The efficient execution of daily activities includes the ability to perform more than one task simultaneously, which is a prerequisite for a functional life, independent and safe; these situations are called dual task. Difficulties in dual task performance are associated with high risk of falling and functional limitation, especially for the elderly people. The aim of this study was to compare the effects of dual task on gait, static and dynamic balance and manual control in young adults and elderly people. This is a cross-sectional study, conducted in São Paulo, Brazil. The study participants were 20 young adults and 17 elderly people. The performance of the 37 participants was observed during the execution of four functional tasks: gait, static and dynamic balance and manual control. The four functional tasks were evaluated when performed alone (called simple task), and also in dual task, performed simultaneously with a secondary motor task (dual motor task) and also associated with a secondary cognitive task (dual cognitive task). The performance of secondary tasks was analyzed too. Statistical analysis was performed using repeated measures ANOVA and post hoc Tukey test. Comparing young and elderly people, the four functional tasks proposals identified differences in dual task performance associated with aging, particularly walking and manual control task. The results showed different pattern of prioritization in groups. As conclusion, the aging process could be associated with decline of capacity to execute dual task that could cause more susceptibility to falls and functional dependence of elderly people

EVALUATION OF THE CLINICAL PREDICTION RULE FOR SPINAL MANIPULATION IN CHRONIC LOWER BACK PAIN

P. Dougherty[1,2], P. Katz[1], D. Savino[2], J. Karuza[1,2], *1. NY Chiropractic College, Seneca Falls, New York, 2. Veterans Health Affairs, Rochester, New York*

Spinal Manipulative Therapy (SMT) and Active Exercise Therapy (AET) have both demonstrated efficacy in the treatment of Chronic Lower Back Pain (CLBP). A Clinical Prediction Rule (CPR) for responsiveness to SMT has been studied in the acute lower back pain (LBP); however there is a need to evaluate the CPR for SMT in CLBP. Design: Randomized controlled trial. Setting: Veteran Affairs (VA) and civilian outpatient clinics. Patients: 181 CLBP older adults. Interventions: SMT or Active Exercise Therapy (AET) twice a week for four weeks. Methods: CLBP patients were randomized based on their status on the CPR. Measurements: Visual Analogue Scale, Oswestry Disability Index, and Bodily Pain subscale of the SF-36 taken at baseline and 5, 12 and 24-weeks post baseline Results: Of the 89 AET subjects, 69 (78%) completed the study and of the 92 SMT subjects, 76 (83%) completed the study. As hypothesized, compared to baseline all subjects showed statistically significant improvements in both SMT and AET groups. Our hypothesized interaction of CPR treatment and time, which would suggest better responsiveness of patients who were positive and underwent SMT, was not supported. Regardless of treatment, those negative on the CPR had greater self reported pain and disability at baseline and follow up compared to those positive on CPR. Conclusions: Further studies are needed to further clarify the patient characteristics that will predict responsiveness to specific interventions for CLBP. Trial Registration: ISRCTN30511490

DEFICITS IN RAPID STEPPING ARE ASSOCIATED WITH RECURRENT FALLING IN COMMUNITY-DWELLING OLDER ADULTS

A. Goldberg, S.A. Talley, *Physical Therapy Department, University of Michigan-Flint, Flint, Michigan*

Introduction: Although risk factors for falls have been well-studied in older adults, there have been relatively few studies investigating risk for recurrent falling in older adults. The ability to step rapidly is associated with reduced falls risk. The purpose of this study was to determine the ability of a rapid stepping test (RST) to discriminate between older adult recurrent fallers (≥2 falls annually), single fallers and non-fallers. Methods: Seventy-one adults (range 60-87 years) were timed as they stepped out to a dime-sized marking on the floor 18 inches in front of them and returned to the starting position as rapidly as possible 30 times. Number of falls in the past 12 months was reported by participants. One-way analysis of variance compared RST among the 3 falls status groups. A receiver operating characteristic (ROC) curve evaluated ability of the RST to discriminate between recurrent fallers and those who are not recurrent fallers (single fallers and non-fallers). Statistical significance was set at $p<0.05$. Results: RST performance was slower in recurrent fallers compared to single fallers (43% slower; $p=0.014$) and non-fallers (31% slower; $p=0.028$), but was similar in single fallers and non-fallers ($p>0.05$). ROC analysis indicated AUC was 0.74 ($p=0.02$). RST cut-off time of 46.4 seconds exhibited sensitivity of 77.8% and specificity of 67.7% in predicting recurrent fallers. Discussion/conclusions: The RST is able to discriminate between older adult recurrent fallers and individuals who are not recurrent fallers. RST may be a useful test of risk for recurrent falling in community-dwelling older adults.

SOMATOSSENSORIAL COMPONENT OF BALANCE MAINTENANCE SYSTEM IS SIMILAR IN OLD ADULT AND OLDEST OLD

C.C. Soldera[1,2], A.G. Bós[1], *1. Institute of Geriatrics and Gerontology, Pontifical Catholic University of Rio Grande do Sul, Porto Alegre, RS, Brazil, 2. Federal University of Health Sciences of Porto Alegre, Porto Alegre, RS, Brazil*

Loss of balance limits the life of the elderly as it is related to falls. The balance is maintained by the action of four Balance-Maintenance-Systems(BMS) : Vestibular, visual, somatosensory, and visual preference. The oldest-old (80 years or older) is the age group with the highest prevalence of falls and least studied. Propose is to compare the participation of SME in two groups: 32 elderly (60-69 years) and 30 oldest-old (80 years or more) performing cognitive assessment (Mini Mental State Examination - MMSE), risk of falls (Timed Up and Go - TUG), fear of falling (Falls Efficacy Scale - FES) and Sensory Organization Test (SOT) by dynamic posturography. The oldest-old performed worse in all SOT, significantly in those with somatosensory conflict. Significant differences were observed between elderly and oldest-old in the systems: visual (91.1±6.1 and 54.8±43.7), vestibular (76.5±9.8 and 38.3±33.3) and visual preference (78.9±17.8 and 64.2±23.3), with similar performance in somatosensory (86.8±7.9 and 83.8±17.3). TUG and FES differ significantly between the groups and associated with scores of SME. The association between TUG and the visual system was affected by the MMSE and FES. Physical activity and education were associated with scores of SME. We conclude that SME most affected were the vestibular and visual. Differences between elderly and oldest-old were higher than expected for the visual and vestibular systems, but smaller in the somatosensory system. Dynamic posturography may be efficient to guide rehabilitation programs encouraging the use of more appropriate strategies for each elderly or oldest-old.

PREVALENCE OF DISABILITY AND ASSOCIATED FACTORS AMONG OLDER ADULTS IN INDIA: FINDINGS FROM THE LONGITUDINAL AGING STUDY IN INDIA

A. Kumar[1], S. Al Snih[1], A. Karmarkar[1], S. Teppala[1], K.A. Kulkarni[1], D.M. Collins[2,1], J. Graham[1], K. Ottenbacher[1], *1. Division of Rehabilitation Sciences,University of Texas Medical Branch, Galveston, Texas, 2. Department of Occupational Therapy, UTMB, Galveston, Texas*

Background: India is undergoing unprecedented sociodemographic and economical changes with its unexpected growing aging population and burden of chronic diseases. Objective: To estimate the prevalence of disability and associated factors among older adults in India. Methods: Epidemiological data of 1,284 participants from the 2010 pilot wave of Longitudinal Aging Study in India (LASI) was investigated. The LASI survey was conducted in four states to capture cultural and geographic variations across India. The four states included were: Karnataka, Kerala, Punjab, and Rajasthan, with rural and urban districts. Disability was defined as limitation in one or more activity of daily living (ADL). Measures included sociodemographic characteristics, medical conditions (hypertension, arthritis, diabetes, lung, and cardiovascular disease), falls, depressive symptoms, and disability. Logistic regression was used to examine the factors associated with disability. Pooled weights were applied to make a sample representative across the four states. Results: Average age was 62.6 years (standard error=0.3), with 54.3% of the 1,284 participants being female. Hypertension (20.1%), diabetes (10.7%), and arthritis (9.6%) were the top three prevalent medical conditions. Ninety-nine (8.4%) participants reported at least one ADL disability. Multiple logistic regression analyses (full model) found that hypertension (OR=2.10, 95% CI= 1.0-4.0), lung disease (OR=2.4, 95% CI=1.0-5.7), and arthritis (OR=4.1, 95% CI=2.1-7.9) were the medical conditions associated with disability. Conclusions: Older adults with arthritis, hypertension, and lung disease were more likely to develop disability, during the life course. Understanding public health perspective of the burden of disability is vital for resource allocation in the Indian healthcare system.

DIFFERENTIAL IMPACT OF DISABILITY ON MORTALITY ACCORDING TO RENAL FUNCTION AMONG OLDER ADULTS

K. Kim, H. Chin, C. Kim, *Internal medicine, Seoul National University, Seongnam, Republic of Korea*

Background: We tried to investigate the temporal association between renal function and disability, and to identify the influence of disability on mortality according to renal function in an elderly Korean cohort. Methods: A total of 984 community-dwelling Koreans ≥ 65 years of age were followed for 5 years with a 70.9% participation rate. Activities of Daily Living (ADL) and Instrumental ADL (IADL) were evaluated and mortality data were obtained. Results: The participants were categorized into 3 groups according to their baseline estimated glomerular filtration rates (eGFR) (group I, ≥60; group II, 45–59; and group III, <45 mL/min/1.73 m2). Group III had a 3.0-fold higher risk for the presence of IADL disability over group I (95% CI: 1.57~5.75, p=0.001). Baseline eGFR was substantially higher in participants who maintained functional status compared with participants who died or had disability at follow-up examination. Renal function deterioration was associated with ADL/ IADL decline. The incidence of ADL/ IADL decline was 13%, 12.5%, and 29.5% in participants who showed improvement, no change, and aggravation in renal function, respectively (p=0.01).The impact of disability on mortality differed according to the renal function. The hazard ratio for mortality in the subgroup with IADL disability was 1.87 (95% CI: 1.10~3.20, p=0.022) in group I, and 2.53 (95% CI: 1.57~4.09, p<0.001) in group II and III after adjustment. Conclusions: Impaired renal function was related to disability and ADL/ IADL decline. The effect of ADL/ IADL disability on mortality was more prominent in participants with impaired eGFR.

PROGRESSION OF DISABILITY AMONGST COMMUNITY-DWELLING WOMEN IN THE TENTH DECADE OF LIFE

S. Diem[1], L. Fredman[2], L. Lui[3], J.A. Cauley[4], M.L. Paudel[1], B. Taylor[5,1], T.A. Hillier[6], K. Ensrud[5,1], *1. University of Minnesota, Minneapolis, Minnesota, 2. Boston University, Boston, Massachusetts, 3. Californa Pacific Medical Center, San Francisco, California, 4. University of Pittsburgh, Pittsburgh, Pennsylvania, 5. Veterans Affairs Medical Center, Minneapolis, Minnesota, 6. Kaiser Permanente Center for Health Research, Portland, Oregon*

More women are living to very old age, but there is little prospective data on changes in functioning in this age group. We examined 930 women ≥ 90 years old (mean 92.6, SD 2.6) enrolled in the Study of Osteoporotic Fractures with functional status assessment in 2009 and followed for an average of 2.6 years. Among the cohort, a minority (21.6%) were initially residing in a nursing home (NH). Of the 729 living in the community, 68.4% reported no major impairment in performing basic ADLs (bathing, dressing, transferring, toileting, or eating); of these, 166 (33.3%) also reported no major impairment in performing IADLs (shopping, preparing meals, housework, managing money, using telephone). Another 16.7% reported much difficulty with or inability to perform 1 basic ADL; 14.5% reported much difficulty with or inability to perform 2+ basic ADLs. Of the 499 community-dwelling women able to perform basic ADLs without much difficulty at initial assessment, 35.7% died and 15.6% moved to a NH during follow-up. Of the 243 (48.7%) still community-dwelling, 30.1% continued to report no major impairment in basic ADLs, 32.1% developed impairment in 1 basic ADL, and 37.0% developed impairment in 2+ basic ADLs. Only 14 reported no major impairment in performing all basic ADLS and IADLS (5.8%). These results indicate that amongst women in the tenth decade of life living in the community with little impairment of ADLs, a range of significant functional decline occurs over 2-3 years. Future work should explore factors associated with preserved function in this group.

PHYSICAL PERFORMANCE AND BALANCE CONFIDENCE AMONG NONAGENARIANS

D. Klima[1], R. Knowles[1], K. Martin[1], K.D. Foor[1], M.C. DiBartolo[2], *1. UMES, Princess Anne, Maryland, 2. Salisbury University, Salisbury, Maryland*

Introduction: Given the population of older adults in the United States is living longer and staying more active in the community, there is a need to establish age-referenced physical performance values to track gait and balance performance. Moreover, balance confidence constraints and associated fear of falling can significantly impede functional mobility. Objectives: The purpose of this cross-sectional study was to 1) Determine age-referenced gait, balance, and balance confidence values for community-dwelling older adults age 90 years and older and 2) Describe relative fall risk in this population. Methods: Fifty-four participants (age 92.02± 2.10; 31 female-57%) completed the: demographic questionnaire, Timed Up and Go (TUG) Test, Dynamic Gait Index (DGI), and Activities-specific Balance Confidence (ABC) Scale. Statistical analyses included descriptive statistics, confidence intervals, relative fall risk, and Pearson Product correlations for variable associations. Significance was set at the 0.05 level. Results: Findings of the study demonstrated the following mean times: 20.1 ± 8.8 seconds on the TUG Test, 15.5 ±3.2 seconds on the DGI, and a mean ABC scale score of 65.7 ± 19.4 percent. Pearson product-moment correlation demonstrated a significant inverse relationship between the ABC scale and TUG time (r= -.35, p=.01). All physical performance mean times fell within fall risk ranges. Conclusions: Data provide reference norms for the oldest old population of elders. Future Directions: Performance data warrant follow-up for fall prevention strategies and interventions to facilitate continued community-dwelling residence.

COGNITION AND FUNCTIONALITY: HOW DO THEY RELATE TO TIME LIVED AFTER 100 YEARS OF AGE?

L. Teixeira[1], L.J. Araújo[1], N. Duarte[1], D. Brandão[1], M. Azevedo[1], C. Paúl[1], O. Ribeiro[1,3,2], *1. UNIFAI/ICBAS-UP, Porto, Portugal, 2. ISSSP, Porto, Portugal, 3. ESSUA, Aveiro, Portugal*

Introduction: The number of centenarians has greatly increased in Portugal in the last decades. Therefore, the analysis of survival time after becoming a centenarian and related factors constitute an important issue for the quality of care provision. The objective of this study is to identify health related factors associated with the time lived after being 100 years of age. Methods: Data come from the population-based study PT100 (Oporto Centenarian Study) and considers information gathered through face-to-face interviews with centenarians and their proxies during 2013. Study eligibility criteria included being 100 and more years old and living in the Oporto Metropolitan Area. Survival analyses were performed in order to identify factors associated with survival after the 100. Functional status (e.g., walking, being bedridden) and specific health conditions (e.g. presence/absence of cognitive impairment) were considered as potential factors. Results: The sample comprises 140 centenarians with approximately 14.5 months as median survival time after their 100th anniversary. Centenarians who were bedridden presented a higher probability to live after 100 years when compared with functionally independent centenarians. Presence of cognitive impairment was not associated with the time lived after 100 years old. Conclusions: Given the increasing number of centenarians in Portugal, different studies based on this population need to be considered. The present study, focused on the life after 100 years old, provides new information about this topic contributing to the formulation of new scientific questions for this population.

FACTORS AFFECTING THE PHYSICAL ACTIVITY AMONG MIDDLE AGED ADULTS: FOCUS ON THE EXPECTATIONS REGARDING AGING

M. Choi[1], S. Cho[1], J. Lee[1], H. Cho[2], *1. Department of Clinical Nursing Science, College of Nursing, Yonsei University, Seoul, Republic of Korea, 2. College of Nursing, Kyungpook National University, Daegu, Republic of Korea*

Purpose: Physical activity is important as a health promoting behavior in aging society. Individuals' belief about aging is known to be related to health promoting behaviors, which is needed for middle aged adults preparing for their old age. The purposes of this study were to measure level of expectations regarding aging (ERA) and identify relationship between ERA and physical activity of middle aged adults. Methods: Data was collected from middle aged adults who resided in community of two cities in Korea using questionnaires. A self-reported questionnaire consisted of International Physical Activity Questionnaire (IPAQ), individual characteristics, behavior-specific cognitive factors including Expectations Regarding Aging-12 (ERA-12). Hierarchical multiple regression was conducted to examine whether ERA would predict physical activity when controlling other factors. Results: The mean age of the participants was 51.1±6.9 years. The mean score of ERA (possible range=0 to 100) was 40.04±14.31. Findings demonstrated that more than half of the participants (62.6%) were not engaged in health promoting physical activity. Gender, employment status and exercise confidence were associated with level of physical activity in middle aged adults (F=7.14, p<.001, R2=36). After controlling individual factors and behavior-specific cognitive factors, ERA was independently related to physical activity in middle aged adults (F=7.19, p<.001, R2=38). Conclusion: Our results demonstrated that individuals' belief about aging influenced physical activity of Korean middle aged adults. Thus, focusing on ERA could help increase physical activity in middle aged adults.

WHICH INFLAMMATORY MECHANISMS ARE ASSOCIATED WITH INCIDENT MOBILITY DISABILITY? THE FRAMINGHAM OFFSPRING AND OMNI STUDIES

C. Liu[1,2], A. Lyass[3,4], M.G. Larson[3,4,5], J.M. Massaro[3,5], R.B. D'Agostino[3,4], E.J. Benjamin[3,6], J.M. Murabito[3,6], *1. Boston University School of Medicine, Boston, Massachusetts, 2. Tufts University, Boston, Massachusetts, 3. Framingham Heart Study, Framingham, Massachusetts, 4. Boston University, Boston, Massachusetts, 5. Boston University School of Public Health, Boston, Massachusetts, 6. Boston University School of Medicine-Department of Medicine, Boston, Massachusetts*

BACKGROUND Inflammation is associated with mobility disability, but the precise mechanisms need further clarification. We examined ten biomarkers representing inflammation and oxidative stress to determine the pathways involved with incident mobility disability. METHODS Framingham Offspring and Omni Study participants who attended two exams (1998-2001 and 2005-2008), were > 60 years of age, and without mobility disability at baseline were examined. Biomarkers included C reactive protein, interleukin-6 (IL-6), tumor necrosis factor-α receptor 2 (TNF-αR2), 8-epi-FGFα isoprostanes, lipoprotein-associated phospholipase A2 mass and activity, osteoprotegerin (OPG), intercellular adhesion molecule-1, monocyte chemoattractant protein-1, and P-selectin. Mobility disability was defined as unable to walk up stairs and/or walk a half mile. Multivariate logistic regression assessed the relationships between each individual biomarker and incident mobility disability. Individual biomarkers significant individually at $\alpha=0.10$ were included in a logistic regression model using backward elimination at $\alpha=0.05$. Covariates were age, sex, BMI, smoking, cardiovascular disease, diabetes, cancer, total cholesterol/treatment, hormone replacement therapy, and cohort (Offspring or Omni). Odds ratios (OR) per one standard deviation increase in log-transformed biomarker were calculated. RESULTS Of 1,321 participants (706 (53%) female, mean age 67.4±5.4 years, mean follow-up of 6.7± 0.7 years), 192 (15%) developed mobility disability. IL-6 (OR 1.18 [95% CI 1.00,1.39], TNF-αR2 (OR 1.31 [95% CI 1.11,1.55], and OPG (OR 1.22 [95% CI 1.02,1.47]) were associated individually with the outcome. In the stepwise model, TNF-αR2 remained associated with incident mobility disability (OR 1.29 [95% CI 1.09,1.53]). CONCLUSION Findings suggest the inflammatory mechanism(s) associated with TNF-α may contribute to incident mobility disability.

ANTICHOLINERGIC USE AND RECURRENT FALLS: HEALTH ABC STUDY

Z.A. Marcum[1], S. Perera[1], E.S. Strotmeyer[1], E.M. Simonsick[2], R.I. Shorr[3], S. Studenski[2], J.M. Thorpe[1], J.T. Hanlon[1], *1. University of Pittsburgh, Pittsburgh, Pennsylvania, 2. National Institute on Aging, Baltimore, Maryland, 3. Veterans Affairs Medical Center, Gainesville, Florida*

Design: Longitudinal. Data source: Health ABC Study years 1-7 (1997-2004). Participants: 2,948 participants at year 1 (black 40.8%, female 51.6%, age 70-79 years) with data collected via interview. Main outcome measures: Recurrent falls (2+) in 12-month periods starting at year 2 through year 7. Main independent variables: Anticholinergic use at years 1, 2, 3, 5, and 6 as defined by a list from the 2012 AGS Beers criteria. Results: At year 1, 16.0% reported anticholinergic use; 49.3% took them for 2+ years, and 25.5% took > 2 summated standardized daily dose (SDD; 1 = minimum recommended daily dose for one anticholinergic). Yearly, at least 7.5% of participants reported having 2+ falls. Multivariable GEE models, controlling for demographic, health status/behaviors and access to care factors, found no statistically significant increase in risk of recurrent falls in anticholinergic users (adjusted odds ratio [AOR] 1.34; 95% confidence interval [CI] 0.93-1.93). We found no increase in risk among those taking higher SDDs (>2 SDD, AOR 1.54, 95% CI 0.84-2.82 and 1-2 SDD, AOR 1.40, 95%CI 0.80-2.45), or those with long or short duration of use (AOR 1.36, 95% CI

0.84-2.21, AOR 1.32, 95% CI 0.83-2.10, respectively). Conclusions: Increased point estimates suggest an association of anticholinergic use with recurrent falls, but the associations did not reach statistical significance. Future studies are needed to examine other measures of anticholinergic burden, and their associations with other outcomes such as cognitive function.

CROSS-CULTURAL ADAPTATION OF THE FALLS EFFICACY SCALE-INTERNATIONAL (FES-I) IN THAI COMMUNITY OLDER ADULTS

S. Phongphanngam, H. Lach, *Saint Louis University, Saint Louis, Missouri*

The FES-I was developed to assess concerns about falling by the Prevention of Falls Network Europe (ProFaNE). It has been translated for use in various countries. The purpose of this study was to translate and culturally adapt the FES-I into the Thai language. The ProFaNE ten-step translation protocol was used. The FES-I was translated and back-translated by 5 bilingual persons. Discrepancies between the three-translated versions were solved through discussion and consensus. The three English versions (the original and the two back-translated versions) were compared to identify discrepancies by the second author, who is monolingual in English and an expert in the area of fear of falling. Any inconsistencies were identified, discussed with the back translators, and a consensus reached. The translation process was conducted in the United States, and the revised version was then tested in Thailand with Thai community-dwelling older adults. Although the FES-I was developed to be suitable for translation and use in a wide range of languages and cultural contexts, the three-forward translators encountered difficulty in finding Thai words with the same meaning and conceptual equivalence as the original version for a few words. In the pilot testing, participants mentioned that they understood the content and all items and that each item was clear and understandable. However, they suggested that they preferred to be interviewed rather than to self-report to correctly report their level of concern.

SESSION 1670 (POSTER)

ASSESSMENT

INTERLEUKIN-6 PREDICTS SHORT-TERM GLOBAL FUNCTIONAL DECLINE IN THE OLDEST OLD: RESULTS FROM THE BELFRAIL STUDY

W. Adriaensen[1,2], C. Mathei[1,2], B. Vaes[1,2], G. Van Pottelbergh[1,2], P. Wallemacq[3], J. Degryse[1,2], *1. Department of Public Health and Primary Care, KU Leuven, Leuven, Belgium, 2. Institute of Health and Society, UCL, Brussels, Belgium, 3. Laboratory of Analytical Biochemistry, UCL, Brussels, Belgium*

Background The chronic inflammatory state with old age may be detrimental by contributing to the pathophysiology of chronic conditions that results in functional loss across different aspects of functioning. Our objective was to examine the predictive value of interleukin (IL)-6, C-reactive protein (CRP) and 12 potential serum inflammatory markers, as risk factors for a combined endpoint of global functional decline and the specific determinants. Methods Global functional decline and specific aspects of physical and mental functional decline were assessed over a mean 1,66 (±0.21) years in a heterogenic and representative sample of 303 older persons aged 80 years or older of the BELFRAIL study. Serum levels of 14 inflammatory proteins, including cytokines, growth factors and acute phase proteins, were measured at baseline. Results IL-6 serum levels remained positively associated with global functional decline after correction (Odds ratio: 1.51). The odds ratios for composite scores of physical and mental decline were not significant and those for the individual aspects (physical dependency, physical performance, cognition and depression) of functioning were lower. The predicted probabilities or proportion of individuals with limited or global functional decline increased from the lowest to the highest quintile of IL-6 and decreased for a stable functional state. Conclusions IL-6 is an independent risk factor for an accelerated decline in a representative sample of persons aged 80 years and older. Our results suggest that serum levels of IL-6 may be more useful in short-term identification or evaluation of global functional status among the oldest old, than for the individual aspects of functioning.

INFLAMMATORY MARKERS AND PROGNOSIS IN HOSPITALIZED OLDER PATIENTS: RESULTS FROM THE CAPE HORN STUDY

A. Mello, G. Rubbieri, M. Mengoni, V. Grossi, F. Tarantini, C. Di Serio, N. Marchionni, M. Di Bari, *Research Unit of Medicine of Aging, Department of Clinical and Experimental Medicine and Azienda Ospedaliero-Universitaria Careggi, Florence, Italy*

Objectives. Hospitalization May Have Poor Long-Term Prognosis in Older Patients. Using Data from the Comprehensive Assessment of Prognosis in Elderly Hospitalized Patients Returning Home (CAPE HORN) Study, We Aimed at Assessing the Prognostic Role of Inflammatory Markers, such as White Blood Cell (WBC) Count, C-Reactive Protein (CRP), Tumor Necrosis Factor Alpha (TNFα) and Interleukin-1 Receptor Antagonist (IRAP), in Older Patients Discharged from Acute Care for the Elderly (ACE) Units. Methods. Comprehensive Geriatric Assessment Data Were Collected Pre-Discharge in Subjects Aged 75+ Years Admitted to ACE Units in Florence, Italy, Able to Walk Pre-Admission and with a MMSE Score ≥18. Short Physical Performance Battery (SPPB), Handgrip Strength (HS), Disability Status, Comorbidity (Index of Coexistent Diseases, ICED) and Inflammatory Markers Were Assessed at Baseline. Follow-Up Was Conducted after 6 Months with Phone Interview. Results. Eighty Participants (53% Men, Mean Age 82 Years) Were Enrolled. Average Length of Hospital Stay (LoS) Was 9 Days. IRAP Was Negatively Associated with SPPB (p=0.028) and HS (p=0.006) and Positively with LoS (p=0.020). WBC Was Positively Associated with ICED (p=0.014) and LoS (p=0.008). TNFα Correlated only with Age (p=0.040). After 6 Months, 29% of Subjects Had Fallen, 34% Were Re-Hospitalized and 9% Died (61% Incidence of the Combined Outcome). CRP Was Associated with Death (p=0.014) and the Combined Outcome (p=0.028), and TNFα only with Death (p=0.009). WBC and IRAP Were not Predictors of Long-Term Outcomes. Conclusions. Inflammatory Profile at Discharge May Contribute to Predict Long-Term Prognosis in Older Patients after ACE Units Hospitalization.

VALIDATION OF THE GERMAN SENSE OF COMPETENCE QUESTIONNAIRE AMONG INFORMAL CAREGIVERS AFTER STROKE

A. Pendergrass[1], D. Beische[1], C. Becker[1], M. Hautzinger[2], K. Pfeiffer[1], *1. Department of Clinical Gerontology and Rehabilitation, Robert-Bosch Hospital, Stuttgart, Germany, 2. Eberhard Karls University of Tuebingen, Tübingen, Germany*

A main outcome domain in psychosocial caregiver intervention research is carer burden. One of the available instruments for measuring this domain is the Sense of Competence Questionnaire (SCQ) which was adapted from the Zarit Burden Interview. Its potential for future caregivers' research was emphasized by a consensus paper from the INTERDEM network. The 27-item SCQ measures three domains: "satisfaction with the care recipient", "satisfaction of one's own performance", and "consequences of involvement in care". Some items showed an inconsistent association to the factors in later studies. Goals of this study were: (1) the validation of the German version of the SCQ with informal caregivers of older stroke patients and (2) the identification of items with consistent factor loadings over all validation studies. A psychometric evaluation was performed among 198 stroke caregivers (mean age 64.9 years; 74.2% female). An exploratory principal component analysis was used to investigate whether the SCQ comprises the three subscales. The German SCQ showed satisfactory to good psychometric properties. Cronbach's alpha of the total SCQ score was 0.86 (subscales 0.66-0.85). The factor structure of the SCQ was mostly confirmed. Clinical validity was determined by lower SCQ scores which were associated with higher burden (r = -0.51 with Caregiver Strain Index) and more depressive symptoms (r = -0.52 with Center for Epidemiological Studies-Depression Scale). 16 items with consistent factor loadings were extracted from all present studies and proposed as a new short version of the SCQ (Cronbach's alpha: 0.84). This short version seems promising but needs further validation.

EFFECT OF AGE AND GENDER ON JUMPING MECHANOGRAPHY AND OTHER MEASURES OF MUSCLE MASS AND FUNCTION

E. Fidler[1], D. Krueger[1], R. Ward[2], P. Caserotti[3], E.S. Strotmeyer[2], T. Harris[4], N. Binkley[1], B. Buehring[1,5], *1. University of Wisconsin, Madison, Wisconsin, 2. University of Pittsburgh, Pittsburgh, Pennsylvania, 3. University of Southern Denmark, Odense, Denmark, 4. National Institute on Aging Laboratory of Epidemiology and Population Science, Bethesda, Maryland, 5. William S. Middleton Veterans Administration Medical Center, Madison, Wisconsin*

Age-related loss of physical function (PF), muscle function (MF) and muscle mass is associated with negative health outcomes. Computerized MF tests, e.g., jumping mechanography (JM), may have advantages over traditional PF/MF tests. However, JM has only been analyzed in small or non-US adult cohorts. Traditional PF/MF tests document a decline with age, some differ by gender. We hypothesized that JM parameters are higher in males and lower in older adults. MF (Leonardo JM, grip strength), PF (short physical performance battery=SPPB), and appendicular lean mass (ALM) measured by DXA available from several studies examining community-dwelling young to old adults were included (N=157 females and 102 males; ages 26-97, mean 68.1+/-17.6 SD years). JM measures force to calculate parameters including jump power (JP) and jump height. Univariate analysis using T-tests evaluated differences between gender and linear regressions assessed correlation between age and MF/mass and physical function. Men had higher JM parameters, grip strength and ALM/ht2 ($p<0.0001$) vs. women. No significant gender differences were found in timed chair rise, total SPPB or gait speed. JP was negatively correlated with age (R2=-0.61M/0.47F, $p<0.0001$). Age was unrelated to gait speed but associated with poorer grip strength, chair rises, SPPB, ALM/ht2, and jump height ($p<0.01$). R2-values generally were lower for these traditional PF/MF tests than for JM. In this cohort of US community-dwelling men and women, JM parameters were highly correlated with age with higher R2 values than traditional PF/MF tests. JM is a promising tool to monitor MF decline in adults.

THE PREDICTIVE VALUE OF HAND GRIP STRENGTH AMONG THE VERY OLD

J.M. Jacobs[1,2], Y. Rottenberg[1,2], M. Fisher[2], J. Stessman[1,2], *1. Geriatrics and Rehabilitation, Hadassah Hebrew-University Medical Center, Jerusalem, Israel, 2. The Jerusalem Institute of Aging Research, Jerusalem, Israel*

Background: Hand grip strength (HGS) is an easy and feasible clinically tool. We examined its value in predicting subsequent decline in functional outcomes, and mortality among the oldest old. Methods: Comprehensive data was collected by the Jerusalem Longitudinal Study, which prospectively follows a representative sample born 1920-1921, assessed at home in 1998, 2005, and 2012 at ages 78 (n=1023), 85 (n=1222), and 91 (n=674). Dependence in basic activities of daily living (ADL), cognitive impairment, depression, and all-cause mortality were assessed. HGS was dichotomized to lowest quartile versus upper three quartiles. Adjusted Relative Risks (RR) and Hazards Ratios (HR) were determined (adjusting for gender, education, body mass index, fatigue, physical activity, ischemic heart disease, diabetes, kidney disease, hypertension, cancer history). Results: Low HGS at age 78 was associated at age 85 with subsequent ADL decline (RR 3.20, 95% CI, 1.29 – 7.93), but neither cognitive decline (RR 0.56, 95%CI, 0.09-3.52) nor depression (RR 0.65, 95%CI, 0.1-4.8). Low HGS at age 85 was associated at age 91 with subsequent ADL decline (RR 2.50, 95% CI, 1.10 - 5.67), and depression (RR 3.1, 95%CI, 1.28-7.34), but not cognitive impairment (RR 0.45, 95%CI, 0.2-1.1). Mortality HR's associated with Low HGS at age 78 and 85 and survival from age 78-85 and 85-90 were HR 1.5, 95%CI, 0.95-2.43 and HR 1.6, 95%CI, 1.23-2.1 respectively. Conclusions: Among the oldest old HGS predicts subsequent functional dependence, depression, and mortality, and may be a useful practical clinical tool in geriatric assessment.

USE OF THE COMPUTER-ADAPTIVE VERSION OF THE LATE-LIFE FUNCTION AND DISABILITY INSTRUMENT IN A PACE (PROGRAM OF ALL-INCLUSIVE CARE OF THE ELDERLY) POPULATION

I.M. Kopits[1], C.M. McDonough[2,3], P. Ni[3], A. Jette[3], *1. Boston University, Department of Medicine, Geriatrics Section, Boston Medical Center, Boston, Massachusetts, 2. The Dartmouth Institute for Health Policy & Clinical Practice, Hanover, New Hampshire, 3. Health & Disability Institute, Boston University School of Public Health, Boston, Massachusetts*

Background Little is known about the psychometric performance of assessment measures in older adults with cognitive impairment and co-morbid conditions. We piloted a novel self-report computer-adaptive test (CAT) version of the Late-Life Function and Disability Instrument (LLFDI), in a PACE (Program of All-Inclusive Care of the Elderly) population. Methods We administered the CAT-LLFDI Activity and Participation scales to 21 new PACE enrollees who were English-speaking and oriented to person, place and time. We collected data on performance-based assessment of ADLs, IADLs, TUG (Timed up and go) and the MoCA (Montreal Cognitive Assessment). Results Eighty percent of subjects had 10 or more diagnoses, and 67% had significant cognitive impairment (MoCA <26; n=17). Among all questions about difficulty/limitation, 52% answered 'a lot'or 'unable to do'. Correlation between Activity scores and Participation scores was r=0.661. Correlations of LLFDI Activity scores with performance-based ADLs and TUG (r=0.388, -0.144, respectively); and Participation scores with IADLs (r=0.255) were lower than expected. We use case studies to explore the patterns of patient responses relative to results of cognitive and performance-based measures, and clinician knowledge. Discussion This pilot was limited by sample size. It generates hypotheses for further research to test the relationship between self-report and blinded clinician report for varying levels of cognitive functioning and performance-based measures. Conclusions Strength of correlation between performance based measures and the LLFDI-CAT were lower than expected, possibly due to cognitive impairment and significant disease burden.

PRIOR DEPRESSIVE SYMPTOM CAN PREDICT LOW EXTREMITY FUNCTIONAL DECLINE 2 YEARS LATER IN COMMUNITY-DWELLING ELDERLY IN KOREA: NATIONWIDE LONGITUDINAL SURVEY

J. Lee[1], Y. Nam[1], B. Cho[1], K. Son[1], S. Park[1], S. Cho[2], *1. Department of family medicine, Seoul National University Hospital, Seoul, Republic of Korea, 2. School of Public Health and Institute of Health and Environment, Seoul, Republic of Korea*

Background: A high proportion of older persons suffers from depressive symptoms. Some previous studies showed that functional decline in elderly was associated with depression. In this study, we have tried to reveal the impact of prior depression on low extremitity functional decline in Korean elderly. Methods: We used the KLoSA panel, a national representative sample of aging people in Korea. It was conducted twice (2006 and 2008). Self-administered questionnaire was used in the KLoSA panel to obtain depressive symptom, medical conditions, and demographic informations. To evaluate low extremity function, we performed Short Physical Performance Battery (SPPB) for participants in 2008. We included elderly aged 65 or more without known disability. Depressive symptom was defined by CES-D 10 score (Center for Epidemiologic Studies Depression Scale) ≥10 at baseline. And low extremity functional decline was defined by SPPB score ≤ 11. We performed multiple logistic regression analysis to evaluate the association between the baseline depressive symptom and low extremity functional decline after 2 years. Results: Total 514 elderly participants were included in this analysis. After controlling for possible confounders, depression defined by CES-D 10 was significantly associated with worse functional status 2 years later (adjusted odds ratio [aOR 1.95], 95% Confidence Interval [CI 1.05-3.61]). Conclusion: Prior depressive symptom predicted low extremity functional decline 2 years later in Korean elderly without baseline disabilities.

THE PREDICTION OF DISABILITY, FALLS, AND DEATH WITH FOUR PHYSICAL PERFORMANCE MEASURES IN UNSELECTED OLDER PERSONS: THE ICARE DICOMANO STUDY

C. Minneci[1,2], A. Mello[1], E. Mossello[1], L. Macchi[3], S. Cipolletti[2], M. Di Bari[1], N. Marchionni[1], *1. Research Unit of Medicine of Aging, Florence, Italy, 2. Starbene SrL Rehabilitation Centre, Cerreto Guidi, Italy, 3. Functional Rehabilitation Service, Azienda Ospedaliero-Universitaria Careggii, Florence, Italy*

Aim. To compare Short Physical Performance Battery (SPPB), 4-m Walk Test (4mWT), 6-Minute Walk Test (6MWT) and handgrip (HG) ability to predict mortality, incident BADL disability, worsening mobility, and falls. Methods. In non-disabled older (65+) community dwellers, enrolled in the ICARe Dicomano cohort study, the 4 performance tests, comorbidity, MMSE, and GDS were assessed at baseline. The risk of incident ADL disability, worsening mobility disability, and falls in 3 years was assessed in separate logistic regression models, the risk of death in 7 years with Cox regression models, adjusting for confounders. Results. In 561 participants (age 73 years, men 42%) all performance tests were reciprocally correlated. After 3 years, 33 of 453 re-examined participants were disabled in BADL, 87 had worsening mobility, and 99 had fallen; 141 out of 561 participants died in 7 years. All tests predicted incident BADL disability, with OR (95% CI) of 0.85 (0.77-0.93), 0.08 (0.02-0.36), 0.74 (0.61-0-89) and 0.993 (0.988-0.997) per unit increase in HG, 4mWT, SPPB and 6MWT, respectively. HG, 4mWT and SPPB predicted worsening mobility with OR (95% CI) of 0.88 (0.83-0.93), 0.33 (0.11-0.94) and 0.81 (0.71-0.93). No measure predicted falls. Only SPPB and 6MWT predicted death, with HR (95% CI) of 0.92 (0.85-0.997) and 0.997 (0.995-0.999). Conclusions. Performance measures are independent predictors of relevant health outcomes, except falls. SPPB and 6MWT are stronger predictors with similar statistical performance. Because of ease of use, SPPB is probably more widely applicable than 6MWT.

AMBULATION CHANGES AMONG OLDER ADULTS IN ASSISTED LIVING: IMPLICATIONS FOR THE PREVENTION OF FUNCTIONAL DECLINE

M.E. Bowen[1,2], M. Rowe[3], *1. West Chester University, West Chester, Pennsylvania, 2. The Philadelphia VA Medical Center, Philadelphia, Pennsylvania, 3. University of South Florida, Tampa, Florida*

Introduction: Wandering, or repetitive ambulation, is a dementia-related behavior consisting of random, lapping, and pacing patterns. These ambulation patterns may provide insight into changes in the health and well-being of vulnerable older adults. The aim of this study is to examine how changes in ambulation may precede functional decline among older adults with dementia who wander and their counterparts in an Assisted Living Facility (ALF). Methods: Utilizing a single-subject design, the functional decline of 26 residents of an ALF was measured weekly over the course of 9 months by: the Barthel Index, the Functioning Independence Measure (FIM), the Tinetti Gait and Balance Test). Thirteen of these older adults were diagnosed with dementia/cognitive impairment. Ambulation patterns [random (deviation from a straight line), lapping, and pacing] and time (minutes/week) and distance traveled (meters/week) were measured objectively by a real-time locating system; RTLS. RTLS continuously recorded the time and location of travel (using x and y coordinates) throughout the facility using triangulation methods (hallway-mounted sensors and tags, worn on the resident's wrist). Results: Of the 12 residents who experienced significant functional decline (a 25% change in functioning across assessments from baseline) all had preceding ambulatory changes. These changes included changes in ambulation patterns [from normal (non-wanderer) to pacing (wanderer)] and/or a significant increase or decrease in time and distance travelled two weeks prior to the decline. Discussion: Intra-individual changes in ambulation patterns, time and distance travelled may precede changes in physical functioning. Concurrent with staff observation, RTLS may be useful in establishing ambulation baselines and patterns to predict clinically significant declines in the functioning of this population.

DIAGNOSTIC ACCURACY OF THE BESTEST TO IDENTIFY FALLERS IN COMMUNITY DWELLING OLDER ADULTS

E. Wang-Hsu, H. Chen, J. Meiers, S. Smith, *Physical Therapy & Rehabilitation Sciences, Drexel University, Philadelphia, Pennsylvania*

Background/Purpose: Falls are a leading cause of injury among older adults. Impaired balance is known to contribute to falls. The Balance Evaluation Systems Test (BESTest, Horak et al., 2009) is a clinical performance test that categorizes balance impairments into 6 systems. However, the diagnostic accuracy of BESTest to identify fallers has not been investigated in community-dwelling older adults. Our purpose was to estimate the clinical change threshold and diagnostic accuracy of the BESTest total percentage score for use in identifying fallers in this population. Materials/Methods: 33 community-dwelling volunteers (9 men, 24 women, aged 56 - 94 years, mean = 80.9 yrs) completed a demographic and fall history questionnaire and the BESTest as part of a falls screening. Descriptive statistics were used to calculate demographic information. A receiver operating characteristic (ROC) curve and the area under the curve (AUC) were calculated. Diagnostic accuracy statistics were used to calculate the sensitivity, specificity and likelihood ratios. Results: 15 adults reported falling (46%, mean = 62.1) and 18 reported not falling (54%, mean = 75.8). The clinical change threshold (cutoff score) was 70% with sensitivity and specificity of 0.73 and 0.78, respectively. Positive and negative likelihood ratios were 3.30 and 0.34, respectively. Conclusion/Clinical Significance: The BESTest is useful in identifying fallers in community-dwelling older adults. That is, older adults who score 70% or less on the BESTest may be 3.30 times more likely to fall; conversely, older adults with a BESTest score higher than 70% may be 0.34 times less likely to fall.

ITEM RESPONSE ANALYSIS OF THE BERG BALANCE SCALE IN COMMUNITY-DWELLING OLDER ADULTS

H. Chen, E. Wang-Hsu, J. Meiers, S. Smith, *Rehabilitation Sciences, Drexel University, Philadelphia, Pennsylvania*

Background: The Berg Balance Scale (BBS) is a commonly used balance performance and fall risk test. However, Pardasaney (2012) found that among community-dwelling older adults (CDOAs), 10% (n=111) and 20% of a subgroup (n=33) with mildly limited function scored maximally. This ceiling effect suggests that task items are insufficiently challenging to discriminate adults with less severe balance impairments. Purposes: Determine item difficulty; identify items that are particularly easy/hard to perform; and evaluate construct validity. Methods: BBS a 14-item, 5-point ordinal scale ranging from 0-4, 0 indicates the lowest function. Performance of the BBS was examined with 71 consecutive CDOAs (M=74 yrs, 50-99 yrs; n=17 men, n=54 women). Rasch model Mini-Winsteps, V3.80.1 was used to analyze item and person logit measures, fit statistics, and person and item separation. Results/Discussion: Item logit measures ranged from -5.89 to 2.59. The least difficult item was “sitting unsupported” and the most difficult was “standing on one leg.” Person ability measures ranged from -1.38 to 6.27 logits; the person ability logits indicated that person-ability exceeded test item difficulty. Most items had fit statistics within the accepted range (0.6-1.4 with a standardized $z < 2.0$), except “sitting unsupported,” “reaching forward” and “turning to look behind” suggesting that these items reflect a differing construct. The Person Separation Index (PSI)=2.22 with reliability = 0.83 and Item Separation Index (ISI)=3.64 with reliability=0.94. Conclusion: Ceiling effects of BBS among CDOAs demonstrate the BBS is not an optimal measure to identify adults with less severe balance impairments. More challenging items are needed.

SESSION 1675 (POSTER)

HEALTH SERVICES, EDUCATION & INTERVENTIONS

THE EFFECTIVENESS OF A PATIENT CENTERED COMMUNICATION INTERVENTION ON PATIENT AND STAFF OUTCOMES

K.S. McGilton[1,2], S. Sidani[3], R. Sorin-Peters[4], E. Rochon[1,5], M. Fox[6], V.M. Boscart[7], C.H. Chu[2], *1. Research, Toronto Rehabilitation Institute, Toronto, Ontario, Canada, 2. Lawrence S Bloomberg Faculty of Nursing, University of Toronto, Toronto, Ontario, Canada, 3. School of Nursing, Ryerson University, Toronto, Ontario, Canada, 4. Speech-Language Pathology, Private Practice, Toronto, Ontario, Canada, 5. Department of Speech-Language Pathology, Faculty of Medicine, University of Toronto, Toronto, Ontario, Canada, 6. Faculty of Health - School of Nursing, York University, Toronto, Ontario, Canada, 7. Conestoga College, Guelph, Ontario, Canada*

RESEARCH OBJECTIVES: To evaluate whether the Patient Centered Communication Intervention (PCCI) targeting older persons with aphasia post-stroke improved 1) patients’ quality of life outcomes, and 2) nursing staffs’ comfort communicating with patients with communication impairments. DESIGN: A non-equivalent pre–post design with a control group over a three year period. SETTING: Two inpatient stroke rehabilitation units at a large community hospital. PARTICIPANTS: Sixty-one patients admitted to inpatient stroke rehabilitation between 2010 and 2012 were assigned to the usual care (n=28) or the intervention (n=33) group. INTERVENTION: The PCCI consists of education and training for nursing staff focusing on communication techniques, development of individualized communication care plans with the assistance of a Speech Language Pathologist (SLP), and on-site support from an SLP. MEASUREMENTS: Patients’ quality of life was measured with the Stroke and Aphasia Quality of Life measure (SAQOL) and satisfaction with care using the Relational Care Scale (RCS). Nursing staffs’ quality of communication was assessed using the Communication-Impairment Questionnaire (CIQ) and the Providers Interactional Comfort Survey (PICS). RESULTS: Nursing staff responses on the CIQ and PICS improved, that is, staff expressed more knowledge and comfort communicating with persons with communication impairments post-intervention. There were no differences in patient outcomes. CONCLUSION: Education, training and support for nursing staff and the use of individual communication care plans leads to some positive gains in their ability to communicate effectively with older patients with communication impairments. While there were no outcomes realized for patients, family members and patients found the care plans useful.

EFFECTS OF STAFF EDUCATION TO REDUCE POTENTIALLY HARMFUL MEDICATION USE AMONG RESIDENTS OF ASSISTED LIVING FACILITIES: A RANDOMIZED CONTROLLED TRIAL

K. Pitkala[1], A. Juola[1], H. Kautiainen[1], H. Soini[1], U.H. Finne-Soveri[2], S. Bell[3], M. Bjorkman[1], *1. General Practice, University of Helsinki, University of Helsinki, Finland, 2. National Institute for Health and Welfare, Helsinki, Finland, 3. Sansom Institute, School of Pharmacy and Medical Sciences, University of South Australia,, Adelaide, South Australia, Australia*

Objectives: The objectives of this study were to investigate the effect of nurse training on the use of potentially harmful medications; and on residents’ health-related quality of life (HRQoL), falls and health service utilization. Design: A randomized controlled trial. Methods: In total, 227 residents in 20 wards of assisted living facilities in Helsinki were recruited. The wards were randomized into those in which 1) staff received two 4-hour training sessions on appropriate medication treatment using constructive learning theory and activating learning methods to identify harmful drugs and their adverse events (intervention group), and 2) control group. Outcome measrues were use of potentially harmful medications (Beers drugs, anticholinergics, psychotropics), HRQoL assessed using 15D, number of falls and health service utilization during12 months. Results: During the 12-month follow-up the mean number of potentially harmful medications decreased in the intervention wards (-0.43, 95%CI -0.71 to -0.15) but remained constant in the control wards (+0.11, 95 CI -0.09 to +0.31) (p=0.004). HRQoL declined more slowly in the intervention wards (-0.038 (95%CI -0.054 to -0.022) than in the control wards (-0.072 (95%CI -0.089 to -0.055) (p=0.005). Residents of the intervention wards had significantly less hospital days (1.4 days/person/year, 95%CI 1.2-1.6) than in the control wards (2.3 days/person/year; 95%CI 2.1-2.7) (RR 0.60, 95%CI 0.49-0.75, $p<0.001$). They also experienced significantly less falls during the follow-up. Conclusion: Activating learning methods directed at nurses in charge of comprehensive care can reduce the use of harmful medications, maintain HRQoL, decrease falls and reduce hospitalization in residents of assisted living facilities.

CREATIVE SOLUTIONS TO CHALLENGING HOME CARE - CASE STUDIES ILLUSTRATE SIMILARITIES ACROSS DISCIPLINES

J. Given[1], B.R. Hinson[3], D. Koin[2], *1. Independent provider, San Francisco, California, 2. Stanford University School of Medicine, Palo Alto, California, 3. Independent fitness consultant, San Francisco, California*

Providing specialized care in the home brings with it challenges and rewards not usually encountered in a clinic or office visit. Though evidenced-based practices and research protocols are regularly used, clinicians often find themselves facing unexpected situations when bringing services to the home. A physician, psychologist and kinesthesiologist will share strategies developed to address treatment needs of home care clients. Case studies will be used to show common approaches, creative problem-solving and the importance of education, skills building and family interactions to address complicated health issues. Three in-depth case reviews with measurable and successful outcomes will used: an Asian couple with chronic health problems, including diabetes, and 14 living children (none of whom agrees on medication and diet management); a gay man in mid-60s who went from cold symptoms to hospice care, after medical complications and a massive stroke; and a 95-year-old holocaust survivor whose care is managed by son. In each case, regardless of the provider’s clinical background, physical and emotional needs had to be addressed. Details of interventions used, suggestions for working with different providers and family members, and using a holistic approach will be highlighted.

INTERPROFESSIONAL COLLABORATION IN GERIATRIC REHABILITATION EDUCATION

A. Jackson, S. Mbiza, *Florida Agricultural & Mechanical University, Tallahassee, Florida*

Background: The complex needs of geriatric clients require interprofessional collaboration in order to provide optimal care. Interprofessional education of rehabilitation professionals has been developed before in academic institutions. However, interprofessional collaboration between occupational and physical therapy departments at a historically black college or university (HBCU) is limited in the literature. The purpose of this project is to develop a collaborative module for teaching in geriatric rehabilitation, with the common goal of improving the students' clinical and interprofessional collaboration skills. Methods: Because no previous collaborative teaching existed within the School of Allied Health Sciences (SOAHS), we began by documenting the collaboration steps and developing the module. We will demonstrate the module's effectiveness by examining and evaluating students' (1) changes in attitudes towards aging, (2) competencies in geriatric care skills, (3) knowledge of the needs of the geriatric client and (4) collaborative skills. Results: It is expected that this module will improve the students' attitudes towards aging, as well as improve knowledge and skills in interprofessional geriatric care. It is also expected that students will be better prepared for clinical education/ fieldwork experiences, which should translate into better practices across health care settings and client populations. Conclusions: The process of creating interprofessional education opportunities for students within the SOAHS at a premier HBCU will require commitment and a belief that each department would benefit. Additionally, the students' exposure to other health professionals will be enhanced through these nontraditional partnerships. We envision that additional disciplines within the SOAHS will engage in this opportunity.

RECREATIONAL THERAPY COMPETENCIES FOR GERONTOLOGY/GERIATRIC EDUCATION

N.E. Richeson[1], A. Sardina[2], *1. University of Southern Maine, Portland, Maine, 2. Cyprus Cove, Fort Meyers, Florida*

The purpose of this poster session is to highlight the role of the American Therapeutic Recreation Association's (ATRA) Geriatric Treatment Network's work on developing occupational specific competencies for Recreational Therapists who work with older adults. The competencies were built on industry wide recommendations from the Association for Gerontology in Higher Education's (AGHE) Standard and Guidelines for Gerontology and Geriatrics in Education and Health Professions. AGHE's guidelines were constructed based on the widely endorsed Partnership for Health in Aging competencies. The GTN of the ATRA has voted to adapt these competencies as minimal guidelines that are considered necessary to work with older adults.

MATCHING GERIATRICS CURRICULUM FOR MEDICAL STUDENTS IN CLINICAL YEAR WITH THE MINIMUM GERIATRICS COMPETENCIES IN PUBLISHED CURRICULA FROM 2009-2013: A SYSTEMATIC REVIEW

H. Cheng, *Medicine, University of Virginia, Charlottesville, Virginia*

Background: teaching geriatrics competencies to medical students is critically important. In 2009, the 26 minimum geriatrics competencies (MGC) in 8 domains for all medical students were published. However, it is unknown how well the geriatric curriculum for medical students in clinical year matches the MGC in published curricula, which will be the focus of this systematic review. Methods: The inclusion criterion is the geriatric curriculum for the third or 4th year medical students that reported the learning objectives or any of geriatrics competencies, study design for comparison of effectiveness of teaching, teaching methods and outcome measurement and was published from 2009 to 2013 in English. 26 MGC and 8 domains in the selected papers were assessed. Results: We found 7276 citations through PubMed on 12/15/2013. Total 21 original papers were reviewed. 6 of them met the inclusion criteria. Four of six curricula (67%) reported learning objectives. The competency 4-9 and 12-13 was covered in 83 % curricula (highest). No curriculum covered the competency 17-18, 22-26 (lowest). The domain 3 was covered in 83 % curricula (highest). No curriculum covered the domain 6 (lowest). Three out six curricula (50%) used pre-post test design. Another half curricula used cohort design. All curricula reported the teaching methods and outcomes. Conclusion: the 26 MGC and 8 domains were not fully covered across six published curricula since the MGC was published in 2009.

EMBEDDING ACTIVE, PARTICIPATORY TRAINING WORKSHOPS IN AN EXISTING "UPDATE AND BOARD REVIEW" FOR INTERPROFESSIONAL CONTINUING GERIATRICS EDUCATION

G.H. Manzi, D.L. Brown, K. Denson, S. Denson, E.H. Duthie, *Division of Geriatrics, Medical College of Wisconsin, Milwuakee, Wisconsin*

Background As the US population ages without enough geriatricians, training geriatric principles to primary providers is increasingly essential. We previously reported our experience using interactive geriatrics teaching among residents and family physicians. We now report applying this approach to an interprofessional audience attending a well-established geriatrics board review course. Methods The Medical College of Wisconsin and the University of Wisconsin co-sponsored the 2013 Wisconsin Update in Geriatric Medicine & Board Review Course. Assisted by the Wisconsin Geriatric Education Center, we created a track that allowed us to teach geriatric principles using active learning through workshops, small-group sessions, and interactive simulations. Results The GEC track was embedded in the Course in addition to the core content. Five sessions were presented using active learning strategies around common geriatric topics: urinary incontinence, impaired vision and hearing, dysphagia, dizziness and gait/balance. 79 healthcare professionals attended the conference (47% MD/DO, 24 % APP [PA, NP], 5% pharmacists, 22% social workers). 53 attended these sessions (30% nurses and 40% physicians). Session content, teacher effectiveness and learning received scores >6 (1=poor to 7=excellent) in 100% of evaluations collected. Reported lessons learned included: "Be mindful using written/verbal communication", "Reduce medications", "apply/ utilize tools for falls, life expectancy", and "… a better understanding of diagnoses and medications in the elderly". Conclusion Previously we reported success using active hands-on learning experiences effectively delivered in formal training venues to health care professionals to support their abilities to improve geriatric patient care. We were able to successfully translate this to an interprofessional audience.

GERIATRIC TEACHING AND EVALUATION BY THE STUDENTS AT THE MEDICAL SCHOOL HANNOVER (GERMANY)

K. Hager, M. Brecht, O. Krause, V. Grosse, *Center for Medicine in the Elderly, Hanover, Germany*

Background: Since 2003 teaching of geriatrics at the medical schools in Germany has become obligatory. At the Medical School of Hanover (MHH) there is a lecture week with 20 hours and a practical teaching of 10 hours. The study week is completed by a test, in which every student has to participate. Method: A standard evaluation at the end of the study week offers a possibility for the students to comment on the teaching. With three questions the students can express their opinion on whether the teachers, the content, the study material, the patient related topics, the test or the organization is good or not and whether there is a potential for improvement. In further questions the students can rate several characteristics on a numeric scale ranging from 1-6 or from 1-7, from "very good" to "not at all". In the end the students can give an overall rating on a numeric scale ranging from 0 to 15 (0: insufficient; 15: very good). Results: In the last term in 2013 97 of 107 students (90.7%) took part in that evaluation. The overall rating for the study week was 12.67, which is a result well above the majority of the other disciplines. For example 17 students criticized the material for learning. On the other hand 76 students found that the teachers were good. Another point of criticism was, that the subjects taught were not elaborated enough (3.62 on the numeric scale from 1 to 6). Discussion: The lectures are given by geriatricians and members of other specialties at the medical school in about equal parts. This is intended to guarantee a balance between organ specificity and complex or functional symptoms like falls or delirium. Organ specific teaching is what the students are used to and what they expect. For the teaching of functional problems, activities, participation and context factors geriatricians are more suitable. In the practical teaching items like the assessment are demonstrated and the students than have to do it themselves. Then cases are demonstrated where this knowledge is turned into clinical consequences. Conclusion: In the past 10 years the present organization was developed, partly based upon the evaluation of the students. The teamwork of several medical specialties at the medical school, the teaching in an organ specific and a functional way seems to offer a possibility to communicate geriatric medicine in a way that is accepted by the students. The evaluation by the students is very valuable to further improve the way of teaching geriatric medicine. The prerequisite is to accept the criticism of the students and the will to change things.

