will report on the data collected from clinic's patients, documenting their baseline status in terms of: quality of life, well-being, physical status, emotional status, ADLs, chronic conditions and more. Further, it will provide one-year follow up on these metrics to determine the extent to which the clinic is achieving its desired clinical outcomes, such as reducing re-hospitalization and delaying long-term care placement. Finally, in addition to reporting key quality metrics, this presentation will conclude with a review of financial metrics and clinic viability, demonstrating that it is possible to navigate the current reimbursement system to successfully offer truly comprehensive services.

SESSION 2010 (SYMPOSIUM)

FACTORS AFFECTING HIP FRACTURE RECOVERY: FRAILITY, PHYSICAL FUNCTION, COGNITION, NUTRITION AND SEX

Co-Chair: J.S. Magaziner, *University of Maryland Baltimore*
Discussant: M. Crotty, *Flinders University, Adelaide, South Australia, Australia*

Hip fractures are a common public health problem among older adults. People who experience a hip fracture are often frail with physical and/or cognitive impairment and may have compromised nutritional status. Further, most research on hip fracture recovery has focused on females. With growing numbers of hip fractures among males, it is important to determine whether the two sexes differ with respect to recovery in multiple domains. This symposium brings together international researchers from the Fragility Fracture Global Network's Special Interest Group of Research on Recovery after Hip Fracture. The goal of this Special Interest Group is to promote international discussion and collaboration to expedite research focused on improving outcomes after hip fracture.

In this symposium, presenters will provide an overview of the state of the evidence on the impact of frailty, physical, cognitive and nutritional impairment on recovery after hip fracture. Recent findings from the United Kingdom on the impact of physical impairment on recovery after hip fracture will be presented. Current assessment and management approaches and how they can be incorporated into patient care will also be discussed. In addition, emerging evidence from the United States will discuss the differences in recovery and the trajectory of recovery experienced by men and women after hip fracture. Finally, presenters will discuss identified knowledge gaps and suggest future directions for research, including multi-modal approaches and international collaborations.

DOES KNOWING ABOUT FRAILITY MAKE A DIFFERENCE IN THE CARE OF HIP FRACTURE PATIENTS?

I. Cameron, *University of Sydney, Sydney, New South Wales, Australia*

People with hip fracture are frequently frail and frailty status appears to influence outcome after hip fracture. Whether frailty is an independent predictive factor for adverse outcome is currently unclear. Many evidence based clinical practice guidelines are appropriately applied to frail people with hip fracture. In particular, those related to mobility training and optimal nutrition have relevance for the hip fracture patient population. The principles of geriatric evaluation and management should also be applied to patients after hip fracture. Currently, sarcopaenia (rather than frailty) has been a treatment target for nutritional and pharmacological trials in hip fracture patients. Detecting and treating frailty in hip fracture patients may improve recovery after hip fracture, although this is not currently confirmed based on intervention studies.

PHYSICAL IMPAIRMENTS AFTER HIP FRACTURE

S. Lamb, *University of Oxford, Oxford, United Kingdom*

Modern surgical management of hip fractures leads, in most instances, to successful restoration of skeletal integrity of the femur and the possibility for resumption of weight bearing and early locomotion. However, studies of other organs involved in locomotion reveal substantial impairments that may not recover completely, or take much longer to recover and impact many essential facets of locomotion, including ability and speed of walking, chair standing, and stair climbing. This presentation will use data collected

between 1 and 3 months after hip fracture surgery, including muscle force generating characteristics of injured and uninjured limbs, postural sway, functional balance capabilities, and pain to characterise recovery of locomotion and the pathway between organ impairments, functional limitation, and disability in older people with hip fracture. The presentation will highlight potential avenues for new effective adjuncts to hip fracture management and consider both research and practice implications.

COGNITIVE IMPAIRMENT AFTER HIP FRACTURE

S. Kurrle, *University of Sydney, Sydney, New South Wales, Australia*

The presence of cognitive impairment (i.e. delirium and/or dementia) in hip fracture patients is very common. This presentation will discuss the evidence for how delirium can be prevented and/or managed for these patients in the acute hospital setting. Management of delirium post operatively through the use of non-pharmacological methods such as special delirium units, proper attention to hydration, management of medical comorbidities, and early mobilisation, has been shown to be effective in reducing length of delirium and improving recovery. We will also discuss how the presence of dementia in an older person recovering from hip fracture can make rehabilitation more difficult and in some cases may lead to exclusion from rehabilitation. We will discuss the evidence that these patients can benefit from rehabilitation that takes a simple, functional exercise based approach and will present examples of how these approaches can be delivered.

NUTRITIONAL IMPAIRMENT AFTER HIP FRACTURE

E.F. Binder, *Washington University in St. Louis, St Louis, Missouri*

Hip fracture patients are often undernourished at the time of the fracture event as measured by serum albumin levels and/or standardized dietary assessments. Reduced food intake, particularly during the acute recovery period, further contributes to poor recovery after hip fracture. This presentation will discuss the evidence related to the importance of nutritional status on recovery and the effectiveness of nutritional supplementation after hip fracture to improve patient outcomes. The limitations of research to date in this area will be presented and discussed. Finally, potential strategies to mitigate the risk of malnutrition after hip fracture will be presented in the context of multimodal interventions that include nutritional supplementation.

SEX DIFFERENCES IN RECOVERY TRAJECTORIES AMONG HIP FRACTURE PATIENTS

D. Abraham, D.L. Orwig, M. Hochberg, J.S. Magaziner, *University of Maryland, Baltimore, Maryland*

With hip fractures increasing among men, determining whether recovery differs between sexes is important. Recovery and outcome trajectories in function (physical, cognitive, affective), disability, body composition, and strength were assessed at baseline, 2, 6 and 12 months post hip fracture in 168 men and 171 women. Men had more comorbidities, were more likely to live with spouses and to die during follow-up than women. Changes in outcomes were significantly different between men and women for gait speed,

depressive symptoms, and lower extremity physical activities of daily living. Men and women both improved to six months but only men continued to improve out to 12 months. There were absolute sex differences for most body composition measures and strength. Baseline sex differences, selective survival among males, or the influence of depressive symptoms on rehabilitation may explain differential recovery. Further studies are needed to determine the underlying reasons for sex-differences in recovery.

SESSION 2015 (PAPER)

DETECTING AND MEASURING FRAILTY I

FRAILTY AND USE OF HEALTH SERVICES IN INJURED SENIORS: A POPULATION-BASED STUDY

M. Sirois^{1,2}, V. Fillion^{1,3}, S. Jean³, 1. *Centre d'Excellence sur le Vieillessement de Québec, Québec, Québec, Canada*, 2. *Université Laval, Québec, Québec, Canada*, 3. *Institut National de Santé Publique, Québec, Québec, Canada*

Currently, most information on frailty in seniors comes from cohort or trials studies. Methodologies to identify frail seniors within secondary care data, both at patient and population level, are current surveillance priorities. **Objectives:** to measure frailty using health administrative databases and examine the association between frailty and medical services use among non-institutionalized seniors with a minor fracture. **Methods:** Population-based cohort built from the Quebec Integrated Chronic Disease Surveillance System, including seniors ≥ 65 years, non-institutionalized in the pre-fracture year. Frailty was measured using the *ERA index*. Multivariate Poisson analysis were used to examine the association between frailty level and use of emergency department (ED) and general practitioner (GP) services 1 year post-fracture, adjusting for confounders. **Results:** The cohort included 179,734 individuals (mean age 76.3 years, 74 % women). There were 13 % and 4.7%, frail and non-frail seniors, respectively. Our Poisson regression analyses show that, in the post-fracture year, ED and GP visits were significantly higher in frail VS non-frail seniors: adjusted relative risk (RR)= 2.95; 95% CI: 2.83–3.08 for ED visits and RR=1.24; 95% CI: 1.21–1.28 for GP visits. **Conclusion:** This study suggests that it is possible to characterize seniors' frailty at a population level using health administrative databases. Furthermore, this study shows that non-institutionalized frail seniors require more health services after an incident minor fracture. Screening for frailty in seniors should be part of clinical management in order to identify those at high risk of needing more health services.

COMPARING SUBJECTS EWGSOP SARCOPEMIC STATUS AND THEIR CLINICAL FRAILTY SCALE LEVEL

A. Juby, C. Davis, S. Minimaana, *University of Alberta, Edmonton, Alberta, Canada*

The European Working Group of Sarcopenia in Older People (EWGSOP) classifies normal, presarcopenia, sarcopenia, and severe sarcopenia depending on lean muscle mass, grip strength and gait speed. The Clinical Frailty Scale (CFS)

has 9 classifications. Prevalence of sarcopenia and frailty increase with age. Are they two sides of the same coin?

Seniors participating in an exercise study were evaluated for sarcopenic status. Blinded to this information, they were evaluated using the CFS and classified accordingly.

Data was obtained from 39 participants (6 men), average age 75.7years (67–90). Average MMSE 29.1 (22–30), MoCA 26.4 (18–30). 11 were normal, 11 were obese, the remainder various stages of sarcopenia. 24 were CFS 3 or higher. Poor correlation was found between EWGSOP sarcopenic status and CFS ($R=0.43$), lean muscle mass (appendicular lean mass/height²) and CFS ($R=0.21$ in women), EWGSOP grip strength cut-offs and CFS ($R=0.46$). However, good correlation was found between CFS and 6m absolute walk time ($R=0.82$) and gait speed ($R=-0.61$). This study is limited by fewer individuals in the sarcopenic or frail spectrum.

This study suggests there is poor correlation between sarcopenic status (as defined by EWGSOP criteria), absolute muscle mass or grip strength and CFS. However, there was good correlation with gait time and speed, suggesting that functional measures of muscle are more important than absolute muscle mass in the development of frailty. Sarcopenia, as defined by EWGSOP does not equate to frailty as defined by CFS. The use of standardized definitions has important implications for research into potential therapeutic interventions.