A GROUNDED THEORY OF THE PROCESS OF SPREAD OF BEST PRACTICES IN HOME CARE ORGANIZATIONS

J. Ploeg[1], M. Markle-Reid[1], B. Davies[2], K. Higuchi[2], W. Gifford[2], I. Bajnok[3], H. McConnell[3], *1. School of Nursing, McMaster University, Hamilton, Ontario, Canada, 2. University of Ottawa, Ottawa, Ontario, Canada, 3. Registered Nurses' Association of Ontario, Toronto, Ontario, Canada*

Purpose: The purpose of this study was to understand how best practices related to older adults are spread within home care organizations. Methods: Four home care organizations in Ontario, Canada that had implemented best practices related to older adults (i.e., falls prevention, pain management, management of venous leg ulcers) participated. Using a qualitative Grounded Theory design, interviews were conducted with front line providers, managers and directors at baseline (n=44) and one year later (n=40). Open, axial and selective coding and constant comparison analysis were used. Results: A theory of the process of spread of best practices in home care was developed. The phases of spread included: (1) committing to change, (2) implementing on a small scale, (3) adapting locally, (4) spreading internally to multiple users and sites, and (5) disseminating externally. Factors that facilitated progression through these phases were: (1) leading with passion and commitment, (2) sustaining strategies, and (3) seeing the benefits. Project leads, champions, managers and steering committees played vital roles in leading the spread process. Strategies such as educating/coaching and evaluating and feedback were key to sustaining the change. Spread occurred within the home care context of high staff and manager turnover, time and resource constraints and managed competition. Conclusion: Spread of best practices is optimized through the application of the phases of spread, allocation of resources to support spread and implementing strategies that address potential barriers. Further research will help to understand how best practices are spread externally to other organizations.

ORGANIZATIONAL CULTURE IN THE DEPARTMENT OF VETERANS AFFAIRS: INNOVATIVE HOME BASED PRIMARY CARE PILOT PROJECTS IN COLLABORATION WITH INDIAN HEALTH SERVICE

B. Creekmur[1], B. Kramer[1,2], S. Cote[1], M.L. Katz[1], B.D. Kraus[1], M.N. Mitchell[1], *1. VA Greater Los Angeles Healthcare System, Los Angeles, California, 2. David Geffen School of Medicine at UCLA, Los Angeles, California*

Background: Veterans Affairs (VA) funded 14 VA medical centers to implement innovative Home Based Primary Care (HBPC) programs with Indian Health Service (IHS) on rural American Indian (AI) reservations. Our aim was to explore the relationship between VA organizational culture and program characteristics of successfully implemented HBPC program collaborations. Methods: Using program documents and interviews with key stakeholders we defined three binary typologies to categorize the HBPC programs: 1) traditional HBPC model/non-traditional, 2) planning with IHS/without IHS, 3) implementation by staff who were culturally competent and/or had previous experience with AI or IHS/without. We analyzed the 2008 VA All Employee Survey supervisory-level data using the 14 organizational culture-items, which includes four subscales (entrepreneurial, hierarchical, team, and rational), aggregated to the facility-level. Using exact logistic regression we modeled binary outcomes of each culture subscale and typology. Results: There was a significant outcome for the traditional (n=5) vs. non-traditional (n=6) model typology on the organizational culture subscales of entrepreneurial (M = 3.4 vs. 3.1, p = 0.004) and team (M = 3.5 vs. 3.3, p = 0.011). Conclusion: The results provide statistical substantiation for the researcher defined typology of traditional/non-traditional to describe the HBPC programs. Higher ratings on the organizational culture subscales of entrepreneurial and team are associated with greater flexibility and cohesion which may have allowed the programs to implement the traditional, or standard, model for delivering HBPC in rural areas. These factors should influence dissemination of collaborative programs between VA and IHS at other VA facilities.

PERCEPTIONS OF PATIENT CENTERED MEDICAL HOME AND SELF-RATED HEALTH AMONG MIDLIFE ADULTS

J. Warren-Findlow[1], E. Platonova[1], J. Hutchison[2], W. Saunders[1], *1. Department of Public Health Sciences, The University of North Carolina at Charlotte, Charlotte, North Carolina, 2. The University of North Carolina at Charlotte, Health Services Research PhD Program, Charlotte, North Carolina*

Patient centered medical home (PCMH) is an organizing framework for health care delivery that emphasizes increased access and coordination of care to improve health status. Middle-aged individuals would likely benefit from PCMH as they frequently experience onset of chronic disease, may lack health insurance, but are not yet eligible for Medicare. We surveyed patients (age 45-64; n=266) from three safety net clinics in Charlotte, NC on their perceptions of PCMH, patient satisfaction and health status. We conducted logistic regression using generalized estimating equations to account for clinic clustering. The model was adjusted for demographics, health conditions, and overall satisfaction with clinic care. Patients were predominantly female, Black, with a high school education or better. In unadjusted analyses, higher satisfaction with provider communication (OR=1.77, 95% CI=1.16-2.71), higher levels of satisfaction with access (OR=1.39, 95% CI=1.14-1.70), and increasing satisfaction with care coordination (OR=1.42, 95% CI=1.19-1.69) were associated with better self-rated health (SRH). In multivariate analyses, no PCMH components were associated with good SRH. Having a high school education was associated with 2.95 increased odds of reporting good SRH (OR=2.95, 95% CI=1.62-5.38) as compared to participants who had not completed high school. In this study of middle-aged patients seen at safety net clinics, we found no association between elements of PCMH and better self-rated health after adjusting for demographic factors and health conditions. The Patient

Protection and Affordable Care Act promotes the PCMH model, and future research should further evaluate this model of care in low-income health care settings that serve middle-aged adults.

AN UNUSUAL CASE OF TUBULOINTERSTITIAL NEPHRITIS

S. Tariq, H. Choudhry, J. Smith, *Bayonne Medical Center, Jersey City, New Jersey*

IgG-4 related disease is a recently recognized immune mediated systemic disease and is also termed as "IgG4-associated immune complex Multiorgan Autoimmune Disease (IMAD)". IgG4- related kidney disease is a term that refers to any form of renal involvement by this disease; most common manifestation being acute or chronic renal injury. A 68-year-old male was seen complaining of polyuria and nocturia for the past 2 months, with a 20 lb weight loss. His past medical history and physical examination were unremarkable. His lab results revealed markedly elevated creatinine. Serology did not show any significant abnormalities. Urine analysis revealed non-nephrotic range proteinuria. A clinical diagnosis of acute kidney injury was made but with an unknown etiology. Renal biopsy was performed showing severe interstitial fibrosis and tubular atrophy. The results confirmed a diagnosis of IgG4-related tubulointerstitial nephritis. This type of nephritis is a systemic disease affecting multiple organ systems. A CT scan of the chest, abdomen, and pelvis was performed, showing no other organ involvement. He had a normal cystoscopy and PSA. The patient was started on steroids as his initial treatment. Repeat blood work indicated a significant improvement of his kidney function. He was able to increase his weight by 15 pounds over a period of 3 months. This case illustrates an uncommon type of tubulointerstitial nephritis that is only recently being recognized. There is no standard treatment for this disease at this time. The current literature does indicate that steroid therapy may be a possible initial choice. Studies related to this condition, treatment and its pathogenesis are severely lacking. There is a lack of awareness of this condition and is most likely overlooked and under reported. This case represents an approach to the treatment of IgG4 tubulointerstitial nephritis that should be considered. The patient had improvement of his renal function and improvement of his symptoms. Much more information and research needs to be done so that this disease can be better understood and managed.

FACTORS ASSOCIATED WITH CHOICE OF NONPHARMACOLOGICAL THERAPIES BY OLDER ADULTS WITH CHRONIC PAIN

J. Park[1], R. Lavin[2,3], *1. School of Social Work, Florida Atlantic University, Boca Raton, Florida, 2. University of Maryland, School of Medicine, Baltimore, Maryland, 3. Veterans Administration Maryland Health Care System, Baltimore, Maryland*

This study identified factors associated with current use of NPPT by ethnically diverse community-dwelling older adults with chronic pain. Using a cross-sectional research design, 281 adults age 60 years or older (M = 74.06 years, SD = 8.25) in four ethnic groups (73 European Americans, 71 Hispanics, 70 African Americans, 67 Afro-Carribeans) with chronic pain were surveyed; 260 (92.5%) reported current use of some form of NPPT. Binary logistic regression identified factors associated with choice of type of NPPT: exercise, water exercise, prayer, meditation, physical therapy, or trans¬cutaneous electrical nerve stimulation (TENS). Non-aquatic exercise (67.3%) and prayer (41.3%) were the most common forms of NPPT reported. In the regression model, after controlling for age, ethnicity, education, income, pain intensity, mobility, and sleep disturbance were entered. Lower pain levels predicted use of non-aquatic exercise (p = .035), higher income levels predicted use of water exercise therapy (p = .013), and African American or Hispanic ethnicity predicted use of prayer (p < .0005) or meditation (p < .001)to manage chronic pain. Disposable income was associated with joining a pool use group. Other forms of NPPT were nonsignificant. The negative association between high pain intensity and exercise may be explained by fear of exacerbating pain or causing injury. Health care providers should be sensitive to preferences for types of NPPT, with regard to ethnicity, pain severity, and income. Future research should focus on identifying evidence of appropriate dosage and intensity of each type of NPPT for older adults, including for persons with disability.

COMPARISON OF EPIGENETIC THERAPY VERSUS INTENSIVE CHEMOTHERAPY FOR NEWLY DIAGNOSED ACUTE MYELOID LEUKEMIA PATIENTS ≥60 YEARS OLD

N. Gupta, *1. State University of New York at Buffalo, Batavia, New York, 2. Roswell Park Cancer Institute, Buffalo, New York*

Objective: To compare the outcomes of epigenetic therapy (Epi) versus intensive chemotherapy (IC) for induction in ≥60 years old acute myeloid leukemia (AML) patients (pts). Methods: We retrospectively analyzed 164 pts with newly diagnosed ≥ 60 yrs old AML pts who received induction at Roswell Park Cancer Institute, NY, USA between 3/2008-2/2013. 51% received IC with 7+3, and 49% received Epi with decitabine (Dec) or 5-azacitidine (Aza). Results: Baseline characteristics were similar except median age (IC 67 vs. Epi 75 yrs; p <0.01). Older AML pts receiving IC had superior complete response at (CR) (43% vs. 21%; p< 0.01) versus Epi-treated pts. IC also caused longer median OS compared to Epi (10.6 vs. 7.9 mos; p=0.01). In multivariate analysis, older age and higher ECOG were associated with poor OS but choice of induction did not impact OS (IC vs. Epi, p= 0.31). Conclusions: Our results suggest that IC and Epi represent clinically equivalent approaches for upfront treatment of elderly AML. Despite higher CR in the IC group, our finding of improved OS following IC vs. Epi was not substantiated in multivariate analysis, suggesting that this difference can be explained by the comparatively younger age of pts in the IC group. These data highlight the growing need for prospective clinical trials to conclusively determine the respective roles of IC vs. Epi in older AML pts.

PAIN MEDICATION USE AND EFFECTS IN AN OLDER POPULATION, THE MOBILIZE BOSTON STUDY

A. Nawai[1], S.G. Leveille[1,2,3], R.H. Shmerling[2,3], G. van der Leeuw[1], J.F. Bean[3,4], *1. University of Massachusetts Boston, Boston, Massachusetts, 2. Beth Israel Deaconess Medical Center, Boston, Massachusetts, 3. Harvard Medical School, Boston, Massachusetts, 4. Spaulding Rehabilitation Hospital, Boston, Massachusetts*

Concerns about polypharmacy and medication side effects contribute to undertreatment of geriatric pain. This study examines use and effects of pharmacologic treatments for pain in an older population. The MOBILIZE Boston Study included 765 adults aged ≥70y living in the Boston area, recruited from 2005-2008.We studied 599 participants who reported chronic pain at baseline. Pain severity, measured using the Brief Pain Inventory (BPI) severity subscale (scores 1-10), was grouped as very mild (BPI<2), mild (BPI 2-3.99), and moderate to severe (BPI ≥4). Medications taken in the previous 2 weeks were recorded from the medication bottles during the home interview. More than half of participants in each pain severity category were not using any analgesic medication. Persons with the mildest pain were more likely to use daily analgesics than those with moderate to severe pain (33% versus 22%, respectively). Opioid analgesics were used by 6% of participants. Acetaminophen use was reported by 28% of participants. Those with moderate to severe pain reported less relief overall from pain medications and treatments. Only 6% reported side effects related to use of pharmacologic pain treatments. Nearly one-third of participants (30%) with moderate to severe pain felt they needed a stronger pain medication while 16% of this group were concerned they were using too much pain medication. Many older adults with chronic pain use little or no analgesic medication, counter to current guidelines for pain management. Efforts are needed to understand barriers to effective pain management and self-management in the older population.

PREVALENCE OF OTOTOXIC MEDICATION USE AMONG OLDER ADULTS IN BEAVER DAM, WISCONSIN

Y. Joo[1], M.I. Wallhagen[1], K.J. Cruickshanks[2], R. Klein[2], B.E. Klein[2], *1. UCSF, San Francisco, California, 2. University of Wisconsin, Madison, Wisconsin*

Background: Older adults are often on multiple medications for concurrent chronic illnesses. Many medications are ototoxic. Drug related ototoxicity may interact with the age-related hearing loss causing it to be more severe, yet few data are available on the prevalence of ototoxic medication use in older adults. Aim: To determine the prevalence of ototoxic medication use among older adults Methods: A cross-sectional secondary data analysis was conducted using selected variables extracted from the large dataset of the Epidemiology of Hearing Loss Study (EHLS). A total of 2395 older adults who completed survey were included in the analysis. Ototoxic medication use, including diuretics, nonsteroidal anti-inflammatory drugs (NSAIDs), antibiotics, chemotherapeutic agents, quinine, and acetaminophen, was assessed using a standardized questionnaire that asked about all prescription and over-the-counter medications that they were regularly taken at least once per week. Results: Prevalence of any ototoxic medication use was 91.1%. Prevalence of concomitant ototoxic medications was 34.6%. The mean number of ototoxic medications used was 1.7 (±1.0). The most commonly used was NSAIDS (75.2%). Conclusion: Given the number of medications used by older adults, the high prevalence of hearing loss in this population, and the impact of hearing loss on health and daily living, drug-related ototoxicity may be a critical public health problem. Epidemiological studies are needed to understand the long-term effect of ototoxic medication on age-related hearing loss and healthy aging.

SESSION 1680 (POSTER)

INDEPENDENCE, FUNCTIONING, AND ENGAGEMENT IN COMMUNITY AND WORKFORCE

EDUCATIONAL DRIVER RETRAINING VERSUS AN ALTERNATIVE OR NO INTERVENTION FOR ADULTS AT LEAST 55 YEARS OF AGE: A META-ANALYSIS

N.A. Knechel, *Nursing, Yale University, New Haven, Connecticut*

Background: With the population of older adults growing and a higher crash rate per mile driven, the number of motor vehicle crashes (MVC) involving older drivers is predicted to increase significantly. There is a growing body of literature on older driver retraining programs. Objectives: The purpose of this analysis is to determine the effectiveness of educational, physical, and combination retraining interventions aimed at improving older driver performance. Methods: An electronic search in MEDLINE using Ovid was performed, 1948 to present. Selected studies had to be a randomized controlled trail, with participants at least 55 years old, using an educational training, physical training, and/or no training with the intent of improving older driver abilities. Data Analysis: The Cochrane Handbook for Systematic Reviews of Interventions was used as the framework. Dichotomous MVC data was abstracted for relative risk and risk difference. Continuous on-road driving ability and driver safety knowledge were evaluated by the standardized mean difference (SMD). A fixed effect meta-analysis of the RCTs was conducted using Review Manager Software. Results: Only one RCT looked at MVC involvement and two looked at driver knowledge so these outcomes weren't run in the analysis. For on-road driving ability, the SMD for a combination, educational, or physical intervention was 0.30, 0.37 and 0.39, respectively. Discussion: The data suggest there is evidence of no effect; however, there was considerable heterogeneity which interferes with the ability to draw any conclusions on the effectiveness of retraining programs on driving abilities. This has implications for policies and further research.

THE IMPACT OF ASSISTIVE DEVICE USE ON THE SOCIAL PARTICIPATION OF OLDER ADULTS

J.E. Walsh, J. Troyer, *Public Policy/Economics, University of North Carolina, Charlotte, Charlotte, North Carolina*

Aging can be accompanied by an increased probability of certain chronic health conditions with symptoms that effect an individual's physical functioning and may lead to problems in performing activities of daily living (ADLs). These limitations may make societal participation difficult, putting the individual at greater risk of isolation and further declines in health. However, physical limitations may be offset in full or in part through the use of assistive technology devices (ATDs). This study considers the impact of ATDs to help with mobility, sensory problems and problems with ADLs on five types of active social participation: visiting with family and friends, participating in religious services, joining clubs and attending meetings, going out for enjoyment and performing volunteer work. Using two years of panel data from the nationally representative National Health and Aging Trends Study, we develop relevant subsamples of those with physical impairments and use conditional logistic regression models to consider the impact of ATDs on social participation. Despite significant increases in the use of assistive devices over the two years examined, overall changes in general levels of participation appear negligible. However, when we examine individual types of assistive devices and control for confounders, we find that mobility devices are associated with less social activity, but hearing aids are influential in encouraging participation in many activities. It is estimated that 70% of older hearing-impaired Americans who could benefit from using a device do not use one. Public funding for hearing devices would lead to increased community participation among older adults.

AGE DISCRIMINATION AT WORK: A MEASURE THAT CAPTURES INTERPERSONAL MISTREATMENT

E. Gonzales[1], L.A. Marchiondo[2], S. Ran[2], *1. Boston University School of Social Work, Boston, Massachusetts, 2. Wayne State University, Detroit, Michigan*

PURPOSE. Scholars have increasingly documented the presence of overt forms of age discrimination in the workplace (e.g., not being hired or promoted). Less attention has been given to covert age discrimination at work; and no instrument exists to measure it. We developed and validated an age discrimination measure to capture covert discrimination from the target's perspective. DESIGN AND METHODS. Following Hinkin's (1998) scale development process, we generated prospective items, drawing from existing measures in the literature, expert knowledge, and a qualitative study of older workers' experiences. We administered a list of items to U.S. employees aged 50 and older in MTurk (N=345). We examined descriptive statistics, reliability, and convergent and discriminant validity to arrive at a final set of items; and tested its relationship with job satisfaction, turnover intention, anxiety and depression after controlling for covariates (negative affectivity, pessimism, neuroticism, agreeableness). RESULTS. Age Discrimination at Work Measure consists of 26 items, captures 63% of the variance, and has a Cronbach alpha value of .97. Perceived age discrimination is significantly related to job satisfaction, turnover intentions, anxiety, and depression after controlling for important covariates. IMPLICATIONS. Overt forms of discrimination are unlawful and targets are protected under legislation. However, covert age discrimination leaves older workers unprotected, vulnerable to incivilities and exclusion by co-workers and supervisors. Covert forms of discrimination may be more prevalent than overt discrimination and may have a larger negative impact on health and labor force attachment.

DEMOGRAPHICS AND ATTITUDES: WHICH PREDICTS DRIVING RETIREMENT?

M. Berg-Weger[1], T.M. Meuser[2], J. Pickard[2], T. Richardson[1], K. Freund[3], *1. Social Work, Saint Louis University, St. Louis, Missouri, 2. University of Missouri-St. Louis, St. Louis, Missouri, 3. ITNAmerica, Portland, Maine*

As the number of older drivers continues to increase so will the number of those needing to cease driving for health/safety reasons. Researchers and practitioners need to understand factors associated with transition to driving retirement. This study, based in the Transtheoretical Model (TTM), addresses this need. TSamples from three prior studies are used to focused on aged-related mobility transitions. Participants include 149 adults who retired from driving and joined a rides service (ITNAmerica), and 318 community-dwelling volunteers who still drive regularly. This combined sample of 467 (78% female, mean age 75 years) represents the two ends of the TTM driving transition progression. Available data included group status, living arrangements, self-reported health, three subscales of the Assessment of Readiness for Mobility Transition (ARMT) scale, and demographic factors. Univariate and bivariate results are presented, and binary logistic regression is used to assess the relationship of these factors to participants' transition status. The logistic regression model was significant (x2=106.05, df=8, p<.0001) and revealed that those who are older (OR=1.15), those with higher self-reported health (OR=2.46), those who no longer reside in the community (OR=0.29), and those more concerned they will be a burden on others (OR=2.06), were significantly more likely to have retired from driving. These findings serve to deepen our understanding of the process of transitioning into driving retirement and suggest that person-centered, collaborative planning can help the older driver to avoid the involuntary crisis-oriented driving retirement while moving gradually into retirement with an individualized plan for accessing viable transportation alternatives.

PLANNING FOR LIFE AFTER DRIVING: AN INTERVENTION STUDY

J.D. Stowe[2,1], T.M. Cooney[3], T.M. Meuser[4], M. Berg-Weger[5], C. Snethen[2], N. Schmidt[2], *1. University of Missouri, Columbia, Missouri, 2. Frank L. Mitchell Jr., MD Trauma Center, Columbia, Missouri, 3. University of Colorado, Denver, Colorado, 4. University of Missouri, St. Louis, Missouri, 5. Saint Louis University, St. Louis, Missouri*

Older adults with medical conditions that impair function are at the highest risk for driving retirement. This Randomized Controlled Trial investigated the efficacy of an intervention that facilitated planning for a likely driving transition among medically-impaired elders – those with vision, cognitive, or psychomotor impairment. A 2-to-1 allocation ratio resulted in comparisons between 26 intervention and 13 attention control (n = 39) group members who were recruited from health care sites. The intervention consisted of two sessions of facilitated planning in which the participant's health, transportation alternatives, attitudes/emotions regarding a change in mobility, and actions to ensure continued safe mobility were discussed. Moreover, all participants received supportive phone calls during the 6 month intervention period. Results showed no difference in measures of current awareness of mobility challenges, but an increase in expected future changes in mobility in the intervention group only. One-half of the intervention group changed driving habits, including cessation and self-regulatory behavior, in comparison to 16% of the control group. Likewise, 50% of the intervention group made plans and took steps toward maintaining safe mobility (e.g., used a different transportation mode for the first time) versus 16% of the control group. Results suggest that facilitated planning may help ease the transition to driving retirement among some high-risk older adults.

THE RELATIONSHIP BETWEEN SELF-RATED MEMORY AND DRIVING BEHAVIORS AMONG COMMUNITY-LIVING OLDER ADULTS: EVIDENCE FROM THE HEALTH AND RETIREMENT STUDY

M. Choi[1], G. Kim[2], D. Fardo[3], *1. University of Kentucky College of Social Work, Lexington, Kentucky, 2. The University of Alabama Department of Psychology, Tuscaloosa, Alabama, 3. University of Kentucky Department of Biostatistics, Lexington, Kentucky*

One of the major social concerns related to older drivers is at-risk drivers with cognitive impairments. Previous studies have reported that older adults with cognitive impairments are more likely to stop driving compared to those without cognitive impairments. However, little is known about whether self-perceived memory problem is associated with driving cessation or self-regulatory driving. This study aimed to examine the relationship between self-rated memory and driving behaviors among community-living adults aged 65 and older without dementia diagnosis, using the data from the 2010 Health and Retirement Study (N=9,516, 58.2% women, 16% non-White, average age=75.2 years). Older adults were asked to rate their own memory; their responses (prevalence) were excellent (3.8%), very good (20.6%), good (44.7%), fair (25.5%), or poor (5.3%). We used multinomial logistic regression to determine whether fair/poor self-rated memory was significantly associated with the likelihood that older adults drove without limitation, drove but limited their driving to nearby places, or did not drive. The results showed that older adults with fair/poor self-rated memory were more likely to limit their driving to nearby places than those with excellent/very good/good self-rated memory, after adjusting for sociodemographic and health characteristics (OR = 1.38, 95%CI = 1.23—1.55; reference group=driving without limitation). However, fair/poor self-rated memory was not significantly associated with driving cessation (OR = 1.12, 95%CI = 0.97—1.30; reference group=driving without limitation). The findings of this study imply that self-rated memory problem might help older adults limit their driving, but not necessarily stop them from driving.

ONLINE GOVERNMENT - OFFLINE OLDER CITIZENS

R. O'Sullivan[1], I. Hardill[2], *1. Centre for Ageing Research and Development in Ireland (CARDI), Belfast, Ireland, 2. University of Northumbria, Newcastle, United Kingdom*

As governments across the world move more services online, there is a need to understand implications for older people. The successful transition from face-to-face or telephone-based services to e-government is dependent on citizens having access to the internet (whether through a computer, tablet or smartphone) and possessing the skills or support to enable them to access public services online as and when they need them. This paper provides a summary of the key findings from research carried out in both Northern Ireland and the Republic of Ireland based on a mixed methods approach of policy and literature review, analysis of Government statistics, interviews with key stakeholders (21) and focus groups with older people (31 participants). The research finds that there is a spectrum of 'onlineness' with no simple binary between e-included and e-excluded and the move to online government often replicates and compounds existing inequalities. It highlights that a digital divide is linked to educational attainment, gender, income and age and there is a danger of an increasing digital disconnect with many older people compared to wider society. This paper also includes European and international examples where e-government services have been developed and usage of those services, particularly among key target groups, has been increased. The paper provides a series of recommendations, both practical and policy, which can help ensure that older people are not left behind as public services move online.

NEWS MEDIA PORTRAYAL OF OLDER DRIVERS

M. Choi[1], S. Upadhyay[1], D.S. Chung[2], *1. College of Social Work, University of Kentucky, Lexington, Kentucky, 2. University of Kentucky School of Journalism and Telecommunications, Lexington, Kentucky*

Driving cessation touches many aspects of quality of life among older adults. It is important to discuss the issue of older drivers based on the balance between public road safety and individuals' autonomy and dignity. The news media have played an important role in shaping people's perceptions and attitudes toward older drivers. Based on the framing theory, we employed a content analysis of news articles about older drivers appearing in nine major newspapers over the past 30 years (N=238; 65.5% opinion pieces). A majority of new articles (46.6%) focused on raising questions about the driving competencies of older adults, reporting accidents caused by older drivers, or urging to re-exam the current state driver's license renewal policy on older adults. About 17.6% provided information about training/courses for improving driving skills, mostly through the AARP Driver Safety Program. Only a small portion (5.9%) of articles discussed alternative transportation. News stories (local/national) were significantly more likely to be about state laws on drivers licensing, whereas opinions pieces were significantly more likely to be about training/courses for improving driving skills and topics dealing with intergenerational relationships such as an adult child's concern for their aging parent's driving (Cramer's V = .31, p<.01). In conclusion, the news media tend to have set an agenda more focused on changing individuals' behaviors, such as getting them out of the roads or encouraging them to take a course for safety driving, rather than contextualizing the issue in a broader social system like developing alternative transportation programs.

THE IMPACT OF MEMORY DECLINE ON SOCIAL AND CIVIC ACTIVITY PARTICIPATION: THE ROLE OF SELF-EFFICACY AS A MODERATOR

S. Kim[1], H. Yoon[2], K. Kim[3], *1. Columbia University School of Social Work, New York, New York, 2. The University of Texas at Austin School of Social Work, Austin, Texas, 3. University of Maryland School of Social Work, Baltimore, Maryland*

This study examines the effects of perceived memory decline (compared to one year ago) on participation in social and civic activities among American older adults. The study also explores the moderating effect of self-efficacy in the relationship between perceived memory decline and activity participation. The first wave data of the National Health and Aging Trends Study, collected from the nationally representative sample of older adults aged 65 and older, was used [N=6,097]. Old adults who have not been diagnosed with dementia are included in the analysis. Multiple regression analysis was used. The regression results identified a significant relationship between memory decline and activity participation when holding current memory status, socio-demographic and health-related factors constant [R2 = .29, F(21, 6075)=118.75, p<.001]. That is, older adults who perceived memory decline are more likely to be restricted in social and/or civic activity participation than those who did not have memory decline. People with high self-efficacy are less likely to be restricted from participating in social and/or civic activities than those with low self-efficacy. Importantly, a significant moderating effect of self-efficacy between memory decline and activity participation was identified. This may be interpreted as people with high self-efficacy being more likely to cope with stressful events such as memory decline than low self-efficacy people. These findings suggest that perceived memory decline and self-efficacy are important factors to be taken into account when developing intervention programs to help older adults maintain their quality of life and independence from memory-related changes.

THE CUSTOMER EXPERIENCE: A SHORT MEASURE OF SATISFACTION

N. Castle[1], J. Engberg[2,1], *1. University of Pittsburgh, Pittsburgh, Pennsylvania, 2. RAND, Pittsburgh, Pennsylvania*

Collecting satisfaction information from long-term care (LTC) residents is important. Despite the substantial benefits to collecting satisfaction information, some barriers to effective use of satisfaction surveys exist. In this session, information will be presented on a short survey instrument that can be used for different LTC populations (e.g., short-stay residents, long-stay residents, family members, etc). The surveys were developed using a review of the literature, review of existing surveys, focus groups, and pilot testing. A random sample of >500 LTC facilities (response rate = 69%) from across the U.S. was used with about 5,000 returned surveys (response rate = 70%). Analyses consist of simple descriptive statistics and a presentation of the survey development process. The findings show that 12 domains have considerable relevance to resident satisfaction. Moreover, 3 items are used a score representing "satisfaction." The survey represents a tool that can be used as a screen for quality improvement by LTC facilities and the 3-item score could be used as a metric for public reporting.

A STUDY OF RE-EMPLOYMENT NEEDS AMONG SENIOR CITIZENS IN TAIPEI

S. Lin[1], T. Ho[1], B. Chang[1], Y. Kuo[2], *1. Chinese Culture University, Taipei, Taiwan, 2. National Taiwan Normal University, Taipei, Taiwan*

With the growing populations of older adults and the lengthened life expectancy, re-employment has been an opportunity for older adults to engage in social activities either with paid or unpaid jobs. The purpose of the study is to investigate the needs of re-employment and the influential factors among senior citizens in Taipei. The researchers surveyed participants (N = 528) who were 55 years old and above and enrolled in active aging learning centers in Taipei. The re-employment needs scale includes four dimensions which are financial needs, security, sense of belonging, respect, and self-actualizations. The data was analyzed with t-test and one-way ANOVA. The results revealed that the majority of the participants showed interest in re-employment (74.4%) and many would like to have paid jobs (41.45). Participants' needs of re-employment are strongly influenced by marital status (F = 3.01, p < .05), current work conditions (F = 2.99, p < .05), and re-employment work types (t = 2.58, p < .05). Even though age was not found to be associated with participants' re-employment needs, finical needs were found to be highly associated with age in particular (r = .10, p <.05). The findings suggest that senior citizens would consider entering the workforce after retirement when they remain active lifestyles and have adequate employment opportunities available to them. Future research might include variables, such as geographic and employers, to further discuss the possibilities of re-employment among older adults.

THE RELATIONSHIPS BETWEEN LEARNING NEEDS, PERCEIVED USEFULNESS, PERCEIVED EASE OF USE, AND LEARNING TRANSFER BEHAVIORS AMONG OLDER ADULTS WHO PARTICIPATING IN LIFELONG LEARNING COURSES IN TAIPEI CITY

Y. Kuo[1], S. Lin[2], B. Chang[2], *1. National Taiwan Normal University, Taipei, Taiwan, 2. Chinese Culture University, Taipei, Taiwan*

Older adults nowadays may enhance their abilities through lifelong learning to pursue interests, secure financial needs, and develop career planning after retirement. Learning institutions have been created to offer courses and activities for older adults to assist them become a part of the innovative human resources. The study aims to investigate older adults' learning psychology and behavior while taking lifelong learning courses in a community college in Taiwan. Further, the researchers examine the relationships between learning needs, perceived usefulness, perceived ease of use, and learning transfer behavior among these older adult learners. The researchers surveyed 381 older adults and used confirmatory factor analysis (CFA) and structural equation modeling (SEM) procedures to analyze the collected data. The results show that older adults' learning needs show positive and statistically significant explanatory power to the perceived usefulness and perceived ease of use (β =.79 and .78, $p < .05$), and which also show positive and significance to learning transfer behaviors (β = .37 and .49, $p < .05$). In addition, the perceived usefulness and perceived ease of use play a mediator role in the model, including the indirect but significant effect on the perceived ease of use (ES = .38, $p < .05$).The findings allows us to capture the complex relationships in adult learning behaviors as well as the mediator that contributes to adult learning. The researchers suggest that future study may explore adult learning psychology and behaviors in different settings to strengthen older adults' lifelong learning quantity and quality.

PREDICTORS OF PHYSICIAN SAFETY RATINGS OF MEDICALLY IMPAIRED OLDER DRIVERS

T.M. Meuser[1], M. Berg-Weger[2], D.B. Carr[3], S. Shi[1], S.D. Stewart[1], *1. Gerontology Graduate Program, University of Missouri - St. Louis, St. Louis, Missouri, 2. Saint Louis University, St Louis, Missouri, 3. Washington University, St Louis, Missouri*

State Departments of Motor Vehicles (DMVs) rely on the expert opinions of primary care physicians (PCP) and subspecialists when making licensing decisions for persons reported as medically unfit to drive. Little is known about the types of information and incremental judgments that influence physician decisions on safety. This study examined Physician Statements (N = 224) submitted to the Missouri DMV from 2009-2014. Drivers were 57% male and ranged in age from 50-101 years (M = 81). Most evaluation forms (78%) were completed by PCPs. A three level rating (likely safe, unclear, likely unsafe) was collapsed into two levels (0 safe, 1 unclear/unsafe) and entered as the dependent variable in a Binary Logistic Regression. Predictors included driver age, a recent safety incident (0 nothing, 1 pulled over or in crash), physician rating of driver compliance with past medical care (yes, somewhat, no), and a disease severity rating with respect to the driving task (five levels, unimpaired to severe). The model was significant ($p < .0001$; Nagelkerke R2 = .72) and three of four predictors yielded significant odds ratios (OR): preliminary severity rating (OR 8.6, $p < .0001$), past compliance with care (OR 3.1, $p < .05$), & age (OR 1.09, $p < .005$). While knowledge of recent on-road incidents may be relevant in the evaluation process, these findings suggest that physicians place greater weight on known clinical indicators when making a safety recommendation. Targeted education concerning the interplay between health, function and driving could further enhance physician input to the DMV.

GIVING BACK AND STAYING PUT: VOLUNTEERING AS A STABILIZING FORCE IN RELOCATION

H. Shen[1], T. Perry[2], *1. University of Missouri-St. Louis, School of Social Work, St. Louis, Missouri, 2. Wayne State University, School of Social Work, Detroit, Michigan*

Many older adults anticipate changing residences as an alternative to aging in place when remaining in one's home becomes unsafe or unmanageable. According to Wiseman's (1980) model of relocation, triggering mechanisms, such as push and pull factors, lead to decisions to relocate. Recent scholarship explores aging in community where older adults may change residences within their community. This study explores the relationship between volunteering in a community and relocation outside of one's community, as well as the possible mediating effect of social ties (friends or relatives living nearby) on such a relationship. Data utilized in the present study is from 2008 and 2010 Health and Retirement Study, which included 9,220 community-dwelling older individuals who were 65 years and older. Controlling factors of older people's financial resources, health, environment, and demographics, findings from logistic regression models show that volunteering significantly reduces the likelihood of relocating out of the area two years later. Using Baron and Kenny's (1986) four-step method, the relationship between volunteering and moving out of the area is partially mediated by having friends nearby. This study is innovative because it identifies a possible stabilizing mechanism important for understanding "protective" factors, such as volunteering, of relocation in the later life. Involving older people in voluntary activities could be considered a way communities can help older people age in place.

SOCIAL EXCLUSION IN LATER LIFE: A SYSTEMATIC REVIEW

S. Van Regenmortel, S. Dury, D. Brosens, L. De Donder, *Vrije Universiteit Brussel, Brussel, Belgium*

Most social exclusion research has been focussing on people with mental health problems, younger and mid-life adults. Conversely, little research has been performed concerning social exclusion and older adults. This paper gives an overview of research on social exclusion in later life. Using the PRISMA framework (Preferred Reporting Items for Systematic Reviews and Meta-analysis) a systematic literature review was performed. Relevant studies were identified through searches of databases (e.g. Web of Science & Sociological Abstracts) and bibliographies. Only studies specifically addressing social exclusion or inclusion among home dwelling older adults were incorporated. Because of the heterogeneity of the studies' methods; a narrative synthesis was conducted to review the findings. The review reveals that social exclusion in later life comprises various dimensions (e.g. material goods, social relationships and participation), with some dimensions focusing on later life (e.g. access to elderly services, ageism and neighbourhood exclusion), indicating that social exclusion differs throughout the life course. Research including a validated age specific measurement for social exclusion is scarce. Further, the review presents the drivers of later life social exclusion, in general and for each dimension. Furthermore, the review identifies a distinction between rural and urban context. The discussion highlights the main research gaps concerning social exclusion in later life and formulates four main paths for future research. Finally, a theoretical framework incorporating individual, life-course and contextual variables to build an age specific social exclusion measure is suggested.

BUILDING THE CAPACITY OF OLDER ADULTS TO ADDRESS ISSUES OF FOOD SECURITY IN RURAL COMMUNITIES

J. Crittenden, M.R. Noyes, D.C. Wihry, P.D. Foden, L.W. Kaye, *Center on Aging, University of Maine, Bangor, Maine*

This presentation identifies preferred strategies for successfully engaging older adult volunteer leaders in the growing food security movement in rural communities with an emphasis on employing specialized skill-building and technical support resources. Seventy-seven individuals (mean age: 66.5 years; age range 53-78 years) participated in six technical workshops intending to develop skills and increase knowledge in addressing food security issues through volunteerism. Pre-post surveys were used to measure changes in participant skill and knowledge enhancement levels. The greatest average knowledge increases (on a 10-point Likert scale) were: 1) Understanding the importance of training and orienting new volunteers (8.0 point increase); 2) Understanding the components of an advocacy plan and using a plan to support volunteer work (4.2 point increase); and 3) Creating effective messages to increase awareness of this issue (4.0 point increase). An analysis of the 25 community volunteer projects carried out by project participants reveals that the most common food security activities performed by older adult volunteers include: running food banks, developing community gardens, public education, and advocacy. Eleven participants utilized stipends to support certification through the Master Gardener's Program, to build raised garden beds, create a community event on self-sustaining agriculture, and enable basic upgrades for local food pantries. Additional self-reported training areas of particular importance include: preferred strategies for recruiting and retaining new volunteers, volunteer management, approaches for conducting grassroots outreach and building partnerships, and opportunities for networking with other older adult volunteers in the food security field. Project funding provided by the Elmina B. Sewall Foundation.

AGE COHORT DIFFERENCES IN PERCEPTIONS OF EXECUTIVE LEADERSHIP STYLE AMONG THREE SUBSTANCE ABUSE RECOVERY AGENCIES

D.C. Wihry, J. Middleton, L.W. Kaye, A. Mitchell, J. Crittenden, *UMaine Center on Aging, University of Maine, Bangor, Maine*

This poster examines age cohort differences in staff perceptions of executive leadership within three agencies providing substance abuse recovery and navigation services to rural Maine through use of the Multifactor Leadership Questionnaire (MLQ). The study sample consisted of employees (N=109) with a mean of 12.7 years of human services experience and a mean organizational tenure of 5.1 years. The sample was predominately female (86.1%) and Caucasian (93.6%), and had a mean age of 42.5 years. A dichotomous variable was created to compare 55+ and under 55 populations using an independent sample t-test. Of the nine subscales examining aspects of leadership style, the 55+ staff scored executive leadership significantly higher (based on a 5 point Likert scale) than the under 55 age group on three transformational leadership constructs: "idealized influence behavior (IIB)" (4.1 versus 3.8, p<.05), "inspirational motivation (IM)" (4.4 versus 4.0, p<.05), and "individualized consideration (IC)" (3.6 versus 2.9, p<.005). The 55+ age group scored executive leadership significantly higher on the transactional leadership construct of "contingent reward (CR)" (3.6 versus 3.0, p<.005). A statistically significant but negligible (.197, p<.05) positive correlation was found between tenure and the IIB subscale. Significant differences were detected between supervisors/upper management and direct service staff on the CR (3.7 versus 2.8, p<.001) and IC (3.5 versus 2.9, p<.01) subscales, indicating position may be a confounder when examining leadership perception by age. Limitations, next research steps, and implications of findings for interpreting potential influence of employee age in predicting staff attitudes about executive leadership are addressed.

PRINCIPLES OF PRACTICE FOR REACHING AND ENGAGING OLDER ADULTS IN SOCIAL AND EDUCATIONAL ACTIVITIES THROUGH NONTRADITIONAL SENIOR CENTER PROGRAMING

D.C. Wihry, A. Davidoff, L.W. Kaye, J. Crittenden, *UMaine Center on Aging, University of Maine, Bangor, Maine*

This poster examines principles of practice for reaching and engaging older adults in social, health, and educational activities through nontraditional senior center programming that does not rely on a dedicated, fixed site facility. In 2013, eight community focus groups were held in three rural Maine towns bringing together community members (N=69) including residents of a retirement community, existing seniors centers, and other community stakeholders. Participant ages ranged from 55 to 92 years; 84% were female. Focus group analysis utilized the Constant Comparative Method. Findings indicate that while desired services offered by a senior center are often recreational in nature, there is also interest in having easy access to medical and social services to support community living including health care, retirement and wellness planning resources, and legal assistance. Themes also emerged reinforcing the desire for one-day classes and day trips. Considerations for ensuring the attractiveness of senior center programming include: 1) creating variety in the timing and sequencing of program offerings; 2) establishing sliding scale and subsidized participation fees; and, 3) ensuring that programming is accessible and addresses common travel and mobility barriers in rural communities. Transportation was a frequent theme across all focus groups, with participants identifying bus system navigation, parking, and a general lack of transportation as barriers to accessing and utilizing senior center activities. This poster will also highlight findings related to preferred strategies for supporting intergenerational activities, engaging a variety of stakeholders in senior center design and development as well as marketing startup programming.

FACTORS ASSOCIATED WITH FUNCTIONAL DECLINE AMONG OLDER ASSISTIVE DEVICE USERS IN THE COMMUNITY

L. Peterson[1,2], H. Meng[1,2], K. Hyer[1,2], *1. University of South Florida, School of Aging Studies, Tampa, Florida, 2. Florida Policy Exchange Center on Aging, School of Aging Studies, Tampa, Florida*

Assistive devices are important in helping older adults continue to function in the community despite the onset of disabilities. Using two waves of the National Health and Aging Trends Survey (NHATS), we examine factors associated with functional decline among a group of older adults who lost the ability to successfully accommodate their disabilities, despite continued device use over one year (2011-2012). The sample includes 3,315 community-dwelling adults who reported using a device and had no difficulty functioning in 12 ADL and IADL tasks in 2011. By 2012, 14% of these respondents reported having difficulty in at least one ADL or IADL while still using a device. Descriptive statistics show that 68% of them were female, 36% were married or living with a partner; and 71% had been diagnosed with three or more chronic conditions. A logistic regression model was used to identify factors associated with the change in functioning. We found that controlling for factors including frailty symptoms, gender, and cognition, hospitalization was associated with 37% increased odds of functional decline among device users (CI 1.08-1.74, p=.009). Other factors associated with device accommodation loss included being 85 and older (OR=2.35, CI 1,58-3.51) and worse self-reported health (OR=1.14, CI 1.00-1.29). These results confirm that there is a substantial group of older device users who lost the ability to accommodate their functional decline over one year, and that hospitalization has a large independent impact on disability and the compensatory ability of assistive devices.

IMPACT AND BARRIERS OF LEARNING COMPUTERS AND INTERNET AMONG SENIORS IN COMMUNITY CENTERS

S. Wu[1,2], F. Li[1], H. Jin[1], *1. University of Southern California, Los Angeles, California, 2. RAND Corporation, Santa Monica, California*

Purpose. Computers and Internet are promising technology to assist older people in improving their livelihood. This study assesses the value and impact of learning such technology in public service settings and determines the main barriers among both program participants and nonparticipants. Methods. A mixed-methods evaluation of the San Francisco's Broadband Technology Opportunities Program (BTOP), which provided free access to computers and Internet in community centers for seniors, and offered volunteer-led training courses and one-on-one tutoring. The two-part evaluation included: (1) a sample of 487 seniors from 40 community centers completed a survey, and (2) 119 seniors plus center staff and BTOP instructors participated in focus groups at 10 centers. Data triangulation was applied for analysis. Study population: The population has diverse race/ethnicity background; 68% were computer users. Results. The BTOP program has significantly increased seniors' access to and confidence in using the technology. The program impacted their' lives mainly in less isolation and more connected with family, friends, community, and the world. The technology made their lives more interesting through recreational activities, social contacts, and new knowledge. The main barriers of learning computers, for both users or nonusers, are their concerns about eyesight and their limited capabilities in various computer-related skills. Program staff and volunteers play a significant role in encouraging participants to learn how to use computers and access the Internet. Conclusion: An organized, low-cost community-run computer program may effectively help seniors overcome social isolation and learn skills to manage and improve personal life for healthy aging.

SUCCESSFUL AGING AND ITS DISCONTENTS: A SYSTEMATIC REVIEW OF THE SOCIAL GERONTOLOGY LITERATURE

M. Martinson[1], C. Berridge[2], *1. San Francisco State University, San Francisco, California, 2. University of California, Berkeley, Berkeley, California*

For over two decades, researchers in aging have grappled with the ways in which successful aging models have failed to capture the personal, social, economic, and political contexts of aging. Nevertheless, successful aging models hold a prominent position in research, policy, and practices in aging and health. The purpose of this study was to analyze the range of critiques of successful aging models and the suggestions for improvement within the social gerontology literature. We conducted a systematic literature review of journal articles retrieved from Abstracts in Social Gerontology, published 1987-2013, that included critiques of successful aging models. Qualitative methods were used to identify key themes and inductively configure meanings across the range of critiques. The critiques and remedies fell into four categories. The Add and Stir group suggested a multidimensional expansion of successful aging criteria and offered an array of additions. The Missing Voices group advocated for adding older adults' subjective meanings of successful aging to established objective measures. The Hard Hitting Critiques group called for just and inclusive frameworks that embrace diversity, avoid stigma and discrimination, and intervene at structural contexts of aging. The New Frames and Names group presented alternative ideal models often grounded in Eastern philosophies. The vast array of criteria that gerontologists collectively offered to expand Rowe and Kahn's original successful aging model is symptomatic of the exclusionary nature of a normative model. There is ample evidence to suggest that greater reflexivity and reflection about the concept "successful aging" and its ramifications are needed.

EMPOWERMENT THROUGH ACTIVISM: SENIORS IN URBAN CONTEXT

A. Domaradzka-Widla, *Institute for Social Studies, University of Warsaw, Warszawa, Poland*

Poland underwent rapid political and economic transition during last 25 years. This transition took a toll on society as a hole, but also generated new opportunities for different social groups. As World Values Survey data show, one of the biggest beneficiaries of those opportunities are seniors living in big cities, who in recent years became a driving force behind a blossoming neighborhood movement. This grassroots' activism is especially important as it provides social networks that were shown to be a compensatory mechanism increasing wellbeing of elderly (Antonucci & Ajrouch, 2007). Using data from WVS 2005 and 2012, I analyze how levels of altruism and activism of the elderly changed during last decade in Poland, in the specific context of low interpersonal trust but raising willingness to act together for the sake of those in need or to solve problems of local environment. I show how these changes depend on age, gender and family situation as well as socio-economic status. Here, my results indicate, that especially in case of women aged over 55, we can observe a significant increase in their collective efficacy beliefs. To further illustrate the trend of growing elderly activism, I analyze qualitative data obtained from several case studies of local initiatives in various Warsaw neighborhoods. In all, the results indicate that elderly in Poland, and especially women, see increased opportunities for collective solutions of local problems. This is further corroborated by the fact that they are becoming a driving force behind neighborhood change in Polish cities.

SESSION 1685 (POSTER)

COMMUNITY PLANNING, HOUSING AND ENVIRONMENTAL DESIGN

THE EFFECT OF DINING ROOM RENOVATIONS ON RESIDENTS' DINING EXPERIENCES AND STAFF PRACTICES IN LONG-TERM CARE FACILITIES

H. Chaudhury[1], L. Hung[2], T.B. Rust[3], *1. Gerontology, Simon Fraser University, Vancouver, British Columbia, Canada, 2. Providence Healthcare, Vancouver, British Columbia, Canada, 3. University of Alberta, Edmonton, Alberta, Canada*

The physical environment of dining rooms in long-term care facilities is increasingly recognized to have an important role in providing a functionally effective and socio-psychologically pleasurable mealtime experience for residents. This study examined the effect of dining room renovations on residents' mealtime experiences and staff practices in two units of a large long-term care facility in Edmonton, Canada. A mixed-methods approach was used, utilizing ethnographic observations, staff survey and focus group interviews in the two units pre- and post-renovations. The newly developed Dining Environment Assessment Protocol was used to conduct a systematic evaluation of the overall dining room environment of the care units. Both structured and open-ended observations of mealtimes were conducted using a checklist of behavioral categories and qualitative field notes. Purposive sampling was used to select residents with variable abilities and challenges for observations. Key staff groups, i.e., nursing, care aide, food service aide, were surveyed on the effect of environmental changes on residents' dining experience and staff-resident interactions. Preliminary results indicate that: (a) residents and families highly value the addition of an open kitchenette in the dining room that facilitates residents' autonomy, (b) residents spend more time in dining room for social interaction after the renovations, (c) new staffing model allows nursing aides to spend more time with residents. The findings provide evidence of the importance of physical environmental features, as well as the integral nature of the physical environment and organizational support to provide an effective and meaningful dining experience for residents in long-term care.

PERCEPTION OF RISK FOR RURAL OLDER PEOPLE: CASE STUDIES FROM AUSTRALIA, IRELAND AND NORTHERN IRELAND

J. Warburton[1], T. Scharf[2], K. Walsh[2], *1. John Richards Initiative, La Trobe University, Wodonga, Victoria, Australia, 2. National University of Ireland, Galway, Ireland*

In the current demographic environment, rural communities across the world are likely to be populated by older people, yet there is growing evidence that this group is increasingly at risk of geographic and social isolation. Risk factors for these populations include financial disadvantage, widowhood, not driving, and poor health or disability. Despite this increased need, local services are difficult and costly to provide in rural areas. In this paper, we explore issues of risk and vulnerability facing older people living in rural communities across three diverse countries. Data is drawn from 128 semi-structured interviews with older community residents and key stakeholders, located in thirteen case study sites across Ireland, Northern Ireland and north-east Victoria, Australia. Findings build on the known challenges and risks of rural aging, and suggest that the risk environment is much more complex than previously thought. First, some individuals face extended risk through multiple risk factors. This includes rural newcomers whose risk may be compounded by other factors such as loss of driving ability, poor health or loss of partner. Second, a lack of services has led some communities to rely on a strong social and volunteer environment. Whilst choice is core for risk environments, participants highlight the individualisation of risk for those who choose to live in marginalised or isolated environments or who choose not to be part of the social environment. Overall, these findings suggest a much more complex and multi-dimensional reality facing the growing number of people aging in rural places.

DISASTER, BUREAUCRACY, AND RESCUERS: NARRATIVES OF LOCAL FIRST RESPONDERS TO PROVIDE AID FOR LOCAL AGED IN THE GREAT EAST JAPAN EARTHQUAKE

M. Shimmei[1], Y. Shiomitsu[2], H. Kodama[1], Y. Sugawara[1], H. Mori[1], T. Ishizaki[1], R. Takahashi[1], *1. Tokyo Metropolitan Institute of Gerontology, Itabashi, Tokyo, Japan, 2. Tokyo University of Technology, Ota, Tokyo, Japan*

The Great East Japan Earthquake that occurred on 11th of March 2011 revealed certain vulnerabilities in the modern social systems in place. Life conditions of elderly were directly affected by the inability of the modern social system to provide support during this and other catastrophic incidents. To understand what happened at the initial stage of the natural disaster to the local elder residents, we collected narratives from 21 local first responders about vulnerable residents in two different municipalities. These municipalities were directly affected by the earthquake and either consecutive Tsunami or nuclear plant accident. We employed thematic narrative analysis (Riessman, 2008) in order to examine how institutional and structural boundaries of administrative regions affect the lives of the vulnerable residents. Tentative results of narrative analysis show that responders were affected by "the existing national elder care system," "amalgamation of municipalities," and "available resources" when acting to rescue elderly. The result exemplifies that responders had to adapt to dysfunction in the "chain-of-command structure" of modern bureaucracy and an unpreparedness by local authorities by synthesizing their professional ability with affronted realities, improvising with fragmented social and material resources to provide aid.

SOCIOECONOMIC PREDICTORS OF INFORMAL CAREGIVING AMONG MIDDLE AGED AND OLDER ADULTS: A COMPARATIVE STUDY BETWEEN THE U.S. AND CANADA

Y. Lee[1], K.A. Zurlo[2], *1. Faculty of Social Work, University of Calgary, Calgary, Alberta, Canada, 2. School of Social Work, Rutgers, The State University of New Jersey, New Brunswick, New Jersey*

Canada and the US are liberal welfare states with growing older adult populations. Government provision of health care in each country is challenging to lawmakers, specifically as it relates to long-term care. Due to the expense of long-term care, informal caregiving is an option that many families undertake, but little empirical evidence explores the characteristics of family caregivers and predictors of providing care to older relatives in Canada and the US. This study examines factors that predict the provisioning of informal care to middle aged and older persons with physical, mental or cognitive impairment. We used the Canadian Community Health Survey – Healthy Aging 2009, a cross-sectional survey of persons aged 45 and over living in private dwellings in the ten provinces (N= 30,865) and the U.S. Health and Retirement Study 2006 (N= 36,987). Results from logistic regression indicated that being female, younger, married, highly educated, non-immigrant, non-white, less healthy, and having higher personal income significantly predicted the provision of informal care in Canada. Whereas, in the U.S. being female, older, highly educated, non-white, and having lower personal income significantly predicted the provision of informal care. This study suggests that there are distinct differences in the predictors of informal caregiving in each country. We conclude with recommended policy initiatives that can maximize incentives to provide informal care in Canada and the US.

IDENTIFYING THE MOST VULNERABLE CHINESE ELDERLY

T. Kong[1,2], P. Yang[1], *1. Peking University, Beijing, Beijing, China, 2. Australian National University, Canberra, Australian Capital Territory, Australia*

China faces a massive and rapid demographic change. The number of people aged 60 and above currently stands at 185 million. It is estimated to reach 330 million in 2050 accounting for 34% of the total Chinese population. Traditionally, adult children are the primary source of care for the elderly. However, decline in the number of children, enhanced life expectancy and increase in labour mobility have led to a situation where 46% elderly live either alone or with spouse only. Meanwhile, about 50% of those who live without their children, are incapable of performing basic daily activities without external assistance. In the absence of a developed social security system, these elderly are arguably the most vulnerable group of the aging population. This paper employs data from the China Health and Retirement Longitudinal Study (CHARLS), the only dataset available that is representative of the Chinese population aged 45 and above. We first identify this group of most vulnerable elderly and then investigate the demographics, the social-economic characteristics as well as the access to social and informal assistance. We also analyze the underlying factors of their overall wellbeing, encompassing both the quality of physical life and their mental and psychological state. Preliminary analyses demonstrate that the wellbeing of elderly correlates significantly with their age, gender, rural-urban status, SES and household composition. The interplay between the living arrangement of these elderly and their health status is complex. We conclude with suggestions as to how policies can better target and assist these disabled and isolated elderly.

VIRGINIA'S LIVABLE HOME TAX CREDIT FACILITATES ACCESSIBLE HOUSING COMMUNITIES FOR AGING IN PLACE

M.H. Parker, *Institute for Palliative & Hospice Training, Inc., Oakpark, Virginia*

Only by creating housing in new commercial developments, which is accessible and accommodating to the aging of homebuyers, will true "aging in place" be achieved. Gaining support from the commercial housing industry for visitable/accessible housing has been difficult. In 2004, advocates for aging-in-place gained support of the Virginia Legislature to create The Livable Home Tax Credit Program, providing funds of $1 million for tax credits to owners of homes, who make specified accessibility improvements, and to buyers of new homes that meet more extensive requirements. As a "housing stimulus" effort in 2011, the Virginia Homebuilders Association actively supported legislation to increase the Livable Home Tax Credit to $5,000 per application and permit housing contractors to apply for the tax credit. This "Golden Carrot" encouraged Virginia Contractors and Commercial Homebuilders to more actively develop and market Livable accessible homes and developments. Tax credit awards increased from $197,476 in 2010 to $884,571 (2012) an average of $4,232 per award. Individual homeowners or new homebuyers received, $569,571, representing approximately 135 homes, and $315,000 to contractors or commercial homebuilders, representing construction of over 70 accessible homes Dr Parker will outline Tax Credit guidelines and discuss how the Tax credit as an incentive changed attitudes of the Homebuilding Industry from opposition to interest in creating accessible housing. Data will be presented from interviews with homebuilders, realtors and owners/purchasers of accessible homes. The presentation will provide pictorial examples of accessible housing in new housing developments and of commercial housing developments replicable in other States or localities.

THERAPEUTIC LANDSCAPES THROUGH THE LIFE COURSE: IMPACT OF GREEN AND BLUE SPACE ON OLDER ADULTS

J. Finlay[1,2], T. Franke[2], J. Sims-Gould[2,3], *1. Geography, University of Minnesota, Minneapolis, Minnesota, 2. Centre for Hip Health and Mobility, Vancouver, British Columbia, Canada, 3. University of British Columbia, Vancouver, British Columbia, Canada*

Nature plays an influential role in the everyday lives of many older adults. This paper draws on interview data from older adults who described their enjoyment of and rejuvenating experiences with nature (both "green" and "blue" spaces) across Greater Vancouver, Canada. Blue and green spaces represent affordable and accessible therapeutic landscapes that can be applied to everyday pursuits of mental, physical, and social health for a diversity of older adults. Though scholarship to date predominantly focuses on salutary effects of green space, blue space also encompasses important therapeutic qualities. Participants felt motivated to get out of the house to exercise and enjoy the fresh air (e.g. walking, gardening, swimming, and hiking). These landscapes promoted mental health and sense of wellbeing, in which experiences of nature provoked feelings of renewal, restoration, and rejuvenation. They also provided a space for social interaction and engagement, including planned activities with friends and families, and impromptu social engagements with neighbours. The findings indicate that is important to preserve and construct natural environments to contribute to vibrant healthy communities for older adults (in particular) and people of all ages. Strategies have yet to maximize nature as a health resource for older adults, including the benefits of nature contact as an upstream health promotion intervention. Understanding how older adults experience health and landscape is critical towards developing everyday contact with nature that can improve quality of life for aging populations.

TASK SHARING IN CAREGIVER NETWORKS

E.M. Agree[2,1], T. Wakui[3,1], *1. Population, Family, and Reproductive Health, JHSPH, Baltimore, Maryland, 2. Johns Hopkins University, Baltimore, Maryland, 3. Tokyo Metropolitan Institute of Gerontology, Tokyo, Tokyo, Japan*

Research has shown pronounced differences by relationship, gender, and distance in the help that caregivers provide. Families also tend to negotiate responsibilities for support, especially among siblings, and task specialization often follows gender lines. Decades of change in marriage, divorce, and cohabitation have resulted in diverse support networks for aging individuals. The capacity of these changing families to provide care for older persons with chronic disabilities is not known. Moreover, research has been limited by a longstanding focus on "primary" caregivers. This study uses nationally representative data from the new National Health and Aging Trends Study (NHATS) to examine how caregivers work alone or share tasks. NHATS includes detailed performance and self-reported disability measures, as well as information on families, social networks, and helpers who assist with self-care, mobility, household, and medical care tasks. Models are used to examine characteristics associated with the propensity of caregivers to work alone or to share tasks with others, controlling for shared family characteristics, and the health needs of the older person. Results show the majority are sharing with other caregivers (70%) though almost one-third are the only caregiver, and a small number (about 5%) provide help alone even though there are other caregivers. Spouses are more likely to be solo caregivers and children more likely to share tasks. Stepchildren are minimally involved in care to their stepparent and when they provide care they are more likely to act as a "backup," sharing a single task with other helpers.

DETERMINATION OF GRAB BAR SPECIFICATIONS FOR INDEPENDENT AND ASSISTED TOILET TRANSFERS

J.A. Sanford[1], M. Calkins[2], *1. CATEA, GA Tech, Atlanta, Georgia, 2. IDEAS, Inc., Kirtland, Ohio*

Several studies as well as standards of practice indicate that "ADA" (Americans with Disabilities Act) requirements for a fixed grab bar on the wall 16"- 18" from the centerline of the toilet does not meet the needs of seniors or their caregivers. However, there is little evidence upon which to base changes to these guidelines. The purpose of this project is to identify grab bar dimensions that support independent, and one- and two-person assisted toilet transfers. The study involves a three-phased design to identify preferred dimensions, determine biomechanical efficacy of optimal dimensions and field-test optimal configurations. This presentation reports the results of Phase 1, in which 77 residents, 30 males and 47 females from 6 residential care facilities in the Atlanta and Cleveland used 3 different configurations (typical ADA dimensions, bilateral swing-up grab bars at ADA dimensions, and bilateral swing up bars at user-defined dimensions). Regardless of transfer type (independent vs assisted), the preferred configuration included a fixed grab bar on the side wall at mean distance of 24" from the centerline of the toilet as well as swing up bars on both sides of the toilet located at average distances of 13"-14" from the centerline. For all transfers, both residents and staff gave significantly higher ratings of safety, helpfulness and ease of use to the user-determined configuration (p=.000 - .005), except staff help for 1 person assists (which approached significance at .053). These dimensions, + 1" will be the basis for the Phase 2 biomechanical testing.

LIGHTING METRICS LIMITATIONS FOR DESIGNING TRANSITIONAL SPACES: OLDER ADULTS WITH VISION IMPAIRMENTS

V. Gowda, K.A. Roberto, J. Jones, *College of Architecture and Urban Studies, Virginia Polytechnic Institute and State University, Blacksburg, Virginia*

The onset of vision impairments can depreciate the physiological, psychological and social wellbeing of older adults. Quality and the quantity of lighting in the surrounding indoor environment can have beneficial or detrimental effects on the user's visual functioning. This study examined the potential drawbacks in the current lighting standards and procedures adapted for designing transitional spaces, particularly for older adults with loss of central field of vision (i.e., Macular Degeneration). An immersive case study of an entrance lobby was used to generate simulations of design alternatives demonstrating efficient light adaptation in transitional spaces. Current lighting standards and metrics on glare and luminance ratios were used to generate the design alternatives that fulfilled the lighting requirements for persons with normal vision, older adults, and person with vision impairments respectively. The analysis of the alternatives demonstrated a lack of lighting standards and data to access the appropriate lighting requirements for older adults with different types of vision conditions, suggesting the need to alter the current design process in such a way that the designers have a better understanding on how older adults with visual limitations perceive spaces. Using computer based vision simulators early design phases is the first step toward framing new lighting design guidelines for older adults with Macular Degeneration and other impairments. Findings suggest the importance of future research collaborations between experts from different disciplines, including architecture, vision sciences, and gerontology, and concerned users to identify appropriate lighting design standards for older adults with vision impairments.

VISIONS FOR TOMORROW: THREE INTENTIONAL COMMUNITIES FOR RURAL SOUTHWEST VIRGINIA

N. Brossoie, *Center for Gerontology, Virginia Tech, Blacksburg, Virginia*

Housing in rural southwest Virginia is aging just like its population. Approximately 70% of homes in the region are more than 30 years old, energy inefficient, and in need of repair. Like many older persons, area residents want to age in place and are looking for ways to achieve that goal. In conjunction with a local livability initiative, local architects, building contractors, aging service providers, community planners, housing professionals, academics, and community members participated in a half day workshop to discuss the meaning of aging in place and to design new intentional communities with new housing options for the regions' rural, suburban, and urban areas. The three intentional community designs highlighted in this presentation feature new single and multi-family homes built within the scope of current community infrastructure and resources and with accessibility features inside and outside the homes. Homes include some rentals and low income units. Communities provide private and common areas for community members. Each community design took advantage of local geography and integrated concepts identified as important to residents including independence, self-reliance, and prosperity; social networking opportunities; proximity to local businesses; and protecting rural character, the natural environment, and scenic beauty. Next steps include vetting designs to city planners, contractors, elected officials, and the community.

BIOPHILIC DESIGN OF GREEN BUILDINGS FOR THE SENIOR POPULATION: REPORT OF A HYPOTHESIS-GENERATING SURVEY OF EXPERTS

J. Hyde, M. Jack, *Gerontology, UMass/Boston, Boston, Massachusetts*

For the last twenty years LEED™ certification has encouraged the development of "Green" buildings that achieve "sustainable site development, water savings, energy efficiency, materials selection, and indoor environmental quality." At the same time "culture change" has focused on "biophilic design" - a very different kind of "green building," which supports person centered care by fostering connections to the natural world - light, air, animals, gardens. This paper reports on interviews with architects, researchers and long term care providers regarding the potential advantages and limitations of LEED™ certified Green design with respect to the quality of life and health for elders living in long term care settings. In particular the researchers seek to understand the impacts of sustainable buildings on relevant user outcomes, such as autonomy and accessibility. A grounded theory approach will be used to develop hypotheses that will be tested in future research in this important new area.

ELDER DISASTER PREPAREDNESS – PAST, PRESENT AND FUTURE

C. Rokusek, *Nova Southeastern University, Ft. Lauderdale, Florida*

Preparedness for vulnerable population groups, most especially elders, has been a focus of both the Federal Emergency Management Agency (FEMA) and the Department of Homeland Security in the past three years. Initiatives at the local, state and national levels have resulted in innovative and informative training programs and educational materials. Even with the targeted attention to preparedness for elders, studies have shown that: 1) elders do not often plan for disasters for the long term and are slow to register for disaster assistance (Rokusek, 2013 and AOA, Oct. 2001); 2) elders with several co-morbidities are at most risk during and following disasters (Aldrich, Benson, 2008); 3) elders are more prone to suffer health-related consequences as a direct result of a disaster and to require longer recovery periods for these problems (Morror, 1999); 4) environmental changes post disaster can significantly impact individuals with Alzheimer's and other related dementias (NIH, 2001); 5) elder stress related to disaster impact may increase causing irregular eating and decreased adherence to medication schedules (AOA, Oct. 2001); and 6) communities do not always give elders the attention needed post disaster (Hurricane Katrina, Times-Picayune, August 30, 2005). This paper will summarize a 20 year meta-review of the literature on disaster preparedness for elders. Clustered findings focused on 1) overall elder personal preparedness; 2) chronic diseases and disabilities; 3) community response to elder preparedness and recovery; 4) elder resilience post disaster; 5) dementia preparedness; 6) social factors in elder preparedness will be presented with outlined challenges for the future.

ASSESSING THE BASELINE AGE-FRIENDLINESS OF A COMMUNITY: AN EXAMPLE OF LONDON, ONTARIO, CANADA

M. Dellamora[1,2], A.A. Zecevic[1], D. Baxter[2], A. Cramp[1], D. Fitzsimons[1], M. Kloseck[1], *1. University of Western Ontario, London, Ontario, Canada, 2. City of London, London, Ontario, Canada*

In response to the challenges of demographic aging, London, Ontario, became the first city in Canada to join the WHO Global Network of Age-Friendly Cities. One of the first milestones for Network members is to assess the baseline age-friendliness of the community. The objective of this study was to assess the baseline age-friendliness of London, Ontario using a quantitative survey methodology. Questionnaires were completed by 676 older adults age 55 and older. Respondents came from 16 of the 17 postal code regions in the city. Survey results are presented according to the eight domains of age-friendliness, with each domain assigned a score on a scale from 0 to 5. Domain scores ranged from 2.5 to 3.6, indicating an overall age-friendliness of London somewhere between fair and good. Based on the scores of individual question items, priority areas were identified in each of the eight domains of age-friendliness. These areas include issues such as the need for more public washrooms, availability of affordable, quality housing, better access to information, and availability of quality mental health care. The survey results have informed implementation of the Three Year Action Plan of the Age Friendly London Network. Specific recommendations have been made to address areas that need particular attention in the ongoing work of the Age Friendly London Network. This study offers unique example of quantitative survey implementation for assessment of age friendliness that many communities around the world are striving for.

PATHWAYS TO SAVING FOR RETIREMENT IN MIDLIFE: THE ROLE OF INCOME AND SOCIAL SUPPORT

B.A. Baca, *University of Kansas, Lawrence, Kansas*

Reliance solely on Social Security for income in old age is often not adequate for meeting basic needs for housing, food, and rent. Accumulation of retirement assets is a viable option for supplementing income, but saving is frequently limited among those with lower incomes. Prior research has identified many individual level and structural factors affecting retirement savings. However, the role of financial strain and financial support offered by an individual's social network has been largely ignored. Using two waves of the Health and Retirement Study (2006, 2010), I examine the relationship between informal supports and income on the retirement plans and retirement account ownership of individuals nearing retirement using structural equation modeling. For individuals aged 53 to 58 in 2006, social networks that include the exchange of financial resources negatively impact saving behavior and retirement planning intentions. Individuals who provide financial resources to others are less likely to have retirement savings and those who can depend on others for financial assistance are also less likely to save. These findings point to the need for raising the asset base of entire social networks and not just individuals. The financial needs of others can be a major limitation in setting aside money for retirement and the urgency of saving and planning are lessened by the availability of network members who can provide financial resources when needed. Understanding the role of social networks could lead to new approaches to increasing assets and to improving financial well-being in retirement.

PLANNING A COMMUNITY'S AGING SERVICE NEEDS: ASSETS, CHALLENGES, AND SOLUTIONS

L.M. Quijano, E.K. Dakin, *School of Social Work, Colorado State University, Fort Collins, Colorado*

Purpose: The rapidly changing demographics in the United States present a challenge for communities to proactively plan for their growing older adult populations. To help inform the 2010-2014 strategic plan for a local Area Agency on Aging, a series of community focus groups was held with the goals of identifying assets, challenges, and solutions relative to community aging services needs. Methods: Four focus groups were held with a total of 24 older adults and leaders from the community's aging services, government, business, and faith-based sectors. A semi-structured interview guide was developed for the focus groups. All focus groups were digitally recorded and transcribed. A template analysis (King, 2004) was performed on the transcribed data by two independent coders, and aided by the use of the qualitative data analysis software NVIVO. Results: Data analysis revealed common themes across all four of the focus groups. In this presentation, we report on major themes and codes related to community assets, challenges to the community's aging services needs, and existing community resources that may be leveraged as solutions to these needs. Conclusion: Effective planning for a community's aging services needs requires participation and buy-in from community leaders and older adults themselves. This study provides a valuable exemplar of such an approach that other communities may use.

SESSION 1690 (POSTER)

DEMENTIA, COGNITIVE WELL-BEING AND CAREGIVING

CHANGING HEARTS AND MINDS: NEUROCOGNITIVE ENGAGEMENT (NET) THERAPY AND THE CHALLENGE OF ENGAGING REHABILITATION THERAPISTS IN A NEW CONCEPTUAL MODEL SERVING INDIVIDUALS WITH DEMENTIA

K.O. Carney[1], J. Howanitz[1], A. Donlan[1], M.K. Malek[2], P.A. Lichtenberg[3], *1. Phoebe Ministries, Allentown, Pennsylvania, 2. DeSales University, Center Valley, Pennsylvania, 3. Wayne State University, Detroit, Michigan*

Inspired by the recognition that many short term rehabilitation clients present with some level of cognitive impairment, but the therapists who work with them often feel ill-prepared to address the special challenges presented by this population, Phoebe Ministries, a long term care provider, developed a new conceptual model for delivering rehabilitation services to clients with neurocognitive impairment. The model, called Neurocognitive Engagement Therapy (NET), blends best practices in person centered dementia care with best practices in physical, occupational and speech therapy. NET incorporates cognitive and functional assessment to drive clinical decision making; structuring the therapy environment to support attention and engagement; and use of traditional psychosocial dementia care approaches, such as life history, use of familiar and meaningful activities, sensory stimulation and technology to increase participation in therapeutic activities. In an initial trial of the conceptual model, NET was implemented by 6 therapists from OT, PT and Speech who provided services to individuals with mid to late stage dementia over the course of 6 months. A weekly group review process explored challenges to adoption and implementation of NET by the therapists. This presentation will describe the insights derived through the therapists' experiences, including identification of therapist training and mentoring needs, differences between disciplines in the ability to embrace the new practices and the operational challenges of implementing change within the constraints of an active rehab department. Insights gained have subsequently been incorporated into an enhanced model that is currently under investigation through a formal study in conjunction with academic partners.

MISSOURI QUALITY INITIATIVE (MOQI) FOR NURSING HOMES: LINK TO PALLIATIVE CARE

C.M. Galambos[1], M.J. Rantz[2,3], J. Starr[2], M.K. Flesner[2], L.L. Popejoy[2], G.F. Petroski[3], C. Crecelius[2], *1. School of Social Work, University of Missouri, Columbia, Missouri, 2. University of Missouri Sinclair School of Nursing, Columbia, Missouri, 3. University of MissouriBiostatistics and Research Design Unit, School of Medicine, Columbia, Missouri*

The Missouri Quality Initiative for Nursing Homes is an intervention for long stay Medicare-Medicaid enrollees to reduce the frequency of avoidable hospitalizations. Using an interdisciplinary team, the model places an advanced practiced registered nurse (APRN) in each participating nursing facility (NF), and the APRN is supported by an MOQI intervention team. Palliative care activities in the initiative include: (a)increased discussions about end-of-life care in the facilities, (b) education and training about advance directives, end-of-life-care for NF staff, residents, and families, (c) improved communication in care transitions to ensure advance directive documents are known to sending and receiving facilities, (d) move toward normalizing discussions about advance directives and resident care choices within NF operations, and (e) contribute to public dialogue and understanding about advance directives and advance care planning To support palliative care activities, and to obtain baseline information, this study conducted a content analysis of 1877 resident records in 16 nursing facilities to review advance directive documents. The charts were reviewed by an APRN researcher under the guidance of a senior faculty member. Information was recorded on an excel spreadsheet developed by content experts. Data was uploaded into SAS and analyzed. The analysis included an examination of the frequency of identified health care choices, completeness and accuracy of existing advance directives, and number and type of appointed agents. Specific findings will be highlighted. Results may be used to: (a) inform SNF policies and procedures (b) plan education and discussion activities (c) support caregivers and appointed agents.

TIME COMPARISON OF HOME-BASED AND INSTITUTIONAL CARE MANAGEMENT ACTIVITIES IN JAPAN

K. Kageyama[1], Y. Sawada[2], M. Kunisada[3], H. Ishida[4], H. Sumii[3], M. Ono[1], Y. Inada[5], *1. Human Welfare, Kyushu University, Fukuoka, Japan, 2. Nihon Fukushi University, Nagoya, Japan, 3. Prefectural University of Hiroshima, Mihara, Hiroshima, Japan, 4. J. F. Oberlin University, Tokyo, Japan, 5. Hiroshima Cosmopolitan University, Hiroshima, Japan*

A self-report time study of care management services provided to long-term care insurance recipients by home-based care managers (HBCMs) and institutional care managers (ICMs) in Japan was conducted to examine and compare the time taken to accomplish a care management task. Participants were 343 ICMs and 373 HBCMs (79.7% female), who were asked to record start and end time as well as the types of their activities performed on timesheets using the "Social Work Codes." The mean ages of participants were 39.91±10.4 and 41.59±10.03 in ICMs and HBCMs groups, respectively. Nearly three-quarters (74.3%) of ICMs and more than half (54.7%) of HBCMs hold the dual positions of care manager and nursing assistant. One-seventh (14.3%) of ICMs and more than one-quarter (27.6%) of HBCMs hold the dual positions of care manager and social services designee. The average number of years of work experience in the fields of nursing and social services were 15.25 and 14.5 in HBCMs and ICMs groups, respectively. For ICMs, the longest total amount of time was reported for "indirect activities (e.g., documentation and travel time)" (106.3±75.8 min), followed by "development of care plans" (104.8±74 min), and "other tasks (e.g., break time)" (88.9±58 min). For HBCMs, the longest total amount of time was reported for "indirect care" (174.8±86.8 min), followed by "development of care plans" (108±74.2 min), and "consultation" (34.5±40.6 min). The results suggest that it is important to change their work environment and transform the way they work to provide better care management.

SUBSTITUTION OF PROFESSIONAL CARE BY INFORMAL CARE: MYTH OR MUST? EVALUATION OF GOUDSBLOEM: A PROJECT FOCUSING ON INTEGRATION OF PRIMARY CARE AND WELFARE SERVICES FOR HOME-DWELLING FRAIL ELDERLY IN THE NETHERLANDS

M. Dautzenberg[1,2], L. Donkers[2], E.C. Curfs[3], M. Broese van Groenou[4], *1. Dautzenberg Research & Advice, 's-Hertogenbosch, Netherlands, 2. Transmuraal Netwerk Midden-Holland, Gouda, Netherlands, 3. Open University, Heerlen, Netherlands, 4. VU University Amsterdam, Amsterdam, Netherlands*

Dutch policy reforms in long term care focus on delaying residential care and rely more on nursing and family care at home. Research by Dautzenberg et al. (2013) based on an in-depth analysis of 21 care networks of frail elderly and 52 qualitative interviews with formal and informal caregivers, showed that elderly care recipients depended heavily on homecare professionals. They had on average 13 caregivers of whom 80% were professionals and considered as 'substitute daughters'. Workers were unaware of volunteers and nearby welfare services. Subsequently, an intervention program named Goudsbloem was set up in a large home care organization (Vierstroom) focusing on the integration of primary care services. Interventions aimed (1) to reduce dependency on professional care by strengthening self-reliance and self-care and (2) to substitute professional care by informal care (family and volunteers) in collaboration with welfare services The intervention consisted of a transformed intake-procedure for new clients, a training program for homecare workers and supervision by team coaches. An effect and process evaluation after 9 months showed that the average monthly hours of personal care, nursing care and costs of care had reduced 17%-36%. The process evaluation showed that consistent organizational policy, strong support by the management and efforts made by team coaches were success factors. Involving more informal caregivers or volunteers and collaboration with welfare services increased, but remained limited. The conclusion was that integration of primary care services for frail elderly had moved forward but still has a (long) way to go.

'WE PREFER GREETING RATHER THAN EATING:' LIFE IN AN ELDER CARE CENTER IN ETHIOPIA

M.E. Adamek[1], A. Teka[2], *1. Indiana Unversity, Indianapolis, Indiana, 2. Addis Ababa University, Addis Ababa, Ethiopia*

The need for long term care in developing countries is increasing at a rate that far exceeds the rate in developed countries. In Ethiopia where family care is a centuries-long tradition, living in an elder care institution invariably brings social devaluation. Accordingly, this study explored the psycho-social needs of older adults in a residential elder care center in Ethiopia from the perspective of both staff and residents. Three focus group discussions of 24 residents and interviews with 5 staff persons revealed that elders were living a subsistence lifestyle, eating the same meal every day, mostly cutoff from the surrounding community, and lacking basic amenities. Despite the absence of basic amenities, residents yearned even more so for positive social interaction. Psycho-social support was both undervalued and underutilized by staff members, and thus, residents' psycho-social well-being appeared to be at risk. The addition of social workers in institutional care in Ethiopia may help to promote improved living standards. Advocacy is needed on behalf of residents to establish and implement guidelines on care and support of residents in old age homes. As elders in developing countries are living longer—a growing number with disabilities—at the same time that informal supports are waning, the need for developing long term care policies is becoming critical.

HOME HEALTH CARE AGENCY CHARACTERISTICS INFLUENCE THE RELATIONSHIP BETWEEN CONSUMER COGNITIVE STATUS AND SERVICE VOLUME AND READMISSION

D.B. Kaplan, *Institute for Geriatric Psychiatry, Weill Cornell Medical College, White Plains, New York*

Individuals with neurocognitive disorder experience impaired functioning and require increasing care. Licensed home health care agencies offer services which allow people to remain at home after they acquire a disability and during brief periods of rehabilitation after hospital procedures. Agencies differ considerably in size, staffing, experience, and employee work-life satisfaction. This study uses multilevel analyses of survey data to examine agency characteristics that influence the relationship between consumer cognitive impairment and service use in the United States. The 2007 National Home and Hospice Care Survey is a nationally representative sample survey conducted by the U.S. National Center for Health Statistics. These data are examined through cross-level mixed-effects multivariate regression models to understand the influence of home health care agency characteristics on the association of consumers' cognitive impairment status with home health care service use in terms of readmission status and numbers of medical and non-medical service visits. Consumers with moderate-to-severe cognitive impairment (32% of sample) received services for significantly more days (345 days), on average, as compared to consumers with little-to-no cognitive impairment (230 days), including more medical visits (24.4 vs. 18) and non-medical visits (6.4 vs. 4.6), and were readmitted to home health care in greater proportions (35% vs. 27%). Thirteen characteristics of provider agencies were found to significantly influence the relationship between cognitive impairment and service use, including those describing business size and experience, service profiles, and staffing profiles. These findings can inform research and policy efforts promoting services to meet the needs of people with neurocognitive disorder.

EMBEDDING REFLECTIVE PRACTICE IN A DEMENTIA INTERVENTION: EFFECTS ON STUDENT LEARNING

B. Ingersoll-Dayton[1], B. Spencer[1], S. Park[1], M. Kwak[2], *1. University of Michigan, ANN ARBOR, Michigan, 2. Gachon University, Gyeonggi-do, Democratic People's Republic of Korea*

There is a critical need for helping professionals who can assist the ever-growing population of those who are coping with dementia. Social workers are one group of helping professionals who are trained to address the clinical concerns of this population. Our experiential training project, the Couples Life Story Approach, gives social work students a venue for learning clinical skills with older adults with dementia and their partners while also reflecting on their practice with a supportive team of social work professionals and students. Students undergo training, shadow an experienced social worker, and subsequently deliver the intervention independently. They reflect on their practice experiences while writing process observation notes after each intervention session and during weekly mentored team meetings. A content analysis of the process observation notes, team meetings notes, and exit interviews was conducted for 14 students involved in the project. Findings indicate that students' reflective practice was enhanced by their post-session process observation notes and weekly dialogues during the mentored meetings. Their post-session notes point to the mastery of generic social work skills (e.g., normalizing and validating) as well as clinical skills related to dementia (e.g., helping couples to communicate while dealing with memory loss). The team meeting notes and the exit interviews uncovered students' reflections concerning the importance of belonging to a mentored team and to the reciprocal connections they experienced between themselves and the older couples. This project highlights the promise of this experiential learning model for enhancing students' self-reflection and clinical skills.

TRANSLATING AN EVIDENCE-BASED PROGRAM INTO A GROUP FORMAT: PRELIMINARY RESULTS

K.R. Kearney[1], H.L. Menne[1], S. Bollin[2], *1. Margaret Blenkner Research Institute, Benjamin Rose Institute on Aging, Cleveland, Ohio, 2. Alzheimer's Association, Toledo, Ohio*

The evidence-based 'Reducing Disability in Alzheimer's Disease' (RDAD) program was replicated in Ohio by Alzheimer's Association Chapters in both the original, in-home version, and a newly developed group format. Both versions of RDAD include: a) exercise training, b) behavior management skill building, and c) dementia-related education for person with dementia (PWD) and family caregiver dyads. The primary purpose of our analysis was to determine the acceptability and feasibility of the RDAD program when translated into a group format. Ten groups comprised of 37 care receiver-caregiver dyads completed the 15-session, 6-month program. Groups consisted of an average of 3.7 dyads (range 2-6). Of the 37 dyads that began the program, 30 (81.1%) completed the first 12 sessions without missing more than the two allowable absences. The primary reason dyads left the program before Session 12 is because of non-compliance due to excessive absences. Those completing the program finished with an average attendance rate of 93.9%. Paired samples t-tests indicate a significant decrease in caregiver unmet needs, from a T1 mean of 9.5 to a T2 mean of 4.0 (t(23)=5.33, p=.000). After completing 12 sessions, 94.7% of caregivers report they agree or strongly agree to a series of positive statements about the group program. Strong attendance rates, beneficial improvement in outcomes, and high rates of satisfaction suggest that the group RDAD program was acceptable and feasible to caregivers of persons with dementia. Positive findings point to further considerations of how evidence-based programs can be offered more efficiently for agencies with limited resources.

CAREGIVING OF PERSONS WITH MEMORY LOSS: DEPRESSION, STRESS, AND MULTIPLE MEDIATORS

F. Tang, H. Jang, J. Lingler, L.K. Tamres, J.A. Erlen, *University of Pittsburgh, Pittsburgh, Pennsylvania*

Caring for an older adult with disability is burdensome and stressful. Particularly, family caregivers of the elderly with memory loss could experience high levels of psychiatric morbidity, such as depressive symptoms and anxiety disorders. A stress process model postulates that Alzheimer's caregiver stresses produce negative outcomes such as depression through eroding personal resources and diminishing self-concept. However, previous studies are limited in examining multiple intermediate pathways or mediators of the caregiver's stress to depressive symptoms. This study aims to address this limitation by examining the role of self-efficacy, problem-solving behaviors and attitudes, and social support in mediating the relationship between stress and depressive symptoms. Using a community sample from 91 family caregivers of older adults with memory loss, we applied an asymptotic and resampling strategy for simultaneously testing multiple mediators between caregiver stress and depressive symptoms. Results indicate that self-efficacy mediated the pathway from stresses (measured by daily hassle frequency and severity) and depressive symptoms (B=.138, t=3.16, p=.002; B=2.60, t=2.93, p=.003), but problem-solving and social support did not. Caregiver stresses were associated with decreased levels of self-efficacy (B=-.086, t=-4.27, p=.000; B=-1.58, t=-3.35, p=.001) and perceived social support resources(B=-.436, t=-2.39, p=.02; B=-10.04, t=-2.32, p=.02), while a higher level of self-efficacy was related to fewer depressive symptoms among caregivers (B=-1.60, t=-4.10, p=.000; B=-1.65, t=-4.58, p=.000). Findings point to the importance of improving self-efficacy in psychosocial interventions for Alzheimer's caregivers. Comprehensive interventions with caregivers also need to include coping resources, social support, and problem-solving skills to address caregivers' stress and its negative outcomes.

A COMMUNITY-BASED SKILLED NURSING FACILITY (SNF) FOR DIFFICULT-TO-PLACE PATIENTS: PRELIMINARY DATA

L.C. Barry[1], J. Robison[1], J. Glick[2], *1. UCONN Center on Aging, Farmington, Connecticut, 2. Department of Mental Health and Addiction Services, Middletown, Connecticut*

Patients with serious mental illness and aging inmates/ex-offenders are difficult to place in traditional, Medicaid-paid skilled nursing facilities (SNFs). The recent opening of a SNF for difficult-to-place patients in Connecticut, called "60 West," provides a previously non-existent option for long-term care of these historically marginalized persons. We are using routinely collected data to evaluate pre-post quality-of-care and quality-of-life outcomes for patients transitioning to this SNF from a state of CT-run psychiatric facility or CT correctional facility. The outcomes are Minimum Data Set measures including aggression, wandering, depression, and cognitive status, health care services use, and medication use. Between May 2013 and February 2014, there were 46 patients at 60 West, with enrollment expected to reach 95 patients by January 2015. Of those enrolled, 2 died; 3 were discharged to the community; 1 was transferred to another SNF, and 1 was transferred back to prison. The current 39 patients are age 32 to 86 (49% age ≥60); 8% female; and 46%, 39%, and 18% are White/non-Hispanic, Black, and Hispanic, respectively. The majority (69%) resided at psychiatric facilities prior to transfer to 60 West. Preliminary aggregate data indicate 3 substantiated and 0 reported incidents of aggression and wandering, respectively, and 1 patient was hospitalized for inpatient acute care. Ongoing evaluation of this innovative state initiative will 1) identify areas where transfer to a specialized SNF may be most beneficial to overall patient health/well-being; and 2) inform the development of an evidence-based model for establishing specialized SNFs for difficult-to-place patients in other states.

BARRIERS AND FACILITATORS TO IMPLEMENTING A QUALITY IMPROVEMENT PALLIATIVE CARE TRAINING PROGRAM IN ASSISTED LIVING SETTINGS

D. Dobbs, S. Brande, M. Singleton, K. Black, *University of South Florida, Tampa, Florida*

A growing number of older adults remain in assisted living (AL) until death. There is an increased need for quality end-of-life care in AL. Research indicates that AL administrators perceive a need for more palliative care education for direct care staff. Further, ALs who offer palliative care education have an increased use of hospice care. Previous research indicates an evidence-based quality improvement palliative care training program (QI-PCTP) for staff in nursing homes has been effective at improving end-of-life care. This study focused on the implementation of the QI-PCTP in ALs and the barriers as perceived by different stakeholders. Community based participatory research was used vis-a-vis focus groups and concept mapping methods to generate data from a sample of 30 AL staff (administrators, nurses and aides) from 10 ALs and two hospices (hospice nurses) in Florida in 2013. Results: While all four stakeholder groups recognized the importance of the content of the QI-PCTP, there were barriers to implementing the QI-PCTP in AL. The major barriers from administrators' perspectives were regulations, budget constraints, staff turnover, and time available to implement the QI-PCTP. Making the training mandatory would facilitate implementation. Direct care staff cited staff negative attitudes about required training programs as a barrier. Hospice nurses cited as a facilitator marketing ALs who offer the QI-PCTP as having palliative care certified staff and to have hospice involvement in the facilitation of the QI-PCTP. Participants have made recommendations for the implementation phase of the QI-PCTP, which will be discussed.

PSYCHOMETRIC EVALUATION OF THE FUNCTIONAL CAPACITY CARD SORT: MEASURING CAREGIVER APPRAISAL OF FUNCTIONAL CAPACITY IN PERSONS WITH DEMENTIA

C.V. Piersol, *Jefferson Center for Applied Research on Aging and Health, Thomas Jefferson University, Philadelphia, Pennsylvania*

Families play a vital role in the safety and well-being of their relatives with dementia. Most people with dementia live at home and are cared for by family caregivers. Caregiver appraisal of functional capacity in the person with dementia is an essential element to the provision of care and assurance of safety for the person with dementia. Disparity between the caregiver's appraisal of functional capacity and standardized assessment can be an indication that the caregiver is providing inappropriate oversight, which may place the person with dementia at a safety risk. Family member report has been viewed as a particularly important proxy in dementia care as the person with the cognitive impairment tends to overestimate functional capacity; however, the accuracy of caregiver appraisal when compared to direct assessment of functional ability has been found to be inconsistent with caregivers overestimating and underestimating function. To address this issue, the theory-based Functional Capacity Card Sort was developed to measure and interpret caregiver appraisal of functional capacity by comparing the caregiver rating to the score on a standardized functional capacity assessment. This poster will present the development and utility of the Functional Capacity Card Sort. Psychometric properties including construct validity and interrater reliability will be described. Emphasis will be placed on effective and efficient methods for determining whether a caregiver's estimation is concordant or discordant with a standardized assessment, which offers health care providers the opportunity to educate and train caregivers and promote function and safety in the person with dementia.

MEANINGFUL INTERACTIONS WITH PROVIDERS: PERSPECTIVES OF CAREGIVERS OF PERSONS WITH DEMENTIA

L. Adkison, *1. McLean Hospital, Belmont, Massachusetts, 2. Boston College, Chestnut Hill, Massachusetts*

Purpose: The purpose of this study was to describe meaningful interactions with health care providers (HCPs) from the perspectives of family caregivers of persons with dementia (PWD). A secondary purpose was to understand ways in which family caregivers obtained needed information for managing uncertainty associated with providing care for a PWD. Background: Family members of PWD often assume the caregiver role, but lack preparation for the psychological and practical ramifications of caring for someone with a progressive, terminal illness (Alzheimer's Association, 2011). Lack of preparedness for caregiving impacts well-being and quality of life throughout the caregiving experience (Lilly, Robinson, Holzman & Bottorff, 2012). Methods: Qualitative description was used to obtain rich, straightforward descriptions from perspectives of participants. Results: Caregivers of PWD used multiple strategies to obtain information and manage uncertainty associated with caregiving. Efforts to obtain care for PWD were often complicated by challenges of a health care system that was not designed to meet the needs of PWD. Positive meaningful interactions with HCPs included interactive dialogue, partnering between HCPs and caregivers, and a sense of being known as individuals with unique needs. Negative meaningful interactions were characterized as lacking one or more of those components. Conclusions: Meaningful interactions with HCPs can profoundly affect family caregivers' ability to negotiate the healthcare system and manage uncertainty associated with caregiving. Partnerships with HCPs have a positive impact on family caregivers' well-being.

GERONTOLOGY EDUCATION: HOW ARE WE EDUCATING OUR DIRECT CAREGIVERS?

N. Kusmaul[1], D. Waldrop[2], T. Nochajski[2], *1. College at Brockport, Rochester, New York, 2. University at Buffalo, Buffalo, New York*

Certified Nursing Assistants (CNAs) provide most hands-on care in nursing homes. CNAs receive approximately 100 hours of education for certification with minimal content on mental health and normal aging. Continuing education typically consists of facility-required health and safety in-services. The purpose of the study was to assess CNA knowledge in the context of demographic and life events. The Mary Starke Harper Aging Knowledge Exam (M-SHAKE) measures knowledge about normal aging, mental health, and dementia in health care workers and contains 25 true/false statements. The M-SHAKE was administered to CNAs in a mid-sized city as part of a larger study. There were 106 respondents. Correct items were given one point; zero points were given for incorrect or omitted items. Mean score was 16.76, or 67%. Overall scores and individual item responses raised concerns about CNA education. For example, more than 80% of CNAs thought it was helpful to "re-orient agitated dementia patients," despite evidence supporting redirection, assessment of unmet needs, and environmental modification. This supports the need for education on dementia, agitation, and behavioral management. CNAs also possessed inaccurate information about cognition. Nearly half thought delirium was a permanent condition and/or Alzheimer's disease had an abrupt onset. This is concerning since CNAs are often the first observers of changes in patients. If they think that cognitive changes are normal or irreversible, they may not report potentially treatable conditions. Policy changes are needed to expand the educational requirements for CNAs to enhance patient well-being.

INVESTIGATING BARRIERS TO ACCESS AND DELIVERY OF END OF LIFE CARE FOR PERSONS WITH DEMENTIA IN LONG TERM CARE FACILITIES

E.M. Hill, M.Y. Savundranayagam, M. Kloseck, A.A. Zecevic, *Western University, London, Ontario, Canada*

Dementia is a progressive and terminal illness that affects a significant number of seniors. Toward the end of life, persons with dementia require extensive support often from long term care facilities. The palliative care philosophy aims to maximize quality of life for the dying person without aggressive or unnecessary treatments. Palliative care has been recognized as being both beneficial and under-used in persons dying with dementia. Existing barriers to accessing and delivering palliative care include unpredictable disease trajectory, misconceptions about the terminal nature of dementia, lack of education about palliative care, and policies or funding incentives acting as barriers to care. The purpose of the present study was to investigate the experiences of staff who deliver end of life care to persons with dementia at long term care facilities in Canada. Data was collected through semi-structured interviews with staff (N = 19) who provide support on a direct and indirect basis. Analyses using qualitative methodology indicated that the delivery of care is not standardized across facilities, lacks a holistic approach due to under-funding, and often occurs too late. Communication difficulties with individuals with dementia and a lack of resources to train staff in palliative care also hinder quality care. The findings will be discussed within the context of international comparisons of how palliative care is delivered. Moreover the findings provide insights for staff on delivering better quality, more efficient palliative care for individuals with dementia.

PRACTICES OF GERIATRIC CASE MANAGERS REGARDING SUICIDE AND FIREARM ASSESSMENT AMONG OLDER OHIOANS

N. Pope[1], K. Slovak[2], *1. University of Kentucky, Lexington, Kentucky, 2. Malone University, Canton, Ohio*

Study Purpose: Individuals aged 65+ represent about 12% of the U.S. population, yet 16% of all suicides. Firearm use in suicide is more common for older adults, and the presence of a gun in the home significantly increases elders' risk for suicide by firearm. Providers have suggested that clinical screening for suicide and access to firearms is important in service provision to older individuals, but it is unclear what knowledge clinicians possess regarding this issue, to what degree assessment and screening occurs, and the effectiveness of such efforts. This pilot study examined how suicide and firearm safety is viewed within Area Agencies on Aging (AAA). Methods: Using Qualtrics Survey Software, 100 case managers at four Ohio AAA regional offices completed an online survey that included closed and open ended questions and measured demographic information, practice variables, and knowledge, attitudes, and practices regarding suicide and firearm safety assessment. Findings: Sixty percent viewed clients at risk for suicide and only 8% had received formal training/ education on firearm safety counseling. The majority of case managers did not routinely assess for ownership and access to guns and barriers included a lack of training, lack of time, and lack of agency materials to distribute. Conclusion: Geriatric case managers are positioned to notice warning signs of suicide, screen for depression, and approach the topic of firearm risks with clients and their families. However, findings from this study suggest that these providers need more training and educational resources on issues related to suicide and firearm safety.

PERSONAL AND HOME CARE AIDES: DOES THE TYPE OF EMPLOYER MATTER?

C.M. Kelly[1], J. Deichert[2], L. Holley[2], *1. Gerontology, University of Nebraska, Lincoln, Nebraska, 2. University of Nebraska at Omaha, Omaha, Nebraska*

Purpose: Personal and home care aides comprise a majority of the home health care workforce. Using data from the American Community Survey (ACS), we found that across the groups and individuals that employ these aides (which also include outpatient care centers and private households), the two largest employers are individual and family services agencies (which provide nonmedical services) and home health care agencies (which provide medical and nonmedical services). The purpose of this study is to identify differences between personal and home care aides who work for these two types of employers. Design and Methods: Data were taken from the 1% Public Use Microdata Sample (PUMS) from the 2012 ACS. Logistic regression was used to compare demographic and employment characteristics of aides who work for individual and family services agencies versus those who work for home health care agencies. Results: Personal and home care aides who work for individual and family services agencies are less likely to be female, African American, self-employed, and on food stamps. They are more likely to be never married, non-U.S. citizens, to have health insurance though their employer or Medicaid, and to have an annual income above $15,000. Implications: Personal and home care aides who work for individual and family services agencies have advantages that include higher income and greater health insurance coverage. As the focus of long-term care shifts towards the home, these findings have important implications for educators, service providers, and employers concerning the recruitment and retention of the home health care workforce.

PREDICTING PROVISION OF CULTURAL COMPETENCY TRAINING IN COMMUNITY-BASED HEALTH CARE SETTINGS: AN ANALYSIS OF ORGANIZATIONAL AND LEADERSHIP FACTORS IN THE 2007 NATIONAL HOME AND HOSPICE CARE SURVEY

A. AbuDagga[1], S. Khasawinah[2], R. Weech-Maldonado[3], *1. Health Research Group, Public Citizen, Washington, DC, District of Columbia, 2. Department of Mental Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland, 3. Department of Health Services Administration, University of Alabama at Birmingham, Birmingham, Alabama*

Methods: The final analytic sample in this observational study was comprised of 828 HHH agencies, representing 12,107 weighted agencies. A summary CCT composite score was created based on three items supported by factor analyses (range= 0-3; alpha= 0.6): the agency provided mandatory training to understand cultural differences/beliefs that may affect delivery of services to: 1) all administrative, clerical, and management staff; 2) all direct service providers; and 3) all volunteers. Descriptive, correlational, and ordinal logit regression analyses were conducted, accounting for the complex sampling design using finite population correction. Weighted estimates were obtained for the overall sample and subpopulations: home health (HH), hospice, and mixed agencies. Results: HH, hospice, and mixed agencies comprised 75%, 15% and 10% of the sample, respectively. The overall mean CCT score was 1.7 (95%CI= 1.6-1.9). Regression results showed that JCAHO accreditation increased CCT odds in HH (OR= 2.1, 95%CI= 1.0-4.2) and hospice (OR= 4.4, 95%CI= 2.1-9.4) settings. Medical/social services increased CCT odds in HH (OR= 1.4, 95%CI=1.0-2.0) and hospice (OR=1.5, 95%CI=1.0-2.1) settings. Additionally, in HH, teaching status increased CCT odds (OR=2.7, 95%CI=1.2-6.2). In the hospice setting, formal contracts with outside organizations increased CCT odds (OR=4.0, 95%CI= 1.8-9.0), and non-for-profit status decreased CCT odds (OR=0.2; 95%CI=0.1-0.5). Administrator's tenure increased CCT odds in the mixed setting (OR=1.1; 95%CI= 1.0-1.1). Conclusions: This study demonstrated the influence of organizational and leadership factors on CCT. We also provide practical approaches for HHH agencies to increase their cultural competency practices to more effectively mitigate health disparities in this important community-based setting.

METHODOLOGICAL ISSUES IN COGNITION-BASED INTERVENTIONS FOR AGE-RELATED COGNITIVE DECLINE

N. Shtompel, B. Thomlison, N. Ruggiano, *FIU, Miami, Florida*

Age-related cognitive decline affects the majority of older adults. However, it is not inevitable as some individuals demonstrate intact cognitive functioning well into old age. The implications of age-related cognitive decline include an increased risk of falls and car accidents and reduced ability to perform daily tasks, which may affect health and independence in elderly. Some promising findings have been reported in randomized controlled trials (RCTs) investigating cognitive-based interventions. However, this line of research is marked by certain methodological issues that need to be taken into account when planning such studies in the future. Specifically, most RCTs utilized onsite group interventions, which face an increased risk of selection bias due to attrition and participant burden, as well as lack of individualized approach to intervention; or home-based computerized studies, which are characterized by issues related to adherence to intervention, computer stress, and cognitive training tasks that resemble too closely the assessment measures. Many studies also lacked active control groups and performance-based measures of daily functioning. Overall, RCTs tend to yield relatively small effect sizes and limited transfer to untrained functions, and lack follow-up assessments, uniform cognitive assessment measures, and replication studies. These problems complicate the interpretability of results and identification of the most efficacious format, setting, and dosage for interventions, cognitive functions to be targeted, and assessment measures in RCTs. There is a need to address these methodological issues in order to outline best practices in the area of cognitive training and facilitate the implementation of this intervention in the community.

ORGANIZATIONAL AND LEADERSHIP FACTORS ASSOCIATED WITH CULTURAL COMPETENCY COMMUNICATION PRACTICES IN THE 2007 NATIONAL HOME AND HOSPICE CARE SURVEY

A. AbuDagga[1], R. Weech-Maldonado[2], S. Khasawinah[3], *1. Health Research Group, Public Citizen, Washington, DC, District of Columbia, 2. Department of Health Services Administration, University of Alabama at Birmingham, Birmingham, Alabama, 3. Department of Mental Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland*

Methods: The outcome in this cross-sectional study was a summary CCCP composite score of three survey items that were selected through factor analyses (range= 0-3; alpha= 0.6): whether the agency provided interpreter services; patient-related material translated into language of the commonly represented groups; and multilingual staff. Descriptive, correlational, and ordinal regression analyses were conducted. Weighted survey estimates were obtained for the overall sample and for home health (HH), hospice, and mixed agencies. Analyses accounted for the complex sampling design using finite population correction. Results: The final regression models used data from 900 agencies representing 12,017 HHH agencies when weighted. HH, hospice, and mixed agencies comprised 75%, 15% and 10% of the sample, respectively. The mean CCCP score was 1.9. Overall, 35% of respondents were not-for-profit; 31% were JCAHO accredited; 44% were teaching agencies; 88% were located in urban areas. Multivariate ordinal logistic regression showed JCAHO accreditation increased the odds of CCCP in the overall sample (OR= 1.7; 95%CI=1.0-2.9) and HH (OR= 2.0; 95%CI= 1.0-4.0) setting. Similarly, medical/social services increased the odds of CCCP in HH (OR=1.6; 95%CI=1.2-2.3) and hospice (OR= 1.8; 95%CI= 1.3-2.6) settings. Additionally, in the hospice setting, chain affiliation, teaching status, and formal contracts increased the odds of CCCP: (OR=2.4; 95%CI=1.1-5.5), (OR= 3.4; 95%CI= 1.4-7.9), and (OR=10.3; 95%CI=2.5-43.6), respectively. Administrator's graduate education increased the odds of CCCP in the mixed setting (OR= 2.8; 95%CI= 1.2-6.5). Implications: Given the growing cultural/linguistic diversity, further improvements are needed to increase the adoption of cultural competency communication practices in HHH settings.

COGNITIVE IMPAIRMENT AND MEDICATION MANAGEMENT AS PREDICTORS OF HOSPITAL READMISSION

R.E. Anderson, S.J. Birge, *Washington U. School of Medicine, Saint Louis, Missouri*

Background: The ability of hospitals to identify risk factors for readmission is vital to improving patient outcomes and controlling utilization. Medication non-adherence and cognitive impairment have been identified as a major risk factor for readmission; however, the interaction of medication management and cognitive impairment is unclear. We postulated that cognitive impairment in patients independently managing their medications would increase their risk of hospital readmission. Methods: Prospective observational study of 452 patients aged 65 years or older discharged to home from the medicine service of a tertiary hospital. These patients undertook a cognitive assessment including the Short Blessed Test (SBT), the Clock Completion Test (CCT), and the Trail-making B (TRB). Hospital use and demographic data were obtained. A logistic regression model fitted the likelihood of 30-day readmission on the basis of patient characteristics, medication management, and cognitive performance. Results: For patients managing medications themselves, readmission odds increased 1.67 times per 5 point increase in SBT score (P=0.024) and 1.75 times per 0.05 lines/sec decrease in TRB score (P=0.035); the same association was seen with CCT score but was not significant (P=0.067). For patients not managing their medications, readmission odds increased 1.5 times per 0.05 lines/sec increase in TRB score (P=0.045); no association was seen with SBT or CCT scores (P=0.802; P=0.368). Conclusion: Screening patients for medication self-management and cognitive function, particularly executive function, may enhance the ability of hospitals at the time of discharge to identify those at risk of readmission.

SESSION 1695 (SYMPOSIUM)

MAKING CONNECTIONS: EAST MEETS WEST ON COMMON CLINICAL PROBLEMS

Chair: R. McCarter, *Penn State University, University Park, Pennsylvania*

Increased longevity is a global phenomenon, with China predicted to be the first country reaching over one million centenarians. This increase will lead to explosive growth in chronic diseases of the elderly. The goal of this symposium is to discuss current clinical problems of the elderly in China and the USA: to discuss risk factors, identify treatment modalities and compare the relative efficacies of these. Drs. Cohen and Li will provide the overview, with focuses on cancer and cardiovascular disease. Drs. Besdine, Chan and Dong will discuss cognitive decline and metabolic disorders, followed by Drs. Bai and Barzilai on alterations in body composition and connections to atherosclerosis. General discussion will follow.

EPIDEMIOLOGY OF DEMENTIA IN COMMUNITY ELDERLY: BEIJING LONGITUDINAL STUDY ON AGING

P. Chan, *Geriatrics & Neurology, Xuanwu Hospital of Capital Medical University, Beijing, China*

Dementia is one of the most common neurodegenerative diseases among the elderly. Although it has heterogeneity etiology, Alzheimer's disease (AD) has been suggested to be the most common cause. Both genetic and environmental factors contribute jointly to the development of dementia. In earlier reports, the prevalence of dementia and AD in Mainland Chinese was lower than that in non-Asian populations. However, with the fasting population aging in China, its prevalence was growing fast. The differences in prevalence may reflect different conditions in culture, environment, education, and possibly genetic ethnicity. To investigate these issues, data from the Beijing Longitudinal Study on Aging were used for analysis. Prevalence, incidence, and mortality were studied in respect to potential risk and protective factors in both cross-sectional and longitudinal analysis.

AGING RELATED CHANGES IN BONE MINERAL DENSITY AND ITS ASSOCIATION WITH SUBCLINICAL ATHEROSCLEROSIS BIOMARKERS IN HEALTHY POPULATION IN CHINA

X. Bai[1], D. Liang[2], L. Han[1], X. Zhao[1], K. Yu[1], B. Jin[1], X. Chen[3], *1. Shengjing Affiliated Hospital of China Medical University, Shenyang, China, 2. First Affiliated Hospital of China Medical University, Shenyang, China, 3. General Hospital of Chinese PLA, Shenyang, China*

Objective Investigating the changes of bone mineral density (BMD) with aging and its association with subclinical atherosclerosis in healthy population in China. Method The total hip and lumbar spine BMD of 505 healthy subjects were measured using dual-energy x-ray absorptiometry and categorized into three groups (T score >-1.0; -1.0 - -2.5; < -2.5). The ABI, PWV, and CIMT were measured to assess sunclinical atherosclerosis. Results The lumber BMD (r=-0.587, p<0.001) in women and total hip BMD in women (r=-0.575, p<0.001) and men (r=-0.251, p<0.001) were significantly correlated with age. Total hip BMD was correlated with ABI in women after adjustment for age (r = 0.156, per SD decrease in ABI: -0.130 g/cm2, p=0.022), and was borderline significant after full adjustment (P =0 .045). Conclusion There was gender characteristics in aging-related changes of BMD. The association between low BMD and subclinical atherosclerosis depends on the aging, blood pressure and internal environment.

ASSOCIATION BETWEEN COGNITIVE IMPAIRMENT AND THE COMPONENTS OF METABOLIC SYNDROME IN CHINESE NONAGENARIANS AND CENTENARIANS

B. Dong, *West China Hospital,S.U, Chengdu, Sichuan, China*

Objective: As geriatrician, We focus on relationship between metabolic state and diseases.But there are very few studies about the oldest old on the aspect, so our studies specially examine the relationship among the oldest old. Methods: Participants of our studies were from the Project of Longevity and Aging in Dujiangyan. 870 people aged 90 years and older participated. Results: (1) BMI of around 20 (18.9-21.1) higher FSI, Metabolic Syndrome(MetS) may be associated with enhanced cognitive function; Food items, levels of serum lipid/ lipoprotein, hypertension were not directly correlated with cognitive impairment among Chinese nonagenarians and centenarians; Among male nonagenarians and centenarians, high triglyceride level, the higher level of serum uric acid and systolic blood pressure, current exercise are associated with better cognitive function. (2) Among female nonagenarians and centenarians, extremely low and high BMIs is associated with higher risk of ADL and IADL disability.

THE STUDY OF PRESENT SITUATION ON THERAPY AND SECONDARY PREVENTION OF CORONARY HEART DISEASE IN CHINESE ELDERLY

X. Li[1], L. Wang[2], L. Pu[3], Z. Jian[4], X. Tuo[5], H. Xu[6], J. Fan[1], *1. Chinese PLA General Hospital, Beijing, China, 2. The Second Hospital of Tianjin Medical University, Tianjin, China, 3. Ministry of Health, Beijing Institute of Geriatrics, Beijing, China, 4. The Second Xiangya Hospital of Central South University, Changsha, China, 5. CHANGHAI Hospital of Shanghai, Shanghai, China, 6. Xiyuan Hospital CACMS, Beijing, China*

Objective To investigate the present situation on therapy and secondary prevention of coronary heart disease (CHD) in Chinese elderly. Methods This is a cross-sectional, non-intervention and multicenter survey. 7962 CHD cases with mean age of 73.0±7.9 years from 165 hospitals were interviewed in 2011. 24.1% were ≥80 years old and 63.4% were male. Results 29.6% had coronary revascularization. 76.5% experienced angina pectoris and myocardial infarction. 70.3% were using antiplatelet drug, 54.9% lipid regulating agents, 47.5% BBC, 29.0% ACEI, 22.2% ARB. 38.9% were present smokers and 28.4% were passive smokers. 57.6% were overweight with BMI ≥24. The percentage of hypertension, diabetes, and dyslipidemia were 67.6%, 23.4%, and 33.2%. Female patients, individuals with HbA1c<7.0%, or LDL-C<2.6mmol/L, coronary revascularization had less heart attacks than the others (P<0.05 for all). Conclusions Coronary revascularization and control of high risks are the key points for the treatment of elderly CHD in China.

ALTERATIONS IN BODY COMPOSITION WITH AGING AND CONNECTIONS TO DISEASES AND MORTALITY

N. Barzilai, *Albert Einstein College of Medicine, Bronx, New York*

Numerous previous studies in humans shows that mortality risk according to body mass index (weight corrected for height; BMI), is lowest in the overweight range. It holds true for age, gender and race, and therefore seems biologically universal. Since the efficacy of caloric restriction (CR) in rodents (and probably in primates) varies widely depending upon their genetic background, the question is if human's genetic background is most protective from aging at an overweigh range of BMI. However, a major missing link, that may be even more profound in oriental populations, is the role of abdominal obesity or visceral fat as the consequence of aging and the risk for diseases. it is generally accepted that subcutaneous adipose tissue is the 'good' fat while abdominal, visceral, obesity is the risky one. Thus BMI may not capture the biology associated with obesity or its prevention by diet.

CURRENT CLINICAL PROBLEMS OF OLDER AMERICANS – COGNITIVE DECLINE & METABOLIC DISORDERS (DEMENTIA AND DIABETES)

R. Besdine, *Brown University, Providence, Rhode Island*

Healthcare for American elders is dominated by chronic disease; population health, the key to financial survival, demands we address interventions that broadly benefit independence and quality of life. Dementia and diabetes are prominent and devastating. Alzheimer disease (AD), the commonest dementia, is a family tragedy. Current estimates are that >age 70, ~15% of Americans are afflicted (6 million victims), yet we know precious little about prevention or treatment, in spite of decades of research. Lifestyle interventions hold great promise. Health-promoting Mediterranean-style diet; reducing tobacco, alcohol, and salt; and increased physical activity have shown benefit in observational and a few randomized trials. Since stroke has been shown to exacerbate severity of dementia in AD, preventive strategies become paramount (managing hypertension, tobacco, lipids, diet, and exercise). Diabetes mellitus is the most common metabolic disorder of older Americans. The US obesity epidemic, while worst among children, teens, and adults < 60, also extends to elders. Prevalence and mortality rates have shown little change despite quality metrics required by insurers. Population-based lifestyle interventions, similar to those recommended for AD are essential to improve health of all older Americans. Modifications in transportation, food supply and its regulation, and public space and staffing for physical activity and exercise are all underutilized in the United States. European and some Asian countries have made more progress in these domains. Public policy and research that informs such policy are critical for success.

CLINICAL GERIATRICS ISSUES IN THE US: OVERVIEW AND EXAMPLES

H.J. Cohen, *Duke University Medical Center, Durham, North Carolina*

With the increase in longevity in the US and China, and our more effective treatment of acute disease, many of these same conditions have become chronic diseases. Moreover there is a tendency for such diseases and conditions to accumulate resulting in what has been called Mulitmorbiditiy or Multiple Chronic Conditions (MCC). Designing preventative and treatment strategies that make sense for the individual with MCC is a challenge. The condition of multiple sensory morbidities will be discussed to illustrate this issue. Furthermore even when there is a particular dominant disease, managing it in the context of other MCC which are then seen as Comorbidities, the usual case for older individuals, is also a challenge. The approach to the older patient with cancer will be discussed to illustrate this problem. Ultimately the goal for the treatment of chronic diseases in older people is to optimize the individual's functional status. This involves not only astute medical management but careful assessment of the patient's goals of care. Since the US and China share these common problems, collaborative investigation of these issues has the potential to help all of our patients.