FRAILITY INDEX BASED ON CLINICAL LABORATORY MEASURES (FI-LAB) ASSOCIATES WITH TELOMERE LENGTH

E. Dent¹, E.O. Hoogendijk², M. Moldovan³, 1. *Centre for Research in Geriatric Medicine, The University of Queensland, Woolloongabba, Queensland, Australia*, 2. *Department of Epidemiology and Biostatistics, VU University Medical Center, EMGO+ Institute for Health and Care Research, Amsterdam, Netherlands*, 3. *University of South Australia, Adelaide, South Australia, Australia*

With ageing, there is a reduction in genomic telomere length (TL), and accordingly, TL is used as a biomarker for biological age. This study determined whether a recently developed Frailty Index based on clinical laboratory measures (FI-LAB) was related to TL. The NHANES 1999–2002 dataset was used for all analyses. A standard 23-variable FI-LAB was constructed using systolic and diastolic blood pressures, and routinely collected biomarkers indicating renal function, complete blood cell count, electrolytes, as well as thyroid and liver function. For comparison purposes, a standard 10-variable Allostatic Load score was developed, and included: markers of organ dysfunction (creatinine), inflammatory makers (albumin, CRP), metabolic markers (Body Mass Index (BMI) and glycated haemoglobin), cardiovascular markers (systolic and diastolic blood pressures, total cholesterol, triglycerides and homocysteine). A standard Frailty Index based on clinically observable cumulative health deficits (FI-CD) was also derived. Multiple regression analyses, controlling for sex and education-level were performed. 1725 adults aged ≥ 50 years were included. Results showed that higher frailty level classified by the FI-LAB independently associated with shorter TL [β (95% CI) = -0.18 , -0.030 to -0.07 , $P = 0.002$], as did higher Allostatic Load [β (95% CI) = -0.07 , -0.14 to -0.01 , $P = 0.003$]. The FI-CD did not associate with TL. Findings from this study suggest that

whilst FI-LAB and Allostatic Load are indicators of biological age, the FI-CD was not. Thus the FI-CD may be more of a measure of frailty than of biological age per se.

OPTIMIZED UPPER EXTREMITY FRAILITY PARAMETERS FOR ASSESSING FRAILITY IN TRAUMA PATIENTS

H. Lee¹, B. Joseph², B. Najafi¹, 1. *Interdisciplinary Consortium on Advanced Motion Performance (iCAMP), Department of Surgery, Baylor College of Medicine, Houston, Texas*, 2. *Department of Surgery, The University of Arizona, Tucson, Arizona*

Recently, an innovative upper extremity frailty (UEF) meter was developed and validated based on two inertial wearable sensors and combination of sensor-derived kinematics/kinetics and patient's demographics including age, height and body mass. This study presents an optimized model to predict frailty status based on a single wearable sensor and without demographic/anthropometrics information. A dataset of 100 trauma patients (49 frail and 51 nonfrail) were retrospectively analyzed in which two inertial sensors were attached to elbow and forearm to quantify motor performance during a 20-second repetitive elbow flexion-extension task. The test protocol included performing elbow flexion/extension as fast as possible in supine position for 20-second. The classification accuracy of new algorithm was compared with previous method as well as Trauma-Specific Frailty Index as gold standard. We extracted totally 34 UEF sensor-derived parameters indicators of slowness, exhaustion, flexibility, and weakness. A multivariate linear regression model was used to identify independent predictors. Bootstrap technique was employed for generating training and validation dataset randomly with 1000 iterations. ANOVA statistic and recursive feature elimination technique were used for reducing and optimizing the UEF parameters. After training the model, 5 independent parameters were selected. Using the model, sensitivity of 85.3%, specificity of 78.5% and accuracy of 81.6% were achieved in the validation dataset. While new results were comparable with previous method, it allows identifying frailty using a single sensor and independent of subject's demographic/anthropometrics information and thus making it a more practical tool for busy clinics without the need of specific training or additional measurements.

SESSION 2020 (SYMPOSIUM)

SLEEP PROBLEMS AND DIVERSE STRESSORS IN THE SECOND HALF OF LIFE

Chair: O.M. Buxton

Co-Chair: S. Lee, *Penn State University, University Park, Pennsylvania*

Age and age-related processes degrade sleep. As chronic insufficient sleep (e.g., <7 hours/night) increases in the adult population, additional age-related deterioration of sleep raises concerns about adequate sleep recovery in the second half of life. This symposium showcases contemporary endeavors towards better understanding sleep problems associated with diverse stressors in mid-life and late-life. In **Paper 1**, analyses of a longitudinal data of community-dwelling older adults (Age=65yrs+; Health and Retirement Study,

HRS) test the casual link between insomnia symptoms and falls. In **Paper 2**, analyses of a longitudinal sample of workers from the Midlife in the United States (MIDUS) study examine changes in perceived work inequality predicting changes in insomnia symptoms through changes in negative work-to-family spillover, and age moderation ($M_{age}=50$ yrs). **Paper 3** uses data from the Household, Income and Labour Dynamics in Australia (HILDA) Survey in adults ($M_{age}=40$ yrs) to examine the association between elder care and sleep quality and how workplace entitlements, such as access to special leave to care for family members, modify this association. **Paper 4** uses data from the National Study of Caregivers (NSOC) to examine contextual factors and stressors associated with sleep disturbances among dementia caregivers ($M_{age}=57$ yrs). In a natural experiment from the 2011 Japan earthquake and tsunami, **Paper 5** tests the effects of disaster exposure on sleep disturbances among the elderly ($M_{age}=74$ yrs). At the end of these paper presentations, we will discuss their theoretical and methodological contributions, and consider challenges and opportunities for future research examining sleep in the second half of life.

INSOMNIA SYMPTOMS: A CAUSE OR CONSEQUENCE OF FALLS AMONG OLDER ADULTS?

T. Chen¹, G. Cheng¹, S. Lee^{2,3}, O.M. Buxton^{2,3,4}, 1. *Duke-NUS Medical School Singapore, Singapore*, 2. *Pennsylvania State University, University Park, Pennsylvania*, 3. *Center for Healthy Aging, Pennsylvania State University, University Park, Pennsylvania*, 4. *Division of Sleep Medicine, Harvard Medical School, Boston, Massachusetts*

We conducted a cross-lagged mediation analysis to examine the casual link between insomnia symptoms and falls among older adults using data from three waves of the Health and Retirement Study (2006[Time1], 2010[Time2], and 2014[Time3]; $n=2755$). We hypothesized that, through the development of poor health (Time2), insomnia symptoms (Time1) would lead to future falls (Time3). In the reverse direction, falls (Time1) would cause more insomnia symptoms (Time3) via poor health (Time2). The focal variables were insomnia symptoms (ranging from 0–4) and single falls (yes/no). The mediators were overall health (self-rated-health-status), mental health (Center-for-Epidemiologic-Studies-Depression-Scale), and physical health (balance-tests and timed-walk). Results showed that Time1 insomnia symptoms led to more fall at Time3 via decreased Time2 mental health, but not vice versa. These findings revealed that older adults with insomnia symptoms were likely to fall through decreased mental health, but falls did not seem to cause sleep problems.

PERCEIVED WORK INEQUALITY IMPAIRS EMPLOYEE SLEEP OVER TIME THROUGH NEGATIVE WORK-TO-HOME SPILLOVER

S. Lee^{1,2}, J.A. Mogle^{1,2}, O.M. Buxton^{1,2}, 1. *Biobehavioral Health, Penn State University, University Park, Pennsylvania*, 2. *College of Nursing, Penn State University, University Park, Pennsylvania*

Age impacts insomnia symptoms prevalence. The processes by which changes in contextual factors that also vary with age affect insomnia symptoms are less clear. Using longitudinal data with three time points over 2 decades

(T1:1995–1997, T2:2004–2006, T3:2013) from the Midlife in the United States ($N=1016$, $M_{age}=49.71 \pm 11.29$), we tested whether changes in perceived inequality at work predicted changes in insomnia symptoms (frequency of having trouble falling/staying asleep) through changes in negative work-to-family spillover, and how these effects differed by age. Multilevel modeling revealed that individuals with increased perceived inequality at work over time significantly increased in negative work-to-family spillover over time. Increased negative work-to-family spillover, in turn, significantly predicted increased insomnia symptoms over time. Age moderated the relationship between perceived inequality at work and negative work-to-family spillover. Older workers (60 yrs) were more vulnerable than younger workers (30 yrs) to experiencing negative work-to-family spillover when they perceived higher inequality at work.

ADULT CAREGIVING, WORKPLACE LEAVE AND SLEEP QUALITY

J. Lam, *University of Queensland, Indooroopilly, Queensland, Australia*

This paper examines whether caring for an elderly or disabled relative may be negatively associated with sleep quality. Further, it investigates whether workplace entitlements, such as access to special leave to care for family members may modify this association. Drawing on data from 8,475 employed respondents (mean age: 40; S.D. 14.3) from wave 13 of the Household, Income and Labour Dynamics in Australia (HILDA) Survey, where 689 provided some care to an elderly or disabled relative in a typical week, it finds that high-intensity carers (those who provide at least 8 hours or more of care per week) report poorer quality sleep, higher frequency of having trouble getting to sleep within 30 minutes, having taken medicine to help sleep, and having trouble sleeping because of waking up in the middle of the night. However, it does not find such associations for respondents who report access to workplace leave.

“WHAT HATH NIGHT TO DO WITH SLEEP?”: DEMENTIA CAREGIVER’S EMOTIONAL DISTRESS AND SLEEP DISTURBANCE

A. Leggett¹, D. Maust^{1,2}, H. Kales^{1,2}, 1. *Psychiatry, The University of Michigan, Ann Arbor, Michigan*, 2. *The Department of Veterans Affairs, Ann Arbor, Michigan*

Care provision for persons with dementia (PWD) can be rewarding yet may disrupt caregiver’s health, including sleep health. Using the National Study of Caregiving (NSOC), we examine reports of sleep disruption by dementia caregivers, as well as PWD and caregiver contextual factors, caregiver health and psychological well-being as predictors of sleep disruption. Our sample included 1063 caregivers for 717 PWDs. Waking and having trouble falling back asleep almost every night was reported by 15% of caregivers and 10% reported that helping the PWD caused their sleep to be interrupted almost every night. In a hierarchical linear model, greater sleep disruption was associated with caring for male PWDs, younger age, higher education, more chronic medical conditions, pain, emotional difficulty of the care role, and lower psychological well-being. Caregiver distress was associated with trouble sleeping over and above caregiver health

and PWD disability. Thus, interventions improving caregiver distress may improve sleep health.