SESSION 1700 (SYMPOSIUM)

INFLAMMATION AND AGING

Chair: G.E. Taffet, *Medicine-Geratrics and Cardiovascular Research, Baylor College of Medicine, Houston, Texas, Houston Methodist Hospital, Houston, Texas*

The session will bring researchers studying important aspects of inflammation and aging including potential culprits in the process as well as organs where inflammation may be contributing to damage and the aging process. The overview will bring clinical aspects as well as hypothesis descriptions that will then be addressed by the three leading investigators. Critically, dysregulation of inflammation in aging leads to potential places to intervene in the aging process.

INFLAMMATORY PHENOTYPE CHANGES IN THE BRAIN WITH ALZHEIMER'S DISEASE AND VASCULAR DEMENTIA

D.M. Wilcock, *Sanders-Brown Center on Aging, University of Kentucky, Lexington, Kentucky*

Alzheimer's disease (AD) is defined pathologically by the presence of amyloid plaques and neurofibrillary tangles in the brain. Despite advancement in our understanding about AD pathologies, there remains unexplained variability in course, duration and therapeutic response. In frozen brain tissue samples of frontal cortex and cerebellum from the University of Kentucky Alzheimer's Disease Center autopsy cohort, we measured gene expression profiles from age-matched non-demented controls, early-stage AD and late-stage AD cases. We also examined the neuropathological data on these samples and performed analyses of the serum proteins. We performed gene expression analysis for genes categorizing inflammatory states termed M1 and M2. M2 can be further categorized as M2a, M2b and M2c. We also performed ELISA analysis of Aβ proteins on the same brain samples and the serum samples were analyzed for a profile of inflammatory proteins. Striking heterogeneity was found in early AD. Specifically, early-stage AD brain samples indicated polarization toward either the M1 or M2a states when compared to age-matched non-disease control tissue. Where gene expression indicated an M1 state, there was very little expression of M2 markers. By contrast, in the presence of M2a markers, M1 markers tended to be absent. This polarization was only observed in the frontal cortex, unlike the cerebellum, a region not affected in the early stages of AD. Neuroinflammatory polarization occurs early in the course of AD and is a source of variability in the population of AD patients considered for recruitment to clinical trials. It is hoped that assessment of serum proteins as biomarkers to predict the neuroinflammatory state will combine with in vivo animal studies to personalize the therapeutic approach to treatment of AD.

PROSTAGLANDIN-RELATED MUSCLE INFLAMMATION IN OLDER ADULTS: IMPACT OF EXERCISE & COX INHIBITING DRUGS

T. Trappe, *Human Performance Lab, Ball State University, Muncie, Indiana*

Chronic inflammation in skeletal muscle likely contributes to sarcopenia. Skeletal muscle inflammation is also elicited in extreme exercise conditions in adults and animal injury models. In these conditions, the cyclooxygenase (COX)-derived intramuscular prostaglandins are key regulators of the muscle protein synthesis and breakdown responses. Thus, COX-inhibiting drugs may inhibit intramuscular prostaglandin production and negatively impact the muscle protein turnover responses. In young individuals, cell culture, and animal models this has been confirmed. In older adults performing more typical exercise bouts that effectively treat sarcopenia, this interfering effect of COX inhibitors has not been shown. In fact, in older individuals a substantial enhancement of exercise-induced muscle mass and strength gains has been observed when the inflammatory-related processes regulated by prostaglandins are controlled through COX-inhibition. The mechanisms underlying these findings will be discussed in the context of sarcopenia treatment and COX regulation in other areas of health and disease.

AGING, ADIPOSE TISSUE INFLAMMATION, AND CELLULAR SENESCENCE

J.L. Kirkland, *Robert and Arlene Kogod Center on Aging, Mayo Clinic, Rochester, Minnesota*

Cellular senescence refers to the growth arrest that occurs when cells experience potentially oncogenic insults. Senescent cell burden increases in multiple tissues with aging, including adipose tissue. Adipose tissue chronic, "sterile" inflammation and redistribution occur with aging, together with metabolic dysfunction. Cellular senescence may contribute to this adipose tissue inflammation through the senescence-associated secretory phenotype, or SASP, which involves release of inflammatory cytokines, chemokines, proteases, and growth-promoting and remodeling factors. The SASP potentially explains how senescent cells alter tissue microenvironments, attract immune cells, and contribute to metabolic disease. We found that: 1) senescent cells induce glucose intolerance in vitro and in vivo and 2) eliminating senescent cells ameliorates senescence-related adipose tissue dysfunction and glucose intolerance. We review the mechanisms that induce senescence and the SASP, their associations with age-related adipose tissue dysfunction and diabetes, therapeutic opportunities based on targeting senescent cells and the SASP, and potential paths to clinical interventions.

SESSION 1705 (SYMPOSIUM)

CREATING AND MAINTAINING CONNECTION: QUALITATIVE EXPLORATIONS OF ROMANTIC AND FAMILIAL RELATIONSHIPS

Chair: C. Stelle, *Bowling Green State University, Bowling Green, Ohio*
Discussant: K.A. Roberto, *Virginia Tech University, Blacksburg, Virginia*

The life course presents both opportunities and challenges to relationships in later life. Research indicates that social support and connection with others are critical components for physical, mental, and emotional well-being in later life. Relationships must continue to be created and maintained in order to sustain social support networks and adapt to the transitions that occur across the life course. This symposium explores older adults' connections to others and provides an opportunity to examine the dynamics of the development and maintenance of relationships in later life across multiple relationships types and contexts. Stelle and Watson examine the use of online dating as a mechanism to find new romantic relationships in later life. Benson investigates decision-making among couples living apart but together (LAT) and strategies for maintaining LAT relationships. Smith explores the experience of intergenerational ambivalence among older, minority mothers within their relationship with adult children. Tomkins examines kinship families and the complexities of relationships between grandparents and grandchildren. These studies bring together a focus on the importance of social connectedness and how relationships continue to be developed and require maintenance across relationship types, contexts, and time.

LOVE IN CYBERSPACE: SELF PRESENTATION AND PARTNER SEEKING IN ONLINE DATING ADVERTISEMENTS

C. Stelle, W. Watson, *Bowling Green State University, Bowling Green, Ohio*

Demographic heterogeneity in relationship status indicates more individuals are entering later life as single – divorced, widowed, separated, or never married. Reduced stigma of online dating has resulted in more individuals of all ages using technology as means of finding relationships. The purpose of this study was to examine the use of online dating in later life. Analysis of 200 personal advertisements from men and women ages 60+ from both age specific (ourtime.com) and general (match.com) online dating sites are used to explore how individuals describe themselves and the qualities they seek in a partner. Iterative qualitative content analysis utilizing atlas.ti resulted in the emergence of themes of self-presentation and what the individual is seeking in a potential romantic partner. Results will be discussed around issues of presentation of self and how age and gender are related to the use of online advertisements for seeking out relationships in later life.

MY CHILDREN: MYSELF: OLDER WOMEN MAKE SENSE OF THEIR DEPENDENT ADULT CHILDREN'S PROBLEMS AND REQUESTS FOR SUPPORT

J.R. Smith, *Graduate School of Social Service, Fordham University, New York, New York*

Later life relationships with adult children are explored, using grounded theory, among a sample of 15 women who identified themselves as having "difficult" adult children. Each was seen 3x. While research has established the utility of ambivalence as a lens to understand the quality of late life intergenerational relationships (Pillemer & Luscher, 2004), this study is the first to apply this lens to a sample of low-income and minority mothers. All the women report negative feelings about their children's need for support, yet all continue to do what they can to help. The study describes the strategies used to respond to their adult children's problems. The data shows the women's feelings of self-blame and shame at their children's lack of self-sufficiency. Variation in the women's negative feelings of self differ with their level of autonomy from the adult child's problems and their previous success in parenting, work and relationships.

UNDERSTANDING THE RELATIONSHIPS WITHIN KINSHIP FAMILIES: A CLASSIC GROUNDED THEORY STUDY

C. Tompkins, *George Mason University, Fairfax, VA*

Kinship families are increasingly more prevalent across the United States. To gain a better understanding of relationships within kinship families, a classic grounded theory (CGT) research methodology was used. In-depth unstructured interviews with members of 15 kinship families were conducted. As a result of rigorous comparative analysis, the following three interrelated categories of factors that contribute to complexity in kinship caregiving were found to make up the resulting theory, Understanding Compounding Complexity: situational, relationship and emotional complexity. Complexity increases as situational, relationship and emotional complexity interact, leading to compounding complexity and the need to engage in behaviors to survive the situations. Challenging examples of survival faced by these families will be shared. If survival occurs, will the children come back around and provide care to their kinship caregivers? This question continues to be explored through integrating Attachment theory with Understanding Compounding Complexity theory.

FROM LIVING APART, TO LIVING-APART-TOGETHER: OLDER ADULTS DEVELOPING A PREFERENCE FOR LAT

J.J. Benson, M. Coleman, *Human Development and Family Studies, University of Missouri, Columbia, Missouri*

This study explores living-apart-together (LAT) relationships among Midwestern men and women between the ages of 60 and 88. Twenty-five men and women completed genograms and unstructured interviews addressing decision-making processes leading to living apart together. Grounded theory analyses suggest that deciding to LAT in older adulthood is a gendered process involving seven contributing factors, including: personal and relational goals, age, health, partner factors, relationship history, historical time, and relationship beliefs. Reconciling relationship beliefs represent the core concept because the data demonstrate that reconciling these beliefs — particularly those surrounding commitment and expectations — is key to understanding the process of how older adults decide to LAT. Participants had varied responses regarding their preference to LAT, ranging from opposing the arrangement, being ambivalent, to championing LAT as a lifestyle choice.

SESSION 1710 (SYMPOSIUM)

APPROACHING ALZHEIMER'S DISEASE FROM CELLS TO SOCIETY

Chair: R. Thorpe, *Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland*
Discussant: M.M. Williams, *Texas Tech University, Lubbock, Texas*

Alzheimer's disease (AD) is the most prevalent cause of dementia, accounting for 60-80% of dementia cases and affecting 5.2 million in the United States. Annual direct care costs exceed $203 billion. In 2012, informal caregivers provided more than 17.5 billion hours of unpaid care with an estimated value of $216 billion. Nearly 24 million have AD worldwide; the global prevalence is anticipated to quadruple by 2050. Racial and ethnic disparities in AD are numerous: incidence and prevalence, age of onset, delay in diagnosis, inadequate treatment, AD knowledge, and under-representation in research. Effectively addressing the AD epidemic in an aging and increasingly diverse society requires intensification of research efforts across the spectrum of biomedical research from cells to societies. In this symposium we will bring together investigators from each of the GSA sections: Biological Sciences, Health Sciences, Behavioral and Social Sciences, and Social Research, Policy and Practice. The overarching goal is to present an interdisciplinary perspective that will highlight the major challenges in AD research. Experts from each discipline (biological, translational, clinical, and social) will provide a general context for their work and outline some of the key questions in AD research. This format will provide a framework for discussion in which GSA members can appreciate the questions that drive cutting edge AD research and gain insights into how each of the disciplines fit together. The participation of minority investigators is a major consideration in designing this symposium, as is the inclusion of minority specific elements in the individual presentations.

ALZHEIMER'S DISEASE: THROUGH THE TAU LOOKING-GLASS

N. Ghoshal, *Neurology, Washington University, Saint Louis, Missouri*

The phenotypes of Alzheimer's disease (AD) and other forms of dementia overlap. Diagnostic accuracy at the molecular level is an emerging science. AD pathology is typified by beta-amyloid plaques and tau tangles. While the amyloid hypothesis has garnered much attention, tau protein is the new focus of research. Tau pathology defines a group of neurodegenerative disorders referred to as tauopathies, including AD and frontotemporal degeneration (FTD). Available blood, spinal fluid, and neuroimaging tests can distinguish AD from other neurodegenerative disorders, but not FTD, which has substantial clinical implications due to differences in treatment and course. Flow cytometry-based tau aggregate fingerprinting assay is an emerging technology that detects tau aggregates with specific antibodies identifying a unique tau aggregate fingerprint that can discriminate among tauopathies at the molecular level. The ability to correctly identify the etiology of clinical symptoms will have enormous impact on diagnosis and treatment for patients with cognitive impairment.

RACE DISPARITIES IN DEMENTIA PREVENTION TARGETS IN THE UNITED STATES

J.R. Carrión-Baralt, N. Silva-Castro, L.G. Diaz-Logroño, J. Vélez-Egipciaco, *Gerontology Program, University of Puerto Rico Medical Sciences Campus, San Juan, Puerto Rico*

In 2013 there were 5.2 million cases of Alzheimer's Disease (AD) in the United States, with direct costs of $203B. Research suggests that prevalence of dementia may differ significantly between ethnic groups in the United States. Many dementia cases are potentially attributable to modifiable factors, and specific targets and strategies for the prevention of dementia have been proposed. This study sought to compare the prevalence of some of the most important risk/protective factors for dementia between Whites, African-Americans and Hispanics. We used Behavioral Risk Factors Surveillance System data (2001-2011) to estimate prevalence and analyze longitudinal patterns of these risk/protective factors. In most risk/protective factors, prevalence among Hispanic and African-American populations was significantly higher/lower than among Whites. Longitudinal patterns suggest significant increases in the prevalence of most risk factors. Race- and Culture-specific Public Health prevention initiatives are needed to curb the financial and non-financial costs of dementia in the US.

ALZHEIMER'S DISEASE CAREGIVER'S BENEFIT FROM KNOWLEDGE

C.B. Scott[1], O.J. Clay[2], *1. Social Work, University of Tennessee Chattanooga, Chattanooga, Tennessee, 2. University of Alabama Birmingham, Birmingham, Alabama*

Informal Alzheimer's caregivers experience elevated burden due to the stress associated with the caregiving role. This burden can lead to negative psychological and physical outcomes. Previous literature suggests that greater levels of knowledge related to their family member's disease is linked to better health outcomes, participation in supportive services, and the ability to make appropriate health decisions. This study examined the relationship between Alzheimer's knowledge and caregiver burden. Data were collected from 110 African American and Caucasian informal caregivers. Alzheimer's knowledge was assessed using the Knowledge about Memory Loss and Care Scale (Kuhn et al, 2005). Caregiver burden was measured using the Caregiver Burden Inventory (Norvak & Guest, 1988). There was a significant association between Alzheimer's knowledge and caregiver burden, $p < .05$. Specifically, more Alzheimer's disease knowledge was related to lower levels of reporting caregiver burden. These findings underscore the potential benefits of Alzheimer's specific knowledge/educational interventions for this population.

POLICY INNOVATIONS TO SUPPORT PEOPLE WITH ALZHEIMER'S DISEASE AND RELATED DEMENTIAS AND THEIR INFORMAL CAREGIVERS

B. Hollister[1], D. Cherry[2], *1. University of California, San Francisco, San Francisco, California, 2. Alzheimer's Association, Los Angeles, California*

Policy changes implemented as part of the ACA, such as the creation of accountable care organizations and the dual eligible demonstrations present opportunities to change the way health care is delivered to people with Alzheimer's disease and related dementias (ADRD). Many people with ADRD rely heavily on informal care provided by family or friends, but traditional medical models rarely offer the supports and services that these caregivers need. Support through the use of trained care managers and caregiver education can improve the quality of life of both caregivers and patients and can reduce the utilization of health care services or delay institutionalization.The California Department of Aging (CDA), the Alzheimer's Association, and the University of California San Francisco Institute for Health and Aging are working with Cal MediConnect health plans to build dementia capable systems of care for individuals with ADRD enrolled in a Cal MediConnect health and their caregivers.

SESSION 1715 (SYMPOSIUM)

MAY THE SOURCE BE WITH YOU: MOTIVATIONAL SOURCES OF OPTIMIZING HEALTH AND WELL-BEING IN OLD AGE

Chair: T. Sims, *Psychology, Stanford University, Stanford, California*
Co-Chair: N. Notthoff, *University of California Berkeley, Berkeley, California*
Discussant: S.T. Charles, *University of California Irvine, Irvine, California*

Nearly thirty years ago, Rowe and Kahn (1987) popularized the concept of successful aging. Despite age-related declines in a variety of domains, many adults age successfully by preserving a high level of functioning into late life. Researchers have identified numerous ways in which people are able to age successfully such as maintaining physical health and improving emotional well-being (e.g., Rowe & Kahn, 1997; Carstensen et al., 2011). The accumulating knowledge about successful aging in health and well-being in old age raises the question of why a substantial proportion of older adults are still unsuccessful (Meng & D'Arcy, 2014). The goal of this symposium is to uncover motivational sources that may explain variations in outcomes related to successful aging, drawing on studies of different cultural and situational contexts. Jiang and colleagues explore how age differences in the ability to meet one's affective goals may explain age-related improvements in emotional experience. Yeung and colleagues examine how age differences in the utilization of emotion regulation strategies may give older adults an advantage in the workplace when responding to interpersonal tensions. Notthoff and Freiberger investigate how general and domain-specific future time perspective and subjective perceptions of health-promoting behaviors are related to older adults' motivation for health and health behavior. Finally, Sims and colleagues investigate end-of-life planning as the ultimate marker of successful aging and how failing health may prevent preparation even when time is perceived as limited. Together, these studies highlight tangible points of intervention to motivate successful aging across a variety of contexts.

"I WOULD WALK 500 MILES": VIEWS OF TIME AND EXERCISE SHAPE HEALTH MOTIVATION AND BEHAVIOR IN OLD AGE

N. Notthoff[1], E. Freiberger[2], *1. Institute of Personality and Social Research, University of California, Berkeley, Berkeley, California, 2. Friedrich-Alexander University Erlangen-Nürnberg, Erlangen, Germany*

The general influence of perceived future time horizons on motivation and behavior has been well documented. We examined whether an age-related limited general future time perspective (FTP) is associated with a reduced health- and exercise-related future time perspective (TPQE) as well as how FTP and TPQE are related to health-related motivation (HRM) and to health behavior (walking). We measured FTP, TPQE, HRM, and walking in 59 older adults 61 to 95 years ($M = 75.79$). Older age was associated with lower FTP ($r = -.508$, $p < .001$), but not TPQE or HRM. Only TPQE was related to HRM ($B = .06$, $SE = .02$, $p < .001$). However, neither TPQE nor HRM were related to walking. We will consider to what extent walking is perceived as a health promoting physical activity and discuss the relevance of our findings for formulating health and exercise recommendations for older adults.

HONG KONG CHINESE REGULATE ACTUAL AFFECT BASED ON IDEAL AFFECT

D. Jiang[1], H. Fung[1], T. Sims[2], J.L. Tsai[2], *1. Psychology, Chinese University of Hong Kong, Hong Kong, Hong Kong, 2. Stanford University, Stanford, California*

Affect valuation theory argues that people regulate their actual affect based on the feelings that they value, i.e. ideal affect. To further test this hypothesis, this study examined the longitudinal relationship between ideal and actual affect using an experience sampling study over a 7-day period. Among 321 Hong Kong Chinese aged from 18 to 89 years (M=47.64, SD=21.66), we found that Time 1 (T1) ideal high-arousal positive affect (HAP; e.g., enthusiastic and excited) significantly predict Time 2 (T2) actual HAP, and the magnitude of this correlation was greater in older adults than younger adults. T1 ideal low-arousal positive affect (LAP; e.g., calm and peaceful) significantly predicted T2 actual LAP, and at the same time, T1 actual LAP also predicted T2 ideal LAP. The magnitude of these correlations slightly decreased among participants older than 40 years. These findings provide insights on emotion regulation process among Hong Kong Chinese.

AGE VARIATIONS IN EMOTIONAL AND BEHAVIORAL RESPONSES TO DAILY INTERPERSONAL TENSIONS AT WORK

D. Yeung[1], H. Fung[2], D. Chan[2], *1. City University of Hong Kong, Hong Kong, Hong Kong, 2. The Chinese University of Hong Kong, Hong Kong, Hong Kong*

This paper compares younger and older Chinese employees' emotional and behavioral responses to interpersonal tensions in the workplace. A sample of 150 managerial and executive employees completed an online daily diary study which lasted for 15 working days. Participants reported the experiences of negative and positive events at work. Among them, 139 employees reported at least one interpersonal tension during the sampling period. Preliminary analyses showed that when there was an interpersonal tension, older employees reported more positive (B = .019, SE = .005, $p < .001$) but fewer negative emotions (B = -.019, SE = .005, $p < .001$) relative to their younger counterparts. Moreover, there was an age-related decrease in the use of active and destructive conflict strategies while an age-related increase of passive strategies to handle the workplace tensions.

HEALTH STATUS MODERATES THE ROLE OF FUTURE TIME PERSPECTIVE IN END-OF-LIFE PLANNING

T. Sims[1], L.L. Carstensen[1], M.K. Goldstein[1,2], *1. Psychology, Stanford University, Stanford, California, 2. VA Palo Alto Health Care System, Palo Alto, California*

End-of-life planning may benefit well-being by alleviating physical and emotional pain for individuals and their loved ones. According to socioemotional selectivity theory, as people perceive time as limited, they are more likely to make decisions that enhance social and emotional well-being. Thus, having a limited future time perspective (FTP) may increase the likelihood of end-of-life planning. In two separate studies of older adults, using distinct measures of FTP and health, we found a significant interaction between FTP and health status for end-of-life planning, ps < .05. Among older adults in better health, limited FTP predicted a higher likelihood of having an advance directive (z = 2.53 and 3.59). However, those in poorer health did not show this association (z = -0.37 and 0.43), indicating that poor health may interfere with regulatory goals to enhance well-being. Findings suggest that emphasizing socioemotional benefits of end-of-life planning may be ineffective for older adults in poor health.

SESSION 1720 (SYMPOSIUM)

LIFE TRANSITION AND ITS IMPLICATION AMONG CHINESE OLDER ADULTS

Chair: L. Xu, *UT-Arlington, School of Social Work, Arlington, Texas*
Co-Chair: Y. Li, *San Diego State University, School of Social Work, San Diego, California***Co-Chair:** I. Chi, *University of Southern California, School of Social Work, Los Angeles, California*

Important life transitions such as loss of spouse or loss of children have significant impact on psychosocial well-being on older adults. Older adults rely on various supports to help them cope with the loss and make the transition successful. However, Chinese older adults' experience is less known and being studied before. Authors in this symposium took the initiative to systematically examine the life transition experience and understand how such transition affected older adults psychologically and physically. Using national representative data, Li, Xu, Min and Chi found that older adults who could maintain similar level of social participation before and after loss of spouse benefited most from such participation and reported significantly higher life satisfaction compared with those who decreased their social participation. In another paper using the same national representative data, Min, Li, Xu and Chi found that widowhood was associated with life satisfaction differently between men and women. Such differences were mainly due to the gendered mechanisms linking widowhood and life satisfaction, particularly because of the caregiving strain experienced for men and financial strains encountered by women after loss of spouse. Compared with older adults who lost their spouse, loss of children in old age could be even more heartbreaking, especially among older adults who had only one child due to the one-child policy implemented in late 1970s in China. Using a unique dataset collected among 201 older adults who lost their only child, Pan, Liu and Li used revealed that over 90% of those older adults experienced depression. They also found that the reason of death (i.e. accident) was strongly correlated with depression regardless of the length of the child's death. In the last paper in this symposium, life course perspective was applied to examine the long-term effect of early life experience on multiple health outcomes among Chinese adults aged 45 and over. Using 2011 survey data of the Chinese Health and Retirement Longitudinal Study (CHARLS), Zhang, Liu and Li found that childhood health, father's education and growing up in rural area were related to late-life health.

SOCIAL PARTICIPATION AND LIFE SATISFACTION AMONG WIDOWED OLDER ADULTS IN CHINA

Y. Li[1], L. Xu[2], J. Min[4], I. Chi[3], *1. San Diego State University, School of Social Work, San Diego, California, 2. UT-Arlington, School of Social Work, Arlington, Texas, 3. University of Southern California, School of Social Work, Los Angeles, California, 4. University of Southern California, School of Gerontology, Los Angeles, California*

Objective. This study examines changes in social participation following spousal loss and how such changes affect life satisfaction among older adults in China. Methods. Two-wave nationally representative data from China were analyzed to explore changes in social participation after spousal loss and life satisfaction. A total of 6,569 older adults aged 60 and above from 16 provinces in China were interviewed in both 2000 and 2005. Results. Older Chinese adults who remain married reported the highest level of participation in both waves, followed by those became widowed during the surveys. The largest increase in social participation occurred among those who became widowed, whereas the largest decrease of social participation occurred among those who remained widowed. Higher levels of social participation at baseline were related to higher levels of life satisfaction. Increasing or maintaining the level of social participation was related to higher levels of life satisfaction. This study also found that participants who became widowed and maintained their social participation reported higher life satisfaction compared with those who became widowed and decreased their social participation. Discussion. Our study findings suggest a positive effect of social participation on life satisfaction in general, as well as an especially salient effect when older adults were coping with spousal loss but maintained consistency in their social participation.

DEPRESSION OF OLDER PARENTS WHO LOST THEIR ONLY CHILD IN CHINA

X. Pan[2,1], J. Liu[1], L. Li[1], *1. Southwest University, Chongqing, Chongqing, China, 2. University of Michigan, Ann Arbor, Michigan*

Over one million one-child families had lost their only child by 2012 in China and the population of the elders who lost their only child will continue to swell in the near future. To date, no study has been conducted to investigate emotional well-being of this population. This study explored how health status, social support, and reason of child's decease influence depression in the child-deceased elders using the data collected from 201 child-deceased elders living in a southwest prefecture of China. In the sample, over 90% child-deceased elders were depressed. The regression results show that poor or very poor health, less social support and child's decease in accident were significantly associated with higher level of depression. The findings suggested the necessity of exploring psychological well-being of child-deceased elders and importance of developing interventions to assist these elders obtain social support and cope with the trauma of losing child in accident.

EXPLORING THE DIFFERENT MECHANISMS LINKING WIDOWHOOD AND SUBJECTIVE WELL-BEING BETWEEN MEN AND WOMEN AMONG CHINESE OLDER ADULTS

J. Min[1], Y. Li[2], L. Xu[3], I. Chi[1], *1. Davis School of Gerontology, USC, Los Angeles, California, 2. San Diego State University, San Diego, California, 3. University of Texas at Arlington, Arlington, Texas*

It has been known that widowhood has differential health impact on men and women in Western literature. Gendered mechanism linking widowhood to health outcomes has been proposed to explain such differences: financial strain for women but social relationships for men. However, research among Chinese older adults showed inconsistent results on the gender differences in the effect of widowhood on health. Moreover, little evidence is available about what the linking mechanisms are and whether the mechanisms differ by gender. Using nationally representative data in China, this study examined the association of widowhood and life satisfaction and tested whether the relationship differs by gender. We identified relating mechanisms and examined how they moderated the association between widowhood and life satisfaction between men and women differently. We found a significant gender difference and financial strain was an important factor which explained this difference in the association between widowhood and life satisfaction (B=.042, p<.01).

EARLY LIFE EXPERIENCE AND HEALTH IN MID AND LATE LIFE

Z. Zhang[1], J. Liu[2], L. Li[2], *1. Sociology, Michigan State University, East Lansing, Michigan, 2. University of Michigan, Ann Arbor, Michigan*

There is limited research on the association between early life experience and adult health in developing countries. Drawing on data from the 2011 survey of the Chinese Health and Retirement Longitudinal Study (CHARLS), we investigate the long-term effects of early-life conditions on multiple health outcomes among Chinese adults aged 45 and older. Our preliminary results show that father's education, growing up in rural area, and self-reported childhood health are associated with the risk of functional limitations, ADL disability, and IADL disability, net of age, gender and marital status. After controlling for adulthood educational achievement, we find that the effects of father's education and growing up in rural area on late-life health are reduced substantially, but the effects of childhood health change very little. We plan to continue to explore how other adulthood SES indicators and health behaviors mediate the relationship between early life experience and late-life health.

A STUDY ON THE TIME FOR THE FIRST VISUAL ACUITY EXAMINATION AFTER SENILE CATARACT OPERATION

J. Liu, *Opthalmology, Peking University People's Hospital, Beijing, China*

Purpose: The purpose is to determine the correlation between visual acuity (VA) outcome and examination time after phacoemulsification and intraocular lens (IOL) implantation, to emphasize the importance of opportunity in evaluating VA outcome. Design: Retrospective, comparative case series. Method: 100 eyes with 100 senile cataract patients were included in the trial. Visual acuity was marked in four different times in first post-operative day by masked, certified examiner. Result: 0 minutes after dressing (group0), mean VA is 0.785±0.206. 10 minutes after dressing (group10), mean VA is 0.960±0.182. 30 minites after dressing (group30), mean VA is 0.928±0.152. 60 minites after dressing (group60), mean VA is 0.931±0.159. And after 30 minutes later, VA has become stable and statistical analysis was not significant (P>0.05). Conclusion: The study indicates that satisfactory visual acuity results are achieved 30 minites later after dressing.Visual acuity fluctuates in the first day after phacoemulsification and intraocular lens (IOL) implantation.

SESSION 1725 (SYMPOSIUM)

KEY CHARACTERISTICS OF SOCIOECONOMIC POSITION ACROSS THE LIFECOURSE IN RELATION TO HEALTH AND FUNCTIONING IN OLD AGE

Chair: M. Huisman, *LASA, VU medical center, Amsterdam, Netherlands, VU University, Amsterdam, Netherlands*
Discussant: C. Mendes de Leon, *University of Michigan, Ann Arbor, Michigan*

Social factors, like socioeconomic position (SEP), often are crucial fundamental causes of morbidity and mortality. A full understanding of the influence of SEP on health and wellbeing in old age requires data from studies addressing various parts of the lifecourse. The purpose of this symposium is to showcase four different studies, using data from various cohort studies on aging, investigating key characteristics of socioeconomic position (SEP) and their impact on health and functioning in old age. Key characteristics of SEP in this symposium include aspects of parental SEP in addition to own SEP, education level, and cumulative impact of income and income stability. The importance of these characteristics for the health and wellbeing of older adults is investigated using multiple outcomes, spanning different phases of the disablement process: multimorbidity; functional limitations, accelerated cognitive decline; and active aging. Presenters will touch upon the following research questions: Do measures of cumulative income and income variability predict multimorbidity in old age, beyond one-time measures of income? Is there heterogeneity in the effect of education on functional limitations? Does education level influence the timing of onset of cognitive and/or the acceleration of cognitive decline? And through which pathways does childhood SEP influence active ageing? Data shall be presented from studies that have been conducted in the United States, Europe and India.

SOCIOECONOMIC INEQUALITIES IN SUCCESSFUL AGING: A LIFE COURSE PERSPECTIVE

A. Kok[1,2], M.J. Aartsen[2], D.J. Deeg[1], M. Huisman[1,2], *1. Epidemiology & Biostatistics, VU University Medical Centre, Amsterdam, Netherlands, 2. VU University Amsterdam - Sociology, Amsterdam, Netherlands*

Drawing on Cumulative Advantage/Disadvantage Theory, this paper investigates the impact of socioeconomic pathways through childhood and adulthood on subsequent successful aging trajectories. Data are from participants aged 55-85 in 1992 in the nationally representative Longitudinal Aging Study Amsterdam (LASA). Individuals' scores on a "Successful Aging Index" were based on 16-year longitudinal trajectories in 9 indicators of physical, cognitive, emotional, and social functioning. These indicators reflected the WHO-definition of 'active ageing'. Structural Equation Modeling showed that more socioeconomic adversity throughout the life course predicted lower scores on the Successful Aging Index. The impact of adulthood socioeconomic position on successful aging was partly mediated by social network size and chronic diseases. Moreover, significant indirect effects of childhood via adulthood socioeconomic position on successful aging were found. This suggests that even socioeconomic circumstances during childhood impact the quality of aging by shaping the subsequent accumulation of advantage or disadvantage throughout the life course.

EDUCATIONAL INEQUALITIES IN AGING-RELATED DECLINES IN FLUID COGNITION AND THE ONSET OF DEMENTIA

S. Clouston, *Preventive Medicine, Stony Brook University, Stony Brook, New York*

Educational attainment is associated with healthy aging and incident disease; however, the role of education in cognitive aging and incident cognitive pathology is unclear. Data come from the Health and Retirement Survey, and the Longitudinal Aging Study of Amsterdam. Multilevel pathology models were used to examine the influence of education in early life on level and change in fluid cognition and the onset of cognitive pathology late in life. Education was associated with an increase in baseline cognition, a delay in the onset of cognitive pathology, and a slower pre-decline rate of cognitive aging. The rate of decline in fluid cognition was not associated with educational attainment. Delaying dementia substantially improves quality of life and reduces the burden of disease. Our results support the theory that higher educational attainment is associated with better baseline functioning, healthier cognitive aging, and delays in the onset of cognitive pathology.

EDUCATIONAL INEQUALITIES IN FUNCTIONAL LIMITATIONS AMONG OLDER ADULTS IN INDIA: EXPLORATION OF CAUSAL EFFECT HETEROGENEITY

T. Bhatta[1], J. Kelley-Moore[1], J.M. Albert[2], *1. Sociology, Case Western Reserve University, Cleveland, Ohio, 2. Case Western Reserve University, Department of Epidemiology & Biostatistics, Cleveland, Ohio*

Despite considerable attention to education-specific health inequalities, few studies explicitly model life course processes that contribute simultaneously to both educational attainment and later-life health outcomes. Overlooking such selection processes makes it impossible to isolate the independent effect of education. Grounded in a counterfactual framework and utilizing WHO Study on Global Ageing and Adult Health (N=7,150), we employ an inverse probability weighting approach to document the effect of education on functional limitations among Indian adults ages 50+ years and also explore potential heterogeneity in the effect of education. Our findings reveal that there is a positive effect of education on physical functioning, although the magnitude of the effect diminishes to non-significance at higher levels of education. Unlike previous studies on causal effect heterogeneity, that have observed additional health benefit for educated individuals with lower propensity to receive education, we do not observe heterogeneity in the effect of education on functional limitations.

PATTERNING OF LIFECOURSE SOCIOECONOMIC EXPERIENCES AND MULTIMORBIDITY BURDEN IN U.S. ADULTS

V. Johnson-Lawrence[1], A. Zajacova[2], *1. PHHS, Univ of Michigan-Flint, Flint, Michigan, 2. University of Wyoming, Laramie, Wyoming*

Multimorbidity is an increasingly prevalent public health problem, especially among underserved populations. Fundamental gaps remain in our understanding of multimorbidity burden, particularly in the context of lifecourse socioeconomic patterns. Cumulative impacts and stability of different economic dimensions may be more important indicators of lifecourse economic circumstances. This study uses data from the Panel Study of Income Dynamics (1989-2011, n=5691) to estimate models of multimorbidity as a function of lifecourse socioeconomic patterns measured by cumulative income, income instability (variation), and cumulative wealth. Preliminary findings suggested that higher cumulative income (per \$1000; b=-0.002, SE=0.00006, p<.01) and greater wealth (b=-0.06, SE=0.01, p<.01) were associated with decreased multimorbidity over the lifecourse, net of single point-in-time measures. Cumulative economic well-being is a critical dimension of lifecourse economic circumstances that may put adults at an increased risk for multimorbidity. Studies that only use one-time measures of income may be underestimating the economic impacts on health.

SESSION 1730 (SYMPOSIUM)

REMINISCENCE AND ORAL HISTORY: CONNECTING INDIVIDUALS, COMMUNITIES, AND SOCIETY

Chair: M.B. Ligon, *Behavioral Sciences, York College of PA, York, Pennsylvania*

Discussant: T.W. Pierce, *Radford University, Radford, Virginia*

Connectedness is at the heart of reminiscence—recalling and connecting past experiences, evaluating and connecting the past to the present, sharing and connecting the life of one human being to another. In congruence with this year's conference theme, "Making Connections: From Cells to Societies," this symposium will highlight current research in the field of reminiscence and provide pragmatic models for implementing programs that can benefit and connect individuals, communities, and society. The first presentation highlights the functions and value of reminiscence for nursing home residents. Findings indicate that residents reminisce to maintain intimacy and social bonds and to teach others. The functions and value of reminiscence for nursing home staff members are discussed in the second presentation. Staff members utilize reminiscence to help residents see meaning in life. The third presentation describes results from qualitative interviews, structured around a reminiscence film-making protocol, with older adult master gardeners. Implications of results will be addressed within lifespan theories of consistency and change. The fourth presentation examines outcomes of an intergenerational oral history project in which college students were randomly assigned to either interview a familiar elder through their own contacts or an unfamiliar elder recruited by researchers. Quantitative analysis reveals that positive shifts in students' attitudes toward older adults and the aging process occurred. While reminiscence-related activities take many forms and are used in a variety of settings for divergent purposes, these presentations highlight that the benefits of such activities and the connections made are often profound.

THE FUNCTIONS AND VALUE OF REMINISCENCE FOR NURSING HOME RESIDENTS

L. Henkel, A. Kris, S. Birney, K. Krauss, E. Peters, M. Goguen, *Fairfield University, Fairfield, Connecticut*

This study examined the functions of reminiscence in a nursing home setting, focusing on residents' perceptions of the frequency and value of thinking about and sharing their past experiences with family, fellow residents, and healthcare providers. Nursing home residents (n=23) reported engaging in reminiscence to maintain intimacy, nurture social bonds, and teach others. They were less likely to reminisce for the purpose of preparing for death or to solve problems. Residents were most likely to reminisce alone, and reported engaging in and enjoying reminiscence with family more than with fellow residents. Although they enjoyed sharing personal experiences with healthcare providers, this was rarely done and they expressed desire for more opportunities to do so. Correlational analyses revealed that residents engaged in reminiscence to serve different purposes (e.g., emotion regulation, making sense of the present, and reducing boredom) in relation to their levels of morale, depression, and loneliness.

THE FUNCTIONS AND VALUE OF REMINISCENCE FOR NURSING HOME STAFF

A. Kris, L. Henkel, K. Krauss, S. Birney, *Fairfield University, Fairfield, Connecticut*

The purpose of this study was to understand the perceived value and functions of reminiscence among nursing home staff (both RN's and CNAs). A sample of 17 nurses reported that while they did not feel there was value in sharing memories of their own personal past, they did however feel there was great value in having the residents share their own memories. The majority of nurses reported that they engaged in reminiscence activities with residents occasionally or often (82.3%), and found those interactions moderately to very enjoyable (76.5%). The most important functions of reminiscence as reported by the nurses were to a) help residents see meaning in life b) ease conversation and to c) reduce boredom. On the other hand, they rarely engaged in reminiscence activities to a) help residents remember loved ones, b) lessen resident fears of death or to c) aid residents in preparing for death.

CONSTANT GARDENERS: REMINISCENCE IN OLDER ADULT MASTER GARDENERS

L. Yancura, *University of Hawaii at Manoa, Honolulu, Hawaii*

Continuity theory (Atchley, 1989) proposes that older adults uphold continuity in their lives by maintaining similar behaviors and activities across the lifespan. This study describes results from in-depth qualitative interviews with four older adults enrolled in a community master gardener program. Interviews were structured around a reminiscence film making protocol which prompted them to recall their memories of plants and gardening at four earlier points in the lifespan: childhood, adolescence, young adulthood, and early adulthood. Results showed both continuity and change in how they viewed gardening throughout their lives. Passion for gardening was a constant theme in all of their narratives, although the meaning it served varied over time. Findings will be illustrated with clips and quotes from the gardeners' films.

DON'T TALK TO STRANGERS? FINDINGS FROM AN INTERGENERATIONAL ORAL HISTORY PROJECT

M.B. Ligon[1], K. Ehlman[2], G. Moriello[3], *1. Behavioral Sciences, York College of PA, York, Pennsylvania, 2. University of Southern Indiana, Evansville, Indiana, 3. The Sage Colleges, Troy, New York*

Research indicates that oral history projects contribute to positive shifts in attitudes toward older adults and aging among gerontology students. This exploratory study examines whether attitudinal shifts are more dramatic in students who interview elders they do not know as compared to students who interview a family member or close friend. Undergraduate gerontology students (n=87) conducted three 60-minute interviews with either a familiar elder through their own contacts ('family group') or an unfamiliar elder recruited by researchers ('stranger group'). Initial findings indicate there were significant within group differences from pretest to posttest on the At-O-A: Attitude toward Older Adults Scale ($p<0.001$) and Attitude toward Aging Scale ($p<0.001$), and Anxiety About Aging Scale ($p<0.001$) but not on the Fraboni Scale of Ageism ($p=0.11$). Differences between the "Stranger" and "Family" groups were not statistically significant; therefore, both methods of interviewee selection lead to equal shifts in attitudes toward older adults and aging.

SESSION 1735 (SYMPOSIUM)

NEW RISKS IN RETIREMENT

Chair: S.A. Vickerstaff, *SSPSSR, University of Kent, Canterbury, Kent, United Kingdom*

Until relatively recently retirement seemed to have become a 'settled part of life' to quote Laslett (1989). For the first time in human history large numbers of people in the Global North could expect to enjoy a period of time 'in retirement' and for some a considerable period of relative wealth, health and ease. Now global economic turbulence and the 'certainty of uncertainty' are eroding confidence in such outcomes. The processes of individualisation associated with the risk society have broken up standard biographies (Beck, 2000) and what Moen refers to as: "the taken for granted, scripted exits of earlier generations" (2012); people feel that they have to construct their own pathways and transitions into retirement and in doing so face new responsibilities and risks. This paper considers the implications of these developments for how we think about and define retirement in a new age of precarity.

WORKERS OVER 65 IN THE UK: THE NEW 'PRECARIAT'?

D. Lain[1], W.A. Loretto[2], *1. University of Brighton, Brighton, United Kingdom, 2. University of Edinburgh, Edinburgh, United Kingdom*

UK employment over age 65 is currently rising, against a background of declining defined-benefit pension coverage, rising state pension ages and the abolition of mandatory retirement. Standing (2011) argues declining pensions mean older people are increasingly joining the 'precariat', by taking jobs lacking employment, job and income security. We examine how employment at age 65-69 has changed between 2001, 2008 and 2013 using the UK Labour Force Survey. We find that employment increases, for both employees and the self-employed, are concentrated amongst those with long held jobs. We also see a reduction in the share of workers in lower-level service jobs between 2001 and 2013, and a declining proportion of 65-69 year olds working part-time. We finish the paper by explaining why in the UK context we think a different form of precarity may develop - that of people feeling trapped in their jobs.

EXTENDING WORKING LIFE IN IRELAND: INSECURITY AND PRECARIOUSNESS

A. Ni Leime, A. Callan, N. Duvvury, *Irish Centre for Social Gerontology, NUI, Galway, Galway, Ireland*

Demographic ageing has been identified as a major policy challenge in western countries (OECD, 2012). Ireland, despite having a younger population than many other EU countries, has been quick to adopt policies designed to extend working life. State pension age, now 66, will increase to 68 by 2028. Other policies introduced include a requirement for longer years' participation in the labour market to qualify for the contributory state pension, a measure that is likely to affect those in precarious employment, including carers, cleaners and construction workers (Duvvury et al, 2012). The implications of such policies need to be examined. The severe economic recession in Ireland means there is little employment available for older workers who will not now receive the state pension until later than expected. This paper adopts a lifecourse perspective to explore the implications of extended working life policies for older Irish workers particularly those in precarious employment.

OLDER WORKERS AND EXTENDING WORKING LIFE: THE CREATION OF A NEW PRECARIAT?

C. Phillipson[1], S.A. Vickerstaff[2], D. Street[3], *1. The University of Manchester, Manchester, United Kingdom, 2. University of Kent, Kent, United Kingdom, 3. University of Buffalo, New York, Virginia*

In this book The Precariat – the New Dangerous Class, Guy Standing (2011) reviewed evidence for greater insecurity in the workplace with pressures arising from short-term employment, high levels of youth unemployment, and marginalisation facing disabled workers and others groups. In this Symposium we examine the relevance of the 'precariat thesis' for understanding the lives of older workers, drawing on a variety of conceptual frameworks and international data sets. The discussion will be placed in the context of what has been termed the 'individualisation of risk' (Vickerstaff and Cox, 2005), reflected in changes in the labour market associated with the erosion of jobs for life and reliance on private pension arrangements. For older workers these changes are coming in the context of pressures, across all OECD countries, to extend working life and raise pension ages. The Symposium will provide a critical assessment of the relevance of the 'precariat' thesis for understanding the problems facing older workers as well as indicating new avenues for research and public policy. The papers will, first, outline the historical and theoretical arguments which might suggest increased insecurity within the labour market; second, this thesis will be examined through national (UK and Ireland) and international (OECD) data; third, contributors will assess the policy implications of extending working life in the context of more complex transitions from work to retirement. Finally, the discussant will provide an overview of the key themes identified in the session, outlining an agenda for future debates in the field of work and retirement.

CAN WORKING LIVES BE EXTENDED? PROBLEMS AND PROSPECTS FOR WESTERN ECONOMIES

C. Phillipson, *School of Social Sciences, University of Manchester, Manchester, United Kingdom*

Changing patterns of work and retirement raise important questions for social policy. A key issue concerns a legacy of the 20th Century, the idea of retirement as a major part of the life course. The acceptance of early retirement in the 1970s and 1980s accelerated the growth of post-work lifestyles, consolidated by the cohort of 'first wave' baby boomers. Both aspects are now in collision with the drive to raise pension ages. This paper reviews trends in later working across OECD countries, highlighting the emergence of new forms of insecurity facing older workers. The discussion links these to the impact on employment of de-industrialisation and the post-2008 recession. The paper argues that extending working life is likely to create a range of social, health and income inequalities. The paper provides a critical examination of the extent to which these are illustrative of precariousness as the new reality for older workers.

SESSION 1740 (SYMPOSIUM)

GLOBAL PERSPECTIVES ON SOCIAL AND HEALTH POLICY FOR AN AGING POPULATION

Chair: N. Keating, *Human Ecology, University of Alberta, Edmonton, Alberta, Canada*
Discussant: J.R. Beard, *World Health Organization, Geneva, Switzerland*

Managing population aging has become a preoccupation worldwide. Societal responses have been diverse, arising from differences in rates of population aging, priorities in apportioning national resources, and policy traditions. There are discourses across nations about the relative responsibilities of governments, families, individuals and civil society in supporting older adults; but there is no agreement about sustainable solutions. Yet disparities in the welfare of older people continue apace. In this symposium we address gaps between policy discourses and programs, and in knowledge of needs and resources of older persons and the best policy levers to address them. Objectives are to: 1.propose a critical framework for the development of a global policy agenda to enhance liveability of older persons 2.address the place of civil society in buffering the individualization of financial risk in old age 3.illustrate the place of governments in developing a national social policy to support older persons In the first presentation, Beard speaks to the need for societal responses to population ageing in light of major knowledge and policy gaps, the absence of a global vision on how to fill them, and lack of agreement on cost effective strategies for government. Choi evaluates the national policy framework in Korea which has goals of creating an age-integrated social system and ensuring that older persons benefit from the country's rapid economic development. Finally, Pereira and Angel examine the role of civil society organizations in the context of movement away public pension systems for older people.

GLOBAL POLICY AND INDIVIDUAL CAPABILITY

J.R. Beard, *World Health Organization, Geneva, Switzerland*

Promoting healthy and active ageing, and building systems to address health needs of older adults, are core to societal responses to population ageing. Yet there are major knowledge and policy gaps, no agreed global vision on how to fill them, no agreement on cost effective strategies for government, and many decisions are made on the basis of outdated stereotypes. The World Health Organization has therefore identified ageing and health as an organizational priority and initiated a comprehensive body of work to guide policy development globally. This includes planned publication of the first World Report on Ageing and Health as a resource for policy makers; development of a Global Strategy and Action Plan to build high level government commitment and prioritization; and major projects with governments of Ghana and China to develop evidence informed policy. This presentation will outline how global action can strengthen the capabilities of older people in even the poorest countries.

NATIONAL POLICY PERSPECTIVES ON POPULATION AGING IN KOREA

S. Choi, *Social Welfare, Seoul National University, Seoul, Republic of Korea*

Korean society with 12 percent of older population is expected to be unprecedentedly fast aging in the first half of this century and thus to have 38 percent of older population in 2050. Korean society which was one of the poorest countries after World War II has achieved its GDP per capita of 25,000 US dollars through miraculous economic development. Korean society could be a model to developing countries in social policy development on aging as well as economic development. In this sense this paper, after showing a profile of population aging in Korea, will introduce current national policies on population aging particularly focused on five-year national policy plans begun from 2006 in Korea. Then this paper will address issues in policy perspectives and policy areas on aging, and finally suggest a policy perspective called "age-integrated social system perspective" towards a sustainable aging society.

STRAINED SOLIDARITY: POPULATION AGING, CIVIL SOCIETY, AND ELDERCARE IN LATIN AMERICA

J. Pereira[1], R. Angel[2], *1. Universidad Católica del Uruguay, Montevideo, Montevideo, Uruguay, 2. University of Texas at Austin, Austin, Texas*

With the encouragement of international financial institutions, during the 1990s ten Latin American countries either replaced their public pension systems entirely or introduced mixed public and private systems. These reforms were motivated by looming financial pension system crises resulting from rapid population aging. Although perhaps necessary as one part of reform, privatization represents the rejection of the solidarity and redistributive principles upon which the modern welfare state is based. Nor does it directly deal with problems of poverty, income inequality, labor marked informality, and non-coverage common in Latin America. This study investigates the role of civil society organizations, including non-governmental and faith-based organizations, in advocating for and providing services to the elderly in Buenos Aires (Argentina), Montevideo (Uruguay) and Santiago (Chile). It is motivated by the fact that civil society organizations offer the potential of complementing sate efforts and bringing a human face to the care of infirm and impoverished elderly individuals.

SESSION 1745 (SYMPOSIUM)

HIV AND RESILIENCE: EXAMINING THE ESSENCE AND EFFECT OF LIVING WITH HIV FROM THE EXPERIENCES OF OLDER ADULTS

Chair: L.K. Manning, *Division of Human Services, Concordia University Chicago, River Forest, Illinois*

The population of individuals living into older age with HIV is increasing. Next year, it is estimated that 50% of those living with HIV will be over the age of 50. These individuals have a multitude of experiences and unique conditions related to this disease and illness. These increasing numbers of older adults with HIV are due to multiple causes, for instance older adults are living longer due to the advancement of antiviral drugs, lack education regarding HIV prevention and screening. Furthermore, advancements in medications used to treat erectile dysfunction medications has lead to increased sexual activity among older adults. Despite the increasing number of older adults being diagnosed and living with HIV, research on HIV and aging has lagged behind. This symposium features work from leading scholars in the field of HIV and aging. The papers presented here offer empirical and theoretical explorations of HIV and aging. The researchers consider the negative and positive aspects of living into late life with HIV and consider aspects related recovery, growth, development, spirituality, transformation, wellbeing, and the prevention of the disease. Additionally, leadings scholars articulate an important and emerging agenda of research for burgeoning scholars in the field of aging.

AGING WELL WITH HIV: AN EXAMINATION OF RESILIENCE AND STRENGTHS IN A VULNERABLE POPULATION

C.A. Emlet[1,2], C. Furlotte[2], D.J. Brennan[3], C. Pierpaoli[4], *1. Social Work, University of Washington Tacoma, Tacoma, WA, 2. McMaster University, Hamilton, Ontario, Canada, 3. University of Toronto, Toronto, Ontario, Canada, 4. American University, Washington DC, District of Columbia*

Older adults constitute an increasing proportion of people living with HIV. This qualitative study examines “aging well” among 30 HIV-positive older adults. Methods: Using grounded theory, men and women aged 50+ were recruited in Ontario, Canada. Participants were recruited through AIDS service organizations, clinics and community agencies between February-May 2013. Results: Six themes were identified through consensus by all team members including: 1) Centrality of HIV; 2) Gift of life; 3) Self-Care; 4) Spirituality; 5) Social Connectedness; and 6) Resilience. Participants stated they were not defined by HIV and professed gratitude for a longer than expected life. Social support, as well as traditional and non-traditional spiritual approaches, contributed to well-being. Participants reported self -care and resilience as important factors in overcoming difficult and tragic life events. Implications: Future research should create and test potential intervention strategies for assisting older adults in maximizing wellness as they age with HIV disease.

INCREASING OLDER ADULTS OPPORTUNITY FOR RESILIENCE THROUGH HIV PREVENTION: PERSPECTIVES FROM PRIMARY CARE PROVIDERS

T. Davis[1], P.B. Teaster[2], F. Zanjani[3], A. Thornton[2], J.F. Watkins[2], L. Alexander[2], *1. Rutgers University, Stratford, New Jersey, 2. University of Kentucky, Lexington, Kentucky, 3. University of Maryland, College Park, Maryland*

An increasing number of older adults are being diagnosed with HIV, as a result of multiple factors. Older adults often lack education regarding HIV and are rarely screened for the disease. HIV education and screening can help older adults avoid HIV infection and also help them obtain prompt treatment if they are HIV+ (i.e., resilience). Healthcare providers are in an optimal position to increase HIV prevention efforts among older adults. The purpose of this research is to explore (PCPs) willingness to increase HIV prevention efforts for older adults in primary care settings and to elucidate recommendations to aid in the process. Data for this study was obtained through interviews with PCPs. The majority of providers found it necessary to increase HIV prevention efforts in primary care settings and suggested strategies to increase HIV prevention. These findings inform future research and interventions aimed at increasing HIV prevention in primary care settings.

HOW OLDER WOMEN VIEW SEXUAL DECISION-MAKING AND HIV PREVENTION

W. Watson, C. Stelle, *Bowling Green State University, Bowling Green, Ohio*

Most of what is known about sexual decision-making, condom use, and HIV prevention has been learned from research with adolescents and college students. Older adults are affected by sexually transmitted diseases, including HIV/AIDS, yet little is known about how they are processing information about their sexuality, sexual decision-making, and information about HIV/AIDS. Through semi-structured, in-depth interviews, the narratives of fourteen women between the ages of sixty-five and eighty were examined. Results of this study are organized around the themes of sex and sexuality in later life and HIV awareness and condom use, including that most women feel knowledgeable about HIV and the lack of HIV testing or condom use in this relationship. Trust in partner’s honesty and faithfulness was seen as protection against disease. The paper will discuss HIV prevention-education programs and the need for sexual and STI education programs based on the lived experiences of older adults.

SESSION 1750 (SYMPOSIUM)

ADVANCES AND CHALLENGES IN ENVIRONMENTAL GERONTOLOGY: AUTOBIOGRAPHICAL PERSPECTIVES

Chair: H. Chaudhury, *Gerontology, Simon Fraser University, Vancouver, British Columbia, Canada*

Co-Chair: F. Oswald, *Goethe University, Frankfurt, Germany*

Discussant: L.N. Gitlin, *Johns Hopkins University, Baltimore, Maryland*

As the field of Environmental Gerontology continues to witness growth with new theoretical insights, richer substantive findings and an increased emphasis on various methods, it is timely to take a self-reflective perspective through the lens of pioneering researchers of this field. This symposium will present a set of conceptually oriented papers with an autobiographical slant from key scholars of this field. Autobiographical perspectives allow us to appreciate the associations, inclinations and motivations between career trajectories, personal interests and circumstantial factors, and intellectual advancements and contributions. Moreover, a purposefully undertaken self-reflection has the scientific potential to shed new insights into the whys and hows of intellectual discoveries and contributions in a creative way. First, Sheila Peace draws from her over 35 years of research experience highlighting the intersection of personal and professional interests with a myriad of research areas ranging from care home to home care. Second, Stephen Golant traces the inspirational roots of his recent “residential normalcy” model to his early work on natural hazards and behavioral geography as a graduate student, and its subsequent growth in the 1970/80s. Third, adopting an auto-ethnographic approach, Graham Rowles presents five emergent substantive-theoretical keys that help understand the meaning of place and aging from his more than 40 years of research with older adults. Finally, with M.M.Baltes and M.P.Lawton influencing his early work, Hans-Werner Wahl discusses the evolution of his research in person-environment dynamics, which encompass home environments, out-of-home mobility, technological environments and life-span processes. Laura Gitlin will serve as the session’s discussant.

FROM CARE HOME TO HOME CARE: A BRITISH WOMAN'S VIEW

S.M. Peace, *Faculty of Health & Social Care, The Open University, Milton Keynes, United Kingdom*

How can a life course perspective contribute to gerontological theory concerning person-environment interaction? As a British woman in her 60s; a researcher for over 35 years, and a social geographer interested in environmental psychology, I address this question. My experience of ageing is personal, familial, domestic and institutional (working as hospital and care home assistants). These encounters led to 1970s doctoral work on ageing in place and moving into social gerontology. Research at home and abroad initiated multidisciplinary work with impact for policy and practice. The 1980s addressed the design and quality of care homes through private lives in public places; the 1990s reflected on residential living, and the 2000s considered environment and identity; intergenerational interaction in public spaces; and the demands of kitchen living. Inspired by key players in this field, my autobiography reveals an eclecticism demonstrating environmental complexity in why we take up opportunities that come our way.

THE INTELLECTUAL ORIGINS OF RESIDENTIAL NORMALCY THEORY

S. Golant, *Geography, University of Florida, Gainesville, Florida*

My recent theoretical model equates the construct of residential normalcy to older persons occupying places where they are in their residential comfort and mastery zones and have pleasurable, hassle-free, and memorable emotional experiences and feel competent and in control. Failing to achieve residential normalcy, older persons initiate accommodative or assimilative coping strategies. My research on natural hazards and behavioral geography as a M.A. student (1969) in the Department of Geography, University of Toronto initially inspired the environmental gerontology focus of this work. The favorable intellectual environment in the 1970s and 1980s that witnessed the expansion of "environmentally-related" publications in gerontology, environmental psychology, ecological psychology, and geography helped to sustain my interest. A key influence was my PI role (1977-1981) in a NIA program project grant directed by Dr. Bernice Neugarten (Committee on Human Development, University of Chicago), and my investigation of the subjective experiences of a community-residing older population.