DISASTER EXPOSURE AND SLEEP DISTURBANCES AMONG ELDERLY SURVIVORS OF THE JAPAN EARTHQUAKE AND TSUNAMI

X. Li¹, O.M. Buxton^{2,3,1}, H. Hikichi¹, I. Kawachi¹, 1. *Department of Social and Behavioral Sciences, Harvard Chan School of Public Health, Boston, Massachusetts*, 2. *Department of Biobehavioral Health, Pennsylvania State University, University Park, Massachusetts*, 3. *Division of Sleep Medicine, Harvard Medical School, Boston, Massachusetts*

Natural disasters disproportionately affect older adults. We examined prospectively the associations between disaster exposure and sleep disturbances among elderly survivors over three years of follow-up. Logistic regression models were used to analyze data from a natural experiment where a prospective cohort (aged 65 or older) suffered the 2011 Japan earthquake and tsunami between baseline (2010) and follow-up (2013) surveys. Of 3,567 panel respondents (74±6 years old, 57% female), 13% reported post-disaster sleep insufficiency (not well-rested upon waking), 41% insomnia symptoms, 11% short sleep duration (< 6 hours/day), 27% poor sleep quality, and 22% sleep medication use. Financial hardship was associated with post-disaster sleep insufficiency, insomnia symptoms, and poor sleep quality, net of baseline covariates. Property damage predicted sleep medication use while disrupted access to healthcare predicted poor sleep quality. In contrast, survivors appeared to have recovered from loss of relatives/friends as it did not predict any sleep disturbances.

SESSION 2025 (PAPER)

CHRONIC CONDITIONS IN OLDER ADULTS I

THE ROLE OF BODY COMPOSITION AND STRENGTH ON URINARY INCONTINENCE IN WOMEN FROM THE HEALTH ABC STUDY

A. Suskind¹, P.M. Cawthon², S. Nakagawa¹, L. Subak¹, I. Reinders⁴, S. Satterfield³, S.R. Cummings², A. Huang¹, 1. *UCSF, San Francisco, California*, 2. *CPMC, San Francisco, California*, 3. *The University of Tennessee, Memphis, Tennessee*, 4. *NIH, Bethesda, Maryland*

Objectives: To evaluate prospective relationships between body composition and muscle strength with predominantly stress- and urgency urinary incontinence (SUI and UUI) in older women.

Methods: Prospective community-dwelling observational cohort study of women initially aged 70 to 79 years (Health, Aging, and Body Composition study). Urinary incontinence was assessed by questionnaires. Body mass index (BMI), grip strength, quadriceps torque and walking speed were assessed by physical examination and performance testing. Appendicular lean body mass (ALM) and whole-body fat mass were measured using DEXA.

Results: Of 1475 women, 212 (14%) and 233 (16%) reported at least monthly predominantly SUI and UUI at baseline, respectively. At 3 years, there were 1137 women, 164 (14%) with new/persistent SUI and 320 (28%) with new/persistent UUI. Women had increased odds of new/persistent SUI if they demonstrated ≥5% decrease in grip strength, (adjusted OR [AOR] 1.60, p=0.047). Alternatively, women had decreased odds of new/persistent SUI if they demonstrated ≥5% decrease in BMI (AOR 0.46; p=0.014), ≥5% increase in ALM corrected for BMI (AOR 0.17; p=0.004), or ≥5% decrease in fat mass (AOR 0.53; p=0.010). Only a ≥5% increase in walking speed was associated with new/persistent UUI over 3 years (AOR 1.54; p=0.040).

Conclusion: Among women 70 years and older, changes in body composition and grip strength were associated with changes in SUI frequency over time. In contrast, changes in these factors did not influence UUI. Findings suggest that optimization of body composition and muscle strength is more likely to modify SUI than UUI risk among older women.

CHANGING FROM APPROPRIATE TO INAPPROPRIATE URINARY CATHETER USE AMONG HOSPITALIZED OLDER PATIENTS

F. Hu¹, H. Hsu¹, H. Shih¹, C. Chen², C. Chang¹, 1. *National Cheng Kung University Hospital, Tainan, Taiwan*, 2. *Chang Jung Christian University, Tainan, Taiwan*

To investigate incidence, rationales and related factors for changing from appropriate urinary catheter placement to inappropriate catheter use among hospitalized older patients in emergency department (ED). A longitudinal study was adopted at an 1135-bed tertiary-care medical center in southern Taiwan. Patients aged 65 and older with urinary catheter placed within 24 hours of hospitalization were enrolled. Demographic factors, present health condition, conditional factors of catheter placement, rationales for changing from appropriate urinary catheter placement to inappropriate use were collected through a review of medical records, interviewing participants or their primary caregivers.

Appropriate urinary catheters were placed within 24 hours of admission at the ED in 117 of the 156 patients (75%). Of these patients with appropriate urinary catheter placement, 77 patients (65.8%) experienced changing from appropriate placement to inappropriate use, with a mean duration of 2.88±1.56 days per patient. The common rationales for changing from appropriate urinary catheter placement to inappropriate use were post-operation for hip fracture (36.3%) and no longer need for monitoring of urine output (27.2%). Hierarchical regression model shows changing from appropriate urinary catheter placement to inappropriate use was associated with urinary tract infection diagnosis and no record of indication for catheter placement.

The study highlights a considerable percentage of changing from appropriate placement to inappropriate use. Efforts to improve record of indication for catheter placement and continue attention to urinary catheter use are necessary to reduce the incidence of inappropriate urinary catheter use.

A RETROSPECTIVE COHORT STUDY OF DISCHARGE HEMOGLOBIN IN OLDER PATIENTS AFTER HIP FRACTURE SURGERY

K. Khaw^{1,3}, C. McNally³, P. Shibu^{1,3}, S.C. Yu^{1,3}, M. Chehade³, R. Visvanathan^{1,3}, 1. *Aged and Extended Care, The Queen Elizabeth Hospital, Woodville South, South Australia, Australia*, 3. *Adelaide Geriatric Research and Training with Aged Care (G-TRAC) Centre, University of Adelaide, Adelaide, South Australia, Australia*, 3. *Discipline of Orthopaedics and Trauma, Royal Adelaide Hospital and University of Adelaide, Adelaide, South Australia, Australia*

Anemia and blood loss is common in patients with hip fractures. Preoperative and postoperative anemia in older people with hip fractures have been associated with higher risk of mortality and reduced ambulation. This study aims to evaluate discharge hemoglobin and clinical outcomes after hip fractures in older people. This is a retrospective cohort study of patients (age ≥ 65 years) that had hip fracture surgery in a tertiary referral hospital between 1 January 2011 and 31 December 2012. Main outcome measurements were 1-year mortality (data obtained from the local death registry) and 28-day readmission. Comparisons were made between patients with discharge hemoglobin < 100 g/L and those with ≥ 100 g/L (determined within 3 days before discharge). During the study period, 288 patients were included. Of these, 99 (34%) had hemoglobin < 100 g/L at discharge. The proportion of patients with internal fixation was significantly higher in the group with discharge hemoglobin ≥ 100 g/L compared to < 100 g/L (65% vs. 48%; $p=0.009$). The group with discharge hemoglobin ≥ 100 g/L had higher admission hemoglobin level (123 ± 18 g/L vs. 117 ± 17 g/L; $p=0.005$). The transfusion rate was similar between the two groups. Hemoglobin of < 100 g/L at discharge was not associated with increased risk of 1-year mortality (30% vs. 22%; $p=0.17$) and 28-day readmission rate (11% vs. 10%; $p=0.82$). These data suggest that discharge hemoglobin is not a good indicator of mortality and readmission after hip fracture surgery in older adults. Further prospective studies are necessary to determine if a specific target of hemoglobin level at discharge will influence clinical outcomes.

NONCLINICIAN SLEEP COACHES FOR INSOMNIA: SECONDARY OUTCOMES FROM A RANDOMIZED CONTROLLED TRIAL

C.A. Alessi^{1,2}, J. Martin^{1,2}, L. Fiorentino³, C. Fung^{1,2}, J. Dzierzewski⁴, J. Rodriguez Tapia^{2,5}, Y. Song^{1,2}, M. Mitchell¹, 1. *VA Greater Los Angeles Healthcare System, Los Angeles, California*, 2. *University of California, Los Angeles, Los Angeles, California*, 3. *University of California, San Diego, San Diego, California*, 4. *Virginia Commonwealth University, Richmond, Virginia*, 5. *Pontificia Universidad Catolica de Chile, Santiago, Chile*

Background: Cognitive behavioral therapy for insomnia (CBTI) is recommended for older adults, but availability of behavioral sleep medicine (BSM) specialists to provide CBTI is limited. We recently reported improved sleep (e.g., Pittsburgh Sleep Quality Index [PSQI] and Insomnia Severity Index [ISI] total scores) in a 4-year randomized controlled trial testing CBTI provided by nonclinician sleep coaches among older outpatients with insomnia at one US Veterans

Administration healthcare system. As secondary analyses, we explored intervention effects on participants' beliefs and attitudes about sleep, specific aspects of self-reported sleep quality and symptoms of insomnia.

Methods: Sleep coaches provided 5 sessions over 6 weeks (including stimulus control, sleep restriction, sleep hygiene and cognitive therapy) with weekly telephone supervision by a BSM specialist. Controls received five sessions of general sleep education. Analyses were intention to treat, using mixed effects models testing the Dysfunctional Beliefs and Attitudes (DBAS16) total score and 4 subscales; PSQI 3-factor subscales, and ISI individual items; at post-treatment, 6- and 12-months follow-up.

Results: 159 subjects were randomized (mean age 72.2 years, 97% male, 79% non-Hispanic white). Intervention participants had greater improvement in DBAS16 total score and sleep expectations subscale; PSQI subscales sleep efficiency and perceived sleep quality; and ISI items satisfaction with sleep, daily functioning, noticeability to others, and worry/distress about sleep (all $p < .05$).

Conclusions: CBT-I provided by nonclinician sleep coaches with BSM supervision improved sleep-disruptive beliefs, and multiple aspects of self-reported sleep. The sleep coach approach may be an important option for the management of insomnia in older adults.

SESSION 2030 (SYMPOSIUM)

CONTEXT AND CULTURE: THE IMPACT OF AIDS ON THE HEALTH OF OLDER PERSONS IN SUB-SAHARAN AFRICA

Chair: J. Small, *Oregon State University, Corvallis, Oregon*
Co-Chair: P. Kowal, *World Health Organization, Geneva, Geneva, Switzerland*

Discussant: M. Ralston, *Mississippi State University, Starkville*

The confluence of population aging and HIV/AIDS in sub-Saharan Africa (SSA) has resulted in a wide range of psychosocial and health impacts that have yet to be fully described. Our symposium is a unique interdisciplinary reflection on the differential impacts of demographic shifts and the HIV/AIDS epidemic on older adults in SSA, highlighting insights gleaned from cross-national comparisons. Jeon Small (social scientist) will use a revised version of Knight and Sayegh's (2010) sociocultural stress and coping model to describe results of a systematic literature review on older adult caregivers to persons with HIV/AIDS in SSA. Mark Brennan-Ing (clinical psychology and gerontological research) will present a comparative study of populations who are aging with HIV in high-and-low-resource settings of Uganda and the USA. Gillian Ice (anthropology and social medicine) will present on the benefits and burdens of caregiving using comparative samples of Kenyan and Rwandan caregivers. Paul Kowal (global health and aging) will present preliminary findings from Waves 1 and 2 of the WHO SAGE-WOPS HIV study, which is a longitudinal study of caregiving and HIV/AIDS in South Africa and Uganda. Our discussant will integrate the four papers, highlight the importance of the confluence of context and culture on older adults directly and indirectly impacted by HIV and AIDS.

CAREGIVING AND HIV+/AIDS IN SUB-SAHARAN AFRICA: CONTEXT AND CULTURE IN THE STRESS AND COPING PROCESS

J. Small, *Oregon State University, Corvallis, Oregon*

Jeon Small,¹ Carolyn Aldwin,¹ Paul Kowal,²

Somnath Chatterji,² Ties Boerma², 1. *School of Social & Behavioral Health, Oregon State University* 2. *World Health Organization, Geneva, Switzerland*

In sub-Saharan Africa (SSA), older adults in unprecedented numbers have been recruited into providing care to persons living with HIV/AIDS (PLWHA) across the lifespan. The literature on older adult (OA) caregiving in SSA is fragmented across several disciplines and lacks a unified theoretical framework, we use a revised version of Knight and Sayegh's (2009) sociocultural stress and coping model examine the literature on older adult caregivers to PLWHA. An exhaustive literature review identified 68 articles on OA caregiving in SSA. The SSA experience requires understanding that OAs are often taking care of multiple family members and are often themselves in need of care. Key findings suggest that population aging and HIV/AIDS deplete the amount of social, cultural, and structural capital available to OA caregivers. Interventions which focus on collective solutions to problems such as food insecurity may be needed at both the extended family and the village level.

GLOBAL AGEING WITH HIV: DIFFERENCES BETWEEN HIGH- AND LOW-RESOURCE SETTINGS

M.G. Brennan-Ing^{1,2}, C. MacPhail^{3,4}, J. Seeley^{5,6}, M. Kuteesa⁶, V. Minichiell⁷, F. Venter⁴, K.E. Porter¹, S. Karpiak^{1,2}, 1. *Applied and Translational Research, ACRIA, New York, New York*, 2. *New York University College of Nursing, New York, New York*, 3. *University of New England, Armidale, New South Wales, Australia*, 4. *University of the Witwatersrand, Johannesburg, South Africa*, 5. *London School of Hygiene and Tropical Medicine, London, United Kingdom*, 6. *MRC/UVRI Uganda Research Unit on AIDS, Entebbe, Uganda*, 7. *LaTrobe University, Melbourne, Victoria, Australia*

Globally the HIV epidemic is aging due to the success of life-prolonging antiretroviral treatment. Historically, UNAIDS data reporting stopped at age 49. But the UNAIDS' 2014 Gap Report identified older adults with HIV (OPH) as a group left behind. Challenges faced by this population include multimorbidity management, sexual health, stigma, and access to social care. Referencing three parallel studies in Uganda, South Africa and the U.S., this paper will examine similarities and differences in the complex challenges facing OPH across resource settings. For example, differences in the average number of comorbidities are evident (5.3, 1.2, and 3.2, respectively). In Africa, friends and neighbors provide much greater IADL assistance and emotional support than is observed in the U.S., but OPH in *all* settings report needing more support. The challenges in implementing policy and programmatic responses to the ageing of HIV in the context of available resources across settings will be discussed.

AGING AND HIV: A SUMMARY OF SAGE-WOPS HIV WAVES 1 AND 2 IN SOUTH AFRICA AND UGANDA

P. Kowal^{1,2,3}, N. Naidoo¹, S. Chatterji¹, J. Snodgrass², 1. *SAGE, WHO, Yangon, Myanmar*, 2. *University of*

Oregon Department of Anthropology, Eugene, Oregon, 3. *University of Newcastle Research Centre for Generational Health and Ageing, Newcastle, New South Wales, Australia*

In highly affected countries of sub-Saharan Africa, not only do older people play an important role in the care of HIV-affected adults and children, they themselves are increasingly likely to be infected with HIV. Few studies in the region have directly investigated the topic of older adults who are infected or affected by HIV/AIDS, including the effect of caregiving, antiretroviral therapy (ART) and co-morbidity with chronic diseases on the health and well-being of older people. This presentation describes the main aims of establishing the cohorts in South Africa and Uganda to describe the: 1) health status of older people either infected with HIV themselves, or affected by HIV through having an HIV infected adult offspring or had recently died of HIV-related causes; and 2) impact of role as caregivers. We will present results from SAGE-WOPS HIV Waves 1 and 2 on the direct and indirect effects of HIV on older people in South Africa (W1 n=422; W2 n=519) and Uganda (W1 n=510; W2 n=478).

THE BENEFITS AND BURDENS OF CAREGIVING: A COMPARISON OF KENYA AND RWANDA

G.H. Ice¹, A. Sadruddin², J. Bianco¹, 1. *Ohio University, Athens, Ohio*, 2. *Yale University, New Haven, Connecticut*

The HIV/AIDS epidemic has increased care burden in sub-Saharan Africa but studies on the impact on older persons are equivocal and benefits of caregiving have also emerged. This presentation discusses two qualitative studies in western Kenya and Rwanda. In Kenya, caregiving necessitated an unexpected disruption and many burdens but the change of identity/roles with caregiving was both a source of pride and empowerment for older adults. Caregivers described multiple burdens yet they felt a moral, familial or spiritual obligation to provide care. Further, many participants also assistance from orphans or anticipated reciprocity. In Rwanda, caregiving was viewed as an opportunity for older persons to make themselves useful community members. Caregiving, in this setting, was not considered a burden in the conventional sense but a moral responsibility and a practice that brought communities together. These results suggest that caregiving is multidimensional with a balance of burden and empowerment, caregiving and care-receiving.

SESSION 2035 (SYMPOSIUM)

FONDATION IPSEN LONGEVITY PRIZE 2017 AWARDING LECTURE

Chair: Y. Tanguy, *Fondation IPSEN*

Co-Chair: T. Kirkwood, *University of Newcastle* and S.N. Austad, *University of Alabama*

During this symposium, the Fondation Ipsen Longevity Prize 2017 will be awarded to Andrzej Bartke.

THE IMPORTANCE OF SINGLE GENE INTERVENTIONS IN AGING

S.N. Austad, *University of Alabama, Birmingham, Alabama*

When the history of the basic aging research leading to medical treatments that extend human health is written, a significant milestone is likely to be the 1996 paper by

Brown-Borg, Borg, Meliska, and Bartke describing the first single gene mutant that extended life in a mammal. Previous research beginning in the late 1980's had found such genes in very simple organisms, but many researchers in the field felt that single genes would never be found to extend life in such a complex animal as a mammal. Of course, now we know that there are a number of individual genes – several dozen so far – that can extend life in mammals. The significance of these findings is not that we should begin manipulating the human genome to allow everyone to live longer. It is that each such gene represents a potential drug target for slowing aging. Consequently, drugs doing exactly this -- began to emerge less than 15 years after this initial, pivotal discovery. Dr. Bartke has been a key driver in the field since this original publication as will be described.

GROWTH AND AGING; THE HIDDEN COSTS OF STATURE

A. Bartke, *SIU, Springfield, Illinois*

Elimination of growth hormone (GH) actions by mutations or targeted gene deletion produces a remarkable extension of longevity in both sexes of laboratory mice. Long-lived GH-deficient and GH-resistant animals are characterized by small body size, delayed puberty, reduced fecundity and a striking delay in multiple symptoms of aging, including the decline of gonadal function. These findings lead to a somewhat counterintuitive conclusion that the normal actions of GH incur significant costs in terms of the impact on aging and longevity. Studies in genetically normal (“wild type”) mice, domestic dogs and various human populations indicate that GH signaling is indeed negatively associated with life expectancy across mammalian species. The evolutionary history of the genetic variation underpinning the trade-offs between growth, maturation, reproductive functions, stress resistance, age-related disease and longevity is difficult to decipher. However, persistence of a wide range of the corresponding phenotypes may benefit survival of populations under challenging environmental conditions.

Supported by NIA

SESSION 2040 (SYMPOSIUM)

A BINATIONAL COMPARISON OF FAMILY AND FORMAL SUPPORT IN THE AMERICAS: MEXICO AND THE U.S.

Co-Chair: J.L. Angel, *University of Texas at Austin*
K.S. Markides, *University of Texas Medical Branch at Galveston*

Discussant: W. Vega, *University of Southern California*

This symposium examines the relationship between formal eldercare policy and the actual capacities of various levels of government and other institutions to implement specific agendas. The symposium will place special emphasis on the Hispanic population which is rapidly aging in the U.S., with the number of adults 65 and older expected to increase by more than six times by 2050 to 17.5 million. Mexico's population is also aging and will increase by 227 percent over the next 25 years. Governments recognize that these aging trends will cause a strain on both healthcare systems as well as other community resources.

This symposium will also focus on the consequences of rapid declines in fertility and rising longevity for the U.S. and Mexico. Given immigrants interconnectedness, understanding how aging processes in Latin America influence health and retirement policy there and how the aging of older immigrants in the U.S. influence social delivery here is critically important. As of yet, however, the ways in which those nations can address the problem of rapid aging remain unclear.

Presentations will examine issues related to older U.S. adults, and Mexicans including: 1) the effects of immigration-related factors on financial security, adaptation, and autonomy, 2) the impact of family and economic resources on long-term care alternatives, 3) innovative strategies and concrete solutions to improving health and social welfare, and 4) identifying methodological challenges and opportunities for investigations of informal support in Mexico and the U.S.