MEANING IN ENVIRONMENTAL GERONTOLOGY: AN AUTOETHNOGRAPHY

G.D. Rowles, *Gerontology, Univ of Kentucky, Lexington, Kentucky*

Contemporary environmental gerontology reflects the interweaving of many lives and ideas in time and space. In this presentation, I employ autoethnography to trace one participant's perspective on the role of specific publications, scholarly debates, international research collaborations, chance encounters and serendipity, in shaping a focus on meaning in environmental gerontology. Accepting the individual as a legitimate focus; expanding definition of lived experience to embrace vicarious environmental engagement; temporally framing experiences of place in relation to a life course; recognizing the motivational imperative of each person's lifelong quest for 'being in place;' and "making and remaking place" in response to environmental change, are documented as five keys to understanding the meaning of place. Each theme is illustrated from 40 years of research with older adults in diverse environments. Understand the meaning of place for older adults and its implications for practice and policy has become an essential component of environmental gerontology.

ECOLOGIES OF AGING AND ECOLOGIES OF AGING RESEARCH

H. Wahl, *Heidelberg University, Heidelberg, Germany*

My deep interest in the role of the environment happened, because I had the privilege to start my career supervised by Margret M. Baltes between 1984 and 1988. Her social-ecological research made me aware of the context-dependency of aging. A research visit at the Philadelphia Geriatric Center in 1988, coming with intensive interchange with M. Powell Lawton, finally brought me to the physical environment and Powell's 1977 chapter in the Handbook of the Psychology of Aging became a model for my own research. More concretely, I strived to combine environment-relevant person characteristics (vision and cognitive impairment) with a wide understanding of person-environment (p-e) dynamics including home environments, out-of-home mobility, and technological environments since the 1990's until today. More recently, I found it important to simultaneously consider the physical and social environment in aging (SPOT model together with Frieder Lang) as well as integrate p-e perspectives into existing life-span developing models.

SESSION 1755 (PAPER)

DISCOVERY EXCHANGE: FAMILIES AND DEMENTIA CARE

FAMILY CAREGIVERS' SATISFACTION WITH CARE IN ADVANCED DEMENTIA: THE TESTING OF A CONCEPTUAL MODEL

J. Boogaard[1], P. Werner[2], A. Zisberg[2], J.V. Steen[1], *1. VU University Medical Center, Amsterdam, Netherlands, 2. University of Haifa, Haifa, Israel*

Family caregivers' satisfaction with care may be operationalized as a proxy for quality of care. This approach, however, was criticized because satisfaction may be a result of family caregivers' own psychological and sociological characteristics. We examined this assumption using the stress-coping paradigm of Lazarus and Folkman (1984). We hypothesized that family caregivers' primary and secondary cognitive appraisal of and behavioral and emotional coping with caregiving stressors would relate to their satisfaction with care. To this end, primary appraisals were operationalized as family caregivers' evaluation of their relatives' health condition and of the nursing homes' environment; secondary appraisal as their expectations of care and trust in nursing home staff, emotional coping as emotional burden of care and behavioural coping as involvement in care. Structural Equation Modeling partially confirmed our hypothesis and showed in adjusted analyses that family caregivers' (N=214 Israeli caregivers) expectations of care positively influenced their involvement in social activities but negatively their emotional burden of care. Similarly, more trust in professional caregivers was associated with family caregivers' higher involvement in social activities and less emotional burden. Last, family caregivers who were more involved in social activities and experienced less emotional burden were more satisfied with the care. Surprisingly, family caregivers' evaluation of the health condition of their relative did not influence their appraisal and coping of caregiving stressors nor their satisfaction with care confirming the assumption that family caregivers' satisfaction is more than a proxy of quality of care and also defined by their own emotions, needs and experiences.

GUILT IN DEMENTIA FAMILY CAREGIVERS: RELATED FACTORS

A. Losada[1], M. Marquez-González[2], V. Fernández-Fernández[1], J. Lopez[3], C. Nogales-González[1], R. Romero-Moreno[1], *1. Psychology, Universidad Rey Juan Carlos, Madrid, Spain, 2. Universidad Autónoma de Madrid, Madrid, Saint Barthelemy, 3. Universidad CEU San Pablo, Madrid, Saint Barthelemy*

Introduction Although guilt feelings are frequently reported by caregivers, the number of studies analyzing this variable is sparse. This work explores the relationships between guilt and variables included in the caregiving stress framework. Method Interviews were done with 454 dementia family caregivers (mean age: 60.62 years; SD: 13.6; 78.4% female). In addition to guilt, sociodemographic variables, functional status, frequency of memory and behavioral problems of the care-recipient, cognitive reappraisal, rumination, leisure and depressive symptomatology of the caregiver, have been measured. A model has been tested using structural equation modeling. Results Excellent fit of the data to the model has been obtained ($\chi2 = 42.89$; p = .08; $\chi2/df = 1.41$; IFI = .99; CFI = .99; RMSEA: .03). A 37% of the variance of guilt is explained through the model, and 53% of depressive symptomatology. Being daughter/son, having a higher level of formal education, greater reaction to memory and behavioral problems, higher rumination and less cognitive reappraisal are directly associated with guilt feelings. Other variables, such as frequency of leisure, have an indirect relationship with guilt. Although a strong correlation exists between guilt and depression ($p < .01$), the model suggest that this relationship is not direct, but mediated by, among other variables, the use of rumination. Conclusions The proposed model allows the explanation of an important variance of caregivers' guilt and points to the relevance of some variables as predictors of guilt, which may be targets of interventions aimed to reduce this frequent emotion in caregiving.

BEYOND RESPITE: THE ROLE OF ADULT DAY SERVICES IN SUPPORTING DEMENTIA CAREGIVERS

K.A. Anderson[1], H. Dabelko-Schoeny[2], J.R. Carter[2], *1. University of Montana, Missoula, Montana, 2. College of Social Work, The Ohio State University, Columbus, Ohio*

Background: Dementia caregivers are at a higher risk for emotional and physical health problems compared to caregivers for individuals without cognitive impairment. Adult day services (ADS) is the leading provider of community-based care for persons with dementia and their family caregivers. While the capacity of ADS centers to provide caregiver respite is well-documented, little is known about the provision of other forms of dementia caregiver support. Methods: Using the MetLife National Study of ADS, centers that reported dementia in at least 50 percent of participants were selected for this analysis (N = 297). Frequencies and binary logistic regression analyses were run to determine the presence of and factors related to the provision of case management, caregiver education, caregiver support groups, and individual counseling for caregivers. Results: Between 36% and 66% of the ADS programs offered at least one type of dementia caregiver support program. Social worker hours per shift was a significant predictor of case management services (OR = 1.10; 95% CI 1.03, 1.17). Non-profit status was a significant predictor of caregiver education (OR = 2.11; 95% CI 1.11, 4.01) and caregiver support groups (OR = 2.95; 95% CI 1.11, 4.01). Discussion: A considerable percentage of ADS centers provided dementia caregiver support programs beyond respite. Trained personnel and non-profit status appeared to be key determinants of service provision. With higher levels of reimbursement, ADS centers may find that offering these services can produce revenue and better serve families impacted by dementia.

VA TELE-SAVVY: TRANSLATING A FACE-TO- FACE DEMENTIA CAREGIVER PROGRAM FOR TELE-IMPLEMENTATION

P.C. Griffiths[1,2,3], M. Whitney[1,2], A.E. Vandenberg[2,1], K. Hepburn[2], B. Patel[2,1], *1. Rehab R&D, Atlanta VAMC, Decatur, Georgia, 2. Emory University, Atlanta, Georgia, 3. Georgia Institute of Technology, Atlanta, Georgia*

Dementia caregiving can exact an enormous toll on the emotional, physical and financial resources of the caregiver. VA Tele-Savvy is a quality improvement initiative undertaken to translate a fully manualized, evidence based, multi-session group psycho-educational program for caregivers (CG) who provide care for persons with dementia into a tele-implementation modality. The Savvy Caregiver in-person programs have demonstrated efficacy and effectiveness in multiple culturally and ethnically diverse CG populations in the US. However, challenges with high attrition in face to face programs speak to the value of exploring alternate implementation modalities. The 6-week Tele-Savvy program consists of daily asynchronous video classes, once weekly synchronous tele-video classes and homework and exercises completed using the Tonic Health Platform. The curriculum elements were extracted from Savvy and videotaped for presentation on the iPads. In this presentation we (1) describe the translation process from F2F to Tele (2) report the results of a Delphi content vetting with Savvy experts (3) demonstrate sample video learning modules (4) compare and contrast the components of each program with emphasis on intervention integrity and fidelity and (4) summarize preliminary evaluation results from the first two cohorts of caregivers.

COMMUNITY IMPLEMENTATION OF AN INTERVENTION PROGRAM FOR CAREGIVERS OF ALZHEIMER'S PATIENTS

S.J. Czaja[1], C. Lee[1], D.M. Perdomo[1], D. Loewenstein[1], M. Bravo[2], V. Rosas[2], R. Schulz[3], *1. Psychiatry and Behavioral Sciences, University of Miami Miller School of Medicine, Miami, Florida, 2. United HomeCare, Miami, Florida, 3. University of Pittsburgh, Pittsburgh, Pennsylvania*

Caring for a relative/friend with an illness or disability often causes distress in caregivers and compromises their health and well-being. This study evaluated a community-based implementation of the REACH II evidenced based program with family caregivers of Alzheimer's patients. The sample included 148 caregivers who were largely female (77%) and primarily providing care for a spouse or parent. Their average age was 66 years (M = 65.7, SD = 12.8) and they had been providing care from 6 months to up to 32 years (M = 4.43 yrs.; SD = 4.4 yrs.). The care recipients were moderately impaired; their average MMSE score was 11 (M = 11.1, SD = 7.80). The intervention was a multi-component psychosocial intervention delivered in the caregivers' homes over a period of 6 months. Assessment measures, administered at baseline and 6 months follow-up, included measures of: depression, burden, social support, self-reported health and perceptions of the caregiving role. The study was a pre-test post-test design. One hundred and nine caregivers completed the follow-up assessment. The results indicated a significant decrease in depressive symptoms ($t(1) = -4.83$, $p < .001$), and in burden (t (1) = —4.39, $p < .001$). There was also an increase in perceived social support ($t(1) = 2.07$, $p < .01$) and in positive feelings about caregiving ($t(1) = 2.30$, $p < .05$). The findings indicate that the intervention was effective in improving caregiver outcomes and that it is feasible for community agencies to implement evidenced-based intervention programs.

SESSION 1760 (PAPER)

LIFE COURSE AND DEVELOPMENTAL CHANGE

THE ROLE OF TRANSCENDENCE IN THE ADAPTIVE PROCESS OF THE VERY OLD

E. Schuster, *Eastern Michigan University, Ypsilanti, Michigan*

Transcendence theory takes a positive approach to aging and is grounded in the perspective that late life may be a time of dynamic inner growth and transformation whereby older adults transcend barriers and achieve a state of inner peace. Late adulthood involves an ongoing process of adaptation due to physical and mental deterioration. Too often the emphasis is on this decline, even though the developmental process of transcendence may also be occurring and may serve as an important inner resource and counterbalance to inevitable loss and frailty. This presentation describes a qualitative research study that explored the role the late life developmental stage of transcendence plays in the adaptive process of individuals 90 years of age and older. Two 2-3 hour in-depth interviews and observations were conducted with a diverse group of 15 individuals whose ages ranged from 90-106 years old. The study focused on the participants' daily activities, their adaptation strategies (particularly compensation), and their experiences involving transcendence. Transcribed interviews were analyzed through the theoretical perspective of the Selection, Optimization and Compensation (SOC) model and transcendence theory. Findings indicate that the participants experienced the following elements of transcendence that have a relationship to adaptation: contemplation and reflective solitude; a decline in self-centeredness and materialism; an acceptance of the way things are; positive detachment; and, tolerance and wisdom. This study makes an important contribution to late life developmental theory and to our knowledge base regarding transcendence and its role in the adaptive process during the final stage of life.

LIFETIME WORK-FAMILY EXPOSURES PREDICT SUBSEQUENT MORTALITY RISK AMONG OLDER AMERICAN WOMEN

E.L. Sabbath[1], I. Mejia[1], M. Glymour[2], L.F. Berkman[1], *1. Center for Population and Development Studies, Harvard University, Cambridge, Massachusetts, 2. University of Cailfornia San Francisco, San Francisco, California*

Background: Work-family conflict predicts multiple short- and long-term health outcomes. However, few studies have used life course methods to understand associations between trajectories of work-family demands and health disparities in later life. Methods: We analyzed women in the US Health and Retirement Study born 1935-1956. Employment status, marital status, and parental status (child under 18) was determined for each year of a woman's life between ages 16 and 50. We used sequence analysis to identify seven prototypical work-family trajectories. We calculated age-standardized mortality rates (ASMR) between ages 55-75 for each work-family state, overall and stratified by known mortality risk factors. Results: Married women who stayed home with children for a few years before entering or reentering the labor force had the lowest ASMR (48 per 1,000 women, 95% CI 46,51). Single mothers who did not work had the highest mortality rates (ASMR 122 per 1,000, 95% CI 111,132), followed by single mothers who worked (ASMR 83, 95% CI 77,90). Low education, black race, and current smoking predicted mortality for all groups, but the relative excess was most marked among individuals who had been single mothers, compared with women in the other groups. Additionally, factors associated with decreased mortality risk—high education, non-Hispanic white race/ethnicity, and never smoking—conferred less protection on single working mothers than on consistently married working mothers. Conclusion: Prolonged exposure to single motherhood during early and middle adulthood predicts increased mortality risk in later life, and may exacerbate effects of known mortality risk factors.

THE INFLUENCE OF MARITAL QUALITY ON MENTAL HEALTH IN MIDLIFE AND OLDER AGE: A U.S. LONGITUDINAL STUDY

S. Kang[1], H. Choi[2], *1. South Dakota State University, Brookings, South Dakota, 2. Penn State Altoona, Altoona, Pennsylvania*

Guided by a life course perspective, this study aimed to investigate the influence of marital quality over time on multiple dimensions of mental health in midlife and older age. Specifically, this study examined how continuously high marital strain, decreased marital strain, or increased marital strain (in contrast to continuously low marital strain) over ten years is linked to change in three dimensions of mental health (overall psychological well-being [Ryff's total score], positive affect, negative affect), and evaluated how gender might moderate these linkages. Data from continuously married respondents in the National Survey of Midlife in the U.S., 1995-2005 (MIDUS) ages 33 to 83 (N = 995; 519 men, 476 women) were used to estimate multivariate models. Results revealed that married men and women reporting continuously high marital strain over ten years exhibited greater decrease in overall psychological well-being and positive affect. Similarly, men and women reporting increased marital strain over time exhibited greater decrease in overall psychological well-being and positive affect. Gender differences were observed in predicting negative affect: Men reporting continuously high strain and men reporting an increase in marital strain over time reported greater increases in negative affect over time than women. In sum, results revealed that continuous and increased marital strain is linked to declines in multiple dimensions of mental health for both men and women, but men are even more disadvantaged in terms of increases in negative affect.

THE CONTINUITY OF CHANGE: BELIEFS AND VALUES AMONG OLDER ADULTS

A. Hoogland, *University of Kentucky, Lexington, Kentucky*

Introduction: Aging research often focuses on decline in old age, but there has been an upsurge in studies addressing positive change in late life. Current scholarship suggests a positive developmental change experienced by some older adults as a product of life experiences, but it remains unclear how this change might influence core beliefs and values. Specifically, it is unknown how personal worldview changes with age. Methods: Eighteen older adults (aged 62-85; 14 F) were recruited into three age-stratified focus groups. In each 90-minute session, participants were asked to articulate their core beliefs, and explore how these beliefs may have evolved over time. Interviews were digitally recorded, transcribed, and analyzed using a constant comparative method following initial code determination. Findings: Three primary themes emerged: continuity of core beliefs; change in core self and other-oriented beliefs; and increased acceptance over time. Conclusions: There is continuity of the changing self with age as influenced by life experiences. One's beliefs and values appear to shift with time and can allow older adults to adopt an increasingly transcendent perspective of life that includes a decreased emphasis on matters related to the self, and an increased focus on the welfare of others and general harmony. Future Directions: Building on Tornstam's theory of Gerotranscendence and Reed's theory of Self-Transcendence, these findings offer compelling directions for research investigating typologies of worldview change in old age, and how beliefs and values might alter behavior, particularly for those suffering with a chronic or terminal illness.

THE IDENTIFICATION OF REGIONS OF SIGNIFICANCE IN THE EFFECT OF MULTIMORBIDITY ON DEPRESSIVE SYMPTOMS USING LONGITUDINAL DATA: AN APPLICATION OF THE JOHNSON-NEYMAN TECHNIQUE

P. Rast, J. Rush, A.M. Piccinin, S.M. Hofer, *University of Victoria, Victoria, British Columbia, Canada*

The investigation of multimorbidity and aging is complex and highly intertwined with aging-related changes in physical and cognitive capabilities. Under these circumstances it is important to understand how the effects of chronic conditions evolve over time relative to aging-related and end of life changes. The identification of periods in time where multimorbidity impacts particular outcomes, such as depressive symptoms, versus periods of time where this is not the case, reduces the complexity of the phenomenon. We present the Johnson-Neyman (J-N) technique in the context of a curvilinear longitudinal model with higher-order terms to probe moderators and to identify regions of statistical significance. In essence, the J-N technique allows one to identify conditions under which moderators impact an outcome from conditions where these effects are not significant. To illustrate the use of the J-N technique in a longitudinal sample, we used data from the Health and Retirement Study (HRS). Analyses were based on time-to-death models including participants who died within the study duration of 12 years. Multimorbidity differentially affects rates of change in depression. For some periods in time the effects are statistically significant while in other periods the same effects are not statistically different from zero. The J-N technique is useful to continuously probe moderating effects and to identify particular interactions with the model for time when certain effects are or are not statistically significant. In the context of multimorbidity this method is particularly useful for interpreting the complex interactions with differential change over time.

SESSION 1765 (PAPER)

FAMILY CONTEXTS AND CAREGIVING

SHOULD I DO THIS? FACTORS INFLUENCING THE DECISION TO RAISE A GRANDCHILD AMONG CUSTODIAL GRANDPARENTS

B. Hayslip[1], J. Fish[1], C.A. Fruhauf[2], *1. Psychology, University of North Texas, Denton, Texas, 2. Colorado State University, Ft. Collins, Colorado*

Previous work exploring custodial grandparenting has focused upon reactions to the newly assumed parental role. Over and above a simple description of the reason for assuming care (e.g. incarceration, divorce, or drug use of the adult child), no work has explored in depth those factors that influence the decision to raise one's grandchild. The present study explored in detail those parameters impacting the decision-making processes among grandparents in developing a typology of influences framed in terms of negative (i.e.,"escape/avoidance") and positive (i.e., "enrichment/strengthening") poles influencing such decision-making. Eighty-nine custodial grandparents (85% women, Mage = 58.6, 73% Caucasian) described this decision-making process in detail, wherein 15 derived dimensions regarding decision-making processes was coded as both positive and negative in nature (e.g. love for the grandchild vs. acting on concerns for his/her safety; enhancing one's self vs. undermining one's lifestyle; positive parenting vs. guilt over past failures) were derived. Based upon 15 randomly selected protocols, we found that the positive and negative poles of each dimension could be scored (presence/absence) reliably (> 80% agreement). The elicited frequency of both the positive and negative poles was independent of both grandparent caregiver and grandchild characteristics, and with the exception of the normalcy dimension, was elicited in at least 30% of the cases. The typology of decision-making derived here enables a more in-depth and qualitative understanding of those influences on the choices grandparents make in raising a grandchild, over and above a simple accounting of events leading to the adoption of the grandparent caregiving role.

COMPARATIVE EFFECTIVENESS OF INTERVENTIONS FOR IMPROVING THE WELL-BEING OF CUSTODIAL GRANDMOTHERS AND GRANDCHILDREN

G.C. Smith[1], B. Hayslip[2], J. Montoro Rodriguez[4], F.H. Strieder[3], M.L. Williamson[1], P. Greenberg[3], G.R. Hancock[5], *1. Kent State University, Kent, Ohio, 2. University of North Texas, Denton, Texas, 3. University of Maryland, Baltimore, Maryland, 4. California State University, San Bernardino, California, 5. University of Maryland, College Park, Maryland*

No large randomized clinical trials (RCT) have yet examined the efficacy of pschoeducational interventions delivered to custodial grandmothers (CGM). We conducted a multi-site RCT with 343 CGM (M age = 54) of target grandchildren (TGC) ages 4-12 (M age = 7.81; 51% male) enrolled across four states comparing the efficacy of Behavioral Parent Training (BPT), Cognitive Behavioral Coping (CBC), and an Information-only control condition (IOC). Each RCT condition was administered to CGM through 10 two-hour group sessions co-lead by professionals and peers. Consistent with the Family Stress Model, outcomes included multitrait-multimethod indices of CGM psychological distress; CGM parenting practices; and TCG behavioral difficulties assessed within one month windows at pre and post-intervention. Intent-to-treat analyses were performed using a repeated measures latent difference score model with dummy variables created to compare RCT conditions on pre to post-intervention change across all outcomes with missing data considered (Mplus 7.1). No significant differences by RCT condition emerged for the latent constructs of CGM distress (self-reports and clinical ratings of anxiety and depression) and parenting warmth (nurturance and positive regard). However, compared to IOC, both CBC and BPT were more effective at reducing (a) CGM ineffective discipline (harsh and inconsistent); (b) TCG externalizing symptoms (conduct problems and hyperactivity); and (c) TCG internalizing symptoms (emotional and peer problems). Effect sizes for these comparisons ranged from .32 to .72. The applied and theoretical implications of these findings will be discussed from the perspective of the Family Stress Model. [Funded by R01NR012256]

FAMILY PARTICIPATION, SUPPORTIVE STAFF, AND FAMILY MEMBER WELL-BEING IN ALZHEIMER'S CAREGIVING

S. Ashida[1], C.S. Marcum[2], A.F. Goergen[2], L.M. Koehly[2], *1. Community and Behavioral Health, University of Iowa College of Public Health, Iowa City, Iowa, 2. National Human Genome Research Institute, Bethesda, Maryland*

Caregiving distress among the family of individuals affected by Alzheimer's disease continues to be an important public health concern. Limited participation in caregiving among family members can negatively impact the well-being of family caregivers. Evidence also suggests positive impacts of support from formal care staff. Using social network methodology, we evaluated the roles of family participation in caregiving processes and presence of supportive staff at care facilities on the psychological well-being of family members. Seventy-two family members from 30 families recruited through three residential and two adult day care facilities in Memphis, TN, were interviewed and provided information about 908 network members (family, friends, formal caregivers). Hierarchical linear regression analyses were conducted to account for the clustered nature of the data. Higher participant distress (CES-D) was associated with lower proportion of family members over-contributing in direct care (b=-3.66, p=0.005) controlling for caregiver burden and demographic covariates; however, this became marginally significant (p=0.08) when the number of supportive staff (b=-0.28, p=0.04) was included. Higher proportion under-contributing in support provision to family caregivers (b=2.35, p=0.03) was associated with higher distress which became marginal (p=0.06) when staff support (b=-0.32, p=0.04) was added to the model. Presence of supportive facility staff may be particularly important in family caregivers' psychological well-being when expectations about participation in care within family are not being met. Future research will investigate how best to involve facility staff in preventing or minimizing psychological distress among family caregivers associated with limited family participation in caregiving processes.

DOES CAREGIVER BURDEN MEDIATE THE RELATIONSHIP BETWEEN BEHAVIOR DISTURBANCES AND LONG-TERM CARE IN PERSONS WITH ALZHEIMER'S?

C.N. Porter, M.C. Miller, *University of South Carolina, Columbia, South Carolina*

The relationship between behavioral disturbances, caregiver burden, and nursing home admission (NHA) has been investigated but is not completely understood. The purpose of this study was to evaluate if Zarit Burden Interview (ZBI) scores mediate the relationship between Neuropsychiatric Inventory (NPI) outcomes and NHA. Cases and controls were selected from the South Carolina Alzheimer's Disease Registry and were eligible for NHA. Cases (n=352) had entered a NHA within 6 months of study initiation; controls (n=289) remained in the community. Registry data was combined with data from a survey of caregivers, which included the 12-domain NPI and the ZBI. Mediation analyses were assessed for statistical significance of the Sobel test and percent of the total effect mediated. Mediation was evaluated with and without adjustment for covariates. The NPI, NPI-4 (i.e. NPI scale assessing 4 behavioral disturbances: agitation, irritability, disinhibition, and aberrant motor behavior), and 12 individual domains of the NPI were all considered as independent variables. The results of the Sobel tests were statistically significant for all mediation models. Adjustment for covariates increased the percentage of total effect mediated for all NPI outcomes except for NPI-4 and the domains of hallucinations, disinhibition, aberrant motor, and sleep. ZBI score mediates the relationship between NPI and NHA, meaning behavioral disturbances influence caregiver burden which in turn influences nursing home admission. These results suggest interventions that support caregivers and help to alleviate their sense of burden may be effective in reducing and/or delaying nursing home admission, in effect, alleviating burden on the healthcare system.

SESSION 1770 (PAPER)

EMOTIONS AND WELL-BEING

POSITIVE AFFECT COUNTERACTS THE BIASING EFFECT OF NEGATIVE AFFECT ON PERCEIVED HEALTH IN OLDER ADULTS

B. Whitehead[1], C.S. Bergeman[2], *1. Behavioral Sciences, University of Michigan-Dearborn, Dearborn, Michigan, 2. University of Notre Dame, Notre Dame, Indiana*

Subjective health reports biased by affect—or affective health bias—is a persistent concern, particularly in studies of later life. This project address two gaps present in the existing literature. First, most studies have focused on Negative and high-arousal affect within the context of health bias; here, the role of both Positive and Negative Affect (PA/NA)—represented by both low- and high-arousal items—are examined. Second, the majority of health bias literature focuses on samples suffering from a certain diagnosis or on reports of a specific symptom; here, we investigate health bias in a more general sample of community-dwelling older adults. 153 adults aged 56-82 years (M=71.2) completed a global questionnaire (assessing Perceived Health and Affect) and a physical health battery (assessing Objective Health via cholesterol, blood pressure, heart rate, and physician diagnoses). Structural equation modeling tested the extent to which the association between Perceived and Objective Health was moderated by PA or NA. All measurement models demonstrated good fit, with significant factor loadings ($p<.0001$) and strong model fit (CFI's from 0.93-0.99). Structural models revealed evidence for a moderation (biasing) effect for NA ($B=-0.187$, $p=.036$), but not for PA; the combined model indicated a mediating role for PA, however, such that it serves to make the NA bias term non-significant ($p=.07$). Results provide evidence that health bias does occur within a general health context, and not only within specific symptom or diagnostic paradigms; the findings also reveal that both PA and NA play important—albeit distinct—roles in the process.

THE INFLUENCE OF CONTROL ON DAILY AFFECT REGULATION IN LATER LIFE: LONGITUDINAL AND DEVELOPMENTAL APPROACHES TO UNDERSTANDING CHANGE

A. Russell, S. Scott, C. Bergeman, *University of Notre Dame, South Bend, Indiana*

Control is not a unidimensional construct, and different aspects of control, such as control over one's environment (primary control) or one's emotional responses (secondary control), may be important at different points in the lifespan or under different life circumstances. Data from the Notre Dame Study of Health & Well-being was used to assess the complementary and compensatory nature of primary and secondary control as well as individual differences in intraindividual change in these important processes. A three-level MLM was used to maximize the three levels of data (day-level, burst-level, and person-level). Results indicated a significant daily relationship between environmental control and negative affect, and that this relationship decreased in strength across a 5-year period. Global emotion control (but not global environmental control) moderated the daily relationship; specifically, on days of lower environmental control, individuals with higher global emotion control had lower negative affect than those with lower global emotion control. Age also moderated the daily relationship, with relatively older adults demonstrating lower negative affect on days of lower environmental control. Implications of these findings are discussed with regard to the compensatory nature of secondary control, aging, and intraindividual change and interindividual differences.

DAILY INTERACTIONS AND AFFECT BALANCE: FUNCTIONS OF FRIEND AND FAMILY SUPPORT

M. Montpetit[1], S.S. Tiberio[2], *1. Illinois Wesleyan University, Bloomington, Illinois, 2. Oregon Social Learning Center, Eugene, Oregon*

Although scores of studies suggest that family and friend support differentially impact well-being, relatively few investigate how these relationships function day-to-day. The current study explored how interactions with family and with friends related to individuals' daily experience of positive and negative emotion. Multilevel random coefficient modeling illuminated these linkages in data from 83 participants from Successful Aging in Context: The Macroenvironment and Daily Lived Experience (Mage=66.7 years, SDage=5.3 years; 45% Male, 55% Female). Results revealed significant relationships between affect balance and satisfaction with the amount of support provided by family and by friends; in general, individuals reported a higher ratio of positive to negative affect on days they were more satisfied with the amount of support received. Results of Level-2 analyses suggested that both relying on friends for help and affection and seeking advice and companionship from them moderated the relationship between daily support and affect balance, but in different directions. Utilizing friend support for coping purposes was negatively related to the daily friend support-affect balance association; it could be that individuals sought more of this type of support on days that they were struggling. Conversely, utilizing friend relationships for release and relaxation was associated with a stronger relationship between daily friend support and reporting more positive emotions than negative. The variables did not predict individual differences in the daily relationship between family support and affect balance. Results can be applied toward explicating the process by which elders use social support to facilitate emotional well-being on daily basis.

PSYCHOLOGICAL IMPACT OF PAST LIFE EVENTS: MEDIATING EFFECTS OF EMOTION REGULATION STRATEGIES IN THE EXPLANATION OF PSYCHOLOGICAL DISTRESS

V.F. Fernández[1], M. Marquez-González[2], A. Losada[1], R. Romero-Moreno[1], C. Nogales-González[1], J. Lopez[3], *1. Fac. de Ciencias de la Salud, Universidad Rey Juan Carlos, Alcorcón, Spain, 2. Universidad Autónoma de Madrid, MADRID, Spain, 3. Universidad San Pablo Ceu, MADRID, Spain*

Introduction and objectives Life events have a direct impact on psychological well-being. While it is known that emotion regulation strategies (e.g. rumination, experiential avoidance or personal growth) have a mediating effect on the impact of life events on well-being, this effect has been sparsely studied in elderly. The objective of this study is to analyze the impact of past life events (positive/negative) on the well-being of elderly, and to analyze the possible mediating role of emotion regulation strategies in this relationship. Method Participants in this study were 393 people older than 60 years (mean age: 71.5 years; d.t: 6.9, 70.2% women). Life events, emotion regulation variables (experiential avoidance -EA-, ruminative style -RS-, ruminative-thinking about life events -RTLE- and personal-growth associated to life events –PGLE-) and psychological distress (well-being and depressive symptoms) were assessed. A model of psychological distress, based on the stress and coping model, was analized through structural equation modeling. Results The model fit excellently ($\chi 2$/df=1.77, GFI=.98, CFI=.99, TLI=.97, RMSEA=.04). The occurrence of positive life events exerts a direct effect on psychological distress (r= -.14, p≤0.01). However, the impact of negative life events on distress is indirect, mediated by emotion regulation strategies, which have a direct effect on distress (EA: E=.34; RS: r= .40; RTLE: r= .14; PGLE: r= -.15, p≤0.01). The final model explained 71% of the variance of psychological distress. Conclusions Emotion regulation strategies have a significant role in the explanation of how past negative life events have an impact on current psychologic

AGING, REACTIVITY TO DAILY STRESSORS AND LONG-TERM HPA-AXIS DYSREGULATION

J.R. Piazza[1], S.T. Charles[2], D. Almeida[3], *1. Health Science, California State University, Fullerton, Fullerton, California, 2. University of California, Irvine, Irvine, California, 3. Pennsylvania State University, University Park, Pennsylvania*

Daily stressors have been linked to short-term changes in physiological biomarkers (e.g., Stawski, Cichi, Piazza, & Almeida, 2013). It is unclear, however, whether these minor daily hassles have long-term physiological consequences. The current study examined this question by determining whether an individual's reactivity to daily stressors predicted their likelihood of experiencing long-term HPA-axis dysregulation. Participants from the Midlife Development in the United States Survey (n = 287; ages 34-84), completed a series of daily diary interviews in the mid-1990's. Ten years later, participants were re-contacted for a second series of interviews and a comprehensive physiological assessment. Results revealed that age and reactivity to daily stressors worked synergistically to predict HPA-axis dysregulation. No differences in HPA-axis dysgregulation emerged for younger adults, regardless of level of stressor reactivity. Highly reactivity older adults, however, were significantly more likely to show evidence of HPA-axis dysregulation than were less reactive older adults (β = .051, p < .05).

SESSION 1775 (SYMPOSIUM)

MULTIPLE PERCEPTIONS ON GAIT MECHANICS AND MOBILITY: FROM THE BALTIMORE LONGITUDINAL STUDY OF AGING

Chair: E.M. Simonsick, *National Institute on Aging, Baltimore, Maryland*
Discussant: S. Studenski, *National Institute on Aging, Baltimore, Maryland*

Perceptual feedback from sensory processes and perceived effort likely condition short and long-term behavioral choices (e.g., preferred gait speed and activity level) critical for maintaining functional capacity with aging. This symposium uses data from the Baltimore Longitudinal Study of Aging (BLSA), a continuous enrollment cohort study of initially healthy well-functioning individuals evaluated every 1-4 years depending on age during a 2-3 day clinic stay, to examine the association between multiple perceptual factors including ankle proprioception, visual contrast sensitivity and stereo-acuity, mechanical work and mechanical load and their association with subjective and objective assessments of mobility and activity level. Ankle proprioception assessed using a newly developed automated performance test is examined in relation to gait mechanics derived from a state-of-the-art gait laboratory in persons with and without impaired balance and in relation to multiple gait speed parameters and reported walking ability. Using measures of mechanical work at multiple joints derived from force-plate readings in the gait lab, the impact of perceived effort is evaluated in relation to self-selected daily activity levels from accelerometry testing in the home environment. Comprehensive measures of visual impairment are investigated with respect to longitudinal change in preferred gait speed and perceived walking ability. Lastly, cross-sectionally and longitudinally, the association of excess body weight (i.e., mechanical load) on distance walked at preferred speed is evaluated. Findings support the important role of sensory-related perception in the disablement process and perceived effort or work in conditioning self-selected activity level and gait speed.

CONTRAST SENSITIVITY AND STEREOACUITY IMPAIRMENT AND MOBILITY DECLINE

B. Swenor[1], E.M. Simonsick[1], G.J. Jerome[2], *1. NIA/NIH, Baltimore, Maryland, 2. Towson University, Baltimore, Maryland*

Capacity to distinguish contrast and depth perception has received limited attention in the disablement process. In 520 non-mobility limited BLSA participants aged 60-95 years (52% men, 25% black), we examined whether impaired contrast sensitivity and stereoacuity predicted change in usual gait speed and self-reported walking ability over a mean follow-up of 2.3 years. Overall, 11.7%, 6.7% and 2.5% had impaired contrast sensitivity (logContrast <1.55), stereoacuity (>85 arc seconds) and distance visual acuity (worse than 20/40), respectively. Adjusting for age, age-squared, sex, race, BLSA visit status, other visual impairment, initial gait speed (or self-report ability) and follow-up time, persons with contrast sensitivity impairment had slower gait speeds (β=-0.061; p=0.013). The stereoacuity impaired had slower gait speeds (β=-0.066; p<0.033) and trended toward poorer walking ability (range 0-9) (β=-0.458; p=0.062). Ascertaining broader and potentially more prevalent visual impairments may aid in identifying an overlooked threat to mobility loss in clinical and research settings.

ANKLE PROPRIOCEPTION ASSOCIATED GAIT PATTERNS IN OLDER ADULTS WITH AND WITHOUT IMPAIRED BALANCE: RESULTS FROM THE BLSA

S. Ko[1], D. Kauffman[2], N. Deshpande[3], E.M. Simonsick[2], *1. Department of Mechanical Engineering, Chonnam National University, Yeosu, Republic of Korea, 2. Translational Gerontology Branch, National Institute on Aging (NIA/NIH), Baltimore, Maryland, 3. School of Rehabilitation Therapy, Queen's University, Kingston, Ontario, Canada*

Ankle proprioception training has been found to improve balance-related gait disorders; yet, the relationship between ankle proprioception and specific gait patterns in older adults with impaired balance has not been systematically examined. This study characterizes gait patterns of 208 older adults aged 60-92 evaluated in the Baltimore Longitudinal Study of Aging (BLSA) gait laboratory with (n=66) and without impaired balance and examines ankle proprioception performance. Participants with impaired balance defined as inability to successfully complete a narrow walk had poorer ankle proprioception performance than those with unimpaired balance (p<0.001). Stride length, ankle ROM, and hip concentric MWE were negatively associated with ankle proprioception performance (p < 0.050 for all) but only in participants with impaired balance. Results indicate that assessment of ankle proprioception performance in older adults especially those with impaired balance may provide important insights and better targeting of interventions to improve balance-related gait disorders.

ANKLE PROPRIOCEPTION AND OBJECTIVE AND SUBJECTIVE MOBILITY IN OLDER PERSONS

N. Deshpande[1], E.M. Simonsick[2], S. Ko[3], *1. Queen's University, Kingston, Ontario, Canada, 2. NIA/NIH, Baltimore, Maryland, 3. Chonnam National University, Yeosu, Republic of Korea*

Ability to sense body position at the ankle may influence walking ability. We examined the association of threshold for perception of passive movement (TPPM) at the ankle joint in 685 BLSA participants aged 65-85 who completed TPPM measurement. Gait speed was measured as usual fast and on a narrow-path (20cm width). Walking index score (0-9) ranged from self-reported inability to walk ¼ mile to "very easy" to walk 1 mile. Adjusting for age and height, usual gait speed was slower in the lowest two TPPM quintiles ($p<0.001$). These differences persisted for fast walking ($p=0.001$) and narrow-path walking ($p=0.003$) even after adjusting for usual speed. Adjusting for age, higher ($p=0.011$) proportion of participants in the lowest two quintiles failed narrow-path walking. Walking-index was worse in lowest two quintiles ($p<0.001$). Persons with ankle TPPM>1.35 degrees, consistently demonstrated worse objective and subjective mobility supporting assessment of ankle proprioception for preventative intervention.

ASSOCIATION OF WEIGHT AND WALKING ENDURANCE: CROSS-SECTIONAL AND LONGITUDINAL PERSPECTIVES

G.J. Jerome[1], D. Kauffman[2], S. Ko[3], E.M. Simonsick[2], *1. Towson University, Towson, Maryland, 2. National Institute on Aging, Baltimore, Maryland, 3. Chonnam National University, Yeosu, Republic of Korea*

Excess mass or weight may create additional burden when walking even short distances. Using data on 385 BLSA participants (48% men, 29% black) aged 60-80, with average BMI of 28(SD=4.8) who completed a 2:30 normal-pace walk on two separate visits which were on average 2.3 years apart. Cross-sectional analysis accounting for age, sex, race, height, and self-reported physical activity level, indicate that for every 3 kg of body weight above average weight of 79 kg, distance covered was lower by 1.6 meters ($p<.001$) which was similar in magnitude to an additional year of age. Longitudinal analyses indicated that for every 3 kg of body weight above the average at baseline, distance covered at follow-up was lower by 0.5 meters ($p=.05$) adjusting for the aforementioned covariates, baseline distance walked and time to follow-up. Results indicate that excess weight may threaten current and future walking endurance and contribute to accelerated aging.

SEX AND AGE-SPECIFIC ASSOCIATIONS BETWEEN GAIT EFFICIENCY AND DAILY ACTIVITY

D. Kauffman[1], E.M. Simonsick[1], G.J. Jerome[2], J.A. Schrack[3,1], S. Ko[4], S. Studenski[1], *1. National Institute of Aging/National Institutes of Health, Baltimore, Maryland, 2. College of Health Professions, Towson University, Towson, Maryland, 3. Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland, 4. Chonnam National University, Yeosu, Republic of Korea*

Energetic cost of moving may be related to physical activity level. However, relationships between gait efficiency and activity in men and women and at different ages have not been investigated. Work expenditure was calculated from the kinematics and kinetics of a 3D gait analysis system in 240 participants of the BLSA (age 60-93) without walking limitation who wore the Actiheart accelerometer/heart rate monitor 7.2(±3.2) days in their home environment. Gait efficiency and activity were associated beginning in the 7th decade in women and 8th decade in men. These associations were mainly attributed to hip joint movements in women and ankle joint movements in men, largely in the frontal plane. Efficiency was lower in the lowest versus the highest activity tertile in both older women ($p=.004$) and men ($p=.022$). Sex-specific interventions are needed to determine directionality of the gait efficiency and physical activity relationship.

SESSION 1780 (SYMPOSIUM)

NOT ALL ACTIVITY THAT COUNTS CAN BE COUNTED: METHODS FOR OBJECTIVE ASSESSMENT OF ACTIVITY IN OLDER POPULATIONS

Chair: J.A. Schrack, *Epidemiology, Johns Hopkins School of Public Health, Baltimore, Maryland, National Institute on Aging, Baltimore, Maryland*
Co-Chair: T. Glass, *Epidemiology, Johns Hopkins School of Public Health, Baltimore, Maryland*
Discussant: L. Ferrucci, *National Institute on Aging, Baltimore, Maryland*

The advent of wearable devices has introduced a new layer of complexity to assessing physical activity and mobility in older adults. These devices collect data with an unprecedented level of detail and produce massive amount of data that can be managed, analyzed, and interpreted in multiple dimensions. This symposium focuses on the methodological challenges associated with analyzing and interpreting accelerometry data from participants of the Baltimore Longitudinal Study of Aging (BLSA), the Developmental Epidemiological Cohort Study (DECOS), and the LifeMETER study. We will discuss challenges to assessing physical activity in older adults using the standard population-level activity count cut point thresholds and general daily summaries, and demonstrate methods to: (i) aggregate and analyze raw activity data using a multi-layered analytic approach, (ii) quantify day-to-day variability and fragmentation of activity, and (iii) assess the effects of age-related covariates on activity metrics over the course of a day. These issues will be presented with a special emphasis on quantitative approaches that provide reproducible and highly reliable measures crucial to translating physical activity data into meaningful analyses of health and functional status in older populations. Development of appropriate methodology to collect and analyze behavioral and physiological information will: (i) provide a new level of detail to analyses of daily activity, (ii) ultimately transform the way data is utilized across research disciplines, (ii) be widely used in the implementation of prevention efforts, and (iii) contribute to efforts to optimize interventions that extend healthy aging and improve longevity.

QUANTIFYING SEDENTARY BEHAVIOR IN OLDER POPULATIONS USING COUNTS AND CUTPOINTS

J.A. Schrack[1,2], L. Xiao[3], V. Zipunnikov[3], E.M. Simonsick[2], L. Ferrucci[2], C. Crainiceanu[3], *1. Epidemiology, Johns Hopkins School of Public Health, Baltimore, Maryland, 2. National Institute on Aging, Baltimore, Maryland, 3. Johns Hopkins School of Public Health - Biostatistics, Baltimore, Maryland*

Accurately quantifying sedentary behavior is vital to understanding changes in activity with age and preventing comorbidities and conditions. We modeled the association between sedentary behavior and age at four activity count-per-minute thresholds (0, 25, 50, 100) in 611 BLSA participants (50% male, mean age 67, range 32-93) adjusted for age, sex, BMI, and comorbidities. Sedentary time increased with age regardless of cutpoint, but varied greatly according to definition of "activity" from 57.7% at cutpoint 0 to 94.3% at cutpoint 100 ($p<.001$). Women were less sedentary than men at all cutpoints except 100 counts/min ($p<.05$), suggesting women are more likely to engage in low levels of activity similar to those associated with activities of daily living, not typically classified as "physical activity." Future studies assessing activity in older adults should consider using lower cut points to include low levels of activity that may provide meaningful insight on health and functional status.

MODERN STATISTICAL APPROACHES FOR ACTIGRAPHY DATA

V. Zipunnikov, J.A. Schrack, J. Goldsmith, J. Bai, L. Ferrucci, C. Crainiceanu, *Biostatistics, Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland*

Current methods for analyzing actigraphy data fail to make use of the full range of data collected, often relying on summaries such as multi-day averages, and may miss opportunities to provide insight into activity metrics that may be quite meaningful for health outcomes in older adults. We will discuss three fundamental issues of this oversimplification: (i) the loss of information about the temporal distribution of activity over the course of a day, (ii) the loss of potentially informative features beyond activity intensity (e.g., distribution and variability of activity intensity within activity bouts, fragmentation of activity profiles with respect to alternating activity and inactivity bouts), and (iii) day-to-day variability in activity patterns over all observed days. We will apply new methods to actigraphy data of 611 participants of Baltimore Longitudinal Study of Aging and recover several previously unknown hallmarks of age-related functional decline.

ACCELEROMETRY DATA AT MULTIPLE RESOLUTIONS: QUANTIFYING HUMAN ACTIVITY IN THE WILD

C. Crainiceanu[1], J.A. Schrack[1,2], V. Zipunnikov[1], J. Bai[1], N.W. Glynn[3], T. Harris[2], T. Glass[1], L. Ferrucci[2], *1. Johns Hopkins University, Baltimore, Maryland, 2. National Institute of Aging, Baltimore, Maryland, 3. University of Pittsburgh, Pittsburgh, Pennsylvania*

Wearable devices deployed in large observational studies allow continuous monitoring of activity at unprecedented resolutions. Such devices are altering the way we think about activity and are disrupting the current status quo in activity research. Indeed, cheap waterproof accelerometers can now record tri-axial accelerometer data at 100Hz (300 observations per second) for weeks at the time without changing the battery or replacing the device. This raises questions about what information and at what resolution should be quantified and how to relate such information with health outcomes. Indeed, information can be visualized in its native, sub-second, space or can be aggregated at the minute, hour, or daily level. I will discuss the various levels of data aggregation, the types of analyses required by different levels of data compression, and the opportunities provided by a multi-layered analytic approach. Data from several studies including BLSA, DECOS, and LifeMETER will be discussed and analyzed. Several experimental designs for future studies will be suggested, while current opportunities and limitations of data and analytic methods will be discussed.

USING FUNCTIONAL DATA METHODS TO ASSESS COVARIATE EFFECTS ON DAILY ACTIVITY PATTERNS

J. Goldsmith[1], W. Tang[1], V. Zipunnikov[2], C. Crainiceanu[2], J.A. Schrack[2], L. Ferrucci[3], *1. Columbia University, New York, New York, 2. Johns Hopkins University, Baltimore, Maryland, 3. National Institute on Aging, Baltimore, Maryland*

Characterizing observed activity in older populations requires the development of regression models in which measures of activity, observed minute-by-minute over several days for each subject, are the outcome of interest. Specifically, studying the effect of age, BMI, and other covariates on activity counts may provide vital information when planning physical activity interventions in older populations. We formulated regression methods that allow for complete daily time courses as the response of interest using data from the Baltimore Longitudinal Study of Aging. Our model is directly related to standard multilevel models using daily average activity as a scalar outcome, but utilizes the minute-level data to assess covariate effects over time. Simulations indicate that the proposed method yields accurate estimation and inference and suggest time-specific age and BMI effects on physical activity, which may be quite meaningful to future studies assessing specific effects of age-related conditions on physical activity.

SESSION 1785 (SYMPOSIUM)

IMPLICATIONS OF HEARING IMPAIRMENT FOR PHYSICAL AND MENTAL FUNCTIONING IN OLDER ADULTS

Chair: F.R. Lin, *Johns Hopkins University, Baltimore, Maryland*
Discussant: M.K. Pichora-Fuller, *University of Toronto, Toronto, Ontario, Canada*

The potential functional consequences of age-related hearing loss for older adults are beginning to surface in epidemiologic studies demonstrating independent associations of hearing with cognitive and physical functioning. Multiple mechanisms may mediate these observed associations including effects of hearing loss on cognitive load, social isolation, poorer health related oral literacy, and reduced awareness of the auditory environment. Alternatively, a common pathologic cause could also underlie hearing loss and impaired functioning in older adults. These pathways are not mutually exclusive, and multiple pathways could likely co-exist and contribute to functional impairments. Importantly, the hypothesized mechanistic pathways are intriguing because they suggest that hearing rehabilitative treatments could potentially help mitigate cognitive and physical functional declines in older adults. The public health impact of investigating these associations is substantial given that hearing loss is prevalent in nearly two-thirds of all adults over 70 years and fewer than 20% use a hearing aid. In this symposium, we will present recent epidemiologic and experimental studies from the United States and Canada that have investigated the association of hearing loss with frailty, gait, depression, and hospitalizations, and we will discuss the practical and research implications of these findings for geriatrics and gerontology.

HEARING IMPAIRMENT AND INCIDENT FRAILTY IN OLDER ADULTS

R.J. Kamil[1], J. Betz[2,7], H.N. Ayonayon[3], S. Satterfield[4], B. Brott Powers[5], E.M. Simonsick[6], F.R. Lin[7,8], *1. Albert Einstein College of Medicine, Bronx, New York, 2. Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland, 3. University of California San Francisco, San Francisco, California, 4. University of Tennessee Health Science Center, Memphis, Tennessee, 5. University of Pittsburg Medical Center, Pittsburgh, Pennsylvania, 6. National Institutes of Health, Baltimore, Maryland, 7. Johns Hopkins Center of Aging and Health, Baltimore, Maryland, 8. Johns Hopkins Departments of Otolaryngology-Head and Neck Surgery, Geriatric Medicine, Mental Health, and Epidemiology, Baltimore, Maryland*

Frailty is a state characterized by decreased physiologic reserve and weakness. Whether hearing impairment which is associated with physical and cognitive decline is also associated with frailty is unknown. We analyzed 2,000 individuals aged 70 and older with complete data who were followed prospectively in the Health, Aging, and Body Composition Study for up to 11 years (1997-2008). Audiometry was conducted from 2001-2. Incident frailty was defined as a gait speed of less than 0.6 m/s and/or inability to rise from a chair without the use of arms. The association of hearing impairment with incident frailty was analyzed using Cox Proportional Hazard models adjusted for demographic factors, cardiovascular risk factors, depression, and cognition. Individuals with moderate or greater hearing impairment had a 61.3% increased risk of incident frailty compared to normal hearing individuals [HR 1.61, (95% CI 1.24, 2.09)]. Hearing impairment in older adults is independently associated with incident frailty.

LISTENING WHILE WALKING: AN EXPERIMENTAL EXAMINATION OF THE HEARING-MOBILITY CONNECTION

K. Li[1,2], V. Nieborowska[1,2], S. Lau[3], E. Alexandrov[1], L. Truong[4], M.K. Pichora-Fuller[2,3,5], J. Campos[2,3,5], *1. Concordia University Dept. of Psychology, Montreal, Quebec, Canada, 2. Centre for Research in Human Development, Montreal, Quebec, Canada, 3. Toronto Rehabilitation Institute – University Health Network, Toronto, Ontario, Canada, 4. Ryerson University Dept. of Psychology, Toronto, Ontario, Canada, 5. University of Toronto Dept. of Psychology, Toronto, Ontario, Canada*

Epidemiological aging research links hearing loss with cognitive decline, slower walking, and falls risk. A candidate explanation for these links is that both hearing and motor performance involve the recruitment of cognitive capacity. To examine this possibility, concurrent listening while walking was assessed in young, old, and older adults with hearing loss. Each task was also assessed singly (walking or listening). The listening task involved memory for simple target sentences presented simultaneously with two distractor sentences. Self-paced treadmill walking was done within an immersive Virtual Reality lab simulating a dynamic street-crossing. Listening task accuracy was negatively affected by age, unpredictable target location, and concurrent task load. Conversely, kinematic parameters of walking regularity suggest that in challenging circumstances older adults prioritize their physical safety and task performance due to reductions in cognitive capacity. Together, the results provide early experimental evidence to explain the link between age-related hearing loss and reduced mobility.

ASSOCIATION OF HEARING IMPAIRMENT AND INCIDENT DEPRESSION IN OLDER ADULTS

D.J. Mener[1], J. Betz[1], D.K. Houston[1], E.S. Strotmeyer[3], S. Satterfield[2], T. Harris[4], E.M. Simonsick[4], F.R. Lin[1], *1. Departments of Otolaryngology-Head & Neck Surgery, Johns Hopkins University, Baltimore, Maryland, 2. University of Tennessee, Memphis, Tennessee, 3. University of Pittsburgh, Pittsburgh, Pennsylvania, 4. National Institute on Aging, Baltimore, Maryland*

Associations between hearing impairment (HI) and worsening depressive symptomatology were studied in 1056 women and 940 men (mean age 73.9, 34% Black) Health ABC study participants, who had audiometric testing and repeated CES-D-10 administrations for up to 10 years follow-up. Participants were classified as having major depressive disorder (MD) (5.0%) when CES-D-10 scores ≥ 10. Associations between HI and longitudinal CES-D-10 scores and incident MD were analyzed respectively, using linear mixed effects and continuous time Cox proportional hazard models adjusted for demographic and cardiovascular risk factors. Participants with untreated moderate or greater HI had higher CES-D-10 scores 5 years after hearing assessment (β=1.01, p< 0.007) had an increased risk of incident MD (HR(95% CI):1.55 (1.15-2.09)) at 10 year follow-up than participants with normal hearing; hearing-aid users had no increase in depressive outcomes. Recognition and treatment of HI may diminish risk of elevated depressive symptoms and MD in community-dwelling elders.

ASSOCIATION OF HEARING IMPAIRMENT WITH RISK OF HOSPITALIZATION IN OLDER ADULTS

D. Genther[1,2], J. Betz[2,3], K.R. Martin[4], D.C. Bauer[5], A.B. Newman[6,7], E.M. Simonsick[8], F.R. Lin[1,2,3], *1. Otolaryngology, Johns Hopkins School of Medicine, Baltimore, Maryland, 2. Johns Hopkins Center on Aging and Health, Baltimore, Maryland, 3. Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland, 4. University of Aberdeen School of Medicine and Dentistry, Aberdeen, United Kingdom, 5. University of California, San Francisco School of Medicine, San Francisco, California, 6. University of Pittsburgh Graduate School of Public Health, Pittsburgh, Pennsylvania, 7. University of Pittsburgh School of Medicine, Pittsburgh, Pennsylvania, 8. National Institute on Aging, Baltimore, Maryland*

Hearing impairment (HI) is independently associated with poorer cognitive and physical functioning in older adults. Whether HI is associated with broader outcomes is unclear. We analyzed 12 years of data from 2,176 older adults in the Health ABC Study to investigate prospective associations of HI with incidence and annual rate of hospitalization. Hearing was defined as pure-tone average of thresholds at 0.5-4 kHz in the better ear (mild >25-40 dB; moderate-or-greater >40 dB). Hospitalization details were adjudicated with hospital records. After adjusting for demographics and cardiovascular comorbidities, mild and moderate-or-greater HI, respectively, were associated with a 16% (HR:1.16, 95%CI:1.04-1.29) and 19% (HR:1.19, 95%CI:1.03-1.37) increased risk of incident hospitalization, and a 14% (IRR:1.14, 95%CI:1.02-1.29) and 15% (IRR:1.15, 95%CI:1.00-1.33) increased annual rate of hospitalization compared to normal hearing. Hearing impairment is independently associated with increased risk of hospitalization in older adults. Understanding the basis of this association requires further study.

SESSION 1790 (SYMPOSIUM)

LINKING STUDY OF OSTEOPOROTIC FRACTURES (SOF) COHORT DATA WITH MEDICARE CLAIMS DATA: PROCESS, HEALTH CARE UTILIZATION OUTCOMES, RESULTS, AND LESSONS LEARNED

Chair: K. Ensrud, *University of Minnesota, Minneapolis, Minnesota, Minneapolis VA Health Care System, Minneapolis, Minnesota*
Discussant: J. Schousboe, *University of Minnesota, Minneapolis, Minnesota*

Linking existing cohort data with Medicare claims provides an innovative opportunity to determine associations of distinctive phenotypes identified using cohort data with health-care utilization (HCU) outcomes defined using claims data. However, there are challenges when combining these comprehensive and complex data sources as well as when analyzing associations of cohort phenotypes with claims-based HCU outcomes. We present our experience of linking data from participants in the Study of Osteoporotic Fractures (SOF, a large and well characterized cohort of community-dwelling women aged ≥65 years at enrollment in 1986-1988) to their Medicare claims data (1991-2010). First, we provide an overview of the linkage and outline methodology used to define and analyze HCU outcomes. Then, in separate presentations, we present findings regarding the associations of SOF phenotypes (sarcopenia, physical performance, cognition function and prevalent vertebral fracture) with HCU outcomes (hospitalization, rate of inpatient days among hospitalized women, longterm placement in nursing facility). Finally, we present methodology for calculation of total outpatient health care costs from claims data. In conclusion, despite challenges, linking cohort data with claims data provides the unique opportunity to quantify effects of individual patient characteristics such as impaired cognition and poor lower extremity physical performance on health care utilization. Findings are important for health care policy planning and for designing future intervention studies to reduce HCU among older adults.

LINKAGE OF STUDY OF OSTEOPOROTIC FRACTURES (SOF) WITH MEDICARE CLAIMS DATA AND METHODS TO ANALYZE HEALTH CARE UTILIZATION OUTCOMES

M.L. Paudel[1], B. Taylor[1,2], J. Schousboe[3], P.M. Cawthon[4], J.A. Cauley[5], C.E. McCulloch[6], T.A. Hillier[7], K. Ensrud[1,2], *1. Division of Epidemiology and Community Health, University of Minnesota, Twin Cities, Minneapolis, Minnesota, 2. Center for Chronic Disease Outcomes Research, VA Medical Center, Minneapolis, Minnesota, 3. Park Nicollet Clinic, St. Louis Park, Minnesota, 4. California Pacific Medical Center, San Francisco, California, 5. University of Pittsburgh, Department of Epidemiology, Pittsburgh, Pennsylvania, 6. UCSF, Department of Epidemiology, San Francisco, California, 7. KPCHR, Portland, Oregon*

Methods exist to identify health-care utilization(HCU) outcomes in Medicare claims data, however linking long-term cohort study participants to their claims is complicated by lengthy follow-up periods and enrollment in Medicare Advantage plans. We linked 9,228 (92.4%) women enrolled in the Study of Osteoporotic Fractures to their Medicare Claims from 1991-2010 to identify HCU outcomes including inpatient hospital days and long-term nursing home placement, the latter by adapting an algorithm from Yun (2010). 6,435 (69.7%) of women (aged>= 75.1 years) were enrolled in >1 months of fee-for-service. To model risk of hospitalization and rates of inpatient hospital days, we used logit-Poisson hurdle models with bootstrapped confidence intervals and compared that approach to alternative methodologies. While methodological challenges must be overcome, linkage of cohort to Medicare claims data allows quantification of effects of individual participant characteristics on HCU.

HEALTH CARE UTILIZATION (HCU) AND SARCOPENIA IN OLDER WOMEN

P.M. Cawthon[1], L. Lui[1], C. McCulloch[2], J.A. Cauley[4], M.L. Paudel[3], B. Taylor[3], J. Schousboe[3], K. Ensrud[3], *1. Research Institute, California Pacific Medical Center, San Francisco, California, 2. University of Minnesota, Minneapolis, Minnesota, 3. University of California, San Francisco, California, 4. University of Pittsburgh, Pittsburgh, Pennsylvania*

We quantified HCU by sarcopenia status per consensus definitions [International Working Group; European Working Group for Sarcopenia in Older Persons; Foundation for the NIH Sarcopenia Project], using Study of Osteoporotic Fractures data (women aged ≥ 68, Year 10 visit, 1997-8) and Medicare Claims over 3 years post-visit. Using unadjusted logit-Poisson Hurdle models and bootstrapped 95% confidence intervals, we analyzed the likelihood of hospitalization; the rate ratio (RR) of inpatient days among those hospitalized; and the annualized rate of inpatient days among all participants by sarcopenia status. Sarcopenia was not associated with HCU by any definition. When summary definitions components were evaluated separately, only slowness but not weakness nor low lean mass, was associated with greater HCU. For example, those with slowness (gait speed ≤0.8 m/s) by FNIH were more likely to be hospitalized (OR: 2.5, 95%CI: 1.7, 3.6) and had greater rates of inpatient days than women without slowness.

PHYSICAL PERFORMANCE, COGNITION, AND INPATIENT HEALTH CARE UTILIZATION (HCU) IN OLDER WOMEN

K. Ensrud[1,2], L. Lui[3], M.L. Paudel[1], J. Schousboe[1,4], J.A. Cauley[5], P.M. Cawthon[3], C.E. McCulloch[3], B. Taylor[1,2], *1. University of Minnesota, Minneapolis, Minnesota, 2. Minneapolis VA Health Care System, Minneapolis, Minnesota, 3. California Pacific Medical Center Research Institute, San Francisco, California, 4. Park Nicollet Clinic, St. Louis Park, Minnesota, 5. University of Pittsburgh, Pittsburgh, Pennsylvania*

The inter-relationship of physical performance and cognition with risk of inpatient HCU is uncertain. We studied 387 women (mean age 87.6 years) enrolled in Fee-for-Service with adjudicated cognitive status (normal, mild cognitive impairment [MCI], dementia) and the Short Physical Performance Battery (SPPB) at visit 9 (2006-2008). Inpatient HCU was determined over the following 12 months. We analyzed likelihood of inpatient hospitalization and the rate ratio of inpatient days among those hospitalized (Logit-Poisson Hurdle models and bootstrapped 95% CI). Physical performance and cognition were associated with the odds of hospitalization in a graded manner. Compared with women with high performance (SPPB 10-12)/normal cognition, women with low performance (SPPB 0-3) and MCI/dementia were 5-fold more likely to be hospitalized (OR 5.0 [2.3-10.5]); once hospitalized, they had a 2.5-fold (1.2-5.3) higher rate of inpatient days. Quantification of effects of physical performance and cognition on inpatient HCU is important for health care policy planning.

HEALTHCARE UTILIZATION AND VERTEBRAL FRACTURE IN OLDER WOMEN: STUDY OF OSTEOPOROTIC FRACTURES (SOF)

J.A. Cauley[1], L. Lui[4], C.E. McCulloch[2], M.L. Paudel[3], B. Taylor[3,5], P.M. Cawthon[4], J. Schousboe[3], K. Ensrud[3,5], *1. Epidemiology, University of Pittsburgh, Pittsburgh, Pennsylvania, 2. University of California, San Francisco, San Francisco, California, 3. University of Minnesota, Minneapolis, Minnesota, 4. San Francisco Coordinating Center, California Pacific Medical Center, San Francisco, California, 5. Center for Chronic Diseases Outcomes Research, Department of Veterans Affairs Health Care System, Minneapolis, Minnesota*

Vertebral fractures (VFx) are the most common osteoporotic fractures. We tested the hypothesis that VFx impacts healthcare utilization. We studied 3552 women enrolled in SOF (mean age 75y) who had radiographic information on VFx at visit 3 (1990-91). Healthcare utilization was determined over the 3 years after the visit using linked Medicare claims data. We analyzed unadjusted likelihood of inpatient hospitalization and the rate:ratio (RR) of inpatient days among those hospitalized with Logit-Poisson Hurdle models and longterm (>100 days) in a skilled nursing facility (SNF) by Cox proportional Hazards models. Women with a VFx were 36% more likely to be hospitalized, odds ratio=1.36(1.16, 1.59); once hospitalized, they had a 12% higher RR of inpatient days. The hazard ratio for longterm SNF within 3 years was 2.57(1.35, 4.90). Preliminary analyses suggest that the public health impact of VFx may include an increased risk of hospitalization with longer stays and SNF placement.

DOES MEDICARE PAYMENT ACCURATELY REFLECT TRUE RESOURCE COSTS OF OUTPATIENT CARE FOR MEDICARE BENEFICIARIES?

J. Schousboe[1,2], M.L. Paudel[3], B. Taylor[3,4], P.M. Cawthon[6], C.E. McCulloch[5], J.A. Cauley[7], K. Ensrud[3,8], *1. Park Nicollet Institute for Research and Education, Minneapolis, Minnesota, 2. Division of Health Policy and Management, University of Minnesota, Minneapolis, Minnesota, 3. Division of Epidemiology, University of Minnesota, Minneapolis, Minnesota, 4. Center for Chronic Diseases Outcomes Research, VAMC, Minneapolis, Minnesota, 5. University of California, San Francisco, San Francisco, California, 6. California Pacific Medical Center, San Francisco, California, 7. University of Pittsburgh, Pittsburgh, Pennsylvania, 8. Department of Medicine, Univeristy of Minnesota, Minneapolis, Minnesota*

Improving efficiency of care for the elderly requires accurate estimates of the costs. Medicare payments have been used as a surrogate measure of these, but Medicare adjusts provider payments based on provider characteristics and geographic location regardless of patient medical acuity and comorbidity. For each Study of Osteoporotic Fractures (SOF) participant in each year 2004 to 2010, we used the merged dataset of SOF with Medicare claims to estimate the yearly sum of outpatient Medicare allowable charges in the Carrier and Outpatient

Standard Analytic Files (SAF), and the yearly sum of standardized resource costs after removing Medicare adjustments from each line of utilization. Spearman rank correlations for total allowable charges and standardized resource costs for each year were 0.99 in all years and within a mean $121 of each other. Allowable charges in Medicare Carrier and Outpatient SAF claims are reasonable surrogates for true outpatient care resource costs.

SESSION 1795 (SYMPOSIUM)

EVOLVING CHALLENGES IN DRUG PRODUCT DEVELOPMENT IN INCREASINGLY OLDER AND COMPLEX PATIENT POPULATIONS

Chair: S. Stegemann, *Geriatric Medicine Society, Aachen, Germany*
Co-Chair: M. Gogol, *Geriatric Medicine Society, Aachen, Germany*

Geriatricians and gerontologists are increasingly faced with patients at very old age that due to multimorbidity and polypharmacy represent a largely heterogeneous and complex patient population. The drug approval process, labeling and the prescription decisions of new drugs are based on clinical trials that should be performed in representative patient populations. While this requirement should not be compromised, the rapidly changing representative patient populations are leading to several new issues and challenges in generating meaningful and reasonable clinical and non-clinical data. This symposium will review and discuss these issues and try to identify the areas that need to be addressed urgently in a multidisciplinary environment to support future drug development.

KEY DIFFERENCES IN REAL DRUG THERAPY TO OLDER AND MULTIMORBID PATIENTS

M. Gogol, *Geriatric Department, Krankenhaus Lindenbrunn, Coppenbruegge, Germany*

Drug research usual not include greater numbers of elderly patients which will take the most drugs for chronic conditions. The real world drug consumers differ widely in terms of different biological state, comorbidity, polypharmacy, functional health, and specific conditions (e.g. cognitive decline, low social support, low health literacy). The key question is how research has to be designed to solve this problems. As randomized controlled trials seems to be the gold standard the first goal has to be to perform research in elderly real world patients. This will lead to the fact that more concomitant factors has to be included into trial analyzes and outcomes variables will change. Well designed cohort studies could be an alternative solution. Another major question is how and when to include elderly persons and consumer healthcare organizations into drug and device development and how adherence can be improved over a longterm period.

THE IMPACT OF OLDER AGE, MULTIMORBIDITY AND POLYPHARMACY ON THE RISK FOR ADRS AND PK/PD VARIANCES AND MEDICATION MANAGEMENT ISSUES

J.L. Beizer, *College of Pharmacy & Health Sciences, St. John's University, Queens, New York*

Older adults are at risk for adverse drug events due to a number of factors that can affect the pharmacokinetics and pharmacodynamics of medications. Some of these factors include physiologic changes that occur with aging, the effect of multiple disease states, and drug interactions. In addition, the burden of polypharmacy can make adherence difficult for older adults. This session will discuss the common problems associated with medication use in the elderly and the role of the pharmacist in medication management.

CLINICAL OUTCOME ASSESSMENTS, INCLUDING PATIENT-REPORTED OUTCOME ASSESSMENTS, IN OLDER ADULTS AND MULTIMORBID PATIENTS: A REGULATORY PERSPECTIVE ON GOOD RESEARCH PRACTICES

A.F. Slagle, *CDER/OND, FDA, Silver Spring, Maryland*

Clinical outcome assessments (COAs), including patient-reported outcome (PRO) assessments, can be used to determine whether or not a drug has been demonstrated to provide treatment benefit. A conclusion of treatment benefit is described in drug labeling in terms of the concept of interest, or the thing measured by the COA. The appropriateness of a COA for use in clinical trials to support drug approval or labeling depends on a review of the evidence and a conclusion that the COA is a well-defined and reliable assessment of a meaningful concept of interest in the specified context of use. This session will provide a regulatory perspective on the development or selection of COAs. Key considerations will be discussed, including understanding the disease or condition, conceptualizing treatment benefit, and evaluating measurement properties of a COA to ensure well-defined, reliable, and interpretable outcome assessments are used in trials of older adults and multimorbid patients.

SESSION 1800 (SYMPOSIUM)

PERFORMANCE AND PARTICIPATION IN MEDICALLY COMPLEX-OLDER ADULTS

Chair: C. Ciro, *OUHSC, Oklahoma City, Oklahoma*
Discussant: L.N. Gitlin, *Johns Hopkins University, Baltimore, Maryland*

In our symposium, we will highlight research which advances the understanding of performance of and participation in daily activities among medically complex-older adults, including those with mild cognitive impairment (MCI), Alzheimer's disease and related dementias, and frailty. Paper one will highlight preclinical disability in performance of instrumental activities of daily living in older adults with MCI compared to those with normal cognition using an observation-based assessment, the Performance of Self-Care Skills. These results may improve our understanding of changes in performance of daily activities for older adults with MCI and inform the diagnostic process. Paper two will describe quantitative and qualitative results of delivering the STOMP (Skill-building through Task-Oriented Motor Practice) intervention for improving performance in older adults with mild-moderate dementia, comparing a home (multi-site) and clinic trial. Demonstrating the capacity for improvements in the performance of daily activities in older adults with mild-moderate dementia is an important step in improving the quality of life for both older adults with dementia and their caregivers. Paper three will review preliminary results of a study examining the feasibility of an intervention anchored by Goal Attainment Scaling that employs compensatory strategies to increase participation in daily activities of frail older adults transitioning out of a nursing home. As we move away from institutionalization models for older adults and the population of older adults living with multiple, chronic conditions continues to increase, we need evidence for interventions that improve function and quality of life.

FEASIBILITY OF IMPLEMENTING A CLIENT-CENTERED INTERVENTION FOR FRAIL OLDER ADULTS TRANSITIONING TO THE COMMUNITY

P.E. Toto, E. Skidmore, N. Castle, *Occupational Therapy, University of Pittsburgh, Pittsburgh, Pennsylvania*

This presentation will highlight the implementation and preliminary evaluation of TRANSITIONS, a compensatory-focused intervention anchored by Goal Attainment Scaling (GAS) to facilitate activity-based goal achievement, limit disability, promote participation, and reduce adverse events in frail older adults transitioning back to the community following short-term rehabilitation in a skilled nursing facility (SNF). Specifically, this presentation will: (1) outline the overall rationale and components included in the TRANSITIONS intervention; (2) describe the process used to identify and establish goals through GAS and deliver a community-based intervention targeting compensation; (3) describe the design and constructs used to evaluate TRANSITIONS and (4) discuss preliminary results addressing feasibility and opportunities/challenges learned about implementation and evaluation during the pilot phase. Preliminary outcome data examining change in GAS, disability, participation and occurrence of adverse events will also be shared.

PERFORMANCE IN DAILY ACTIVITIES AMONG OLDER ADULTS AT-RISK FOR DEMENTIA

J. Rodakowski, E. Skidmore, K.D. Raina, J.C. Rogers, *Department of Occupational Therapy, University of Pittsburgh, Pittsburgh, Pennsylvania*

We examined performance in cognitively- and physically-focused instrumental activities, functional mobility, and self-care among individuals at-risk for dementia. The Performance Assessment of Self-Care Skills (PASS) assessed daily activities through standardized observations of 122 individuals who had a history of major depression. A generalized estimating equation assessed the relationship between daily activities and dementia conversion over 2-years. Results indicated that on average improvements in physically-focused instrumental activities were protective against conversion (p=0.03), and slight decreases in cognitively-focused instrumental daily activities were associated with increased conversation (p<0.001), even after adjusting for medication effects. Functional mobility and self-care were not associated with conversion. Changes in performance of daily activities may predict conversion to dementia in a population of individuals at-risk for dementia due to a history of depression. Interventions addressing cognitively- and physically-focused instrumental daily activities may be able to slow conversion to dementia among individuals at-risk for conversion.

COMPARING TREATMENT OUTCOMES OF THE STOMP DEMENTIA INTERVENTION DELIVERED IN THE HOME VERSUS CLINIC ENVIRONMENTS

C. Ciro[1], J. Poole[2], C. Robinson[1], T. Hamilton[1], L.A. Hershey[1], J.E. Knoefel[2], *1. OUHSC, Oklahoma City, Oklahoma, 2. University of New Mexico, Albuquerque, New Mexico*

Purpose: Examine differences in time to ADL improvement and 90-day ADL retention scores for the STOMP (Skill-building through Task-Oriented Motor Practice) dementia intervention delivered in the home vs. in the clinic. Methods: Two distinct quasi-experimental studies with baseline, post-intervention and 90 day assessment of examiner -rated ADL using Goal Attainment Scaling delivered either in home or the clinic analyzed through survival analysis and Student's t-tests. Results: Despite moderate dementia, participants in both groups demonstrated improvement in examiner-rated ADL (p<.05) which was retained at 90 days post-intervention. ADL improvement was achieved sooner in the home (M=4.9 days) than in the clinic (M=6.3 days; p<.05). Ninety-day retention scores between home (M=50.47) and clinic (M=49.98) were not significantly different (p=.86). Discussion: While both groups made significant improvement in ADL performance, participants treated in the home achieved ADL goals sooner and with similar 90 day retention scores compared to people treated in the clinic.

SESSION 1805 (PAPER)

SUCCESSFUL AGING

CORRELATES OF OPTIMAL COGNITIVE AGING IN 80+ WOMEN: THE WOMEN'S HEALTH INITIATIVE MEMORY STUDY (WHIMS)

J.S. Goveas[1], S. Rapp[2], P. Hogan[3], K. Yaffe[4], J.E. Manson[5], H. Tindle[6], S. Resnick[7], M.A. Espeland[8], *1. Medical College of Wisconsin, Milwaukee, Wisconsin, 2. Wake Forest, Winston-Salem, North Carolina, 3. Wake Forest, Winston-Salem, North Carolina, 4. University of California-San Francisco, San Francisco, California, 5. Harvard Medical School, Boston, Massachusetts, 6. University of Pittsburgh, Pittsburgh, Pennsylvania, 7. National Institute on Aging, Baltimore, Maryland, 8. Wake Forest, Winston-Salem, North Carolina*

Objectives. The objectives of this study were to identify factors associated with being free from cognitive impairment, and having a high level of cognitive functioning in women > 80 years of age. Methods. 2228 women who participated in the WHIMS were included in this analysis. Participants were assigned research diagnoses of cognitively normal (n=1905, 85.5%), mild cognitive impairment (n=88, 3.9%), dementia (n=121, 5.4%) or other cognitive impairment (n=114, n=5.1%)) by central adjudication. Global cognitive functioning was assessed by the Telephone Interview for Cognitive Status-modified (TICS-m). Differences between women grouped by cognitive status with respect to each potential risk factor were assessed using chi squared tests and t-tests. Backward stepwise logistic regression was used to select factors that were associated with cognitive status. For inclusion, factors were required to have associations with p<0.05. Results. Factors associated with being free of cognitive impairment were younger age, higher education and family incomes, being non-hispanic white, better emotional wellbeing, endorsing less depressive symptoms, being free of diabetes, more insomnia and not carrying the Apo e-4 allele. Women who were cognitively normal and had high global cognitive functioning (i.e. a TICSm score >39; N=467 (21.0%)) had younger age, higher education, better self-reported general health and had not been randomly assigned to hormone therapy after age 65 in the WHI Hormone Therapy trials. Conclusion. Understanding the differences between good and poor cognitive aging in women over 80 years of age can assist in designing effective interventions that may prevent pathological cognitive decline in the oldest-old.

SEXUAL HEALTH, QUALITY-OF-LIFE AND WELLBEING AMONG OLDER MEN AND WOMEN IN ENGLAND: A DYADIC ANALYSIS FROM THE ENGLISH LONGITUDINAL STUDY OF AGEING

D. Lee[1], J. Nazroo[1], N. Pendleton[2], *1. School of Social Sciences, The University of Manchester, Manchester, United Kingdom, 2. Institute of Brain, Behaviour and Mental Health, The University of Manchester, Manchester, United Kingdom*

Positive sexual relationships and good sexual health are increasingly recognised as having important impacts on quality-of-life (QoL) and emotional wellbeing among older people. There has, however, been little research on couples. We used data from the English Longitudinal Study of Ageing (ELSA), the latest wave of which included a comprehensive Sexual Relationships and Activities questionnaire (SRA-Q), to examine the association of own and partner's sexual health with QoL and wellbeing, adjusting for age, self-rated health and depression. A total of 2030 heterosexual couples (male age=66±9; female age=64±9) were identified as married or cohabiting, with both partners completing the gender specific SRA-Q. The CASP-19 was used to assess quality-of-life (QoL) and the Satisfaction With Life Scale to measure subjective wellbeing. In ordinal logistic regression models, the odds of having poorer emotional wellbeing were higher among respondents reporting low levels of sexual activity (e.g. sexual desire, intercourse frequency) and those with sexual problems (e.g. erectile difficulties, arousal problems, pain). Concerns about sexual health, conflicting sexual likes/dislikes, and dissatisfaction with overall sex life were associated with lower QoL scores. In dyadic analyses, measures of the female partner's sexual health were not generally associated with the male partner's QoL or emotional wellbeing. Conversely, poorer sexual health in the male partner (erectile difficulties, low sexual desire, orgasm problems) was consistently associated with poorer QoL and emotional wellbeing in the female partner. Spouses or cohabiting partners do not live in isolation. Management of older adults' sexual health to improve QoL and wellbeing should involve both partners.

RESEARCH AND COMMUNITY PARTNERSHIPS: THE CULTURALLY-INFORMED HEALTHY AGING MODEL

L. Bratton-Mullins, L.E. Skemp, *Our Lady of the Lake College, Baton Rouge, Louisiana*

Southern United States populations are becoming older and more ethnically diverse and at the same time have disproportionate rates of chronic illnesses, a higher poverty rate, and less access to healthcare. Community Based Participatory Research has been used to partner with communities in the conduct of research to design and implement community programs to address chronic illness. However, community readiness for and sustainability of research programming remain problematic, and in particular with ethnically diverse communities. The purpose of this presentation is to describe how the culturally-informed healthy aging model (CIHA) has been used to partner with communities to conduct community capacity building research in the Deep South. The CIHA partnership formation phase was conducted in five diverse communities in the southern United States. Strategies of the partnership phase include: a) conducting a systematic cultural and health assessment of the environment, population and social organizational structures, and b) working with key community members to identify health needs and "cultural capital" to tailor best practices for culturally-informed programming and evaluation. Observational, interview and epidemiological data were collected on partnership formation. Data analysis included content analysis of transcripts and descriptive statistics of epidemiological data. Cultural variables that influenced readiness for research in these communities include demographics and health trends, as well as environmental and regulatory relationships. CIHA strategies and the determination of community partnership formation are described and implications for community research discussed.

AGING VETERANS AND NON-VETERANS: AN AGE-MATCHED ANALYSIS OF COHORTS

C. Cigolle[1,2], J. Ha[1], P. Lee[1,2], L. Min[1,2], T.R. Gure[3], C. Blaum[4,1], *1. University of Michigan, Ann Arbor, Michigan, 2. VA Ann Arbor Healthcare System (VAAAHS) Geriatric Research, Education and Clinical Center (GRECC), Ann Arbor, Michigan, 3. 2. Ohio State University Wexner Medical Center, Columbus, Ohio, 4. 3.New York University Langone Medical Center, New York City, New York*

Most research about veterans focuses on those receiving care in the VA, with less known about the health of all veterans at the population level. Earlier cohort analyses suggested that veterans (including those receiving care in and/or outside the VA) were similar to non-veterans on most health determinants. We hypothesized that these similarities in health status between veterans and non-veterans would persist over time when examined with age-matching at the individual level. We performed secondary data analysis of waves 2004 and 2010 of the Health and Retirement Study, a nationally-representative health survey. The sample included males ≥51 years (2004, n=4,356 veterans; 2010, n=3,885 veterans). For each wave, we grouped veterans into 4 cohorts (WWII/Korea/InterWar/Vietnam), comparing them to age-matched non-veterans. Health status determinants included diseases, dementia (performance-based measure), other geriatric conditions, and basic/instrumental activities of daily living. Statistical methods included propensity score matching and logistic regression. In 2004, all veteran cohorts (vs. non-veterans) had similar/better health status. Dementia was substantially less prevalent in veterans for all cohorts (e.g., WWll, 11.2% vs. 16.8%, p<.01). These findings generally persisted through 2010. However, Vietnam-era veterans now exhibited greater prevalence of certain diseases (heart, lung, arthritis, p<.05 for each) and no longer had decreased prevalence of dementia. Longitudinal population data suggest that veteran health status may be cohort dependent, with more recent survey data indicating that Vietnam-era veterans have poorer health. As Vietnam veterans age and become the dominant veteran cohort, these changes in health have implications for VA health policy and care priorities.

ACUTE IMPACT OF POOR SLEEP ON CEREBRAL OXYGENATION IN OLDER ADULTS

B. Carlson[1], V.J. Neelon[2], J. Carlson[1], D. Bliwise[3], *1. University of Oklahoma Health Sciences Center, Oklahoma City, Oklahoma, 2. Biobehavioral Laboratory, University of North Carolina, Chapel Hill, North Carolina, 3. Department of Neurology, Emory University, Atlanta, Georgia*

Introduction: Poor sleep, characterized by low sleep efficiency, occurring 2-3 times a week, is common in older adults but its effects on brain health are not fully understood. The aim of this study is to explore the acute effects of poor sleep on cerebral oxygenation in a community-dwelling sample of older adults (70+ years). **Methods:** 115 older adults (mean age=78.3yrs, F=64%) underwent 2-nights of standard polysomnography (mean TIB=7.2 hours), including cerebral oximetry measures of percent oxyhemoglobin saturation ($rcSO_2$). RM-ANOVA tested trends in sleep parameters and $rcSO_2$ across the 2 study nights. **Results:** Sleep efficiency on Night 1 (EF1) were low (< 70%) in 51 and normal (≥ 70%) in 64 subjects. Compared to subjects with normal EF1, sleep latencies were significantly lower on Night 2 in those with low EF1 ($F_{(1, 113)}$=3.8, p=.05). Otherwise, the change in sleep parameters, from Night 1 to Night 2, did not differ by group. Across the nights, the time spent in S1&2 NREM ($F_{(1, 113)}$=3.9, p=.05) and REM sleep ($F_{(1, 113)}$=13.8, p<.001) increased, while the time spent in S3&4 NREM sleep remained unchanged ($F_{(1, 113)}$=.52, NS). Cerebral oxygenation did not differ between the two groups but lower EF1 was significantly associated with greater $rcSO_2$ values on Night 2 (r=-.75, p=.03). **Conclusions:** The findings suggest that less efficient sleep has an acute negative impact on cerebral oxygenation. Future studies will explore how this association between sleep and cerebral oxygenation varies together across several days and its association with daytime cognitive function. **Support:** NR08032 and RR00046.

SESSION 1810 (PAPER)

DEMENTIA

STOPPING INEFFECTIVE TREATMENTS FOR PEOPLE WITH DEMENTIA: THE TRACK AND TRIGGER TREATMENT PROTOCOL

C.R. Kovach, *University of Wisconsin-Milwaukee, Milwaukee, Wisconsin*

Failure to stop ineffective and unneeded treatment is a particular concern for people with dementia because of their diminished capacity for tolerating physiological, psychosocial and environmental challenges. This presentation will: a) describe results of two preliminary studies that informed development of the Track and Trigger Treatment (T3) Protocol; and b) describe the development of the T3 Protocol and the pilot testing. The studies were conducted in 14 nursing homes with sample sizes of 112-134. We found a high frequency of failure to conduct an assessment following resident changes in behavior (87 of 112) and the continued use of the same ineffective treatments over multiple days (60 of 112). Controlling for functional status, baseline behavior, and lack of assessment, the continued use of ineffective interventions was the strongest predictor of recurrence of agitation (change in R2 = 20.1%, p < .001). Among the 134 participants, 93 (69.4%) had between 1 and 12 treatments started, and 56 (41.8%) had treatments stopped over six weeks. The total number of treatments stopped was significantly predicted by nursing assessment and follow through. The T3 Protocol is designed to stop ineffective and unneeded treatments through an innovative approach to serial tracking of treatment response by nurses. TheT3 Protocol fills a unique gap by providing a critical thinking system (tracking of treatment effectiveness) coupled with event flags (for treatments that are potentially no longer needed, ineffective, associated with side effects, or are inconsistent with the goals of care) that trigger action (to stop or change treatments).

DIFFERENTIATING SUBTYPES OF APATHY IN YOUNG-ONSET DEMENTIA

L.M. Massimo[1,2], J. Powers[1], L.K. Evans[1], C. McMillan[1], P. Eslinger[2], M. Ersek[1], B. Morgan[1], M. Grossman[1], *1. University of Pennsylvania, Philadelphia, Pennsylvania, 2. The Pennsylvania State University, University Park, Pennsylvania*

BACKGROUND: Apathy, a reduction in goal-directed behavior (GDB), is the most common behavioral syndrome in at least one young onset dementia—behavioral variant Frontotemporal Degeneration (bvFTD), where it occurs in up to 90.5% of patients with mild stage disease. Core GDB processes include initiation, planning and motivation; when any of these processes is compromised, apathy results. The current study sought to identify selective impairments of these apathy components in bvFTD and their underlying neuroanatomical associations. METHODS: In twenty participants with bvFTD, we derived individualized apathy profiles to postulate subtypes of apathy by measuring reaction times using a novel computerized procedure—The Philadelphia Apathy Computerized Test (PACT)—to quantify performance for each of three GDB components – initiation, planning and motivation. We examined neuroanatomical associations of these performance profiles using a region of interest volumetric analysis. RESULTS: We found isolated deficits in each component of GDB in 12 (60%) bvFTD participants: two (10%) with initiation, eight (40%) with planning and two (10%) with motivation impairments. An additional eight (40%) participants were impaired on multiple components of the PACT. Voxel-based morphometry revealed that participants with reduced initiation had anterior cingulate atrophy; those with impaired planning had atrophy in dorsolateral prefrontal cortex, and those with poor motivation had orbitofrontal atrophy. CONCLUSION: Apathy is a complex, multi-component syndrome. We found quantitative reduction in three GDB processes contributing to subtypes of apathy in bvFTD. Future individualized treatments for apathy would be appropriately tailored to the specific compromised component(s) of goal-directed behavior.

RECRUITING OLDER ADULTS INTO RESEARCH (ROAR)

N. Silverberg[1], J.L. Watson[1], K. Gordon[2], H. McKay[2], A. Wiatr-Rodriguez[3], *1. National Institute on Aging, Bethesda, Maryland, 2. Administration for Community Living, Washington, DC, District of Columbia, 3. Administration for Community Living, Chicago, Illinois*

Currently, there are not enough older adults, especially those of diverse backgrounds, in Alzheimer's disease & related dementias (ADRD) research. Clinical trials, other studies to test therapies to prevent or cure diseases like Alzheimer's, and other types of research (e.g., survey) urgently need volunteers, but researchers often struggle to find participants, resulting in delays and greater costs for the research. With the National Plan to Address Alzheimer's as a spark, the Administration for Community Living (ACL), the National Institute on Aging (NIA) and the Centers for Disease Control and Prevention (CDC) collaborated on a project, Recruiting Older Adults into Research (ROAR). The primary goal of this outreach and communications initiative is to increase the number of older adults, including those of diverse ethnic and racial backgrounds, volunteering for research participation, starting with Alzheimer's research, through leveraging state and local Aging Services and Public Health networks. This presentation will share information about the Outreach Plan, including target audiences, and materials created thus far to promote research participation messages as a part of healthy aging. Presenters will discuss examples of local collaborations to promote awareness of research participation as well as information about the utilization of national registries.

NUTRITIONAL STATUS AND NEUROPSYCHIATRIC SYMPTOMS IN DEMENTIA: THE CACHE COUNTY DEMENTIA STUDY

J. Tschanz[1], C.L. Sanders[1], H. Wengreen[1], S. Schwartz[1], S. Behrens[1], C. Corcoran[1], C. Lyketsos[2], *1. Center for Epidemiologic Studies, Utah State University, Logan, Utah, 2. The Johns Hopkins University, Baltimore, Maryland*

Background: Neuropsychiatric symptoms (NPS) are common in dementia and are associated with poorer patient outcomes and caregiver stress. Persons with dementia are also at greater risk for malnutrition. We examined the association between nutritional status and course of NPS in dementia in a population-based sample. Methods: 257 individuals with dementia (72% Alzheimer's disease, 54% female) were followed annually for up to 6.5 years. Mean(SD) age was 86(5.35). Nutritional status was assessed using a modified Mini-Nutritional Assessment (mMNA) and NPS via the 12-domain Neuropsychiatric Inventory (NPI-12). Cluster scores were calculated by summing domains for depression, anxiety and irritability (Affective) and hallucinations and delusions (Psychosis); Agitation and Apathy were single domains. Linear mixed models examined the association between nutritional status (mMNA total score or clinical groups of malnourished, risk for malnutrition, and well-nourished, 13%, 37% and 50% at baseline, respectively), and total NPI-12 score and the four symptom clusters. Covariates tested included demographics, dementia type, age of dementia onset and duration, and APOE genotype. Results: Total NPI-12 scores increased over time (1.3 points/year). In multivariable models, higher mMNA score was associated with lower total NPI-12 score (B=-1.2; SE=.15). Malnourished persons (B=8.10; SE=1.37) and those at risk for malnutrition (B=3.09; SE=0.91) had worse NPS-12 scores compared to well-nourished participants. Higher mMNA scores were associated with lower Affective (B=-.09; SE=.05), Psychosis (B=-.09; SE=0.04), and Apathy (B=-.19; SE=0.05) cluster scores. Conclusion: Nutritional status is associated with NPS in dementia. Addressing nutritional deficiencies may provide a potential intervention to reduce the occurrence and severity of NPS.

MEASUREMENT OF KNOWLEDGE OF ALZHEIMER'S DISEASE IN A RURAL APPALACHIAN POPULATION

L.K. Wiese, C.L. Williams, R.M. Tappen, D. Newman, *Florida Atlantic University, Boca Raton, Florida*

Alzheimer's disease (AD) threatens the health of older rural Appalachians yet research on AD in this population is scarce. In order to improve screening rates for AD, Appalachians need to understand their vulnerability. The first step would be to assess their knowledge about AD but a suitable AD knowledge test has not been developed. The purpose of this study was to test the reliability and validity of a new measure of knowledge about AD that is culturally congruent, and to examine factors that may predict AD knowledge in this rural population. A descriptive study was conducted with 240 participants from four samples of older adults in south central rural Appalachian West Virginia using surveys and face-to-face interviews. Results from tests for stability, reliability including Rasch modeling, discrimination and point biserial indices, and concurrent, divergent, and construct validity were favorable. Findings were that although more diversity in test item difficulty is needed, the test discriminated well between persons with higher and lower levels of education [F(2, 226) = 170.51, p = .001].

Using multiple regression, the predictors of AD knowledge included caregiver status, miles from a healthcare provider, gender, and education; (R2=.05, F(4,187) = 2.65, p =. 04). Only years of education accounted for a significant proportion of unique variance in predicting the total BKAD score (t = 2.14, p =. 03). Implications include the need for testing for health literacy and community based approaches in designing programs that will ultimately increase screening and detection of Alzheimer's disease in rural populations.

SESSION 1815 (SYMPOSIUM)

MAKING CONNECTIONS THROUGH THE ART OF LOSING: USING HUMANITIES APPROACHES TO UNDERSTAND LATER LIFE

Chair: K. de Medeiros, *Sociology and Gerontology, Miami University, Oxford, Ohio*
Co-Chair: R. Maierhofer, *University of Graz, Graz, Austria*
Discussant: S.R. Sabat, *Georgetown University, Washington, DC, District of Columbia*

Unlike research in the social and biomedical sciences, where the focus is on explanatory models or questions of "how," humanities research focuses explanations of meaning or questions of "why." Sources of data in the humanities include cultural artifacts, critical essays, interviews, historical documents, and many others. The purpose of this symposium is to present three humanities-based research papers which challenge normative assumptions about aging. The first paper critically examines the positioning of dementia within tropes of threats and catastrophes linked to older age. The second paper explores how patients' stories can inform the clinician about the experience of aging, thereby providing insights that extend far beyond skills learned during medical training. The third paper provides an analysis of a recent television show, Derek, whereby the title character and the residents he cares for challenge ageist stereotypes in a unique and non-glamorized way. Overall, the papers provide new ways of addressing key concepts in gerontology and demonstrate the ways in which humanities-based research can inform approaches to understanding older age.

LIVING A LONG LIFE BY INTERCONNECTEDNESS: CELLS, CULTURE AND SOCIETY

T.R. Cole, *University of Texas, Health Science Center, Houston, Texas*

As the Alzheimer Association has not become tired of insisting, the "greatest known risk factor for Alzheimer's is advancing age." Based on a need for funding and recognition, the American Alzheimer's Association has shown how a successful campaign can in the public imagination establish a disease as a discourse of anxiety and fear. Discussion of dementia has been dominated by images of risk and metaphors of natural catastrophes. During the G8 summit in December 2013 in London, David Cameron spoke of a global threat. The binary opposition of nature versus culture has played a major role in shaping our understanding of life-course identity. My paper will deal with the topic of age and aging by investigating how our understanding of natural risks influences our notion of agency, and offer a subversive deconstruction of normative age concepts.

FOSTERING HEALING BY LISTENING TO OUR PATIENTS' STORIES

A. Green, *Johns Hopkins University School of Medicine, Baltimore, Maryland*

"The art of losing isn't hard to master," writes Elizabeth Bishop in her poem "One Art." "So many things seem filled with the intent to be lost." Aging is an emotional experience as much as a physical one. Clinicians who care for older adults know that there are some calamities we cannot fix, and that the answers do not always lie in our medical toolbox. Four structured vignettes will demonstrate the importance of listening to patients' stories. These cases will illustrate how clinicians can foster healing by cultivating the humanistic care of older adults.

CHANGING THE PERFORMANCE OF OLD AGE: A CRITICAL ANALYSIS OF *DEREK*

K. de Medeiros, *Sociology and Gerontology, Miami University, Oxford, Ohio*

In 2013, comedian/actor Ricky Gervais launched a new series, *Derek*, in which he portrays a socially awkward, middle-aged man who works at a retirement home. While outsiders to the home view Derek and the residents as having lives filled with continuing loss, Derek and the others see their lives as full of hope despite challenging circumstances. The purpose of this paper is therefore to provide a critical analysis of Derek Season 1 in light of the question: Who loses is old age? Is it older people themselves or "outsiders" to the experience who fear change? Drawing on work by Cruikshank, Gullette, and other theorists, I argue that Derek offers a new window through which to consider how old age is performed and understood

SESSION 1820 (SYMPOSIUM)

INCREASING REPORT CARD PATIENT-CENTEREDNESS AND RELEVANCY FOR DIVERSE ELDERS

Chair: J. Gaudet Hefele, *Brandeis University, Waltham, Massachusetts*

Consumer engagement lies at the heart of any strategy to improve quality through public reporting. Yet studies show minimal consumer use of healthcare report cards, despite consumers' reported interest in seeing this information and using it for decision-making. While research on what consumers are looking for in report cards is lacking, the disconnect between consumers' interest in and use of report card information may be driven by current report card content, which may not be meeting consumers' needs. In particular, consumers often report the desire for personalized health care information to inform their decision-making, which current report cards often fail to provide. Meeting consumers' needs in this domain is crucial if report cards are to have their intended effect of informing consumers' decisions and driving quality improvement. This session brings together researchers whose empirical studies address these questions from a variety of perspectives. The panel will discuss research results from studies of consumer preferences for report card information and racial differences in these preferences; hospital discharge team use of report cards and perceptions of patient choice laws; the development and testing of a personalized, interactive report card; and an assessment of how quality information impacts nursing home choice for dually enrolled Medicare/Medicaid residents.

MINORITY VOICES OFFER INSIGHTS TO ENHANCE VALUE OF NURSING HOME COMPARE REPORT CARDS

J. Gaudet Hefele, A. Acevedo, L.A. Nsiah-Jefferson, C.E. Bishop, Y. Abbas, E. Damian, *Brandeis University, Waltham, Massachusetts*

This study assessed consumer preferences for nursing home information and determined how preferences vary across race/ethnicity. Data were collected through 11 focus groups and 29 interviews (Black, Latino, and White adults aged 40+). Participants expressed interest in detailed information on staff and pricing; suggested several new measures related to preventative care and formal complaints; and wanted ratings conducted by families/residents and measures stratified by race/ethnicity. Black and Latino participants expressed more skepticism about the reports and wanted information on languages spoken and race/ethnicity. Most of the information participants desired is not currently available in Nursing Home Compare (NHC). Consumer needs can be better met with more detailed information and customer reviews. Given minorities' low report card use rates, focus should be on meeting the information needs of these users. The overall lack of awareness of

NHC underscores the need for a marketing campaign and the role of navigators.

DO DUALLY ELIGIBLE CONSUMERS BENEFIT FROM PUBLIC REPORTING OF NURSING HOME QUALITY?

R. Konetzka[1], D. Grabowski[2], M. Coca-Perraillon[1], R.M. Werner[3], *1. University of Chicago, Chicago, Illinois, 2. Harvard Medical School, Boston, Massachusetts, 3. University of Pennsylvania, Philadelphia, Pennsylvania*

Individuals enrolled in both Medicare and Medicaid ("duals") are attracting increasing health policy attention due to their disproportionate use of health care services and costs. The nursing home sector has long been a target of concern about low quality of care, and duals are often disproportionately affected by these quality problems. Public reporting of nursing home quality is an important policy initiative intended to improve quality. In this study, we use 2006-2010 national resident-level assessment data from nursing homes to test whether duals are less likely to respond to, and benefit from, quality information than non-duals, and why. Preliminary results reveal that, rather than choosing higher-quality facilities, duals have increased propensity to be admitted to low-quality facilities under public reporting. By assessing the relative importance of barriers to effective use of quality information by duals, we identify promising avenues to improve access to high-quality care for a particularly vulnerable population.

CONSUMER AND HOSPITAL CASE MANAGER PERSPECTIVES ON HOME HEALTH REPORTS

S. Gravenstein[1,2,3], R. Baier[1,4], E. Cooper[1], A. Wysocki[4], V. Mor[4,5], M. Clark[4], *1. Healthcentric Advisors, Providence, Rhode Island, 2. Case Western Reserve University School of Medicine, Cleveland, Ohio, 3. Warren Alpert Medical School of Brown University, Providence, Rhode Island, 4. School of Public Health of Brown University, Providence, Rhode Island, 5. Providence Veterans Affairs Medical Center, HSR&D Research Service, Providence, Rhode Island*

We aimed to determine how consumers and hospital case managers (CMs) use existing Rhode Island or Medicare home health public reports, and what changes they recommend. We conducted focus groups (consumers) and structured interviews (CMs), and then performed qualitative analysis. None of the subjects were familiar with existing reports. Both groups expressed a desire for logistical information (e.g., insurance, service area, services); consumers were comparatively more interested in quality and satisfaction. CMs reported routinely asking patients to choose agencies based on lists, and were reluctant to provide any information that could be construed as noncompliance with Medicare and Social Security 'patient choice' laws. These findings may help to tailor the form and content of public reports to overcome barriers (real or perceived) to engaging patients in informed decision making. This is timely given policies to increase patient engagement and to require hospitals to assume financial risk for patients' post-discharge care.

NURSING HOME COMPARE PLUS (NHCPLUS): A PERSONALIZED, PATIENT CENTERED, REPORT CARD FOR NURSING HOMES

D.B. Mukamel[1], A.N. Amin[1], D. Weimer[2], J. Sharit[3], D. Gustafson[1], D. Sorkin[1], *1. University of California, Irvine, Irvine, California, 2. University of Wisconsin-Madison, Madison, Wisconsin, 3. University of Miami, Miami, Florida*

The Nursing Home Compare (NHC) report card published by the CMS includes 19 clinical quality measures (QMs), staffing, and citation information. These measures are not correlated, making choosing a nursing-home difficult for consumers. This study was designed to develop an alternative: an iPad-based application (NHCPlus) allowing consumers to create composite scores for nursing-homes based on their personal health needs and preferences, effectively creating a personalized, patient centered report card. Key informant interviews were performed with patients and family members (N=20) to obtain feedback about usability, usefulness, and applicability. All informants reported that NHCPlus would have been extremely helpful in choosing a nursing-home, and that they were willing to spend a substantial amount of time (20-30 minutes or more) with the application to help them make their choice. The NHCPlus application we developed and pilot tested offers a prototype for combining personalized preferences with quality metrics for other report cards.

SESSION 550 (SYMPOSIUM)

POLICY SERIES: ELDER FINANCIAL EXPLOITATION: NEW FEDERAL AND STATE INITIATIVES FOR PREVENTION, DETECTION AND RESPONSE

Chair: N. Karp, *Consumer Financial Protection Bureau, Washington, District of Columbia*

The Consumer Financial Protection Bureau (CFPB), launched in 2011, has an Office for Older Americans—the only federal office specifically dedicated to the financial health of Americans age 62 and over. The Office is collaborating with a multitude of stakeholders and experts to enhance protection for older adults and their nest eggs through policy and practice. CFPB staff and experts from several disciplines will present key projects including: guides for "financial caregivers" handling finances for older adults who can no longer manage their money; strengthening the role of financial institutions in preventing financial abuse; tools for assisted living and nursing facilities to protect residents; and supporting state-level coalitions working to strengthen state policy and services.

SESSION 1830 (SYMPOSIUM)

SUCCESSFUL AGING: CONNECTING CRITICAL GERONTOLOGY AND CRITICAL ANTHROPOLOGY

Chair: J.C. Robbins-Ruszkowski, *Anthropology, University of Michigan, Ann Arbor, Michigan*
Co-Chair: S. Lamb, *Brandeis University, Waltham, Massachusetts*
Discussant: T. Calasanti, *Virginia Polytechnic Institute and State University, Blacksburg, Virginia*

The successful aging paradigm provided a necessary corrective to previous theories that assumed decline, decay, and decrepitude to be old age's dominant characteristics. "Successful aging" has now itself succeeded, having become a well-established field of study and an inspiring goal for researchers, community organizations, older adults, and the public alike. This paradigm holds that we each have the potential—and a moral, political obligation—to make our own aging "successful," staving off late life's potential disabilities and burdens. However, this symposium reveals this model's inherent assumptions, which arise from its cultural and political context. That is, "successful aging" is underpinned by North American and European ideals of personhood, the life course, and biomedicine. This symposium challenges such naturalized assumptions by presenting mixed-method qualitative research findings from diverse cultural, political, and economic contexts: the US, Poland, India, Thailand. Panelists will connect experiences of Catholic nuns, Alaska Native Elders, Hindu ashram dwellers, Thais of diverse ethnicities, Polish and American lifelong learning aspirants, and dementia sufferers, to gerontological, medical, and public discourses on successful aging. This symposium's critical perspective expands gerontological theories of successful aging by: 1) decentering Euro-American perspectives through cross-cultural data; and 2) suggesting that "successful aging" is only one model of a worthy old age—and that, given its increasingly global status as the dominant form of valued elder personhood, "successful aging" may be counterproductive and exclusionary. By connecting critical gerontological and anthropological perspectives, this symposium integrates empirical data with social theory to suggest new directions for gerontological research.

STRATIFICATION AND HETEROGENEITY OF SUCCESSFUL AGING CONSTRUCTS IN THAILAND AND USA

M.R. Luborsky[1,2], C. Thianthai[3], *1. Institute of Gerontology, Wayne State University, Detroit, Michigan, 2. NVS, Karolinska Institutet, Stockholm, Sweden, 3. Chulalongkorn University, Bangkok, Thailand*

The 2013 World Bank systematic study, Global Burden of Disease Injuries and Risk Factors, documented both continued life expectancy gains and elderly living more years with injury and illness. Trenchant questions remain about how to think about what should be the form of a just societal life for all which is attuned to diverse elders, community and culture-specific constructions of a good later life. Using in-depth interviews with elders and minority elders in Thailand (Thai, Muslim, Chinese) and Michigan (African American) and public document analyses we compare notions and pathways of successful aging. Findings indicate: socially stratified ideals cross-cutting national contexts; local specific contents; and shared situated dilemmas. Final discussion explores findings in light of competing models for healthy aging and their political embeddedness. [Funding acknowledgement: Chula Unisearch]

THE IMPORTANCE OF OPTIMISM IN MAINTAINING HEALTHY AGING IN RURAL ALASKA

J.P. Lewis, *School of Social Work, University of Washington, Seattle, Washington*

Many Alaska Native Elders attended government-run boarding schools as children, were forbidden to speak their native language, and were forced to abandon their traditional subsistence lifestyle, yet they maintained an optimistic outlook and continued to age well. The Explanatory Model Interview Protocol was adapted to interview a purposive sample of Alaska Native Elders ($n = 26$) and grounded theory was used to develop a model of successful aging for Alaska Native Elders in Bristol Bay, Alaska. The theme of optimism was significant in the findings and was also found in each of the elements of successful aging, which were spirituality, emotional well-being, community engagement, and physical health. The Elders believed they were able to age successfully because they continued to be optimistic despite the challenges they faced (and are currently facing) in their communities.

MEASURING SUCCESS: AGING WELL IN A CATHOLIC CONVENT

A. Corwin, *Anthropology, UCLA, Los Angeles, California*

American Catholic nuns have been found to experience greater physical and psychological well-being than their lay counterparts. While these nuns have been heralded as models of "successful aging," analysis reveals that the nuns' ideologies of health and aging may, in fact, contradict many of the tenants of "successful aging" seen in the popular and academic literature such as independence, productivity, agency, and control. Drawing on a corpus of hundreds of hours of audio- and video-recorded ethnographic data collected over four years in a Catholic convent infirmary, the paper examines the models of well-being and aging as they emerge in everyday interaction within the community. The paper expands critical theories of successful aging by: 1) demonstrating that the nuns' model of well-being contradicts the values held in Western models of successful aging; and 2) proposing an expanded model for the evaluation of "success" at the end of life.

THE POLITICS OF SUCCESSFUL AGING IN POLAND: FINDINGS FROM AN ETHNOGRAPHIC STUDY

J.C. Robbins-Ruszkowski, *Anthropology, University of Michigan, Ann Arbor, Michigan*

Older people who participate in Universities of the Third Age (UTAs) in Poland often connect such experiences to Poland's post-socialist transformations and European Union membership. That is, lifelong learning is associated with living—and aging—in an idealized West. Successful aging in Poland is thus a political practice in which older Poles can overcome stigma associated with the socialist past by striving for a European future. However, this possible future is not equally accessible to everyone; achieving ideals of successful aging is limited by class and health status. Moreover, some achieve a worthy old age through different means than those promoted by UTAs. Drawing on twenty months of ethnographic research in Polish educational and medical institutions, this paper demonstrates that successful aging is culturally specific and connected to global politics, and can be exclusionary. "Successful aging" thus benefits from a political-economic perspective as a step towards overcoming its exclusionary nature.

AGELESS AGING OR MEANINGFUL DECLINE? PERSPECTIVES FROM INDIA, THE U.S. AND A CRITICAL ANTHROPOLOGY

S. Lamb, *Anthropology, Brandeis University, Waltham, Massachusetts*

The successful aging paradigm rests on cultural biases that often go unrecognized. Drawing on two decades of ethnographic fieldwork on aging in social-cultural life in India as well as twelve months of fieldwork among two groups of (financially-privileged and low-income) Boston-area elders, the paper illuminates Western successful-aging assumptions while offering alternative perspectives to explore. Although the majority of the financially-privileged US elders in this study embrace and are inspired by Western ideals of successful aging—which emphasize independence, activity, self-responsibility, and agelessness—others in India and the U.S. critique the model for overemphasizing independence and insufficiently incorporating the human realities of mortality and decline. The paper uses the critical perspectives of interviewees to ask: Does the prevailing successful aging model overemphasize independence and declining to decline at the expense of coming to meaningful terms with late-life changes, situations of (inter)dependence, possibilities of frailty, and the condition of human transience?

SESSION 1835 (SYMPOSIUM)

SUPPORTING ENGAGEMENT IN CARE: HIV KNOWLEDGE, THE SOCIAL CONTEXT, AND ACCESS CONCERNS FOR OLDER ADULTS WITH HIV

Chair: A.K. Hughes, *School of Social Work, Michigan State University, East Lansing, Michigan*
Discussant: S.E. Karpiak, *ACRIA, New York, New York*

Access and active participation in health care is essential for older adults with HIV/AIDS. Knowledge of HIV can increase awareness among older adults and supports their ability to be an engaged participant in health care. The social context of medical care interacts in important ways with access to care. The papers in this symposium will examine issues of knowledge, experience, and access from multiple perspectives. First, we ground the symposium in epidemiological data on healthcare service use from a national data set of emergency room and hospital use by older adults with HIV/AIDS. This paper discusses the costs associated with, and implications of, care needs that are met in the emergency room setting. The next paper will detail the development of the first HIV/AIDS knowledge measure developed specifically for use with older adults. This measure has good initial validity and its uses in research and practice will be discussed. Because social supports are instrumental to care experiences among older adults with HIV/AIDS, the next paper uses qualitative methods to explore social supports among older Black women who regularly attend HIV-care. Findings indicated that engagement in care was negatively affected by disease stigma and insufficient social supports, while receiving social support was found to be key in maintaining regular participation in care. The discussion will explore how these multiple sources of data increase our understanding of the myriad factors related to engagement in health care among older adults with HIV/AIDS, including implications for policy, practice, and future research.

HIV-RELATED EMERGENCY DEPARTMENT VISITS AMONG OLDER ADULTS

M. Carter, *Towson University, Towson, Maryland*

Increasing rates of HIV infection among adults aged 50 and over is an immediate public health concern. In comparison with their younger counterparts, older adults with HIV are more often diagnosed later in the course of the disease and experience more rapid immune-system decline. However, patterns of healthcare service use and outcomes among older adults with HIV are not well understood. In response, this study draws upon the Nationwide Emergency Department Sample to examine the epidemiology of HIV-related ED visits among older adults. Descriptive and multivariate analyses are used to describe HIV-related visit rates, service use, costs and outcomes, including per capita estimates, hospital admission status, and commonly occurring comorbidities observed during the visit. Findings suggest that roughly 101,112 HIV-related patient-visits occur annually among adults aged 50 and over, with nearly 2/3 or these resulting in hospitalization. Implications for access, care, and healthcare costs are discussed.

HIV/AIDS KNOWLEDGE MEASUREMENT: PROCESS AND PRODUCT

A.K. Hughes, *School of Social Work, Michigan State University, East Lansing, Michigan*

There are currently no available HIV knowledge measures that are targeted to older adults. This study aimed to fill this gap by developing and validating a measure specifically for older adults. Through review of extant knowledge measures and expert feedback we created a pilot measure. It was reviewed by three HIV experts and eight focus groups of older adults for face and content validity, and updated based on their feedback. A validation sample of adults aged 50 and older was then recruited from the community to complete the pilot measure as well as other measures to assess concurrent and divergent validity. This measure shows initial promise given the favorable internal consistency reliability and convergent validity results. The measure performs well in a racially diverse sample. It has potential for use in clinical research evaluating HIV educational efforts with older adults as well as in healthcare settings.

THE PERCEIVED EFFECTS OF STIGMA AND SOCIAL SUPPORT AMONG OLDER BLACK WOMEN ATTENDING REGULAR HIV CARE

M. McDoom[1,2], M. Drainoni[5,3,4], B. Bokhour[5,3], M. Sullivan[4], *1. Social Science Research Center, Mississippi State University, Starkville, Mississippi, 2. Department of Global Health and Population, Harvard School of Public Health, Boston, Massachusetts, 3. Department of Health Policy and Management, Boston University School of Public Health, Boston, Massachusetts, 4. Department of Medicine, Boston University School of Medicine, Boston, Massachusetts, 5. Center for Healthcare Organization and Implementation Research, Edith Nourse Rogers Memorial VA Hospital, Beford, Massachusetts*

Despite the fact that consistent engagement in HIV care improves outcomes among people living with HIV, engagement in HIV care among older populations has been less studied compared to younger populations, and few studies have focused on this issue from the perspective of older Black women. To further understand how older Black women (age 50+) perceive the effects of stigma and social support on regular attendance to HIV care, we conducted a qualitative study to explore how the roles of stigma and social support were related to engagement and retention in care among 20 older Black women. Women who did not receive social support or experienced ongoing stigma portrayed their social world as a source of distress that affected their ability to engage in care. However, women engaged in care if they could successfully limit their distress by disclosing their HIV status to someone and receive social support.

SESSION 1840 (SYMPOSIUM)

AGING IN PLACE IN SENIOR HOUSING: DEVELOPING A “VILLAGE” MODEL TO INCLUDE LOW INCOME RESIDENTS

Chair: R. Dunkle, *University of Michigan, Ann Arbor, Michigan*
Discussant: A.E. Scharlach, *University of California, Berkeley, California*

The “Village” model has emerged over the last two decades as a way to provide support and services to older people who want to continue to live in the community. Many villages thus far have been grassroots, community-based organizations that are lead and funded by residents living in a neighborhood. While this has been a successful strategy for some older adults, those with lower incomes or living in congregate housing arrangements have had difficulty gaining access to this model. This symposium describes the development of a statewide village initiative formed through a partnership among a service provider, housing provider, and a university that intentionally included low income residents in HUD housing. The first paper examines the necessary steps to develop a strategic alliance among these three organizations. The second paper focuses on the service delivery model, including data used to define the model and strategies to solicit participation by HUD housing residents and older adults living in the community. Using qualitative data collected from service coordinators in current and future intervention sites, the third paper examines the role of service coordination in this model and the challenges of aging in places in congregate housing. Using quantitative data gathered from residents, the fourth paper compares the well-being of those living at intervention sites and those in comparison sites. Implications for designing a village that intentionally includes low income residents in an urban setting as well as recommendations for promoting this model in suburban and rural areas will be discussed.

STRATEGIC ALLIANCE FOR AGING IN COMMUNITIES: COMMUNITY CONNECTIONS IN DETROIT AND BEYOND

K. Harlow-Rosentraub[1], R. Dunkle[1], T. Wintermute[2], J. Robinson[3], *1. School of Social Work, University of Michigan, Ann Arbor, Michigan, 2. Hannan Foundation, Detroit, Michigan, 3. Presbyterian Villages of Michigan, Detroit, Michigan*

Presbyterian Villages of Michigan and the Hannan Foundation, a provider of senior services, having similar interests in senior housing and community services, formed a partnership based on shared values. These two organizations coupled with the research expertise of University of Michigan provided a unique opportunity for planning and development of a Strategic Alliance. The collaborative developed and implemented a new, evidence-based model of service coordination for senior housing and surrounding neighborhoods that adapted some aspects of the national village-to-village model but emphasized both market rate and subsidized housing, focusing on access, wellness, and social engagement for village residents and neighbors in surrounding communities. The cooperation of board members and the development of an MOU helped to align strategies and resources to achieve mutual goals. Process measures, lessons learned and best practices in developing and evaluating a collaboration that is greater than the sum of its individual members will be discussed.