CAREGIVING NETWORKS AND BENEFITS OF CAREGIVING: DIFFERENCES BY RACE AND ETHNICITY

E.M. Agree¹, T. Wakui^{2,1}, 1. *Sociology, Johns Hopkins University, Baltimore, Maryland*, 2. *Tokyo Metropolitan Institute of Gerontology, Tokyo, Japan*

Research on family caregiving has often focused on the experience of care burden, but an emerging literature has shown that caregiving can have benefits for both caregivers and care recipients, and that these benefits may vary by cultural background, race or ethnicity. This study uses nationally representative data from the U.S. National Study of Caregiving (NSOC) and National Health and Aging Trends Study (NHATS) to examine the structure of caregiving networks and the experience of benefits by caregivers from different backgrounds. NHATS studies late-life disability and NSOC collects data on informal caregivers to NHATS participants. Preliminary results show that African American elders have a slightly larger care networks, but are no more likely to live with their helpers than white elders. Although previous research has reported higher levels of positive caregiving among minority caregivers, we find that health of the care recipient and relationships are more important than background.

DEMENTIA AND SOCIAL SUPPORT TRAJECTORIES IN THE MEXICAN-ORIGIN POPULATION

S. Rote¹, J.L. Angel², T. Hill³, K.S. Markides⁴, 1. *Kent School of Social Work, University of Louisville, Louisville, Kentucky*, 2. *University of Texas at Austin, Austin, Texas*, 3. *University of Arizona, Tucson, Arizona*, 4. *University of Texas Medical Branch, Galveston, Texas*

Given the future growth of the elderly Mexican-origin population, the need for culturally informed dementia care will inevitably grow in the years ahead. Dementia-related needs of older adults living in the community are multidimensional and based on severity of dementia; yet, there is a lack of information on emotional and instrumental support need as cognitive impairment unfolds for the elderly population in general and for the Mexican-origin population in particular. The current explores different patterns or trajectories of emotional and instrumental support need for

3,050 Mexican Americans aged 65 and older from seven waves of the Hispanic Established Epidemiologic Studies of the Elderly (H-EPESE, 1993/94–2010/11). We identify three distinct classes of social support trajectories: stable high support need, increasing support need, and stable low support need. Mexican American elders with increasing cognitive impairment report increasing emotional and instrumental support need throughout the study waves. Predictions of older Latinos at risk of being left without sound support and consequently high dependency on public resources are discussed.

FAMILY AND COMMUNITY-BASED SUPPORT FOR OLDER ADULTS IN MEXICO

L. Gutierrez-Robledo, M. Lopez Ortega, *Instituto Nacional de Geriatria, Mexico City, Mexico*

Mexico is undergoing a rapidly aging process and by the year 2050 the proportion of adults 60 years and older is estimated to increase from the current 10 percent of total population to 28 percent in the year 2050. However, this process is taking place in a context of limited resources, lack of long-term care policies and specific primary care strategies for older adults, as well as insufficient regulation of institutional and community-based care. This study presents a summary of the current state of social care support systems for older adults in Mexico, with an emphasis on family and community-based care and the challenges they face in meeting an increasing care demand. It also presents some recommendations on how to tackle some of these challenges.

AGING IN MEXICO AND THE ROLE OF THE CIVIL SOCIETY ORGANIZATIONS

V. Montes de Oca Zavala¹, P. Rea Angeles¹, R.J. Angel², *1. Universidad Nacional Autónoma de México, Mexico City, Mexico, 2. University of Texas at Austin, Austin, Texas*

The aging population has influenced public policy in many countries, including Mexico, over the past two decades. In Mexico, this new focus on the rights of the elderly influences the positions of civil society organizations. We analyze official communications from civil society organizations in Mexico City and employ qualitative techniques to identify perspectives on active ageing, social participation, and the social rights of older adults. Our most significant finding is that organizations have fought for the labor rights of unions in strategic sectors that have been threatened by the economic policy of privatization. Their missions are not framed in terms of aging, but in terms employment. Other groups focus on concrete needs such as institutionalized care, strengthening community networks, and defending the rights of pensioners. Views of old age and that the experience of aging is heavily determined by one's labor market history and the more general processes of development.

ISSUES IN SURVEYING FOR FAMILY HEALTH SUPPORT IN CROSS-NATIONAL STUDIES IN THE AMERICAS

R.B. Wallace, *Epidemiology, The University of Iowa, Iowa City, Iowa*

Comparative research among countries is critical to promoting improved and optimal support for family health needs among older persons, but conducting household

surveys has challenges in addition to translation across languages and native dialects, including: defining representative samples, gaining permission to approach households; understanding cultural variation in the use of both formal and informal care; crafting useful survey items in the face of substantial differences in general and health literacy; identifying local complementary and alternative health practices; and selecting the best household respondents. Also, given the substantial regional variation in actual and potential health and long-term care services available and accessible to families, including from community and public health sources, many survey formats and items may be inappropriate across diverse settings. Some potential solutions to these challenges will be presented, including techniques not yet widely applied in developed or developing countries.

SESSION 2045 (SYMPOSIUM)

MULTIPLE PERSPECTIVES ON FAMILY LIFE

Chair: K.L. Fingerma, *The University of Texas at Austin, Austin, Texas*

Research on families in late life has often focused on individual reporters, rather than dyadic or family perspectives. This symposium considers multiple perspectives on family relationships as well as the role of changing societies in shaping these perceptions. Suitor and colleagues consider mother's favoritism in late life, and how grown children's perspectives on who is the favorite may differ or coincide with the mother's perspective- with consideration of ethnic differences in the US. Han examines marital partners' discrepant views of gender roles and marital satisfaction in South Korea and considers how changes in society shape these views. Fingerma and colleagues look at parents' and grown children's perceptions of support exchanges. They find greater discrepancies in perceptions of support in younger dyads, with parents reporting receiving less support than offspring report providing. Finally, migration has increased dramatically worldwide and family ties are shaped by this experience. Dykstra and Fokkema examine a large sample of migrants to France, and consider family patterns in their relationships with their grown children. Collectively, these studies suggest family members bring unique perspectives to intergenerational and marital relationships. Individuals have distinct relationships with each of their family members, favoring some children over others and relating to parents differently than to their children. Importantly, societal changes and cultural values shape these perceptions and implications of these perceptions for family members' well-being.

IT'S REALLY NOT ME? ADULT CHILDRENS' MISPERCEPTIONS OF MOTHERS' FAVORITISM AND DISFAVORITISM

J. Suitor¹, M. Gilligan², M. Rurka¹, S. Peng¹, K.A. Pillemer³, *1. Purdue University, West Lafayette, Indiana, 2. Iowa State University, Ames, Iowa, 3. Cornell University, Ithaca, New York*

Recent studies have revealed that both mothers and adult children report that maternal favoritism and disfavoritism are common in later-life families; however, little is known about whether children's perceptions of differentiation

mirror mothers' own reports. In this paper we use data from 310 mothers and 725 offspring from the Within-Family Differences Study to examine patterns and predictors of congruence regarding reports of favoritism and disfavoritism. Contrary to the intergenerational stake hypothesis, mothers and offspring reported similar rates of favoritism and disfavoritism; however, children were very inaccurate reporters of which offspring mothers favored and disfavored. Congruence was more likely when mothers and offspring were the same gender, shared values, and frequently exchanged support. Greater congruence was found in Black than White families. Given that adult children's perceptions of such differential treatment strongly predict depressive symptoms, shedding light on these processes is important in understanding the role of intergenerational relations in well-being.

VARIATION IN PARENT-CHILD RELATIONSHIPS WITHIN MIGRANT FAMILIES

P.A. Dykstra¹, T. Fokkema^{2,1}, 1. *Erasmus University, Rotterdam, Netherlands*, 2. *NIDI-KNAW, University of Groningen, Rotterdam, Netherlands*

Silverstein and Bengtson (1997) were pioneers in examining multiple dimensions of parent-child relations simultaneously. Their typology of American late-life families has been replicated in different countries. Most of these studies focused on one parent-child dyad per family and all but one study² did not pay attention to the specific case of migrants, thereby masking within-family variations in intergenerational solidarity and leaving the question about the impact of migration unanswered. This paper aims to advance our knowledge in both areas. Data are taken from the French 'Route to Retirement of Immigrants' survey in which more than 6000 migrants, aged 45–70 and of different origin, were asked about various dimensions of their relations with each child: geographical proximity, contact frequency, family obligation norms, and personal, practical and financial support exchange. Once parent-child are assigned to latent classes, multilevel multinomial logistic regression will be used to identify significant predictors.

GENERATIONAL DIFFERENCES IN PERCEPTIONS OF SUPPORT EXCHANGES

K.L. Fingerman¹, M. Huo¹, K. Kim³, K. Birditt², 1. *Human Development, The University of Texas at Austin, Austin, Texas*, 2. *University of Michigan, Ann Arbor, Michigan*, 3. *University of Massachusetts, Boston, Massachusetts*

In Western countries, parents typically provide support to their children, even after they are grown; grown children may reciprocate and provide support to parents in late life when parental health declines. Yet, we do not know whether both parties perceive these exchanges in the same manner across adulthood. Participants included two sets of dyads from the *Family Exchange Study*: Middle aged parents and young adult children (n = 664 dyads, 1328 participants) and older parents and middle-aged children (n = 221 dyads, 442 participants). Participants report frequency of giving and receiving 6 types of support using the Intergenerational Support Index (ISI). The older dyads typically agreed in reports of support provided by parents to offspring and by offspring to parents. In the younger dyads, the young adult children reported providing more frequent support of all types than

parents reported receiving. Norms for intergenerational support may shape perceptions of such support.

KOREAN MIDDLE AGED COUPLES' DISCREPANCIES IN GENDER ROLES, MARITAL AND LIFE SATISFACTION

G. Han, Y. Bae, *Seoul National University, Seoul, Korea (the Republic of)*

Due to gender inequalities, men and women have different subjective experiences of marriage. This discrepancy between partners might be particularly salient in a rapidly changing society like Korea. This study asked how discrepancies among Korean middle aged couples' beliefs about gender roles affect marital stability and well being. We used dyadic data from 1074 middle-aged Korean baby boomer couples to examine this question. Data were analyzed using actor-partner interdependence model (APIM). Dependent variables were marital stability and life satisfaction. Main independent variables were gender role attitudes, spousal relationship satisfaction and discrepancies in gender role attitude and spousal relationship satisfaction. Results show that only 42% of the couple shared an outlook of their marriage where neither husband nor wife ever considered divorce. In many couples, more wives considered divorce than husbands. When gender role attitude discrepancies between partners was larger, marital stability of the couple tend to be lower.