COMMUNITY CONNECTIONS: A DATA-DRIVEN, VILLAGE-TO-VILLAGE MODEL PROGRAM

A. Smyth[2], R. Dunkle[1], S. Savas[1], K. Harlow-Rosentraub[1], P. Allen[1], *1. School of Social Work, University of Michigan, Ann Arbor, Michigan, 2. Presbyterian Villages of Michigan, Southfield, Michigan*

This presentation describes the development of the Community Connections model. This community-centric model is designed to support aging in place for community members and village residents regardless of place and income. Three models (urban, suburban, and rural) are in various stages of implementation. Data collected to support the launch of the model and facilitate successful community entre will be presented. Collection sources included community conversations, focus groups, and mapping (asset and ArcGIS). The data were gathered to inform recruitment strategies, community member engagement, business engagement, and initial service offerings. Results indicated that members can identify their aging in place "wants", their service needs (current and anticipated), and their connection to the community. Local businesses are interested in partnering with Community Connections to meet the gaps in providing home health care, handyman, and housekeeping services for older adults. Logic model and data collection protocols will be shared.

VILLAGE RESIDENT VOICES: RECRUITING, INTERVIEWING AND DOCUMENTING

K. Harlow-Rosentraub, R. Dunkle, S. Savas, *School of Social Work, University of Michigan, Ann Arbor, Michigan*

As the Michigan Village Initiative moved forward with design plans for a variation of the Village-to-Village model for senior services, a Planning Information Pyramid model was developed. At the fourth or top level, primary databases are required. Two village sites where a service coordinator was in residence (n=108) were compared to two comparison sites without a coordinator (n=51). Recruitment involved gift certificates for small amounts and completion rates ranged from 67-69%. Interviews were conducted on-site in apartments or common areas. Survey developed from UC Berkeley data and Legacy Corps focused on access, utilization, well-being and social engagement. Baseline assessment found few differences in intervention and comparison sites but the residents are substantially different from other village studies with more low income and minority participants. Recontact within a year will measure changes in health status, wellness perceptions and increased engagement in village and community activities and governance.

THE ROLE OF SERVICE COORDINATORS IN AGING IN PLACE AND POTENTIAL CONTRIBUTIONS TO A VILLAGE MODEL

A.J. Lehning[1,3], B. Carney[2], H. Wiseman[1], *1. University of Maryland, Baltimore, Maryland, 2. The Luella Hannan Memorial Foundation, Detroit, Michigan, 3. University of Michigan, Ann Arbor, Michigan*

Service coordination is thought to have numerous benefits for older adults including helping them age in place. The mechanisms by which service coordination contributes to positive outcomes, however, are not well understood because of limited research. Using interview data collected from service coordinators in current and future intervention sites of a village initiative, this presentation explores service coordinators' perceptions of 1) their roles and responsibilities, and 2) the barriers to aging in place experienced by low-income residents living in HUD housing. Content analyses indicate that service coordinators perceive their ability to monitor residents and detect potential problems early as key to facilitating aging in place. The ability of service coordinators to assist residents is limited, however, by challenges from family members, community infrastructure, requirements of the job and, most commonly, residents themselves. The paper concludes with implications of including formal service coordination in a village initiative.

SESSION 1845 (PAPER)

CHRONIC ILLNESS CARE AND DISEASE MANAGEMENT

INTEGRATED TELEHEALTH EDUCATION ACTIVATION FOR MOOD AND CHRONIC ILLNESS IN GERIATRIC HOMECARE PATIENTS: THE I-TEAM STUDY

Z.D. Gellis[1], B.L. Kenaley[2], *1. University of Pennsylvania, Philadelphia, Pennsylvania, 2. Boise State University, Boise, Idaho*

Approximately 20% of geriatric home care patients with chronic diseases are readmitted to hospital within one month of discharge underscoring health system challenges. Delivering integrated telehealth services may provide one effective approach to this problem by monitoring physical symptoms, increasing communication on patient status with primary care, and delivering evidence-based treatments for depression. This is the first study to report the results of a randomized controlled trial of I-TEAM© (Integrated Telehealth Education and Activation of Mood), an integrated telehealth care model for chronic illness and co-morbid depression vs usual in-home care plus psychoeducation. The 3-month intervention was comprised of a telehealth nurse conducting daily telemonitoring of symptoms, body weight, and medication use, providing problem-solving treatment for depression, and communicating with the patient's primary care physician who prescribed antidepressants. The two groups were compared at baseline, 3 and 6-months post-baseline on depression, health status, problem solving, and health utilization (number of readmissions, patient episodes of care, and ER visits). At 3 and 6 months post-baseline, depression scores decreased by 50% in the I-TEAM group as compared to usual care. The I-TEAM group reported significant improvement in problem solving skills and self-efficacy in managing their medical condition compared to controls. The I-TEAM group had significantly lower ER visits ($P < .03$) at 12-month post-baseline compared to usual care. Patients reported that telehealth services were feasible and satisfactory. After attending this activity, participants will be able to discuss the I-TEAM integrated health and mental health model and associated benefits with telehealth technology.

EFFECTIVENESS OF INTENSIVE HOME HEALTH AND PHYSICIAN VISITS IN REDUCING HEART FAILURE READMISSIONS

C.M. Murtaugh[1], P. Deb[2], T. Peng[1], C. Zhu[3], S. Moore[4], Y. Barrón[1], S. Shah[1], E. Cohen[5], *1. Center for Home Care Policy & Research, Visiting Nurse Service of New York, New York, New York, 2. Hunter College, New York City, New York, 3. Icahn School of Medicine at Mount Sinai, New York, New York, 4. Independent Contractor, Bonny Doon, California, 5. Princeton University, Princeton, New Jersey*

Objective. To identify the most effective strategy for reducing readmissions among heart failure (HF) patients discharged to home health care by comparing the effectiveness of: (1) early, intensive home health nursing (i.e., at least 1 visit within 24 hours of discharge and 3+ visits in the first week); (2) at least 1 outpatient physician visit in the week after discharge; and (3) both "interventions." Methods. Medicare data were used to identify all fee-for-service beneficiaries hospitalized for HF and then discharged to home health care between 7/1/09 and 6/30/10. There were 98,722 index hospitalizations where patients had a full week following hospital discharge in which to receive the interventions. Instrumental variables estimation was used to produce unbiased estimates of intervention effects on 30-day all-cause readmission rates relative to patients who did not receive any intervention. The instruments are hospital-level practice patterns excluding HF patients. Results. The rate of rehospitalization was reduced 7.2 percentage points (SE=2.6; $p<0.01$) for patients receiving both interventions (11.1% of all observations). Neither intervention alone had a statistically significant effect. Conclusions. Among Medicare HF patients discharged to home health care, the combination of early, intensive nursing services and at least 1 outpatient physician visit in the week after hospital discharge very substantially reduces the risk of rehospitalization. No change in Medicare policy is necessary for home health agencies and physicians to more widely implement these practices. Thus, the findings have the potential to rapidly change clinical practice and directly benefit the growing number of older persons with HF.

DELIVERING MULTIPLE EVIDENCE-BASED PROGRAMS TO AT-RISK SENIORS

S.D. Towne[1], M.L. Smith[2,1], S. Ahn[3,1], B. Belza[4], M. Altpeter[5], K. Kulinski[6], M.G. Ory[1], *1. Health Promotion and Community Health Sciences, Texas A&M Health Science Center, College Station, Texas, 2. University of Georgia, Athens, Georgia, 3. University of Memphis, Memphis, Tennessee, 4. University of Washington, Seattle, Washington, 5. University of North Carolina at Chapel Hill, Chapel Hill, North Carolina, 6. National Council on Aging, Center for Healthy Aging, Washington, District of Columbia*

The Chronic Disease Self-Management Program (CDSMP), A Matter of Balance/Volunteer-Lay-Leader (AMOB/VLL) and EnhanceFitness (EF) are evidence-based programs (EBP) that have been disseminated nationwide but comparable reach/retention among vulnerable populations has limited documentation. We conducted cross-sectional analyses of three EBPs disseminated throughout the US (2006-2009) as part of the AoA Evidence-Based Disease Prevention Initiative. Our objective was to document the extent to which these EBPs reached vulnerable older adults, the presence of multiple programs across service sectors, and factors associated with successful completion. All programs attracted participants with comorbidities (63% for CDSMP, 59% for AMOB/VLL and 64% for EF) and approximately one-quarter of participants in all programs had incomes under $15,000. EnhanceFitness had the highest reach in terms of both minority (43% for EF vs 38% for CDSMP and 26% for AMOB/VLL) and rural (25% for EF vs 18% for CDSMP and 17% for AMOB/VLL) penetration among EBPs. The presence of multiple programs was less common in rural areas where having one of the three EBPs was more likely. Successful completion of CDSMP (attending 4+ of 6 sessions) was significantly associated ($p<.05$) with race (White-versus-Black), residing in rural areas or partial HPSA and having few chronic conditions, while successful completion of AMOB/VLL (attending 5+ of 8 sessions) was associated with race/ethnicity (White-versus-Hispanic and Black-versus-White), residing in a full HPSA and being in a lower income group. These programs reached more vulnerable older adults than reached previously. Variations in successful completion suggests the importance of tailored strategies for obtaining higher completion rates.

ORAL CANCER SCREENING IN LONG-TERM FACILITIES FOR OLDER ADULTS

T. Cadet[1,2], P. Maramaldi[1,2,3], *1. School of Social Work, Simmons College, Boston, Massachusetts, 2. Harvard School of Dental Medicine, Boston, Massachusetts, 3. Harvard School of Public Health, Boston, Massachusetts*

An estimated 41,000 Americans will be diagnosed with oral cancer in 2014, while almost 8,000 will die. Approximately 25% of these deaths are attributable to late diagnosis and treatment. Most recent data (2011) indicates that approximately 40% of those diagnosed with oral cancer were over age 65, and almost 60% of the deaths occurred in people age 65 and older. Older nursing home residents are most vulnerable to poor oral health, which is associated with late stage diagnosis of oral cancer. Early diagnosis—through screening—is key to improved oral cancer morbidity and decreased mortality. The reported study used a conceptual framework and analysis integrating the Health Belief Model, Transtheoretical Model and Implementation Science. We interviewed and surveyed administrators responsible for overall care of elders in long-term care facilities across the Commonwealth of Massachusetts. Results from our NIH funded pilot study indicate that regular oral cancer screening is not generally provided to nursing home residents despite the commitment of administrators to excellent oral care. We found a lack of knowledge about oral cancer risk among nursing home residents, family members, and staff combined with low self-efficacy about oral cancer screening contributed to low screening rates. Furthermore, findings suggest high motivation to divert resources toward safety and nutrition might be redirected to include oral health. This investigation provides formative data for the development of empirically grounded interventions that identify opportunities, and motivations to implement oral cancer screening across disciplines involved in the care of elders in residential facilities.

PREDICTING NURSING HOME FALLS: METHODOLOGY USING ELECTRONIC MEDICAL RECORDS

A. Marier[1], W.D. Spector[2], W. Rhodes[1], *1. Abt Associates, Inc., Bethesda, Maryland, 2. Agency for Healthcare Research and Quality, Rockville, Maryland*

Falls are the most frequently reported adverse event among frail nursing home residents, and are associated with considerable mortality, morbidity, and reduced functioning. Nursing home fall rates range from approximately 0.2 to 3.6 falls per bed per year with a mean of 15 reported falls per year for an average nursing home with 100 beds. In 2000, the average estimated direct medical cost associated with a non-fatal fall was $7,307 for adults older than 65 years of age. Falls in a nursing home setting can be prevented before they occur with an appropriate risk factor alert system and staff vigilance. Most nursing home fall literature employs a resident's Minimum Data Set (MDS) assessments as a primary data source. However, MDS assessments can relay lagged information about resident fall risk. The recent emergence of electronic medical record (EMR) data in nursing homes has spurred research that uses timelier fall risk information. This paper provides a methodological framework that uses time-varying clinical data to predict nursing home resident fall risks. We use EMR and MDS data jointly to predict the probability of a nursing home resident's fall using a piece-wise exponential hazard model. We show that the predictive power of the model using both primary data sources is superior to that of a model using MDS assessments alone. Electronic medical records allow clinicians the ability to assess health service provision in real time. Our proposed model provides the missing link between health technology and quality improvement efforts.

SESSION 1850 (SYMPOSIUM)

EMERGING MECHANISMS & INTERVENTIONS

Chair: R. De Cabo, *National Institute On Aging, Baltimore, Maryland*

This session will focus on newly identified mechanisms underlying age-related decline in function related to epigenetics and metabolism. Dana Miller, University of Washington, wil present "Epigenetic memory of hydrogen sulfide declines with age in C. elegans'; Marcia Haigis, Harvard University, will present work on "The role of mitochondrial metabolism in immune aging. In addition, one talk from submitted abstracts will be included.

EPIGENETIC MEMORY OF HYDROGEN SULFIDE DECLINES WITH AGE IN C. ELEGANS

E.M. Fawcett, D.L. Miller, *Washington University School of Medicine, St. Louis, Missouri*

One consequence of aging is a decline in the ability to respond appropriately to fluctuating environments. As a result, the aged are generally less able to maintain homeostasis and survive stressful conditions. One strategy to survive harsh environments is to predict environmental changes based on previous experiences. Epigenetic bookmarking is one example of this, where a physiological memory of exposure to an environmental factor allows for a more robust response if that factor is encountered again. We have discovered a new epigenetic bookmark in C. elegans that is formed by exposure to the gas hydrogen sulfide (H2S). A short, transient exposure to H2S allows animals to survive subsequent exposure to otherwise lethal H2S exposures. The H2S-induced bookmark can persist through embryonic cell divisions and requires the conserved SWI/SNF chromatin-remodeling complex. This adaptive response is less effective in old animals. In older animals, the initial adaptation to H2S is intact, but the physiological memory is not efficiently maintained. This decline in epigenetic function is associated with the end of reproduction, suggesting a mechanistic links with germline-related aging signals. We propose that signals from the germline act to promote the function of SWI/SNF in young animals, allowing for remodeling of the chromatin landscape at H2S-inducible gene promoters and more efficient transcriptional activation upon subsequent exposures to H2S.

MICROVASCULAR MECHANISMS OF AGE-RELATED COGNITIVE DECLINE

Z. Ungvari, *Reynolds Oklahoma Center on Aging, Department of Geriatric Medicine, University of Oklahoma Health Sciences Center, Reynolds, Oklahoma*

Hypertension in the elderly substantially contributes to cerebromicrovascular damage and promotes the development of vascular cognitive impairment. Despite the importance of the myogenic mechanism in cerebromicrovascular protection, it is not well understood how aging affects the functional adaptation of cerebral arteries to high blood pressure. Hypertension was induced in young (3 mo) and aged (24 mo) C57/BL6 mice by chronic infusion of angiotensin II. In young hypertensive mice, the range of cerebral blood flow autoregulation was extended to higher pressure values and the pressure-induced tone of MCA was increased. In aged hypertensive mice autoregulation was markedly disrupted, and MCAs did not show adaptive increases in myogenic tone. In young mice the mechanism of adaptation to hypertension involved up-regulation of the 20-HETE/TRPC6 pathway and this mechanism was impaired in aged hypertensive mice. Downstream consequences of cerebrovascular autoregulatory dysfunction in aged angiotensin II-induced hypertensive mice include exacerbated disruption of the blood-brain barrier and neuroinflammation (microglia activation, up-regulation of pro-inflammatory cytokines and chemokines), which were associated with impaired hippocampal cognitive function. Collectively, aging impairs autoregulatory protection in the brain of mice with angiotensin II-induced hypertension, potentially exacerbating cerebromicrovascular injury and neuroinflammation.

MAKING CONNECTIONS: FROM STRESS RESISTANCE TO A LONGER HEALTH SPAN

T.E. Johnson[1], W. Chick[2], J. Cypser[1], G. Fahy[3,1], D.A. Kitzenberg[2], M. Ludwig[2], B. Newell[1], P. Tedesco[1], *1. Univ of Colorado Boulder, Boulder, Colorado, 2. Univ of Colorado Denver, Denver, Colorado, 3. 21st Century Medicine, Santa Monica, California*

Increased resistance to multiple stressors is a biomarker that can be used to predict subsequent longevity and health span. We have developed a platform enabling the production of novel longevity mutants in the mouse. Non-targeted genetic screens allow the detection and rapid cloning of genes that are firm candidates for slowed aging and extended life in the mouse model. The platform is extremely high throughput with the ability to selectively screen 25,000 mutant clones in 2 weeks. Both dominant and recessive mutants can be isolated and the origin of the mutational events can be determined within a week. The platform has been applied to several distinct phenotypes, including multi-stress resistance and a variety of genes have been implicated and drug development is underway.

SESSION 1855 (SYMPOSIUM)

THE PINE STUDY- THE POPULATION-BASED STUDY OF CHINESE ELDERLY IN CHICAGO: RESEARCH, METHODS, IMPLICATIONS, AND OPPORTUNITIES

Chair: X. Dong, *Rush University, Chicago, Illinois*

Population-based studies in aging sciences have constituted an important basis for the understanding of the distribution of illness and diseases, thus allowing estimation of population-attributable health and aging factors needed for leveraging public decision making and policy changes. While the U.S. older population grows larger and faster as reflected in the recent demographic changes, the call to examine the needs of its diverse populations is present and clear. In order to expand current knowledge base, The PINE study - Population Study of Chinese Elderly in Chicago-is a comprehensive survey that examines the health and well-being of over 3,000 Chinese older adults aged 60 and over in the greater Chicago area. To our knowledge, the PINE study is among the largest cohorts of Chinese elderly assembled for epidemiological research in Western countries. Session 1 will provide a brief introduction of the PINE study and its place within an increasing set of population-based longitudinal studies on aging. Session 2 will detail the survey methodology of the PINE study, including the survey development, sample design, innovative data collection, and field implementation with culturally and linguistically sensitive measures. Session 3 will briefly summarize the findings of the baseline survey with respect to the social and psychological well-being of Chinese older adults. Session 4 will highlight the challenges faced and lessons learned from developing impact-driven health community-academic partnerships through conducting the PINE study guided by community-based participatory research approach. Session 5 will discuss the study's policy and practice implications for advancing social change.

INTRODUCTION TO THE POPULATION-BASED STUDY OF CHINESE ELDERLY IN CHICAGO (THE PINE STUDY)

X. Dong[1], M.A. Simon[2], E. Chang[1], R. Chen[1], *1. Rush Institute for Healthy Aging, Rush University Medical Center, Chicago, Illinois, 2. Northwestern University Medical Center, Chicago, Illinois*

U.S. Chinese population is amongst the fastest growing ethnic/minority group in the country. While there is a pressing socio-demographic imperative to investigate their health and well-being of Chinese older adults, population-based research with Chinese older adults has been scarce due to multiple structural and cultural barriers in research participation. Influenced by a history of population-based survey research in the field of health and aging, the PINE study is a population-based epidemiological study of 3,159 community-dwelling Chinese older adults aged 60 years and older in greater Chicago area. With its data collection took place between July 2011 to June 2013, the PINE study assessed a wide array of psychological, social, and other health indicators closely intertwined with their cultural ideal on health and well-being. This introduction will also briefly summarize the findings of the baseline survey.

STUDY DESIGN AND SURVEY METHODOLOGY FOR THE PINE STUDY

M.A. Simon[2], E. Chang[1], M. Zhang[1], X. Dong[1], *1. Rush Institute for Healthy Aging, Rush University Medical Center, Chicago, Illinois, 2. Northwestern University Medical Center, Chicago, Illinois*

With the goal to collect a representative population-based sample of Chinese older adults in the greater Chicago area, the PINE study partnership developed up-to-date scientific strategies to increase resource efficiency, cost-effectiveness, and is carried out with several noteworthy features in its study development, design, and field implementation. First, we implemented a targeted community-based recruitment strategy guided by community-based participatory research approach, yielding a response rate of 91.9%. Second, the study was operationalized on a multi-lingual and multi-cultural infrastructure, ranging from survey design, interviewer training, study materials, to data collection, with each step the field implementation designed toward serving the needs of linguistically and culturally diverse Chinese community. Third, data were collected using state-of-the-science innovative web-based software applications which recorded simultaneously in English and Chinese. In conclusion, the PINE study was implemented in accordance with the local cultural, social, and environmental contexts of Chinese aging population. Implications for minority aging research studies are discussed.

PSYCHOLOGICAL AND SOCIAL WELL-BEING OF U.S. CHINESE OLDER ADULTS: KEY FINDINGS FROM THE PINE STUDY

E. Chang[1], M.A. Simon[2], J. Ruan[1], R. Chen[1], X. Dong[1], *1. Rush Institute for Healthy Aging, Rush University Medical Center, Chicago, Illinois, 2. Northwestern University Medical Center, Chicago, Illinois*

Despite the fact that health disparities continue to disproportionately affect older adults, vast knowledge gaps still persist in understanding the late-life psychological and social well-being of Chinese immigrant older adults – one of the fastest-growing minority communities in the U.S. This paper will examine some of the key findings based on the PINE study findings with respect to depression, anxiety, loneliness, and suicidal thoughts and attempts, as well as social well-being indicators of social isolation and elder abuse. Collectively, the PINE study findings show that contrary to the model minority image, U.S. Chinese older adults were significantly affected by psychological and social distress. These results call for further longitudinal studies to examine how the health and well-being of these older adults' changes over time in order to better examine risk and protective factors associated with health disparities among Chinese older adults.

CHALLENGES FACED AND LESSONS LEARNED FROM SUSTAINING COMMUNITY-BASED PARTICIPATORY RESEARCH PARTNERSHIP IN THE CHINESE COMMUNITY IN CHICAGO

R. Chen[1], M.A. Simon[2], E. Chang[1], Y. Li[1], X. Dong[1], *1. Rush Institute for Healthy Aging, Rush University Medical Center, Chicago, Illinois, 2. Northwestern University Medical Center, Chicago, Illinois*

Community-academic partnership is among the most commonly practiced collaborations in community-based participatory research (CBPR) projects. Despite growing interests and demands in partnerships, less attention is given on partnership sustainability— a critical issue to the management of successful community health initiatives. Following the community-based, action-oriented collaboration model, the PINE study was led by a synergistic community-academic partnership to overcome barriers in minority health research. In this presentation we aim to present challenges faced and lessons learned from our CBPR experience in the Chinese aging community in Chicago. Working with Chinese older adults requires trust, respect, and understandings of their unique historical, social and cultural positions in the Chinese community. We will also discuss culturally appropriate strategies to sustain evidence-based, impact-driven partnership and ways to leverage research for health advocacy.

MAXIMIZE THE IMPACT OF POPULATION-BASED RESEARCH WITH MINORITY OLDER ADULTS: IMPLICATIONS FOR COMMUNITY HEALTH

X. Dong[1], M.A. Simon[2], E. Chang[1], C. Li[1], *1. Rush Institute for Healthy Aging, Rush University Medical Center, Chicago, Illinois, 2. Northwestern University Medical Center, Chicago, Illinois*

The PINE Study has created a rich dataset on the psychological and social being of U.S. Chinese older adults within a culturally appropriate context. The assessments hold potential produce a significant number of critical findings that contributes to our understanding to the health and well-being of minority aging populations in the U.S. Our findings suggest that Chinese older adults were disproportionally affected by psychological and social distress. An expanded research agenda is needed to deepen our current knowledge of the biological, behavioral, familial, social, and cultural factors that may predispose minority older adults to health disparities. In addition, we call for increased family and community care, improved delivery of care, practice changes and policy reform, to prepare for the growing numbers of older adults who may need more culturally and linguistically appropriate health and social services.

SESSION 1860 (SYMPOSIUM)

SUCCESSFUL ADAPTATION TO HEALTH EVENTS AND DISABILITY: FINDINGS FROM LARGE LONGITUDINAL SURVEYS

Chair: S.M. Spuling, *German Centre of Gerontology, Berlin, Germany*
Co-Chair: J.K. Wolff, *German Centre of Gerontology, Berlin, Germany*
Discussant: S. Wurm, *Friedrich-Alexander University, Nuremberg, Germany*

With advancing age sudden declines in health due to serious health events (e. g., the onset of diseases or accidents) or the development of disability become more and more likely. Consequences of these changes in health may affect indicators of successful aging. The present symposium focuses on factors that facilitate adapting successfully to serious health events (SHE) and disability in several domains with longitudinal data of older adults. Analyzing DEAS-data – a German representative longitudinal survey of people aged over 40 – Spuling et al. examine the role of age and education as possible moderators for the effect of SHE on self-rated health. Using both data from DEAS and PREFER, Wolff et al. show that in case of SHE, negative self-perceptions of aging are related to short-term positive as opposed to long-term negative effects on well-being and health. Deeg et al. demonstrate with the Dutch LASA survey that among others instrumental support and sense of mastery are related to experience ongoing positive affect despite long-term. Infurna and Wiest show that disability shapes developmental trajectories of life satisfaction and self-rated health with different factors associated with better adaptation using longitudinal data of 4,155 persons from the Socio-Economic Panel Study (SOEP). All of these presentations demonstrate with large longitudinal datasets that diverse factors (e.g., age, education, social participation, mastery, aging perceptions) may support successful adaptation to SHE and disability. Susanne Wurm will integrate these findings from a health and developmental psychology perspective and draw implications for prevention and resilience in old age.

THE EFFECT OF SERIOUS HEALTH EVENTS ON SELF-RATED HEALTH: THE MODERATING ROLE OF AGE AND EDUCATION

S.M. Spuling[1], J.K. Wolff[1], S. Wurm[2], *1. German Centre of Gerontology, Berlin, Germany, 2. Friedrich-Alexander University, Nuremberg, Germany*

The present study examines if age and education – and in particular their interplay – moderate the effect of a serious health event (SHE) on self-rated health (SRH). Using longitudinal data of two waves of the German Ageing Survey (DEAS), 2,842 participants aged 40 years and older were analyzed. Between 2008 and 2011, 581 participants experienced a SHE. 66.1%, however, reported a stable or even better SRH afterwards. Multiple regression analyses showed a significant three-way interaction between SHE, age and education. Post hoc analyses revealed that without experiencing a SHE, higher educated participants showed a more favorable trajectory of SRH than those with lower education (both in younger and older adults). However, in case of a SHE, only younger adults with higher education were able to maintain a relatively high level of SRH. Possible underlying explanations and mechanisms such as differences in initial health status and availability of psychosocial resources are discussed.

NEGATIVE SELF-PERCEPTIONS OF AGING IN OLD AGE: SHORT-TERM GAINS AND LONG-TERM LOSSES AFTER A SERIOUS HEALTH EVENT

J.K. Wolff[1], L.M. Warner[1,2], J.P. Ziegelmann[1], B. Schüz[3], S. Wurm[4], *1. German Centre of Gerontology, Berlin, Germany, 2. Freie Universität, Berlin, Germany, 3. University of Tasmania, Hobart, Tasmania, Australia, 4. Friedrich Alexander University, Nuremberg, Germany*

Longitudinal studies show that older adults with negative self-perceptions of aging (SPA) experience steeper declines in health. However, in the short-run negative SPA may have beneficial effects, because older adults who associate aging with physical losses might be better mentally prepared for serious health events (SHE). These persons may experience on the one hand less negative affect shortly after the event and on the other hand worse functional health later on, e.g., through less rehabilitation efforts. In the PREFER study, a subsample of the German Aging Survey (DEAS) was investigated over a 6 month period (309 older adults, 65+). 2.5 years later, this sample was re-interviewed. In the case of a SHE, negative SPA were related to less negative affect six months later, but to more functional limitations after 2.5 years. Mechanisms such as preparatory behavior and exhaustive coping and similarities to research on unrealistic optimism are discussed.

THE EFFECT OF DISABILITY ON LIFE SATISFACTION AND SELF-RATED HEALTH: RESILIENCE IS NOT THE PROTOTYPICAL PATTERN

F.J. Infurna[1], M. Wiest[2], *1. Psychology, Arizona State University, Tempe, Arizona, 2. German Centre of Gerontology, Berlin, Germany*

Disability is a major stressor that affects one's developmental trajectory. Relatively little is known, however, about the effect of disability on facets beyond that of life satisfaction (LS), such as self-rated health (SRH) and whether individuals display differential trajectories. We applied growth mixture modeling to 4,155 (Mage =60, SD=14, 48% women) individuals from the SOEP who experienced disability. Four and three patterns of how LS and SRH changed were identified, respectively. Although similar patterns were found, their distribution varied and only for LS, a pattern reflecting resilience (high stable levels), was identified. Factors associated with belonging to favorable patterns were younger age and social participation. Our findings suggest that disability shapes developmental trajectories differently depending on the domain and furthermore, that resilience may not be the norm when confronted with disability. We discuss reasons why resilience may not be the norm when confronted with disability and factors promoting resilience.

RESILIENCE AS PRESERVED WELL-BEING DESPITE LONG-TERM DISABILITY

D.J. Deeg[1], M. Broese van Groenou[2], H.C. Comijs[4], M. Huisman[1], M. Visser[3], *1. VU University Medical Centre Department of Epidemiology and Biostatistics, Amsterdam, Netherlands, 2. VU University Department of Sociology, Amsterdam, Netherlands, 3. VU University Institute of Health Sciences, Amsterdam, Netherlands, 4. VU University Medical Cantre Department of Psychiatry, Amsterdam, Netherlands*

Ample evidence shows that health limitations are inversely associated with well-being in older persons. It is also widely acknowledged that the older population shows heterogeneity in its experience of health limitations. This study examines the subgroup that preserves well-being despite long-term disability. Nine-year follow-up data from the Longitudinal Aging Study Amsterdam were used, including four waves (1992-2002, N=1503). 348 (23%) reported difficulty doing daily activities at all waves. Among them, 19% (n=66) reported positive affect at all waves. This 'resilient' group was characterised by older age, slower gait speed, a higher prevalence of lung diseases and arthritis, but also a higher sense of mastery, and more instrumental support received. Education, gender, partner status, and cognitive impairment were not significantly associated with resilience, and resilience was not associated with subsequent 9-year mortality. Thus, we identified a resilient subgroup that did not add years to life, but added life to years.

SESSION 1865 (SYMPOSIUM)

HEALTH DISPARITIES: DISABILITY, MORTALITY, AND HEALTH CARE USE DIFFERENTIALS AMONG IMMIGRANT AND MINORITY GROUPS

Chair: R. Saenz, *Public Policy, University of Texas at San Antonio, San Antonio, Texas*

Discussant: K. Markides, *Public Policy, University of Texas at San Antonio, San Antonio, Texas*

Health disparities in health status, healthcare utilization, and clinical outcomes have been documented by race, ethnicity, gender, immigration status, and social class both in the U.S. and other countries. Immigrant and minority populations in the United States are much younger in age structure than the non-Hispanic white and native-born populations. As such, there has been more limited research on the health outcomes of immigrant and minority populations in comparison to the white population. In an era characterized by rapid diversification of the population and substantial inequalities in resources across population groups, it is crucial that researchers and policymakers devote greater attention to the health, disability, and mortality patterns of immigrant and minority populations in the United States, particularly in the context of population aging. As such, the overall goal for this symposium is to analyze the health, disability, and mortality patterns of immigrant and minority populations residing in the United States, with particular attention to the underlying patterns of aging within all of the population subgroups to be analyzed. For this session, papers are sought that extend the understanding of the sociological forces that lie behind persistent and emerging disparities in health, disability, mortality, and healthcare utilization as well as research that examines social factors and/or public policy initiatives designed to reduce or eliminate these disparities among immigrant and minority groups residing in the United States.

ACCULTURATION, GENDER AND ACTIVE LIFE EXPECTANCY IN THE MEXICAN-ORIGIN POPULATION

M.A. Garcia[1], R. Angel[1], C. Chiu[2], *1. Sociology, University of Texas-Austin, Austin, Texas, 2. Health Services and Systems Research, Duke-NUS, Singapore, Singapore*

Objective: This study explores the role of acculturation on active life expectancy based on Activities of Daily Living (ADLs) and Instrumental Activities of Daily Living (I-ADLs) in a 17 year cohort study of Mexican-origin men and women 65 and older at baseline. Method: We employ multistage life tables to examine the impacts of level of acculturation and gender on life expectancy. Results: Life expectancy is modestly higher for men and women with low or medium levels of acculturation compared to those with the highest level. However, those with low or medium levels of acculturation spend a larger fraction of their remaining years with disability. Discussion: While lower levels of acculturation as associated with longer life spans, they are associated with lower active life expectancy. Given the rapid aging of the older Latino population and their relatively long life spans, public health interventions designed to prevent functional disability deserve serious attention.

SUBJECTIVE DISABILITY AND MORTALITY RISK AMONG ELDERLY MEXICAN AMERICANS WITH SEVERE PHYSICAL LIMITATIONS

P.A. Cantu, R. Angel, *University of Texas at Austin, Austin, Texas*

Using the disablement process framework for understanding the gradient in functioning and disability, we study how concordance of objectively measured functioning, measured through performance oriented mobility assessments (POMAs), and self-assessed disability, measured through survey questions on activities of daily living (ADLs), shapes the mortality for elderly Mexican Americans. Individuals who experience negative concordance, POMA's limited and ADL disabled, are "realist" while those who experience discordance, POMA's limitation but no ADL disability, are optimists. We investigate the association between "optimism" and mortality for elderly Mexican Americans of the Southwest US using data from the Hispanic Established Populations for the Epidemiologic Study of the Elderly(HEPESE). Using Poisson models, we find that mortality rates are higher for "realists" than "optimists". The association between optimism and mortality is mediated by more complex measures of disability. We discuss the implications of the discrepancies for understanding predictors of functional decline in the older Mexican-origin population.

IMPACT OF LIVING ARRANGEMENTS AND HEALTH INSURANCE ON ROUTINE CARE FOR OLDER MINORITIES

A.M. Reyes, *Sociology, Pennsylvania State University, University Park, Pennsylvania*

Health care spending for older adults is five times that of individuals in their 20s, which is why understanding health care utilization is particularly important for this group. This study examines how racial differences in routine care are shaped by living arrangements and health insurance stability among older adults. Using the Survey of Income and Program Participation 2004-2008, this study focuses on individuals, ages 50-64 and those 65+, and uses logistic regression models to predict having been to the doctor and having been to the dentist in the past year. Both living arrangements and health insurance are strong predictors of both types of routine care. However these effects are moderated by race. Results indicate that health insurance is less protective for Blacks and Latinos and living with extended family is less detrimental for Blacks and Latinos, whereas overall it reduces the likelihood of obtaining routine care controlling for socio-demographics.

DURATION OF U.S. STAY, AGE, AND HEALTH AMONG LATINO AND ASIAN IMMIGRANTS: A TEST OF THEORETICAL PATHWAYS

A. Ro[1], G. Bostean[2], *1. UC Irvine, Irvine, California, 2. Chapman University, Orange, California*

This study tested theoretical pathways through which duration of U.S. stay may affect self-rated health and chronic conditions among Latino and Asian immigrants of various ages. Using the National Latino and Asian American Survey, we conducted logistic regressions separately by age group to address: what is the relationship between duration of stay and health; to what extent do health behaviors, English proficiency, migration-related stress, social support, and discrimination mediate the relationship between duration and health? Preliminary analyses showed little support for a duration effect among Latinos, and an inverse effect among Asians, especially older immigrants (OR=0.38, p<.10 for 21+ years vs. 0-4 years). Age differences highlight that adaptation processes may impact younger immigrants more. In some cases, hypothesized pathways magnified the negative duration effect. Thus, multiple pathways with opposing effects link duration and health. Not accounting for pathways may mask important duration patterns. Additional pathways will be examined.

FACETS OF SOCIOECONOMIC POSITION AND DISABILITY ONSET AND PROGRESSION: THE CASE OF MEXICO

J. Saenz, *Preventive Medicine and Community Health, University of Texas Medical Branch, Galveston, Texas*

Introduction: United States research has found education to predict disability onset while income predicts disability progression. This framework has not been applied to developing countries experiencing rapid aging such as Mexico to understand socioeconomic status (SES) disability pathways. Aim: To determine if education is associated with Activities of Daily Living (ADL) disability onset and if income is associated with disability progression (new ADL disabilities among those with existing disability). Method: Data come from the Mexican Health & Aging Study and include respondents age 50+. Full analyses will use all three Waves of data (2001-2012), longitudinal mixed-effect models and instrumental variables for education and income. Preliminary Results: In preliminary logistic and multinomial regression models using only Waves one and three, lower education and income were associated with disability onset but neither were associated with disability progression. Discussion: Pathways between SES and disability may differ across the United States and Mexico.

SESSION 1870 (SYMPOSIUM)

POPULATION AGING AND HEALTHY LIFE EXPECTANCY IN INDIA: IMPLICATIONS FOR THEORY AND POLICY

Chair: T. Samanta, *Social Sciences, Indian Institute of Technology, Gandhinagar, Ahmedabad, Gujarat, India*

Empirical health research on older adults in the developing world has often constructed later life as a social pathology of disease, disability, burden and dependence. India is no exception. Drawing mortality data from the World Health Organization and the Census of India (2011) and health (specifically, functional limitations and chronic diseases) data from Longitudinal Aging Survey of India (LASI, 2011), this paper examines both life expectancy (LE) and Healthy Life Expectancy (HLE) to realistically examine the link between active aging, social connectedness and quality of life of older persons in India. Preliminary findings suggest that inequalities in healthy life expectancies exist by gender, residence (rural/urban) and region (selected states in India). In addition to advancing the scholarship on HLE by examining life expectancies through a critical gerontological theory lens, the study makes a case for a forward looking social policy on aging that is more enduring and inclusive.

HEATH EXPECTANCIES AMONG CHINESE OLDER ADULTS: EVIDENCE FROM CHINA HEALTH AND RETIREMENT LONGITUDINAL STUDY

H. Luo[1], G. Wong[1], T.Y. Lum[1], C.H. Gong[2], H. Kendig[2], *1. Sau Po Centre on Ageing, The University of Hong Kong, Hong Kong, Hong Kong, 2. The Australian National University, Canberra, Australian Capital Territory, Australia*

Although life expectancy in China is increasing, what proportions of life spend in a good health is unknown. This study aims to calculate different types of age-specific health expectancies for Chinese older adults who aged 50 and older by sex in 2011. Combining the information of life table from World Health Organization and 2011 baseline survey of China Health and Retirement Longitudinal Study, we calculated health expectancies in terms of self-reported health, chronic disease, ADL, and disability using Sullivan's method. We found that men and women have similar health expectancies for self-reported health and chronic disease. Women have longer health expectancies in terms of ADL and disability. However, women's proportions of life spend with good health are generally lower than men. This study calls for a thorough investigation of the trend of China's HLE for older adults so that health-care cost and pension provision schemes can be adjusted accordingly.

HEALTHY AGING IN KOREA: AN INVESTIGATION OF GEOGRAPHIC VARIATIONS

J. Min, J. Lee, *Davis School of Gerontology, USC, Los Angeles, California*

Korea, with remarkable economic growth and strategic public health investment, has achieved significant increase in life expectancy from 61.9 years in 1970 to 81.2 in 2011. However, both economic development and life expectancies are unequal across regions within the country: according to the 2011 Census, the residents in the richest region had 33.4% more disposable income and 3 additional years of life expectancy than those in the poorest region. Using the 2012 Korean Longitudinal Study on Aging, we investigated geographic variations in health among older adults and examine their association with stage of economic development and health care resources (both personnel and facilities) of the regions. We found health, particularly difficulties with daily activities, differed significantly across 15 regions (F=2.49, p <.001) and such geographic variations were significantly associated with disposable individual income of the regions.

HEALTHY LIFE EXPECTANCIES AND HEALTH INEQUALITIES AMONG THE ASIA-PACIFIC COUNTRIES: EVIDENCE FROM AUSTRALIA, KOREA, CHINA, SINGAPORE AND INDIA

Y. Saito[1], C.H. Gong[2], H. Kendig[2], *1. Nihon University, Tokyo, Japan, 2. Australian National University, Canberra, Australian Capital Territory, Australia*

The Life Expectancies (LE) have increased dramatically in both developed and developing countries, however, old people might have to live longer with an increasing burden of diseases, disabilities, hence needs for assistance in core activities of daily living. It is important to understand both LE and Healthy Life Expectancies (HLE). However, the international comparison literature of HLE is dominated by Europe and North America, with significant gaps existing for the Asia-Pacific countries. The objective of this symposium is to bring together world experts to present their emerging research on HLE and health inequalities in Australia, Korea, China and India. This country configuration of East-West and levels of development will bring a new range of studies into the international comparison literature of HLE with different culture and social economic environment. By drawing the information of life tables from WHO or national statistics, and health information from Census or longitudinal surveys of ageing (such as HILDA, KLoSA CHARLS and LASI), the four papers in this symposium will look at the gender and regional disparities in terms of HLE measured by different health variables, including self-assessed health, diseases, disabilities, need for assistance in core activities and dependence. Sullivan method will be used to calculate HLE and a cross-state meta-regression analysis to identify socio-economic factors influencing the inequalities in healthy life years among older people.

HEALTHY LIFE EXPECTANCY AMONG OLDER AUSTRALIANS: EVIDENCE AND DRIVING FACTORS OF GENDER AND REGIONAL DISPARITIES

C.H. Gong[1,2], J.C. Enticott[3], H. Kendig[1,2], C. Browning[4], H. Luo[5], *1. Centre for Research on Ageing, Health and Wellbeing, Australian National University, Canberra, Australian Capital Territory, Australia, 2. ARC Centre of Excellence in Population Ageing Research, Canberra, Australian Capital Territory, Australia, 3. School of Psychology and Psychiatry,Monash University, Melbourne, Victoria, Australia, 4. School of Primary Health Care, Monash University, Melbourne, Victoria, Australia, 5. Sau Po Centre on Ageing, the University of Hong Kong, Hong Kong, China*

Population is ageing rapidly in Australia and its associated needs for assistance in core activities of daily living and utilizations of aged care service are increasing. This paper draws on data from a national census in 2011 to calculate Life Expectancies (LE) and Need-assistance Free Life Expectancies (NAFLE) for men and women at age 50 years. Preliminary findings indicate that LE is 3.70 years longer for women than for men while NAFLE is 2.03 years longer for women. Men, however, can expect to have a higher proportion of their remaining years without needs for assistance (87.28%) as compared to women (82.95%); NAFLE findings varied slightly between the states and territories. A cross-state meta-regression analysis will be used to identify socio-economic factors influencing the inequalities in healthy life years among older Australians. Implications for the future and for health promotion and aged care will be discussed.

ACTIVE LIFE EXPECTANCY AND FUNCTIONAL LIMITATIONS AMONG OLDER SINGAPOREANS: GENDER, EDUCATIONAL AND ETHNIC DIFFERENCES

C. Chiu[1], A. Chan[1], V. Haldane[1], D. Matchar[1], Y. Saito[2,1], *1. Duke-NUS Graduate Medical School Singapore, Singapore, Singapore, 2. Nihon University, Tokyo, Japan*

As the world's population ages it's also urbanizing - the intersection of these factors creates challenges in planning and policies to meet the needs of the increasing numbers of urban elderly. The WHO has proposed an Age-Friendly City approach to planning urban spaces and communities, so as to address the challenges of urban aging and best capitalize on the resources available in urban centers to promote active aging. The first aim of this paper was to provide information base for "Age-Friendly City" in Singapore through better understanding age-specific transition probabilities of functional limitations. The second aim was to examine health inequality for older Singaporean. Significant differences in functional limitation incidence and health expectancy have been shown in this study. This study highlights the importance of devising policies, programs and services that recognize the nuances and differing effects of sex, ethnicity and education on functional limitations in an "Age-Friendly City".

SESSION 1875 (SYMPOSIUM)

CONNECTING PERCEPTIONS OF AGING AND DEVELOPMENTAL OUTCOMES: NEW INSIGHTS ON PATHWAYS AND DOMAINS

Chair: J. Menkin, *University of California - Los Angeles, Los Angeles, California*
Co-Chair: A.E. Kornadt, *Bielefeld University, Bielefeld, Germany*
Discussant: B.R. Levy, *Yale School of Public Health, New Haven, Connecticut*

Perceptions of aging influence how we age. Longitudinal and experimental research has linked more positive perceptions of aging to greater physical and cognitive function and even increased longevity. This symposium brings together research from the US, Canada, and Germany to examine the role of perceptions of aging across a variety of outcomes. In addition to extending findings to relatively unexplored domains (preparation and social outcomes), the symposium investigates pathways through which perceptions of aging operate and interact with contextual factors to influence established outcomes like memory and health. The symposium first offers longitudinal evidence from domains where beliefs about aging may have a substantial impact. Kornadt et al. illustrate how domain-specific perceptions of aging influence one's preparation for anticipated age-related changes. Menkin et al. present how expectations regarding aging are related to social behavior (e.g. social integration). Next, the symposium offers mechanisms linking perceptions of aging to established outcomes. Two presentations link implicit theories or beliefs about malleability of memory and the aging process with subsequent memory performance. First, Chasteen will introduce how believing memory and abilities in general are more fixed (vs. malleable) predicts worse memory performance for older adults. Second, Weiss & Staudinger will further examine how essentialist beliefs, expecting less malleability, changes how experimental exposure to negative age stereotypes influences memory performance. Finally, Wurm & Benyamini propose optimism as a moderator of the self-perceptions of aging - health relationship. Becca Levy will integrate the contributions and offer future questions for theory and research.

PERCEPTIONS OF AGING AND PREPARATION FOR AGE-RELATED CHANGES – RESULTS FROM A LONGITUDINAL STUDY

A.E. Kornadt[1], P. Voss[2], K. Rothermund[2], *1. Bielefeld University, Bielefeld, Germany, 2. Friedrich-Schiller-University Jena, Jena, Germany*

Perceptions of aging, such as age stereotypes and future self-views, influence how people actually age. One mechanism linking perceptions of aging and actual developmental outcomes might be how people prepare for anticipated age-related changes. Since preparation and perceptions of aging have been demonstrated to be domain-specific, we investigated the relationship between age stereotypes, future self-views and preparation for age-related changes in different life domains. In a 4-year longitudinal design (core sample N = 593, aged 30 to 80 at T1), age stereotypes as well as future self-views predicted subsequent changes in self-reported preparation in the majority of domains. For the domains finances and work, preparation also predicted changes in perceptions of aging. The results point to the importance of perceptions of aging for age-related preparation, and call for further research linking the affordances and constraints of life domains to this relationship.

EXPECTATIONS REGARDING AGING AND SOCIAL INTEGRATION IN LATER LIFE

J. Menkin[1], T. Robles[1], T. Seeman[1], T.L. Gruenewald[2], E. Tanner[3], *1. University of California - Los Angeles, Los Angeles, California, 2. University of Southern California, Los Angeles, California, 3. Johns Hopkins University, Baltimore, Maryland*

Negative schemas of aging predict worse mental and physical functioning, but do they influence social engagement? With older adults alternately portrayed as lonely curmudgeons or perfect grandparents, more positive expectations about aging likely provide greater motivation to maintain or bolster one's social network. In a subset of participants (age 59 to 85) from the longitudinal Baltimore Experience Corps Trial (a civic engagement intervention), positive expectations regarding aging were related to greater social integration over time. Independent of intervention group status, participants with more positive expectations at baseline had greater perceived support availability 12 months later, controlling for baseline levels of perceived support availability, depression, health status, and demographic characteristics (N = 386). The correlates of new friendship formation, potential third variables and causal directionality will be discussed. Enhancing age-related self-stereotypes may facilitate more positive trajectories of social engagement in older adulthood and consequently promote better health and well-being.

CAN A LEOPARD CHANGE ITS SPOTS? HOW OLDER ADULTS' LAY THEORIES ABOUT ABILITIES PREDICT THEIR MEMORY PERFORMANCE

A. Chasteen, J. Plaks, *University of Toronto, Toronto, Ontario, Canada*

There is growing evidence that the memory performance of older adults is significantly influenced by subjective beliefs regarding aging and memory. In this talk I will extend this literature by introducing a more general class of implicit theories that may affect memory function in older adults. Specifically, I will present recent work from our lab that investigated whether older adults' implicit theories regarding the fixedness (entity theory) or malleability (incremental theory) of memory in particular and abilities in general would predict memory performance. In addition to demonstrating the role that implicit theories play in older people's memory performance, I will consider a possible mechanism through which these theories have an effect. Taken together, these studies suggest that individual differences in entity versus incremental beliefs may represent a key influence on older adults' memory performance.

CORRELATES AND CONSEQUENCES OF ESSENTIALIST BELIEFS ABOUT AGING

D. Weiss, U.M. Staudinger, *Sociomedical Sciences, Columbia University, New York, New York*

Essentialist beliefs about the aging process are defined as views that link chronological age with underlying, immutable, and dispositional properties. In light of negative age stereotypes, then, older adults are often seen as incompetent, harder to train, and inflexible. A first study (N = 93, 18-81 years) showed that essentialist beliefs about aging are associated with a more restricted future time perspective and lower levels of perceived control. In a second study (N = 79, 61-87 years) we tested the moderating role of older adults' essentialist beliefs in the face of activating negative age stereotypes on memory performance. Results showed that depending on their degree of essentialist beliefs older adults showed a more or less impairment of their memory performance when confronted with negative age stereotypes (vs. control condition). We discuss mediating mechanisms and propose a novel intervention to stimulate positive plasticity by changing essentialist beliefs about old age.

DOES OPTIMISM BUFFER THE DETRIMENTAL EFFECT OF NEGATIVE SELF-PERCEPTIONS OF AGING ON PHYSICAL AND MENTAL HEALTH?

S. Wurm[1,2], Y. Benyamini[3], *1. Institute of Psychogerontology, Friedrich-Alexander University Erlangen-Nuremberg, Nuremberg, Germany, 2. German Centre of Gerontology, Berlin, Germany, 3. Tel Aviv University, Bob Shapell School of Social Work, Tel Aviv, Israel*

Previous studies have shown a detrimental effect of negative self-perceptions of aging (SPA) on physical health outcomes. The present study examined whether an optimistic outlook to the future can buffer the effect of negative SPA on physical and mental health outcomes. Data for this study comes from the 2008 and 2011 waves of the German Aging Survey (DEAS; n = 6,205), a population-based representative survey of adults aged 40 to 85 years. Multiple regression analyses indicated that negative SPA predicted deterioration in the three health outcomes over a three-year period, controlling for demographics and illnesses. The most remarkable finding is the interaction with optimism: People who were prepared for physical losses (negative SPA) and who were nevertheless optimistic, were better able to maintain better physical functioning, and lower depressive symptoms. A multidimensional perspective on aging therefore seems to be best for the maintenance of good health.

SESSION 1880 (SYMPOSIUM)

GEOGRAPHIC DISPARITIES: THE INFLUENCE OF REGIONAL AND LOCAL CHARACTERISTICS ON INDIVIDUAL DEVELOPMENT IN OLD AGE

Chair: N. Vogel, *Humboldt University, Berlin, Germany*
Co-Chair: C. Tesch-Roemer, *German Centre of Gerontology, Berlin, Germany*
Discussant: M.P. Cutchin, *Wayne State University, Detroit, Michigan*

Lifespan and life course perspectives highlight the contextual embeddedness of individual development. Local and regional contexts can be expected to support or constrain processes of adaptation and regulation, particularly when individual resources are scarce, and create geographic disparities which are often overlooked. The sources of these geographic discrepancies come from various levels: Differences across states in regulations in old age policies, variations across counties in wealth and infrastructure, dissimilarities across neighborhoods in resources and barriers. This symposium brings together five papers that highlight how geographic factors at various levels of analysis shape individual development in later adulthood both theoretically and empirically in Germany and the US. Giasson & Smith use data from the Health and Retirement Study (HRS) to examine variations of satisfaction with aging in states and regions of different population density in the United States. Simonson et al., using data from the nationally representative German Aging Survey (DEAS), explore regional disparities in volunteering. Wiest et al., using data from the DEAS, study county-level economic and demographic structures in social activity and health. Vogel et al. explore the role of county-level care characteristics for development of life satisfaction with the German Socio-Economic Panel Study (SOEP). Ailshire examines the link between neighborhood socioeconomic status and development of well-being using data from the HRS. The discussion by Malcolm P. Cutchin integrates the papers, highlights their theoretical contributions from a geographical perspective, and considers challenges and opportunities of research linking geographic variations and individual-level outcomes.

REGIONAL VARIATIONS IN SATISFACTION WITH AGING: CORRELATES IN THE UNITED STATES

H.L. Giasson[1], J. Smith[1,2], *1. Psychology, University of Michigan, Ann Arbor, Michigan, 2. Institute for Social Research, Ann Arbor, Michigan*

This study explores variations in satisfaction with aging between states in the U.S. Regional differences in patterns of satisfaction with aging by population density are also explored. Although there was no main effect of population density (urban, suburban, rural) on satisfaction with aging, there was a significant interaction between population density and region. Follow-up analyses revealed that in some regions satisfaction was higher in the rural areas than in the urban areas, whereas in other regions the reverse pattern was true. Such findings emphasize the need for sensitivity to regional variations in community-level predictors of aging experiences. Because satisfaction with aging is related to health and well-being outcomes, understanding geographic and community-level predictors of satisfaction with aging will help inform policy efforts to reduce health and well-being disparities among older individuals across the U.S. Discussion will focus on examining the linkages between state and region level social ecological characteristics.

REGIONAL DISPARITIES IN VOLUNTEERING AND EDUCATIONAL ACTIVITIES

J. Simonson[1], C. Hagen[1], C. Vogel[1], A. Motel-Klingebiel[2], C. Tesch-Roemer[1], *1. German Centre of Gerontology, Berlin, Germany, 2. Linköping University, Linköping, Sweden*

Societal participation like volunteering and continuing education is socially and spatially structured. Lower SES individuals are less often involved in educational activities or in volunteering, and it can be expected that spatial disparities reinforce this effect of social inequality. Based on two waves (2008, 2011) of the German Ageing Survey (DEAS) we investigated access to and dynamics of volunteering and educational activities depending on social and spatial aspects of inequality (spatial units: German counties or “Kreise”). Cross-sectional analyses (n=4,025) show that individuals living in economically disadvantaged counties are less likely to participate in volunteering and educational activities than those in economically strong counties. Longitudinal analyses (n=1,834) show that individuals living in advantaged counties remain more often active over time than individuals living in less advantage counties. Disadvantages accumulate if low individual resources overlap with poor economic conditions in the living area.

REGIONAL STRUCTURES OF ECONOMIC AND DEMOGRAPHIC DEVELOPMENT IN GERMANY AND THEIR EFFECTS ON INDIVIDUAL AGING

M. Wiest, S. Nowossadeck, C. Tesch-Roemer, *German Centre of Gerontology, Berlin, Germany*

Societal and economic conditions shape individual aging not only on the individual level (e.g. socio-economic status of a person), but also on the level of regional contexts, like neighborhoods and counties. We assumed that regional characteristics influence different domains of functioning in old age, independently of individual SES. We analyzed national representative data of the German Ageing Survey of 2,774 participants (Age M = 73,1, SD = 5,3; 45,2% women) living in 206 counties (“Kreise”) using multi-level modelling. All analyses were controlled for age, gender, education, income, marital status and migration background. Results showed that living in counties with a shrinking and rapidly aging population was associated with worse health and fewer social activities, as compared to demographically stable counties. We discuss how individuals are challenged by the characteristics of the regions they live in and point out that regional resources (and barriers) contribute to individual differences in old age.

HOW DO LOCAL CARE AMENITIES SHAPE LATE-LIFE DEVELOPMENT IN WELL-BEING?

N. Vogel[1,2], D. Gerstorf[1,2,3], N. Ram[2,3], J. Göbel[2], G.G. Wagner[2,4,5], *1. Humboldt University, Berlin, Germany, 2. German Institute for Economic Research, Berlin, Germany, 3. Pennsylvania State University, State College, Germany, 4. Max Planck Institute for Human Development, Berlin, Germany, 5. University of Technology, Berlin, Germany*

Both psychologists and sociologists highlight the role context plays in shaping individual development across the life span. We combine 22 waves of yearly, longitudinal reports of life satisfaction obtained from now deceased participants (n = 3,257) in the Socio-Economic Panel Study (SOEP) with German Statistics of Care (German Federal Bureau of Statistics) to examine associations between context, operationalized as the characteristics of care services in one’s county, and late-life development, operationalized as terminal decline in life satisfaction. We find that between-county differences contribute 7 % of variance to between-person differences in both level and rates of change in life satisfaction. Specifically, availability of beneficial care services (e.g., lower working load in inpatient facilities) contributes to more positive life satisfaction trajectories. Our results support long-standing notions that local amenities play a role for individual late-life development, and we discuss possible routes through which local care services contribute to well-being trajectories.

NEIGHBORHOOD SES AND 4-YEAR CHANGE IN PSYCHOLOGICAL WELL-BEING AMONG OLDER ADULTS

J.A. Ailshire, *Andrus Gerontolgoy Center, Univ Southern California, Los Angeles, California*

The links between neighborhood conditions and physical health are well-documented, but the potential influence of neighborhoods on residents' psychological well-being has received less attention. This study examined the association between area-level indicators of socioeconomic status (SES) and 4-year change in psychological well-being. Individual data from the 2006 and 2010 Health and Retirement Study were linked to 2000 tract-level Census data. Respondents living in tracts with a higher proportion of college educated neighbors reported feeling less hopeless and more in control both at baseline and follow-up. Higher neighborhood median income was also associated with less hopelessness and a greater sense of control. Respondents living in tracts characterized by high levels of poverty were more likely to feel hopeless and not in control both at baseline and over time. Neighborhood SES is associated with psychological well-being and provides an important context for understanding change in well-being over time.