SESSION 2050 (SYMPOSIUM)

TRAJECTORIES OF CARE FOR LGBT (LESBIAN, GAY, BISEXUAL AND TRANS) AGEING POPULATIONS

Chair: R.L. Jones, *The Open University, UK, Milton Keynes, United Kingdom*

Co-Chair: A.D. King, *University of Surrey, Guildford, Surrey, United Kingdom*

This symposium presents research from the UK, US and Canada which focuses on aspects of care and the care needs for ageing lesbian, gay, bisexual and trans (LGBT) people. The symposium will offer insights which contribute to broader understandings of the heterogeneity of ageing. It showcases cutting edge research in the field which provides compelling evidence for the need to recognize and address the unique care needs of older LGBT individuals - a diverse new ageing population worthy of more attention within gerontology. In particular, this symposium demonstrates that despite recent socio-legal shifts, LGBT people are still an invisible and marginalised population in care settings and their life-stories and relationships are frequently overlooked by care providers. The paper by Hafford-Letchfield et al., present findings from a pilot scheme designed to find ways to enhance the inclusion of older LGBT residents in English care homes. Flatt et al., address the area of long term care in the US, identifying predisposing, enabling and need factors of older LGBT people. The papers by both Almack and De Vries et al., focus on the unique experiences and diversity of support needs of LGBT older people towards the end of life, in the UK and Canada respectively. All four papers raise issues of intersections between ageing, gender identity and sexual orientation in different geographical contexts and across a range of care settings.

PREPARATIONS FOR END OF LIFE AMONG LGBT OLDER CANADIANS

B. deVries^{1,2}, G.M. Gutman², L. Chamberland⁴, J. Fast³, J. Gahagan⁵, A. Humble⁶, S.E. Mock⁷, 1. *Gerontology, San Francisco State University, San Francisco, California*, 2. *Simon Fraser University, Vancouver, British Columbia, Canada*, 3. *University of Alberta, Edmonton, Alberta, Canada*, 4. *University of Quebec at Montreal, Montreal, Quebec, Canada*, 5. *Dalhousie University, Halifax, Nova Scotia, Canada*, 6. *Mount St. Vincent University, Halifax, Nova Scotia, Canada*, 7. *University of Waterloo, Waterloo, Ontario, Canada*

Research over the last decade has documented the unique historical experiences and demographic characteristics of lesbian, gay, bisexual and transgender (LGBT) older adults. To explore the influence of these and other variables on end-of-life planning, focus groups were held in five Canadian cities (Vancouver, Edmonton, Montreal, Toronto, and Halifax) with lesbians and bisexual women ($n=29$), gay and bisexual men ($n=39$) and transgender individuals ($n=23$) age 55+. All groups described difficulty identifying potential caregivers and engaging others in discussion of end-of-life issues. Lesbians and bisexual women highlighted the need for community intervention, gay and bisexual men issues of trust and the legacy of HIV, transgender persons the insensitivity of health care settings. The findings show both similarities and differences between LGBT groups and while focused on the experiences of stigmatized sexual minority groups, have broad implications for others challenging traditional family norms. Service provider data ($n=26$) compliment the LGBT data.

IS EVERYONE EQUAL IN OLD AGE? END-OF-LIFE CARE FOR OLDER LESBIAN, GAY, BISEXUAL AND TRANS PEOPLE

K. Almack, *Health Sciences, University of Nottingham, Nottingham, United Kingdom*

The heterogeneous care needs of older people are often neglected. This paper examines older LGBT people's experiences and perceptions of care towards the end of life as a 'critical case' in addressing diversity within the delivery of end of life care services in the UK. In doing so, the paper discusses findings from the qualitative strand (60 in-depth interviews with LGBT people aged 60+) of The Last Outing - a large mixed methods UK project. Findings revealed that despite legislation providing equality and protection for LGBT people, a significant number of barriers and stressors still exist in accessing services and support. It is clear that older LGBT people's histories and pathways have profound influences on well-being and access to support towards and at the end of life. These are issues that need to be addressed to ensure equitable access to end of life care services for all in old age.

PREDICTORS OF INFORMAL AND FORMAL LONG-TERM CARE USE AMONG SEXUAL AND GENDER MINORITY OLDER ADULTS

J.D. Flatt¹, S. Karpiak^{2,3}, E. Seidel^{2,5}, B. Larson⁴, M.G. Brennan-Ing^{2,3}, 1. *Institute for Health and Aging, University of California, San Francisco, San Francisco, California*,

2. *ACRIA, Center on HIV and Aging, New York, New York*, 3. *New York University College of Nursing, New York, New York*, 4. *Center on Halsted, Chicago, Illinois*, 5. *Fordham University, New York, New York*

Few studies have examined long-term care (LTC) use among sexual and gender minority (SGM) older adults. Guided by Andersen's Healthcare Utilization Model, we identified predisposing, enabling, and need factors associated with informal (caregiving) and formal (homecare, long-term/continuing care, hospice care) LTC use in a community-based sample of SGM older adults ($n=210$), mean age 59.6. Nearly 20% used informal or formal care in the past year and 10% used both. Informal LTC use was associated with identifying as female (OR:8.8; 95%CI:2.2–35.2), HIV positive (OR:8.5; 95%CI:2.0–35.1), having one or more instrumental activities of daily living (ADL) impairments (OR:5.2; 95% CI:2.0–13.2), and having greater service needs (OR:1.4; 95% CI:1.2–1.7). Formal LTC use was associated with access to Medicare (OR:4.2; 95% CI:1.7–10.9) and comorbidities (OR:1.3; 95%CI:1.1–1.6). A greater understanding of LTC needs of SGM older adults is necessary for developing policies and services aimed at improving care and quality of life for this population.

DEVELOPING INCLUSIVE CARE HOME ENVIRONMENTS FOR OLDER LGBT PEOPLE: A PILOT SCHEME IN ENGLAND

P. Willis¹, T. Hafford-Letchfield², K. Almack³, P. Simpson⁴, 1. *University of Bristol, Bristol, United Kingdom*, 2. *Middlesex University London, London, United Kingdom*, 3. *University of Nottingham, Nottingham, United Kingdom*, 4. *Edge Hill University, Manchester, United Kingdom*

We present findings from an evaluation of a pilot scheme in England aimed at enhancing the inclusion of older LGBT residents in care home environments. Implemented in 2016, six LGBT community members were recruited and trained to undertake community audits of current care home practices. The scheme was implemented in one locality across six homes, which belonged to a national provider of housing for older people. Based on their findings, Community Advisors (CAs) advised home managers on ways of developing LGBT-inclusive environments. As an external team we conducted a qualitative evaluation, which included pre- and post-intervention interviews ($N=39$) with CAs ($n=8$), home managers ($n=6$) and other management staff ($n=3$). Based on the findings, we discuss how the scheme took a 'co-production' turn and identify ways in which CAs can be a valuable resource in bridging the gap between hetero-centric cultures of homes and the lived realities of older LGBT people.

SESSION 2055 (SYMPOSIUM)

EVALUATION OF KNOWLEDGE MOBILIZATION IN GERONTOLOGY: DIGITAL TOOLS, PAPER TOOLS, OR BOTH?

Chair: L. McDonald, *University of Toronto, Toronto, Ontario, Canada*

Discussant: T. Goergen, *Criminological Research Institute of Lower Saxony*

The purpose of this research was to evaluate the impact of pocket tools in digital and paper formats that contained evidence-based information about the core challenges of aging. The tools, based on current research in aging, were created by interdisciplinary teams for an established national/international knowledge mobilization network of older adults, students, policy makers, academics and practitioners. The overarching goal of the network was to place the most recent knowledge on aging in the hands of users in a rapid and straightforward way. Over 230 tools including care giving, financial literacy, legal issues, policing, dementia, mental health, ethnicity, elder mistreatment and technology were developed and have been utilized by over a million users nationally and internationally. All researchers, and community partners to this project have had strong vested interests in knowing if the tools were effective, which format worked best for their stakeholders, and how the information was used. The investigation included a survey of current users of the tools (n=800) to evaluate how the tools were used; digital and paper tool users (seniors, practitioners, caregivers) were compared on outcomes of effectiveness in 9 random clinical trials (n=783) and 40 respondents were interviewed in-depth about their challenges in using the tools. Here we report on the survey and the first random trial of tools, the outcomes, challenges and the roles and implications for international partners. The results suggested that both digital and paper tools were very helpful in uptake but the digital divide still existed according to age and education.

THE CONTINUING DIGITAL DIVIDE: RESULTS FROM THE KNOWLEDGE MOBILIZATION SURVEY

L. McDonald, *University of Toronto, Toronto, Ontario, Canada*

Knowledge mobilization (KM) is practical because it is cost-efficient, makes use of existing research and can happen at a faster pace than waiting to change the behaviours of whole generations of seniors, students, practitioners and policymakers. While KM seems obvious, there is a lack of research about the effectiveness of KM in the field of gerontology. This research traverses new terrain in aging and technology by evaluating KM through the use of pocket tools, delivered on paper or digitally. The analyses were based on a random sample of 3,500 members of a KM network (n=800) who were surveyed in one hour, standardized telephone interviews. The results showed digital tools were useful to the professionals depending on education, occupation and method of use and caregivers according to age and education; for seniors, paper tools were preferred depending on age and purpose of the tools. Age acted differently across the groups.

A RANDOM CLINICAL TRIAL OF THE EFFECTIVENESS OF DIGITAL AND PAPER CAREGIVING TOOLS

R.M. Mirza¹, P. Donahue², *1. University of Toronto, Toronto, Ontario, Canada, 2. King's University College, Western University, London, Ontario, Canada*

This research is part of a multi-method research program that evaluated the impact of knowledge mobilization of evidence-based information for older adults, professionals and caregivers. This research reports the results from nine

caregiving clinical trials with one group of older adults, one professional group and one of carers, exposed to three levels of the intervention in each trial (n=261). The null hypotheses were that caregiving knowledge would not differ across the three conditions of no tools, paper tools or digital tools. Respondents were randomly assigned to one of three conditions for each of the three groups. The computed sample size required 29 respondents assigned to each of the three conditions for each of the three groups. Respondents were tested on knowledge of caregiving pre-post. F tests showed there were significant differences across each of the three conditions. Professionals achieved higher scores with digital tools and older adults, the paper tools.

THE PLACE OF INTERNATIONAL PARTNERSHIPS IN KNOWLEDGE MOBILIZATION

A. Lowenstein, *Max Stern Yezreel Academic College, Haifa, Israel*

The purpose here is to examine the role of international partners in knowledge mobilization (KM) using Israel as a case example. The International Initiative for the Care of the Elderly is an international collaboration across fourteen countries: Australia, Canada, Israel, China, England, Germany, India, Israel, Japan, Scotland, Brazil South Africa, Ireland and Switzerland. The international partnership has enhanced the universality of the content of the pocket tools as exemplified by Israeli physicians improvement of an elder abuse tool, or the dementia tool expanded by South Africa. Second, countries have developed new tools as in Switzerland for consulting and Brazil on caregiving. Third, partnership countries have enriched cultural sensitivity especially about dying as adapted in Brazilian tools. Fourth, translation of the tools has made them available in Hebrew, English, French, Portuguese, Hindi, Japanese and Spanish. Lastly, PhD students have been participants in many international meetings to improve their networking.

THE CHALLENGE OF INTERNATIONAL PARTNERSHIPS FOR ADAPTING KNOWLEDGE MOBILISATION

A. Phelan, *School of Nursing, Midwifery & Health System, University College Dublin, Dublin, Dublin, Ireland*

Knowledge mobilisation has become an important aspect for both funding agencies and research applications where findings of studies are required to make a tangible impact between research or expertise on policy and/or practice. Within the knowledge mobilisation research focusing on the use of pocket tools (paper or digital), the National Initiative for the Care of the Elderly (NICE) convened an international advisory panel. This paper examines the emerging issues and challenges inherent in knowledge mobilisation beyond the national research site. Although such social innovation seems logical, issues such as cultural context, legislative and policy boundaries and health and social care structures can mean that knowledge mobilisation on an international scale requires careful localisation and adaptation for transferability. This paper considers these issues related to the NICE project and offers some recommendations for similar projects. Participants will be introduced to the relevant, experiential based challenges for international partnerships related to knowledge mobilisation. In addition, participants will gain

knowledge on how to address the emergent issues within similar projects.

SESSION 2060 (PAPER)

NURSING CARE IMPROVING PATIENT CARE OUTCOMES

PREPARE OLDER PATIENTS FOR CARDIAC SURGERY: DEVELOPMENT AND FEASIBILITY OF A NURSING INTERVENTION

R. Ettema^{1,2}, M. Hoogendoorn³, C. Kalkman², M. Schuurmans^{2,1}, 1. *University of Applied Sciences Utrecht, The Netherlands, Utrecht, Utrecht, Netherlands*, 2. *University Utrecht, The Netherlands, Utrecht, Utrecht, Netherlands*, 3. *Isala Hospital, Zwolle, Overijssel, Netherlands*

Background and aim: In older patients undergoing elective cardiac surgery, timely identification and preparation of patients at risk for frequent postoperative hospital complications provides for the opportunity reducing their risk. We developed an evidence based multi component nursing intervention (PREDOCS-Program) to improve patients' physical and psychosocial condition in order to reduce their risk on postoperative complications and we tested the PREDOCS-program on its feasibility and estimated theoretical cost savings.

Method and material: In a team of researchers, experts, cardiac surgeons, cardiac surgery nurses and patients, the first phase of the revised guidelines for developing and evaluating complex interventions of the Medical Research Council (MRC) were followed. Subsequently, in a mixed-methods multicenter study, following the second phase of the MRC guidelines, we tested the feasibility in three hospitals and calculated theoretical cost savings.

Results: PREDOCS-program is administered during a consult by the nurse, two to four weeks before the surgery procedure. Twenty one females and 49 males out of the 114 eligible patients completed the intervention. Patients were equally satisfied with the usual care and the PREDOCS-program (satisfaction rates on a scale from 1–10 respectively: 7.5 (95%CI: 6.4–8.7) and 7.6 (6.6–8.6)). The PREDOCS-program will be cost-effective when postoperative complications are prevented in six to sixteen of 1,000 cardiac surgery patients.

Conclusion: In creating transparency in the assumed working mechanisms, an extended stepwise multi-method procedure was used to develop the PREDOCS-program, which will be already cost-effective when postoperative complications are prevented in six to sixteen of 1000 cardiac surgery patients.

LIVING WITH PAIN: EVALUATING CLINICAL OUTCOMES WITH THE ROY ADAPTATION MODEL

S.G. Robinson-Lane, *Physical Medicine and Rehabilitation, University of Michigan, Livonia, Michigan*

Disparities exist in pain management amongst Black elders in the US. Although many barriers have been identified, few studies examine the experience of managing pain

from the participant's perspective. It is hypothesized that the Roy Adaptation Model provides an appropriate framework to evaluate clinical pain outcomes in ways that prioritize care needs and identify culturally relevant interventions.

A 10-month ethnographic study was completed in an independent living facility housing predominately Black adults, age 55+ (n=470). Following participant observation and informal interviews, participants (n=106) completed questionnaires comprised of a demographic tool, the Brief Pain Inventory, the PROMIS Global Health tool, and the Psychological Stress Measure-9 as well structured interviews (n=20). Structured interview transcripts, fieldwork journal notes, and questionnaire responses were descriptively and thematically analyzed. Findings were clarified with participants and evaluated for model fit.

Severe persistent pain is a primary stressor that causes discomfort, disability, loss of income, difficulty maintaining social relationships, and impaired emotional well-being. Multiple comorbidities, functional status decline, and poverty exacerbated the pain experience. Fear of dependence motivated engagement in health promotional activities and self-care, which may have influenced the overall mild to moderate stress of the group. Identified care priorities included: improved medication management, patient education, integration of non-pharmacological treatments into care, and encouragement of social engagement. Effective coping resulted in a positive sense of self, decreased psychological distress, spiritual well-being, and satisfaction in social relationships.

The Roy Adaptation Model provides an appropriate framework for bridging research and clinical practice that addresses disparities in culturally diverse populations.

CARE INSTABILITY IN NURSING HOMES; A QUALITATIVE STUDY

M. Rahimi¹, R. Fadayeveatan², H. Abedi³, 1. *Gerontology Department, university of Social Welfare and rehabilitation sciences, Tehran, Tehran, Iran (the Islamic Republic of)*, 2. *Iranian Research centre of Aging, Gerontology Department, Tehran, Iran (the Islamic Republic of)*, 3. *Nursing-Midwifery Department, Islamic Azad University, Isfahan, Iran (the Islamic Republic of)*

The use of long-term care services has risen and this trend is expected to continue as the population reaches old age.

This study was conducted with a qualitative approach using conventional qualitative content analysis. The study was conducted on 23 Iranian participants including 14 elders and 9 caregivers. Data were collected with unstructured interviews and continued to the point of data saturation. Analysis of the data was performed continually and concurrently with data collection through a comparative method.

As results three themes emerged from 595 open codes including *care as unpleasant task*, *sustained care* and *insufficient resources*. Ten subthemes indicated participants' experiences and understanding of caring conditions in a nursing home.

The prevailing given care was the routine one with a focus on physical aspects although there was some psychological care given to the older people. The findings of this research are guidelines for managers and care planners in nursing homes who should also pay attention to physical and

psychological care needs of older people. In addition, it is important to pay close attention to the needs of the caregivers and provision of instructions for treatment, supervision, education of caregivers and medical students and finally better care.

ORAL HEALTH MATTERS FOR THE NUTRITIONAL STATUS OF FRAIL OLDER PERSONS

L. Johansson², H. Jansson³, C. Lannering¹, I. Johansson³, U. Lindmark³, 1. *Institute of Gerontology, Jönköping University, Jönköping, Sweden*, 2. *Institute of Gerontology/ Department of Nursing, Jönköping University, Jönköping, Sweden*, 3. *Centre for Oral Health, Department of Natural Sciences and Biomedicine, Jönköping University, Jönköping, Sweden*

Oral conditions such as dry mouth, dental caries and periodontitis increase with age and affect a person's ability to chew and swallow, which is why eating a healthy diet and obtaining a satisfactory nutritional status may be a problem. Oral health is therefore of great importance within elderly nursing care. The aim of this study was to evaluate oral health and nutritional status among older persons in a daily care context. Data from the Swedish quality register, Senior Alert, including structured assessments of oral and nutritional status using the Revised Oral Assessment Guide-Jönköping and the Mini Nutritional Assessment-Short Form. In total 1190 persons (mean age 82.3 ± 7.9) had both oral and nutritional assessments registered by nurses in daily care. Approximately 29% had moderate oral health problems and another 12% severe problems. Over 60% were considered at risk of malnutrition or malnourished. There was a correlation between poor nutritional status and poor oral health ($r=0.2$, $p<0.001$) and about half of persons at risk or malnourished simultaneously had oral problems. A multivariate logistic regression revealed that the risk of being at risk or malnourished increased with voice problems (Exp B CI 1.4–5.7 $p=0.003$), mucous membranes (Exp B CI 1.0–5.4 $p=0.042$) and swallowing (Exp B CI 1.4–4.1 $p=0.002$). Consequently, there was a relationship between oral problems and nutritional status, indicating the importance of evaluating oral status for older persons with nutritional problems. To improve oral health there is a need for exchanging knowledge between nursing staff and oral health professionals.

EFFECTIVENESS OF EDUCATIONAL NURSING HOME VISITS: A RANDOMIZED CONTROLLED TRIAL

A. Buss², K. Wolf-Ostermann², S. Strupeit², 2. *Munich University of Applied Sciences, Munich, Germany*, 2. *University of Bremen, Bremen, Germany*

Facilitating and maintain functional ability and quality of life is a major task of nursing. Home visits may have positive effects on functional ability and quality of life in elderly people. The aim of this study was to determine the effectiveness of educational home visits on the functional status, quality of life, and care dependency in older adults with mobility impairments.

A randomized controlled trial was performed in the living environments of patients with functional impairments from Hamburg, Germany. The intervention group received an additional nursing consultation intervention on mobility and quality of life. The control group received the usual

care. Data were collected from August 2011 to December 2012 at baseline, 6 months and 12 months of follow-up. The main outcomes were functional status (Barthel Index), quality of life (WHOQOL-BREF), and care dependency (Care Dependency Scale). Data were analyzed using descriptive statistics and generalized linear models.

In total, 113 participants were included in the study. The intervention had no effect on functional status, quality of life, and care dependency. However, self-efficacy and younger age were related to better functional status over time. Better self-efficacy and less depression resulted in a better quality of life and better self-efficacy resulted in a better functional status and lower care dependency.

Further studies on the effects of educational nursing interventions should be performed using different concepts and rigorous research methods. However nursing education should be part of nursing practice and may be integrated in everyday care.

SESSION 2065 (SYMPOSIUM)

MAPPING A CRITICAL ETHICAL LANDSCAPE FOR DEMENTIA: RESEARCH, POLICY, AND PRACTICE

Chair: P. Kontos, *University Health Network*

Co-Chair: A. Grigorovich, *University of Toronto, Toronto, Ontario, Canada*

In the field of dementia, ethical issues have primarily been considered from a biomedical perspective, with a focus on norms for medical treatment and participation in medical research trials. The primacy of the biomedical approach to ethics in dementia has eclipsed a broader understanding of the cultural, political and philosophical assumptions that underpin current research, policy and practices. This symposium will interrogate current ethical issues in dementia, raise concerns about the appropriateness of biomedical approaches to support ethical decision-making, and identify gaps that require critical ethical intervention. Paper presentations will explore these issues through empirical studies and critical analyses of case examples including: 1) New policy and ethical frameworks for guiding future research and funding efforts in dementia (e.g. Responsible Innovation and Institutional Corruption); 2) Mild Cognitive Impairment (MCI) and the ethical fallout of anticipating testing, being tested, being diagnosed, and living with MCI; 3) A new ethic of sexuality that upholds and supports the sexual rights of older adults living with dementia in long term residential care settings; and 4) Application of ethical perspectives on flourishing and solidarity to dementia care in order to shift societal response from a disability model to an agency preserving model, and from custodial (comfort and control) goals to ecologically enabling (relational) goals of care. Conclusions consider how these case studies map a new and critical ethical landscape for research, policy, and practice for dementia care.

ETHICS AND DEMENTIA: NEW EVIDENCE-BASED PERSPECTIVES ON INNOVATION AND PUBLIC HEALTH

P.J. Whitehouse, *Case Western Reserve University, Cleveland, Ohio*

Dementia is a huge public health challenge with value conflicts affecting efforts to treat and care for persons with cognitive impairment. Standard biomedical ethical frameworks that focus primarily on the clinical or research arenas do not provide an adequate moral lens to find the necessary balance in setting priorities in a world of limited resources, global climate change, and competing social concerns. What appears missing in part is a focus on organizational ethics, including examining the roles of advocacy and professional organizations, as well as pharmaceutical and diagnostic device manufacturers. Well-developed and empirically-supported organizational value and social justice frameworks such as institutional corruption and responsible innovation will be reviewed. Evidence-based contributions of the arts and humanities to practice are growing at the interface between ethics and aesthetics. Increasingly data-driven prevention efforts and community transformation will play a role in addressing the social challenges of dementia.

NARRATIVE PRACTICES AND ETHICAL FALLOUT IN THE CASE OF MILD COGNITIVE IMPAIRMENT (MCI) DIAGNOSIS

S. Katz, *Trent University, Peterborough, Ontario, Canada*

This paper is informed by emerging critiques of MCI diagnoses, validity, capitalization, treatment, biomarkers, and psychometric landscape. Using an interpretive analysis of data collected with 12 focus groups of older individuals, families, and care-givers, discussion focuses on the ethical uses of hybrid vocabularies, metaphors, and narratives to highlight the

the importance of subjective and lay accounts of aging and cognitive health. Given that MCI is a category laden with the threat of Alzheimers disease, the focus group data reflect a need for meaning-making and caring practices around diagnoses, as well as creative questioning and contesting of the MCI category itself. Conclusions explore how diagnoses of cognitive impairment are ethical as well as scientific practices, such that experts and practitioners need to consider how older individuals embed and share diagnoses in their everyday contexts through narrative practices that render disruption and apprehension into livable, acceptable, and coherent stories.

RELATIONAL CITIZENSHIP, SEXUAL RIGHTS, AND A NEW ETHIC FOR DEMENTIA CARE

P. Kontos^{1,2}, A. Grigorovich^{1,2}, 1. *Dalla Lana School of Public Health, University of Toronto, Toronto, Ontario, Canada*, 2. *Toronto Rehabilitation Institute - University Health Network, Toronto, Ontario, Canada*

Despite the important contributions the citizenship movement has made to improving the status and treatment of persons with dementia, it has not accounted for their sexual rights. Drawing on a new model of relational citizenship, we advance an ethic of embodied relational sexuality that importantly broadens the exclusive goal of biomedical ethics from only the duty to protect individuals from harm, to also the duty to uphold and support the sexual rights of persons living with dementia in long-term care settings. The ethic is grounded in empirical research in long-term residential care and draws from scholarship on sexual citizenship, human rights, embodiment, and relationality to articulate a

multiscalar approach (micro-, meso-, and macro-level). The adoption of this ethic ensures that persons with dementia experience freedom from discrimination and have equal opportunities to pursue intimate sexual activities and relations to the fullest extent possible.

DEMENTIA AND THE HUMAN GOOD: RECOGNITION, SOLIDARITY, AND FLOURISHING

B. Jennings, *Vanderbilt University Medical Center, Nashville, Tennessee*

Dementia care is often reduced to the custody of the patient's comfort and safety due to an overly limited understanding of the achievable quality of life and the relational capabilities of persons living with dementia. This does not appropriately recognize the meaningful agency of persons with dementia, nor does it appreciate the enabling relationships persons can have in an ecology of caring. I offer an approach to dementia care informed by an empirically grounded and theoretical work by philosophers and social scientists, including M. Nussbaum, T. Kitwood, R. Harré, S. Sabat, and J. Hughes. This approach focuses on the enabling effects of the overall ecology of dementia care (social relationality of care providers and the built environment of facilities) rather than on the neurological deficits of the brain and its behavioral limitations.

SESSION 2070 (SYMPOSIUM)

NETWORK CHANGES AND HEALTH: WHAT DRIVES WHAT?

Chair: H. Litwin, *Hebrew University of Jerusalem, Jerusalem, Israel*

Discussant: J. Lubben, *Boston College, Boston, Massachusetts*

Research has pointed to the relationship between social network and health in late life. However, it is still unclear whether greater network resources are responsible for better health or whether people with better health tend to recruit and maintain more social ties. This symposium attempts to disentangle the network/ health nexus by means of uniquely appropriate longitudinal databases that employ state-of-the-art social network inventories. We focus, especially, on data derived from name-generating network mechanisms. The papers also address a range of populations. The study by van Tilburg and Broese van Groenou looks at 25 years of data from the Longitudinal Aging Study Amsterdam (LASA) and finds that social networks are influenced by cognitive health, but also protect against mortality. Using data from the German Ageing Survey (DEAS), Deindl and Brandt discovered effects of health on social networks over time and vice versa. Schwartz and Litwin employed structural equation modeling to examine data from the Survey of Health, Ageing and Retirement in Europe (SHARE). The results show that social networks and mental health have a reciprocal relationship, but the effect of mental health is stronger. Webster, Ajrouch and Antonucci examined two waves of data (1992; 2015) from the longitudinal Social Relations Study in Detroit and found that later-life health and relationship transitions are inter-connected and moderated by education. Finally, the study by Chi looks at three groups of

Chinese older adults in immigrant, transnational, and non-migrant families, and finds that worry about future health needs are moderated by network factors.

SOCIAL NETWORKS AND PHYSICAL, SENSORIAL AND COGNITIVE FUNCTIONING IN A 25-YEAR LONGITUDINAL STUDY

T. Van Tilburg, M.I. Broese Van Groenou, *Sociology, Vrije Universiteit Amsterdam, Amsterdam, Netherlands*

Social relationships protect against incidence of diseases, poor physical functioning and early mortality. However, poor health impoverishes social network size and diversity by exhausting supporters and limiting investments to maintain and renew relationships. We study the causal process from network functioning to health, and from health to network functioning, exploiting eight observations of the Longitudinal Aging Study Amsterdam between 1992 and 2016. Included are 2956 people aged 55–102. Networks have 80 members at a maximum, and individual network members are followed longitudinally. First analyses show that having daily network contact, a large and variegated network, and a stable network composition are threatened in old age but promoted by good physical, sensorial and in particular cognitive functioning. A large network, in particular when including non-kin, is protective against early mortality, also when controlled for physical, sensorial and cognitive functioning.

RECIPROCAL RELATIONSHIPS BETWEEN SOCIAL NETWORKS AND MENTAL HEALTH

E. Schwartz^{1,2}, H. Litwin^{1,2}, 1. *Paul Baerwald School of Social Work and Social Welfare, Hebrew University of Jerusalem, Haifa, Israel*, 2. *Israel Gerontological Data Center, Jerusalem, Israel*

This study considered the relationship between social network and mental health among older Europeans. The data came from Waves 4 (2011) and 6 (2015) of the Survey of Health, Aging and Retirement in Europe (SHARE). The analytical sample numbered 26,238 respondents. Social network was measured as the degree of connectedness—an index composed of several network characteristics assessed through a name generator, and by a global measure of satisfaction with the network. Mental health was a composite construct based on three mental health indicators: CASP, Euro-D and a global life satisfaction measure. A cross-lagged analysis was employed, using structural equation modeling. Preliminary results indicated that social networks and mental health have a reciprocal relationship across time. These results showed significant links between both the network indicators and subsequent mental health changes and between mental health and subsequent network change. Gender differences in these associations did not emerge.

LONG-TERM BIDIRECTIONAL LINKS BETWEEN SOCIAL ISOLATION AND HEALTH: THE MODERATING ROLE OF EDUCATION

N.J. Webster¹, K.J. Ajrouch², T.C. Antonucci¹, 1. *University of Michigan, Ann Arbor, Michigan*, 2. *Eastern Michigan University, Ypsilanti, Michigan*

This study considers the influence of health changes on social isolation among older adults and examines how this

association varies by education. The analysis employed two waves of data (1992; 2015) from the longitudinal Social Relations Study. Data include a U.S. regionally representative sample (N=314) of adults age 60+ in 2015 from the Detroit, MI Metropolitan area. Social isolation, determined using two measures of network size (total number of network members and number of people respondents couldn't imagine life without) were assessed using the hierarchical mapping technique, an ego-centric name generating instrument grounded in the Convoy Model of Social Relations. Bidirectional cross-lagged effect models were conducted to test main effects as well as competing theories of cumulative advantage/disadvantage and age as leveler. The findings identify how later-life health and relationship transitions are inter-connected. Investigation of the role of education in this process highlights potentially vulnerable subgroups of older adults.

CAUSAL LINKS BETWEEN SOCIAL NETWORKS AND HEALTH