SESSION 1885 (SYMPOSIUM)

CONNECTING CLINICIANS & CANCER PATIENTS: MODES OF COMMUNICATING, MHEALTH, AND SMS TEXT MESSAGING

Chair: S. Spoelstra, *College of Nursing, Michigan State University, East Lansing, Michigan*
Discussant: S. Cotten, *Michigan State University - Department of Telecommunication, Information Studies, and Media, East Lansing, Michigan*

Cancer patients are challenged to find ways to obtain information to self-manage. This includes health promotion (physical activity and nutrition), disease prevention (mammograms and colonoscopies), and disease management (symptom management and treatment adherence) needs. Presently, research on preferred modes of obtaining information and testing mHealth innovations are limited. This symposium will highlight preferred modes of communication among older cancer patients across the care continuum, from active treatment to the post-treatment survivorship phase of life. This will be followed by a mHealth text message trials experience with recruitment and enrollment activities; and acceptability and preliminary efficacy on symptom severity and medication adherence. In the first presentation, Dr. Leach will describe the preferred mode of receiving cancer, nutrition, and physical activity information stratified by age. Next, Ms. DeKoekkoek will present on cancer patients undergoing active treatment, and their preferred mode of receiving symptom management and treatment adherence assistance from clinicians. Dr. Given will then explore recruitment and enrollment of older cancer patients in a mHealth text message intervention to promote strategies to self-manage medication adherence and symptom management for active treatment. Next, Dr. Spoelstra will report on acceptability and a preliminary efficacy of a mHealth text message intervention built on self-efficacy theory, to promote strategies to self-manage medication adherence and symptoms for active cancer treatment. Finally, the discussant, Dr. Cotten, an aging researcher focused on eHealth and use of computers in older adults, will emphasize how these presentations underscore the need for research initiatives to promote clinicians and cancer patient communication.

PREFERRED MODES FOR CANCER-RELATED INFORMATION RECEIPT AMONG OLDER VERSUS YOUNGER CANCER SURVIVORS

C. Leach[1], D. Wiatrek[2], A. Troeschel[1], *1. American Cancer Society, Behavioral Research Center, Atlanta, Georgia, 2. American Cancer Society, Health Promotions Department, Atlanta, Georgia*

Many cancer survivors struggle during and after treatment to get the cancer-related information they need, in a format they prefer. Data from a national study of breast, prostate, and colorectal cancer survivors (N=1240) were used to examine age differences in information mode preferences for cancer-related information. In general, both older (> 65, n=559) and younger (<65, n=681) survivors preferred receiving cancer-related information from a health professional (87.4% wanted information in this form) or in hard copy/print format (76.3% wanted information in this form) over other modes of information delivery. Younger survivors were more likely to prefer receiving cancer-related information from a health professional (p=.03), by phone from a cancer information service (p<.001), in hard copy print format (p<.001), from the internet (p<.001), and from email (p<.001) or online chat (p<.001) with a cancer service/organization than their older counterparts. Older survivors were more likely to be unsure of their preferences.

PREFERRED MODES FOR SELF-MANAGEMENT INFORMATION WHILE UNDERGOING ACTIVE CANCER TREATMENT IN OLDER ADULTS

T. DeKoekkoek[1], B.A. Given[1], C.W. Given[2], S. Spoelstra[1], *1. Michigan State University College of Nursing, East Lansing, Michigan, 2. Michigan State University Department of Family Medicine, Institute for Health Policy, East Lansing, Michigan*

Over 50 oral anti-cancer agents are on the market, and growing rapidly. This has shifted delivery of active treatment from infusion centers to the home setting. This 8-week study assessed 30 cancer patients via 5-interviews while taking oral agents at 3-cancer centers in the Midwest. Patients were asked their preferred mode for information to self-manage. Mean age was 65.2 years, 50% were Female, 87% Caucasian and 13% African American. Of the 30 patients, 36.7% (n=11) preferred phone calls (30% land-line; 6.7% cell phone); 26.7% (n=8) preferred written material; 23.3% (n=7) email; 10% (n=3) face-to-face; and 3.3% (n=1) text messages. There was no difference in preference by age, gender, race, and type of cancer, oral agent or other treatment (IV chemo and radiation). Patients with later stage cancer preferred written material (p=.03). Combining cell and landlines, confidence intervals were 19.9-56.1, 28.3-65.7, 26.5-64.3, 23.5-61.1, and 31.3-68.7 across assessments, respectively.

RECRUITMENT AND ENROLLMENT OF OLDER CANCER PATIENTS IN A TEXT MESSAGE TRIAL

C.W. Given[1], B.A. Given[2], A. Sikorskii[3], C.K. Coursaris[4], A. Majumder[3], T. DeKoekkoek[2], M. Schueller[2], S. Spoelstra[2], *1. College of Human Medicine, Michigan State University, East Lansing, Michigan, 2. Michigan State University College of Nursing, East Lansing, Michigan, 3. Michigan State University Department of Statistics and Probability, East Lansing, Michigan, 4. Michigan State University Department of Telecommunication, Information Studies, and Media, East Lansing, Michigan*

Data on enrollment of older adults in trials using text messaging are lacking. Recruitment from 2 trials (N=88) of 21-day SMS interventions to promote oral agent adherence and/or symptom management are presented. Five cancer centers and a specialty pharmacy participated. Mean age of consented patients was 58.5 (range 34-82); 58% female; compared to 57.2 years (range 32-93); 38% female for eligible not enrolled; and 63.9 years (range 26-88); 45% female for ineligible. Difference by sex was significant for consented versus eligible but not enrolled (p=.02); no difference was found in age. 58.7% of eligible (88/150) consented (60.6% [20/33] <50 years; 55.1% [38/69] 50-64;

and 62.5% [30/48] 65+). Regarding non-participants, 16.1% (10/62) were not interested in SMS; 11.3% (7/62) thought SMS would not help; 1.6% (1/62) did not want to learn SMS; 32.2% (20/62) were not interested in the study; and remainder was unknown. Enrollment is ongoing. Results will be updated.

ACCEPTABILITY AND PRELIMINARY EFFICACY OF A SMS TEXT MESSAGE INTERVENTION IN OLDER CANCER PATIENTS

S. Spoelstra, *College of Nursing, Michigan State University, East Lansing, Michigan*

With 68% of adults owning cell phones, text messaging (herein, SMS) may be a means to prompt self-management. A 10-week trial of a 4-week SMS intervention enrolled 80 patients from 2 cancer centers and a specialty pharmacy. Regarding acceptability, 56.3% (80/142) of eligible consented. Mean age of consented was 58.5 (range 39-82); eligible not consented 57.24 (range 32-92); and ineligible 63.6 (range 26-82). Of 142 approached, consent rate according to age was: 60% (27 of 45) for those 65+; 53% (35 of 66) for those 50-64; and 58.1% (18 of 31) for those <50. Females represented 59% (n=47) of consented, 39% (n=24) of eligible not consented, and 46% (n=54) of ineligible. A significant difference by sex was found between consented versus eligible but not enrolled (p=.02) with females participating at a higher level; no difference was found in age. Data collection is ongoing. Preliminary adherence/symptom severity efficacy will be reported.

SESSION 1890 (SYMPOSIUM)

RESIDENT-TO-RESIDENT ELDER MISTREATMENT: FINDINGS FROM A LARGE-SCALE PREVALENCE STUDY

Chair: K. Pillemer, *Cornell University, Ithaca, NY*
Discussant: L. Mosqueda, *University of California, Irvine, Irvine, California***Discussant:** N. Castle, *University of Pittsburgh, Pittsburgh, Pennsylvania*

Over the past two decades, a growing body of research has addressed abuse experienced by older persons in long-term care facilities. This literature primarily has focused on mistreatment of residents by staff, but preliminary research and clinical experience suggest that residents are at much greater risk of aggression from other facility residents. However, the prevalence of and risk factors associated with resident-to-resident elder mistreatment (R-REM) are unknown, despite the fact that R-REM events have serious physical and psychological consequences. In this symposium, we report findings from the first in-depth study of the prevalence of R-REM, which identified incidents of R-REM in 10 long-term care facilities (1903 residents) over a 2-4 week observation period. Using resident and staff interviews, a forensic chart review, direct observation by research assistants, a staff event log, and facility reports, we identified and adjudicated over 600 cases and controls to identify the prevalence rate of overall R-REM as well as subtypes: physical, verbal, sexual and other. Lachs et al. present findings on prevalence of various types of mistreatment, showing that R-REM is sufficiently widespread to be of significant clinical and policy concern. Pillemer et al. identify main correlates of R-REM and relate these findings to prior research on resident aggression. Teresi et al. present findings from an R-REM intervention study that found positive treatment effects on staff and residents. These findings suggest that R-REM should be a high priority issue for future research and intervention. Two experts will discuss implications of the findings.

RESIDENT-TO-RESIDENT ELDER MISTREATMENT IN LONG TERM CARE: A PREVALENCE STUDY

M. Lachs[1], K. Pillemer[2,5], J.A. Teresi[3], M. Ramirez[3], K. Van Haitsma[4], S. Silver[3], J.P. Eimicke[3], *1. Weill Cornell Medicine College, New York, New York, 2. Cornell University, Ithaca, New York, 3. Research Division, Hebrew Home at Riverdale, Riverdale, New York, 4. Polisher Research Institute, Abramson Center for Jewish Life, North Wales, Pennsylvania, 5. Columbia University Stroud Center, New York, New York*

Resident-to-Resident Mistreatment (R-REM) is a likely common but understudied form of nursing home violence. Establishing the prevalence of R-REM is a necessary step in intervention planning, but to date no prevalence studies have been conducted. We conducted the first such study in long-term care facilities (n=1903 residents) over a 2 to 4 week observation period. This presentation reports the first prevalence estimates of R-REM in long-term care. Using triangulated case finding methodology that included resident and staff interviews, chart reviews, direct observation by research assistants, a staff event log, and facility reports, we estimated the prevalence rate of overall R-REM as well as subtypes: physical, verbal, sexual and other. Among the 1405 residents of the 5 larger urban sites, the prevalence of R-REM ranged from 9.8% to 31.2%. The impact on resident quality of life is discussed, as these rates suggest that intervention strategies are greatly needed.

CORRELATES OF RESIDENT-TO-RESIDENT MISTREATMENT IN NURSING HOMES

K. Pillemer[1], J.A. Teresi[3], E.K. Chen[1], M.S. Lachs[2], *1. Cornell University, Ithaca, NY, 2. Weill Cornell Medical College, New York City, New York, 3. Research Division - Hebrew Home for the Aged, Bronx, New York*

Observed and clinical evidence indicates that Resident-to-Resident Elder Mistreatment (R-REM) is widespread in nursing homes and that incidents of R-REM are potentially harmful to residents. To date, evidence-based R-REM prevention interventions are scarce, in part because risk factors are unknown. In this study of 1405 nursing home residents, factors significantly ($p<0.05$) associated with being involved in an R-REM event included behavioral problems and depression. R-REM was more likely to occur among residents who were less cognitively and functionally impaired. Black residents were less likely to be involved in R-REM events than non-Latino white and Latino residents. Residing in facilities with lower staff to resident ratios, and with higher levels of crowding. increased the likelihood of R-REM. The identification of risk factors is a first step in the development of effective interventions to reduce R-REM; implications for prevention are discussed.

RESIDENT TO RESIDENT ELDER MISTREATMENT (R-REM): EVALUATION OF A STAFF TRAINING PROGRAM

J.A. Teresi[1,2,3], M. Ramirez[2,3], S. Silver[2,3], G.D. Boratgis[2], R. Meador[5], M. Lachs[3], K. Pillemer[4], *1. Columbia University Stroud Center, New York, New York, 2. Research Division Hebrew Home at Riverdale, New York, New York, 3. Weill Cornell Medical College, Division of Geratircs and Palliative Care, New York, New York, 4. Cornell University Department of Human Development, Ithaca, New York, 5. Cornell University, Ithaca, New York*

R-REM is little studied, yet occurs with relatively high frequency. The objectives of this session are to 1) describe a training program geared toward front-line staff in recognition and reporting of R-REM and 2) report on the evaluation results. Design: A cluster randomized trial of units within 5 nursing homes was conducted. Intervention: Staff was trained in R-REM: 1) Recognition, 2) Management, and 3) Guideline Implementation. A film and the SEARCH (Support, Evaluate, Act, Report, Care Plan, Help to Avoid) approach were included. Results: The response rate was 80% (685 and 720 in the control and experimental groups). Hypothesis 1: Knowledge gain was evidenced (p<0.001). Hypothesis 2: The intervention group reported significantly more R-REM events than did the control group (p=0.0058). Hypothesis 3. The net reduction in falls, accidents and injuries was 5%, translating to 10 saved events per year. Discussion: Although not significant (p=0.29), the reduction was clinically important.

SESSION 1895 (SYMPOSIUM)

GRANTWRITING FOR EMERGING AND JUNIOR SCHOLARS: FROM BENCH TO BEDSIDE TO POLICY

Chair: E. Hahn, *Brandeis University, Department of Psych, Waltham, Massachusetts*
Discussant: L.C. Barry, *Center on Aging, University of Connecticut, Farmington, Connecticut*

The purpose of this ESPO Presidential Symposium is to provide practical and professional advice to emerging scholars and professionals regarding the grant-writing process. The symposium is intended to be applicable to emerging scholars and professionals of various levels and backgrounds. The symposium will incorporate speakers from each section of GSA (HS, BSS, SRPP, and BS) who have had success in writing different types of grants, including dissertation grants, K awards, F32 awards, internal grant awards from universities, as well as grant awards from national organizations. Speakers will discuss advice that have been helpful in their success, as well as things they have learned from unfunded grant writing experiences. The speakers will discuss these topics within the context of their own expertise and related to specific, strong, and fundable research collaborations that incorporated a multidisciplinary team and interdisciplinary research goals. In doing so, the speakers will also discuss grant writing experiences that have an interdisciplinary focus in correspondence with the conference theme, “Making Connections: From Cells to Societies.” Specifically, some of the topics that the speakers will address will include, but are not limited to, 1) choosing a grant (when and where to start), 2) preparing and applying for a grant (who should you seek for help, how long does it take), 3) peer review process (what is it, timing for submission, review, waiting period), 4) alternative or lesser-known funding sources (University-level funding, foundations), and 5) grant-writing for scholars seeking non-university careers (non-profit foundations, health care, health services research).

WRITING A COMPETITIVE NIH FELLOWSHIP APPLICATION IN AN INTERDISCIPLINARY AGE

T. Vasilopoulos, *University of Florida, Gainesville, Florida*

The National Institutes of Health are committed to preparing young scientists for successful, independent careers. Furthermore, as interdisciplinary approaches play an increasingly important role in biomedical research, it is important that young scientists are exposed to, and participant in, interdisciplinary research early in their careers. This presentation will focus on the NIH Ruth L. Kirschstein National Research Service Awards for Individual Pre- and Postdoctoral Fellows. The first part of this presentation will discuss advice and best practices for preparing a competitive application, from conception to post-submission. Then, the discussion will turn its focus to how to integrate interdisciplinary training into fellowships applications.

GRANT WRITING TIPS FOR EMERGING AND JUNIOR SCHOLARS: KEYS TO SUCCESS

G. Kim, *Center for Mental Health and Aging / Department of Psychology, University of Alabama, Tuscaloosa, Alabama*

This is a part of the ESPO Presidential Symposium focusing on grant writing for emerging scholars and professionals. Representing the BSS section, the speaker will discuss a wide range of topics relating to the grant writing process, especially focusing on NIH K awards. The speaker will use her funded grant as an example of successful interdisciplinary team work. Specific topics that will be discussed include, but are not limited to the following: (1) what kinds of grant mechanisms are available and helpful for emerging and junior scholars; (2) who should consider applying for K awards (i.e., eligibility); (3) when to apply K awards; (4) how to build an interdisciplinary team; (5) how to prepare a successful grant application; and (6) what reviewers want to see in the grant application. In addition, the speaker will share general tips for the grant writing process, as well as NIH K awards specific tips.

GRANT-WRITING TIPS FOR EMERGING SCHOLARS HIGHLIGHTING THE IMPORTANCE OF MENTORSHIP AND PEER REVIEW

S.A. Greenberg, P. Cacchione, *University of Pennsylvania, Philadelphia, Pennsylvania*

The presentation is intended to provide grant writing guidance and tips for emerging scholars in the health sciences. This will include governmental mechanisms, private foundation, and organizational funding, as well as award opportunities. Successful and non-successful experiences in the grant writing and submission process will be shared, including how to benefit and then proceed from constructive criticism and reviewer feedback to reach professional goals. The importance of mentoring and peer review will be emphasized. Interprofessional collaborations in the planning, execution, and dissemination will be highlighted.

WRITING A DISSERTATION GRANT PROPOSAL: HELPFUL TIPS AND ADVICE

K.S. Thomas, *1. Brown University, Providence, Rhode Island, 2. Providence VA Medical Center, Providence, Rhode Island*

In this presentation, I will discuss my experience submitting grant proposals under various funding mechanisms to various funding agencies. In particular, I will highlight my experience writing and receiving funding for an R36 dissertation grant from the Agency for Healthcare Research and Quality. Reflections will be presented on the process of writing a dissertation grant: choosing an interdisciplinary mentoring team, developing a research topic, looking for the appropriate funding source, and responding to the funding agency’s requirements. The discussion will also draw on my experiences submitting an R21 and K01 to the National Institutes of Health and a proposal for seed money from the Providence VA Medical Center. The events and lessons learned should be useful for both students and emerging scholars in the field of aging research.

SESSION 1900 (PAPER)

COST OF CAREGIVING: BENEFITS, BURDEN, OR BOTH?

THE IMPACT OF PUBLIC LONG-TERM CARE INSURANCE ON TIME SPENT ON INFORMAL CARE AMONG AT-HOME CAREGIVERS: FINDINGS FROM JAPANESE MICRO DATA

M. Kan[1], S. Kajitani[2], *1. School of Economics, University of Hyogo, Kobe, Japan, 2. Meisei University, Hino, Japan*

The purpose of this study is to examine the impact of the public long-term care (LTC) insurance, which was introduced in year 2000 in Japan, on the time spent on informal care by at-home caregivers. Did the LTC insurance actually decrease the caring time among at-home caregivers? This is the research question we are asking. The present paper utilizes the micro data from the Survey on Time Use and Leisure Activities (STULA)—a large, nationally representative repeated cross-sectional survey of all the non-institutionalized persons aged 10 and over in the sample households. The samples for our analysis consist of at-home caregivers aged 40 or over. A difference-in-differences estimation was conducted to assess the policy effect as well as a simple before-and-after analysis. The results from the before-and-after analysis show that there is significant decrease in informal care time among female caregivers after the introduction of LTC insurance while there is no significant effect among male caregivers. Considering DID between the treated and the controlled, which are at-home caregivers who care for the elderly aged 65 or older being eligible for the LTC insurance and those who care for other family members respectively, it is found that the time spent on informal care was decreased in year 2006 among female caregivers who do not work. There is no policy effect among male caregivers and female caregivers who have paid work.

“BETTER” OR “WORSE” HEALTH OUTCOME OF UNPAID CAREGIVERS IN THE U.S.?

Y. Lee, H. Oh, I. Chi, *University of Southern California, Los Angeles, California*

Introduction: Caregiving experience has been often seen as a risk factor for caregiver’s health. Studies based on this viewpoint usually involved maladaptive outcomes, such as depression or burnout. However, recent reports demonstrated that caregivers also benefit from time being with their loved ones. Yet, the findings need more empirical evidence. This study aims to investigate predictors associated with both positive and negative caregiver’s health outcomes by analyzing nationally representative sample. Method: 720 primary unpaid caregivers caring for 50+ older Americans were drawn from “2009 Caregiving in the U.S.” data. Multinomial logistic regression analysis was conducted on caregiver’s health outcome related to caregiving experience; categorized into “became better”, “became worse”, and “not affected” (as reference group). Sample weight was given to the final analysis. Results: Caregivers with higher education, higher emotional, and financial strains were more likely to have “worse” health outcome than “not affected”. On the other hand, caregivers who were black or Hispanic (vs. white), less or equal to high school diploma (vs. college above), having 1-3 caregiving years (vs. less than 1 year), having lower financial, emotional, and physical strains (vs. medium or high strains) were more likely to have “better” health outcome than “not affected.” Conclusion: Although many factors were associated with the odds to report both better and worse health outcome, some variables had significant correlations only with better health from caregiving. This finding suggests researchers to investigate predictors on more positive aspects of caregiving for future studies on caregivers of older adults in the U.S.

INVESTIGATING THE PSYCHOSOCIAL IMPACTS OF DEMENTIA CAREGIVING THROUGH BLOGS

J.G. Anderson, *School of Nursing, University of Virginia, Charlottesville, Virginia*

Individuals who suffer from Alzheimer’s disease and other dementias exhibit behavioral and psychological symptoms that can place a great deal of burden on family caregivers. This burden leads to increased stress for family caregivers and reduced quality of life. While the impact of dementia caregiving on levels of depression, anxiety and stress has been explored, more information is needed on the psychosocial impact of dementia caregiving on caregivers and families. Many individuals, including dementia caregivers, use web blogs as online journals to share their lived experiences. These blogs contain rich narratives that represent an untapped resource for understanding the psychosocial impact of caring for a person with dementia at the individual and family level. This study seeks to use blogs to explore the psychosocial impact of dementia caregiving by answering the following research questions: what strategies do caregivers use to support themselves, their families and/or their care recipients; what are the challenges or barriers to using existing support services for dementia caregivers; what is the impact of stigma on dementia caregiving; and what differences exist between caregivers of various racial and ethnic groups in terms of psychosocial impact. Blogs written by self-identified informal caregivers of persons with dementia will be identified using a systematic search method. A qualitative thematic analysis of blog posts will be conducted to gain insight into the research questions. By understanding psychosocial impacts of dementia caregiving, interventions and services can be developed aimed at improving caregiver burden and quality of life.

CONTEMPLATING SUICIDE WHILE CARING FOR A FAMILY MEMBER WITH DEMENTIA

S. O’Dwyer, W. Moyle, M.J. Zimmer-Gembeck, D. De Leo, *Griffith University, Brisbane, Queensland, Australia*

Background Two small studies have suggested that family caregivers of people with dementia might be a high risk group for suicide. The aims of this study were to identify: (1) the rate of suicidal ideation in a large sample; (2) the psychosocial factors associated with suicidal ideation. Method A cross-sectional survey of family caregivers (n=566) was conducted. The majority of participants lived in North America and Australia. Results 16% of family caregivers had contemplated suicide more than once in the previous year and one-fifth of those were likely to attempt suicide in the future. Caregivers who had contemplated suicide were younger and had more difficulty managing on their income than those who had not. They had lower self-efficacy for service use, were less satisfied with social support, used more dysfunctional coping strategies, and had higher levels of burden, depression, anxiety, and hopelessness. They also reported fewer reasons for living. In a multivariate model, age, depression, and reasons for living predicted suicidal ideation. The odds of contemplating suicide increased with increasing depression scores, but decreased with increasing age and reasons for living. Dysfunctional coping and satisfaction with social support mediated the relationship between depression and suicidal ideation. Conclusion Family caregivers of people with dementia contemplate suicide at more than 4 times the rate of US adults. Research is required to identify the rate of suicide attempts and deaths in this population. After this presentation, participants will be able to discuss suicide risk in family caregivers and identify directions for future research.

FUTILE KNOWLEDGE: THE DISSONANCE BETWEEN EVIDENCE-BASED INTERVENTION RESEARCH, MEDICARE POLICY, AND PRACTICE IN HOME CARE FOR PERSONS WITH ALZHEIMER’S DISEASE AND THEIR CAREGIVERS

W. Cabin, *University of Michigan School of Social Work, Ann Arbor, Michigan*

Background & Purpose There is a significant literature addressing the need and direction of evidence-based research to guide evidence-based social work policy and practice (Epstein & Dodd, 2012; Gibbs & Gambrill, 2002; Shaw, 2003, 2004). The objective of the study is to determine social worker and nurse knowledge of, use of, and attitudes toward specific psychosocial evidence-based care interventions for persons with Alzheimer’s disease receiving Medicare home health and their caregivers. Methods A mailed survey was administered to home care social workers (n = 127) and home care nurses (n = 321) between October 2012 and May 2013. Subjects were recruited from the New York State Nurses Association, NASW-New York City Chapter, and NASW-New York State Chapter. Preliminary results indicate 92 percent of nurses and social workers combined had no knowledge of the two specific psychosocial interventions, with social workers’ lack of knowledge being higher (98 percent). 98 percent of social workers and nurses combined have not used either of the two specified interventions in practice. 88 percent of social workers and 95 percent of nurses responded they were taught evidence-based practice (EBP) in their education.100 percent of social workers and 92 percent of nurses responded that Medicare policy limited their ability to use evidence-based practices.96 percent of nurses and social workers combined responded that the inability to use EBP increased unmet patient & caregiver needs.

SESSION 1905 (PAPER)

ISSUES IN GERONTOLOGY EDUCATION AND EVALUATION

CREATING ONLINE GRADUATE PROGRAMS IN AGING AND GERIATRICS: LESSONS LEARNED

L.B. Solberg, C.S. Carter, T.N. Richardson, L.M. Solberg, *University of Florida, Gainesville, Florida*

Development of online degree programs at every educational level at accredited institutions is growing exponentially. The University of Florida values online education, recently approving two new graduate-level programs (one Master's and one Certificate program) in "Aging & Geriatric Practice". The name was chosen to reflect the name of the department through which the programs are offered, the clinical orientation of the program, and the expertise of the faculty who will teach in the programs. A team of faculty and staff took charge of conceptualizing the programs, learning the steps involved in getting new programs University-approved, and drafting the documents to be reviewed by the University committees that would ultimately approve the programs. Throughout the development and approval process, this team learned valuable, globally-applicable administrative, business, and education-oriented lessons. Examples include the investigation of resources at the University and in the private sector to provide a detailed marketing strategy for achieving enrollment goals; the importance of buy-in from the faculty members who will teach in the program; the intricacies of instructional design; and the value of collaboration with other programs on campus. We will discuss these and other lessons in more detail and their importance for creating an outstanding educational experience for learners. These "lessons learned" will be carried over to the implementation phase of the program, and will provide a guide for others in aging-related fields in the creation or continued development of their programs.

NON-PHARMACOLOGICAL APPROACHES IN LONG TERM CARE: EASY TO DO AND EASY TO TEACH TO YOUR STAFF

B. Barba, S. Fitzsimmons, *Community Practice Nursing, University of North Carolina at Greensboro, Greensboro, North Carolina*

The Centers for Medicare and Medicaid Services (CMS) kicked off a new initiative in 2012 that targets improving behavioral health and reducing the use of unnecessary antipsychotic drug use in older adults with dementia residing in nursing homes. This initiative targets person-centered care for older adults, more specifically, those with dementia who exhibit signs of anxiety, agitation or other distress. CMS' goal is for caregivers to use non-pharmacological approaches which are believed to be safer and can be used to prevent, reduce or eliminate the use of medications to attempt to control behaviors. This presentation addresses the CMS initiative by providing hands-on demonstrations of non-pharmacological approaches that take minimal time to carry out and are easily taught to all levels of staff. Demonstrations will include diversional, sensory and nurturing strategies, along with tips to teach the strategies to your staff.

INSTRUMENT DEVELOPMENT: MEASURING INTERPROFESSIONAL CORE COMPETENCIES FOR THE CARE OF OLDER ADULTS

M.G. Owens, C.L. Coogle, L. Hackett, J.H. Mathews, L. Waters, E.F. Ansello, *Virginia Center on Aging, Virginia Commonwealth University, Richmond, Virginia*

In 2008, the Partnership for Health in Aging (PHA) developed interprofessional core competencies for the care of older adults. These competencies were adopted by the Virginia Geriatric Education Center (VGEC) in the design of its curriculum for a160-hour interprofessional faculty development program (FDP). In addition, the VGEC used the PHA competencies to design a self-efficacy instrument to be used as part of its assessment of learner outcomes. Self-efficacy is a performance-based measure of perceived capability (Zimmerman, 2000). The instrument is composed of six primary domains (health promotion and safety, evaluation and assessment, care planning and coordination across the spectrum, interdisciplinary and team care, caregiver support, and healthcare systems and benefits) covering 23 competencies. The VGEC administered the instrument, before and after the training, to twenty-six faculty scholars enrolled in the 160-hour interprofessional faculty development program (FDP) in geriatrics. Faculty scholars demonstrated significant gains in perceived capability in providing older adult care. Results indicated that prior to the training, overall self-efficacy levels were significantly lower ($M = 63.98$; $SD = 16.58$) than the mean ratings following training ($M = 82.82$; $SD = 8.62$). The average difference in perceived competency levels before and after training was 18.84, $t(25) = -5.67$, $p < .001$). Statistically significant gains were also documented for each and every item within and across the six primary domains. GECs may find this instrument useful as a common core assessment of FDP outcomes. Psychometric evaluation of the instrument is pending accumulation of sufficient cases.

HEALTH BEHAVIOR CHANGE FOR OLDER ADULTS IN THE COMMUNITY: HOW TO EFFECTIVELY TRANSLATE EDUCATIONAL THEORY INTO PRACTICE

C. Tannenbaum, *Université de Montréal, Montreal, Quebec, Canada*

Many older people living in the community have under-recognized and under-treated health challenges such as urine leakage or an increased risk of falls associated with sleeping pill consumption. Constructivist education around these issues, combined with training in self-management strategies or increased self-efficacy for engaging health care professionals in shared decision-making, may contribute to improved health, symptom management and quality of life. However, to be effective, health education must be based on educational theory and embedded in frameworks that are sensitive to the unique learning needs of older people. This paper will describe the success of two different health education and self-management interventions for older people in the community: a group continence promotion intervention delivered to untreated women with incontinence, and an educational empowerment intervention delivered individually to chronic benzodiazepine consumers. Each intervention was tested in a randomized trial. The continence promotion trial yielded a number-needed-to-treat of 2 to achieve any improvement in urinary symptoms. Both knowledge and risk reduction behaviors to avoid urine leakage significantly improved. In the second trial, an educational empowerment intervention increased perceptions of risk around sleeping pill use and led 62% of participants to initiate discussions on discontinuing their medication with a health provider. Over one-third of participants succeeded in benzodiazepine discontinuation or dose reduction over the ensuing 6 month time period, yielding a number-needed-to-treat of 5. Particular attention will be paid to the challenges and opportunities in developing and testing education interventions for seniors residing in the community.

SESSION 1910 (PAPER)

DISCOVERY EXCHANGE: GERONTOLOGICAL METHODS

IS THE METHOD DRIVING THE THEORY? LIMITATIONS OF USING SUBGROUP COMPARISON OF TRAJECTORIES AS TEST OF CUMULATIVE DIS/ADVANTAGE VERSUS AGING-AS-LEVELER HYPOTHESES

J. Lin, J. Kelley-Moore, *Sociology, Case Western Reserve University, Cleveland, Ohio*

Decades of empirical research have framed cumulative dis/advantage (CDA) theory and aging-as-leveler perspective as competing hypotheses regarding the extent of inequality in older adulthood. Despite the widely-recognized limitations of focusing exclusively on central tendency measures, comparison of groups' average trajectories in panel data continues to be the "gold standard" approach. Diverging trajectories with age or over time between subgroups is considered empirical evidence in support of CDA whereas persistent gaps or converging trajectories would suggest the "leveling" effect of ontogenetic aging. With the rapid adoption of age-graded trajectory analysis using multilevel models, we argue that this approach is limited and has been somewhat reified in research. Using conceptual illustrations and empirical examples based on the Health and Retirement Study data, we demonstrate that comparing differences in groups' average trajectories does not adequately test either perspective, largely because the possible outcomes of such comparisons (divergence, convergence, persistent difference with age or over time) are not only affected by average differences in rates of change for these groups but also by how the rates themselves are parameterized in the models. Specifically, a linear parameterization of the trajectories (age) only allows one explanation per group comparison, whereas a quadratic parameterization (age-squared) can allow average differences in groups to expand or contract with age by mere virtue of the quadratic function itself. We suggest alternative methods for characterizing patterns of health and social inequality with age and caution against the reliance on a method-driven empirical framework in testing theories such as CDA and aging-as-leveler.

MULTIMORBIDITY AND INCONSISTENCIES IN CHRONIC DISEASE SELF-REPORTS OVER TIME

A.R. Quinones[1,2], C.L. Nagel[3], C. Cigolle[4,5], *1. Public Health & Preventive Medicine, Oregon Health & Science University, Portland, Oregon, 2. VA Medical Center, Portland, Oregon, 3. School of Nursing, Oregon Health & Science University, Portland, Oregon, 4. University of Michigan, Ann Arbor, Michigan, 5. VA Medical Center, Ann Arbor, Michigan*

Chronic disease data from longitudinal health interview surveys are often used in epidemiologic studies. Yet, these data may be limited by inconsistencies in the self-reporting of chronic diseases by respondents across interview waves. We investigated the effect of multimorbidity on the self-report of diseases over time, hypothesizing that respondents with more diseases would have greater inconsistency in their self-reports. We analyzed seven waves (1998-2010) of the Health and Retirement Study (HRS). Our sample included adults ≥51 years (n=24,156). Diseases included hypertension, heart, lung, diabetes, cancer, arthritis, and stroke. We defined multimorbidity as any combination of ≥3 chronic diseases. We used logistic regression to analyze the association of multimorbidity on inconsistency in reporting diseases, both within and across waves (results shown for 2010). 5.7% of HRS respondents in 2010 had at least one inconsistency in their self-report of diseases. 36.9% had multimorbidity in the preceding wave. Multimorbidity was associated with a nearly three-fold increase in the odds of inconsistency (OR=2.73, 95% CI=2.33-3.21), after adjusting for socio-demographic and health characteristics. Being partnered was associated with decreased odds of an inconsistency (p=0.022). Hispanics had a two-fold increase in the odds of an inconsistency (p=0.000). Inconsistent reporting of diseases across health interview survey waves is more likely for respondents having multimorbidity. This finding has implications for clinical and research settings: patients who are not clear that they have been diagnosed with a chronic disease may be less effective in their self-management efforts, and prevalence estimates may be underestimated, particularly for those with multimorbidity.

PREDICTORS OF DISCREPANCIES BETWEEN PATIENT-REPORTED AND OBJECTIVELY-MEASURED SLEEP IN VA ADULT DAY HEALTH CARE PARTICIPANTS

J.M. Hughes[1], J.M. Dzierzewski[2,3], C. Fung[2,3], S. Jouldjian[2], M.N. Mitchell[2], T. Vandenberg[2], C. Alessi[2,3], J.L. Martin[2,3], *1. UNC at Chapel Hill, Chapel Hill, North Carolina, 2. VA Greater Los Angeles Healthcare System, Los Angeles, California, 3. David Geffen School of Medicine at UCLA, Los Angeles, California*

Older Veterans participating in Adult Day Health Care (ADHC) are at high risk for sleep disturbance given medical comorbidities, functional limitations, and decreased activity. Addressing sleep disturbance can enhance rehabilitation and improve quality-of-life, yet our prior work suggests ADHC participants underestimate sleep disturbance. This study aimed to explore the relationship between patient-reported and objectively-monitored sleep and to explore predictors of discordance between the two. 72 ADHC participants (mean age=78.5, 94% male) completed an in-person health (Mini-Mental Status Examination; Geriatric Pain Measure; ADL/IADL function) and sleep questionnaire assessment (Pittsburgh Sleep Quality Index, PSQI; Insomnia Severity Index, ISI) and wore an Actiwatch sleep monitor for 3-5 days/nights. Relationships between patient-reported (PSQI: sleep percent, sleep quality rating, global score; ISI: sleep satisfaction rating, global score) and objective sleep measures were examined using Pearson correlations and Student's t-tests. Patient-reported sleep percent was significantly lower than objective recordings (p<.001). There were no significant relationships between patient-reported and objective sleep measures (all p's>.05). In a regression model predicting discordance between objective and patient-reported sleep percent, higher pain ratings were associated with greater discordance (p=.03) while age, depression, cognitive status, functional status, and number of comorbidities were not (all p's>.05). This finding and the overall low concordance between objective and subjective measures of sleep quality warrant further investigation. Given many healthcare providers use patient-reported sleep measures to identify candidates for behavioral sleep interventions, likely the best option for improving sleep complaints in this population, it is essential that self-report methods accurately identify individuals with poor sleep.

USING A CORRELATION TO ASSESS KNOWLEDGE AND COMPLIANCE

M.J. Rovine, L.L. Lo, *HDFS, Penn State University, University Park, PA, Pennsylvania*

For interventionists interested in determining how successful a public service announcement is, a simple calculation based on a special form of the correlation coefficient can be used to determine the number of people successfully learning the information provided. Suppose a public service announcement is being made regarding the importance of getting the shingles vaccine. As part of a survey, two questions could be asked. The first could be a piece of generally available information; for example, at which age is the inoculation is suggested (60+). The second could relate either to a piece of information describing the benefits of the vaccine specifically presented in the PSA, or to a specific piece of related information that appeared in the PSA that otherwise would be difficult to obtain (e.g. the person presenting the announcement). We show how a correlation between these two measures indicates the proportion of people who heard or saw the PSA and learned the information provided in the announcement. This form of the correlation, developed by Rovine & von Eye (1997) is a continuous variable version of the binomial effect size display developed by Rosenthal and Rubin (1982). Using simulated data we show how this coefficient works in practical situations such as telephone surveys, and further describe how this coefficient can be used to test knowledge (e.g. who has accurate information regarding a specific rule for Medicare enrollment?) and compliance (e.g. which individuals are adhering to a proper drug regimen).

SOURCES AND STRATEGIES OF REDUCING RESPONSE BIAS IN ETHNIC MINORITY ELDERLY RESEARCH: A CASE OF KOREAN AMERICAN SENIORS

M.T. Kim, J. Lee, J. Ko, H. Yoon, Y. Jang, *Nursing, University of Texas, Austin, Texas*

Purpose: Response bias is one of the main sources of measurement error in survey research, which in turn leads to less than accurate conclusions. While the volume of research conducted in the ethnic minority elderly population is increasing, there is relatively little methodological discussion to identify the sources of measurement error in that research, including issues related to response bias. The purpose of this methodological study is to investigate sources of response bias and strategies to reduce such errors using multiple datasets of Korean American elderly (KAE). Methods: The data used was obtained from 5 studies involving the KAE ($N \geq 1{,}000$; aged ≥ 60) in three states (Central Maryland, Arizona, and Central Texas) over the last 10 years. We utilized a series of tests to analyze key psychometric properties of several common measures (e.g., Sense Mastery Scale, CES-D scale). The psychometric properties were generated from both item and exploratory factor analyses. Results: The major sources of response bias identified include: 1) cultural or contextual inequivalence bias and 2) response format related bias. Results of data analysis provided consistent evidence on both categories of response bias. For example, KAE presented reluctance to endorse on items that reflected an optimistic forecast of the future. The pattern may be attributed to their cultural beliefs that such expression is considered a sign of immaturity. Implications: The results indicated that the magnitude of response bias in current research using standard instruments exerts a significant influence on power of the research. Strategies to reduce those biases will be discussed in this paper.

PROMOTING PHYSICAL ACTIVITY AMONG OLDER MALAYSIANS USING SMS REMINDERS. A QUALITATIVE PILOT STUDY

A. Muller, *University of Malaya, Kuala Lumpur, Malaysia*

Physical activity is effective in promoting general health in older adults. However, most older adults are not sufficiently active to gain health benefits. A novel way to address this issue is delivering theory-framed physical activity interventions via mobile technology. The objective of this qualitative study was to explore the feasibility of a physical activity intervention delivered via SMS. Seven inactive, community dwelling older adults (55 to 77 years) were invited to participate in a workshop on physical activity and health. During the workshop the researcher introduced the concept and benefits of moderate physical activity and explained options to be more active. Participants were then asked to formulate concrete physical activity plans for the next 7 days. During the following week three to four SMS reminders containing participants' plans were sent to the participants' mobile phones. Physical activity was assessed using the International Physical Activity Questionnaire. The second meeting after the one week intervention period was conducted as a focus group discussion on the physical activity workshop, used questionnaire, the SMS reminders and the intervention feasibility in the cultural context. The focus group discussion revealed four themes: Guided, home-based programs are needed to encourage older Malaysians who are not regularly exposed to physical activity. Self-monitoring of physical activity and related health outcomes should be part of future interventions. Motivational SMS were expected to be more effective compared to sending plan reminders. Future interventions should be conducted in multiple languages. Study results will now be translated into a randomized controlled trial.

SESSION 1915 (PAPER)

DEMENTIA AND THE ENVIRONMENT

THE HEARTHSIDE BOOK CLUB—DEMENTIA-LEVEL ADJUSTED READING MATERIALS: PRELIMINARY RESULTS

M. Skrajner[1], G. Gorzelle[1], C. Frentiu[1], C.J. Camp[2], *1. Hearthstone Alzheimer Care, Woburn, Massachusetts, 2. Center for Applied Research in Dementia, Solon, Ohio*

The Hearthside Book Club (HBC) is an innovative reading program developed to enhance the lives of persons with dementia (PWD) and increase feelings of success. It involves the use of age-appropriate reading materials that are grade-level and length-adjusted for persons in the Early (MMSE 18+), Middle (MMSE 11-17), Late (MMSE 5-10), and Very Late (MMSE <5) Stages of dementia. We are exploring the effects of regularly-held reading groups on engagement and quality-of-life. To date, 30 participants at two sites have completed the study. The Menorah Park Engagement Scale (MPES) is being used to measure various types of engagement and affect on a scale of zero to two. Participants taking part in reading groups have exhibited significant increases in constructive engagement (+0.70, $p<.01$) and pleasure (+ 0.36, $p<.01$), and significant decreases in distracted engagement (-0.15, $p<.01$) and non-engagement (-.36, $p<.01$), as compared to baseline activities. Total scores on the DEMQOL, the quality-of-life measure used in the study, have significantly increased from baseline to treatment (+3.9, $p<.01$), indicating that regular participation in groups over a relatively long period of time (4 months) has a positive effect on the participants outside of the groups themselves. The greatest increase in DEMQOL scores, as compared to baseline, occurred when participants took part in sessions that utilized HBC books with pictures (+7.1, $p<.05$), indicating that pictures enhance the reading group experience.

MOVING PICTURES: PERSPECTIVES ON DEMENTIA FROM THE CINEMA SCREEN

R. Capp, *Palliative and Supportive Services, Flinders University, Melbourne, Victoria, Australia*

Mainstream cinema remains the dominant form of popular culture and a profoundly influential medium in which to shape attitudes to ageing and age-related illness in the public domain. Arguably the most challenging disease of older age in the 21st century, until recently, dementia has rarely featured on the mainstream cinema screen. The burgeoning multi-disciplinary research focus and concomitant increase in public awareness of the disease in recent decades correlates with a modest but notable increase in representations of dementia on the mainstream screen. In previous decades, films focussed primarily on the clinical accuracy (or otherwise) of depictions of dementia, but this has given way to more complex delineations of the disease and its consequences. Contemporary filmmakers have not only engaged with symptomatology, treatment and care in a more considered fashion, but recent films have also addressed the varying and often conflicting perspectives of the health professional, family member, carer and person with dementia. This paper will offer a thematic analysis of key films over the last two decades, positing three broad typological distinctions in relation to the narrative significance and point of view adopted in the depiction of the disease. This will in turn suggest how each cinematic category can engage and inform different and diverse sections of the viewing public, thereby making a potentially significant contribution to broader community cognizance around the physical, psychological and emotional ramifications of dementia.

MEANINGFUL ACTIVITY FOR PERSONS WITH DEMENTIA: CAREGIVER PERSPECTIVES

K.P. Roland, N.L. Chappell, *Centre on Aging, University of Victoria, Victoria, British Columbia, Canada*

Dementia threatens the capacity to engage in activity, suggesting meaningful activity may be helpful for those with dementia. This study explores the concept of meaningful activity, as defined by informal caregivers of persons with dementia. As part of a larger research program, informal caregivers of persons with Alzheimer's disease, vascular, frontotemporal, and Lewy Body variants who were taking cholinesterase inhibitors (ChEI) were recruited. Caregivers provided a minimum of 3 hours of care over 3 days/week and were interviewed in-person (mean=97.3mins) 6-months after ChEI therapy onset. This study assessed caregiver responses (N=906) to the open-ended question "What do you believe getting involved in activities outside the home means for someone with dementia". The answers were transcribed and subjected to a phenomenological thematic content analysis. Family caregivers emphasized the importance of activity for social connectedness, physical health and mental well-being. However, they questioned whether the quality of the experience or the specific activity provided meaning. In contrast, other caregivers viewed activities as: only beneficial for respite; a reminder of declining interests and abilities; difficult/stressful; and provided no meaning for care-recipient. Finally, caregivers tied care recipients purpose and self-worth to engagement in activity. Implications for self- and social-identity, as well as personhood are discussed. Caregivers had differing views about what made activity meaningful to persons with dementia and vary by stage of disease, although not by type of dementia or gender of care recipient. This new knowledge may indicate areas for improved activity provision and for healthcare support providers.

EFFECTS OF PHYSICAL CAPACITY AND COGNITION ON EATING IN LONG-TERM CARE ADULTS WITH DEMENTIA

W. Liu, E. Galik, B. Resnick, *University of Maryland, Baltimore, Baltimore, Maryland*

Background Eating is the one of most basic and easiest activities of daily living (ADL) to perform and the last ADL to lose among long-term care adults. Various personal and environmental factors can influence eating function. Purpose To examine the effect of physical capacity and cognition on eating among long-term care adults with moderate-to-severe dementia. Methods This study is a secondary analysis of the baseline data from two randomized controlled trials for 199 residents from 8 long-term care facilities. Descriptive data included demographics, type of long-term care setting and comorbidities. Cognitive function was measured using MMSE, physical capacity by Physical Capacity Scale, physical activity by Actigraph, depression and agitation by Cornell Scale for Depression in Dementia and Cohen-Mansfield Agitation Inventory. The outcome of interest, eating function, was measured using the single "feeding" item in the Barthel Index, and was scored on three levels of independence as "0=helper", "5=limited" and "10=intact". Results Almost one third (32.2%) had some level of dependence in eating . Eating function was associated with the type of long-term care setting, comorbidities, cognition and physical capacity. After controlling for type of setting and comorbidities, physical capacity (OR=1.158, 95% CI: 1.036, 1.293) and cognition (OR=1.095, 95% CI: 1.003, 1.196) showed impact on eating function. Conclusions This study provided information on factors of eating for developing effective interventions to optimize eating function in long-term care residents with moderate-to-severe dementia. Other personal factors except for physical capacity and cognition, as well as various environmental and institutional factors should be examined.

EDUCATION DOES NOT MODERATE THE RATE OF COGNITIVE DECLINE PRIOR TO DEMENTIA DIAGNOSIS: EVIDENCE FROM THE OCTO-TWIN LONGITUDINAL STUDY

D. Cadar[1], B. Johansson[2], A.M. Piccinin[3], S.M. Hofer[3], G. Muniz-Terrera[1], *1. MRC Unit for Lifelong Health and Ageing, University College London, London, United Kingdom, 2. University of Gothenburg, Gothenburg, Sweden, 3. University of Victoria, Victoria, British Columbia, Canada*

Dementia represents a major challenge and the search for modifiable risk factors remains a high priority. Increased levels of education are known to be protective in terms of cognitive functioning, but less it's known in terms of cognitive decline. The current analyses have investigated various cognitive trajectories on both fluid and crystallised functions in preclinical stages of dementia and the role of education on these. The participants were drawn from the Swedish Octogenarian Twin study, a sample of individuals aged 80 + years interviewed biannually up to a maximum of 5 times. Only those who developed dementia after the study entry were included in these analyses. The cognitive tests employed were Mini-Mental State Examination, memory, inductive reasoning, language, information task and verbal meaning. Multilevel Models were employed to examine cognitive decline on each measure in relation to time to dementia diagnosis, accounting for education, age and socio-economic position. The results indicate a steeper cognitive decline prior to dementia diagnosis in most of the fluid cognitive abilities measured with MMSE, Prose Recall, Block Design, Digit Symbol, Memory Recognition, Memory Correspondence and Information tests. Education had a significant effect on the level of cognitive functioning at the time of dementia diagnosis (intercept) on both crystallised cognitive measures (synonym and information tests), but not on rate of cognitive decline (slope) in any of the cognitive measures investigated. These findings did not support the cognitive reserve hypothesis, which stipulates a protective role of education against steeper cognitive decline before dementia diagnosis.

SESSION 1920 (PAPER)

MENTAL HEALTH IN AGING POPULATIONS

INTRA-INDIVIDUAL AND CROSS-SPOUSE EFFECTS OF PAIN ON PSYCHOLOGICAL DISTRESS IN AGING COUPLES

K.J. Ishler, A.L. Townsend, *Case Western Reserve University, Cleveland, Ohio*

Research amply documents the negative consequences of pain for individuals (e.g., psychological distress) and society (e.g., costly healthcare). Pain also affects families; elevated psychological distress is common among spouses of pain patients. Because existing knowledge derives mainly from clinical samples (e.g., pain patients & spouses), little is known about couples with pain in the community—especially those in later life. Studies rarely consider that both spouses might have pain. Pain reports were examined in 5,386 aging couples in HRS 1998. In 8% of couples, both spouses reported pain. These 423 "dual-pain" couples were used to study the impact of each spouse's own pain, and the pain of his/her partner, on the psychological distress (depressive symptoms) of both spouses. Severe pain was reported by 22% of wives and 17% of husbands. Depressive symptomatology was correlated within couples (ICC=.28, p<.05). Dual-intercept multilevel models tested intra-individual and cross-spouse effects of pain intensity on depressive symptomatology. Each spouse's own pain intensity was positively associated with his/her own depressive symptoms, though this effect was stronger in wives. A cross-spouse effect of pain was found only in husbands, and it varied depending on husbands' own pain. Increased wife pain intensity was associated with greater depressive symptoms among husbands with mild pain, but lower depressive symptomatology among husbands with severe pain. Wives' depressive symptoms were related only to their own pain intensity. Researchers and practitioners need to consider pain from a dyadic perspective and direct greater attention to dual-pain couples.

POVERTY AND DEPRESSION AMONG OLDER WOMEN IN SOUTH KOREA

J. Ko[1], S. Lee[2], *1. Kyung Hee Cyber University, Seoul, Republic of Korea, 2. ChungAng University, Seoul, Republic of Korea*

The purpose of the study was to examine the factors affecting depression of older women in South Korea and compare the result between the poor and the non-poor subgroups; and to explore the characteristic differences presented upon different poverty lines applied. The data on 2,340 female adults of 60 years of age and over were drawn from the Korean Longitudinal Study of Ageing(KLoSA). The analyses showed that regardless of the poverty line applied, the percentage of people with depression was significantly higher in the poor than in the non-poor. The logistic regression results showed that perceived health status had the most effect on depression. Among the poor, the factors identified to reduce the odds of being depressed were perceived health status, religion, spouse, and satisfaction with the relationship with child(ren); the frequency of contact with relatives and friends increased the odds. Among the non-poor, the factors reducing the odds were perceived health status, spouse, social participation, and satisfaction with the relationship with child(ren); number of chronic disease increased the odds of being depressed. These results were then discussed and the implications to apply differentiated strategies for the subgroups of the female elderly were suggested.

DEPRESSION AMONG OLDER ADULTS FOLLOWING TRAUMATIC BRAIN INJURY

J.S. Albrecht[1], Z. Kiptanui[1], Y. Tsang[1], B. Khokhar[1], X. Liu[2], L. Simoni-Wastila[1], I.H. Zuckerman[3,1], *1. Pharmaceutical Health Serives Research, University of Maryland School of Pharmacy, Baltimore, Maryland, 2. Philips Healthcare, Baltimore, Maryland, 3. IMPAQ International LLC, Columbia, Maryland*

Background: Sequelae of traumatic brain injury (TBI) include depression, which could exacerbate the poorer cognitive and functional recovery experienced by older adults. Methods: We estimated incidence rates of depression following hospital discharge for traumatic brain injury (TBI) among Medicare beneficiaries aged ≥65 years, quantified the risk of depression following TBI, and evaluated risk factors for incident depression post-TBI in an analysis of all Medicare beneficiaries ≥65 years hospitalized for TBI during 2006-2010 who survived to hospital discharge and had no documented diagnosis of depression prior to the study period (n=66,951). We defined incident depression based on the Chronic Condition Data Warehouse date of first diagnosis. Results: The annualized incidence rate of depression per 1,000 beneficiaries pre-TBI was 66.1 (95% confidence interval (CI) 58.9, 61.2) in women and 50.7 (95% CI 49.0, 52.5) in men. Post-TBI, women (119.2; 95% CI 116.5, 122.0) continued to have higher incident rates of depression than men (105.6; 95% CI 102.4, 108.8). In adjusted analysis, TBI increased the risk of incident depression more in men (hazard ratio (HR) 2.0; 95% CI 1.9, 2.1) than in women (HR 1.7; 95% CI 1.7, 1.8). Discharge to a skilled nursing facility, a potential proxy for TBI severity, was associated with depression post-TBI in men (odds ratio (OR) 1.9; 95% CI 1.8, 2.1) and women (OR 1.7; 95% CI 1.6, 1.8). Conclusions: TBI increases the incidence of depression among older adults, especially in men and patients discharged to a skilled nursing facility.

ANXIETY AND DEMENTIA IN OLDER SWEDISH TWINS

A. Petkus[1,2], C.A. Reynolds[3], M. Gatz[4], J. Wetherell[1,5], W.S. Kremen[1], N.L. Pedersen[6], *1. University of California, San Diego, San Diego, California, 2. VA Long Beach Healthcare System, Long Beach, California, 3. University of California, Riverside, Riverside, California, 4. University of Southern California, Los Angeles, California, 5. VA San Diego Healthcare System, San Diego, California, 6. Karolinska Institute, Stockholm, Sweden*

Anxiety is the most common mental health problem in later life. Higher anxiety has been associated with worse cognitive functioning. Furthermore, research suggests some anxiety disorders may be risk factors for developing mild cognitive impairment and/or dementia. No research has examined symptoms of anxiety and risk of dementia longitudinally over a span of many years. The purpose of this study was to examine the association between anxiety and subsequent risk of developing dementia over a span of 23 years. In 1984, 767 Swedish Twins completed an assessment of state anxiety (State Anxiety subscale from the State-Trait Personality Inventory; STPI). From 1986-2007, participants completed as many as six cognitive assessments approximately every three years. Proportional hazard regression analysis, adjusted for sex, education, and baseline age were used to examine if participants who scored above the mean on the STPI in 1984 were at greater risk of subsequently developing dementia. A random effect of twin pair was included in the model to account for the non-independence of the data. Over the period of this study, 124 participants developed dementia. Those participants who developed dementia were significantly more anxious at baseline ($M = 20.1$; $SD = 8.5$) than participants who did not develop dementia ($M = 18.5$; $SD = 7.6$; $p = 0.04$). Elevated anxiety was associated with greater risk of developing dementia over age (hazard ratio = 1.59; $p = 0.013$). Results indicate that anxiety may be an important overlooked risk factor for dementia in older adulthood.

GENDERED ASSOCIATION BETWEEN SPOUSAL SOCIAL CLOSURE AND DEPRESSIVE SYMPTOMS AMONG OLDER ADULTS

Y. Youm[1,2], W. Joo[1], J. Lee[1], *1. yonsei university, SEOUL, Republic of Korea, 2. University of Illinois at Chicago, Chigago, Illinois*

Objectives This study investigates the relationship between depressive symptom and triadic relationship between spouses by using a complete social network of one entire Korean rural village. Method By using the Korean Social Life and Health Project (KSHAP) that is a population-based data set of 60 or older adults and their spouses in one village (95% of response rate), this study selects the people who had a spouse and at least one social tie (network) to examine the effects of triads (respondent, spouse, and respondent's social tie): 270 husbands and 273 wives in total. Logistic regression models are adopted to predict significant depressive symptoms. Results Spousal open triads where the respondents maintained social ties that are separated from their spouses, on average, helped to decrease depressive symptom for wives although this effect becomes statistically insignificant after controlling for the effect of spousal closed triad. Spousal closed triads where spouses shared their ties showed consistent and strongly gender-specific effects. When a son was a mutual tie of his both parents, his mom tended to report the depressive symptom more: adding him in the triad might aggravate his mother's role as a caregiver. In sharp contrast to this, if a daughter was the third person embedded in the closed triad, her father's depressive symptom was eased off: a daughter might play a role of another caregiver for the father. The results highlight the importance of triadic level of older adults' relationship to understand their depressive symptoms more fully.

SESSION 1925 (SYMPOSIUM)

SLOW AND STEADY WINS THE RACE: SEX DIFFERENCES IN PHYSICAL ACTIVITY

Chair: J.A. Schrack, *Epidemiology, Johns Hopkins School of Public Health, Baltimore, Maryland, National Institute on Aging, Baltimore, Maryland*
Co-Chair: T. Harris, *National Institute on Aging, Bethesda, Maryland*
Discussant: C. Crainiceanu, *Johns Hopkins School of Public Health - Biostatistics, Baltimore, Maryland*

Accurately identifying and quantifying active and sedentary behaviors in older men and women is crucial to preventive efforts aimed at delaying the onset of functional decline. The prevailing consensus is that men are more active than women throughout adulthood. However, emerging evidence indicates that women may actually be more active when lower levels of activity are taken into account, and that the true difference between active and sedentary behaviors may be dependent on the underlying methodology used to define “active” status. Further, sex-differences in activity patterns and trends change dramatically later in life due to changes in daily behaviors (e.g., employment) and the corresponding changes in the intensity, duration, and frequency of physical activities. This symposium will focus on the critical factors associated with analyzing and interpreting accelerometry data from participants of the Baltimore Longitudinal Study of Aging (BLSA), the National Health and Nutrition Examination Survey (NHANES), and the AGES-Reykjavik Study. We will discuss how: (i) applying standard cut point thresholds to older adults may contribute to erroneous conclusions regarding daily activity in women, (ii) differences in gait patterns between men and women may influence activity metrics, (iii) activity differences in men and women after heart surgery may contribute to recovery, and (iv) employment may contribute to differences in sedentary behaviors in older men and women. Collectively, these presentations will address critical issues in the interpretation of objective activity data that may hide meaningful insights into sex differences in daily activity with age.

SEX DIFFERENCES IN PHYSICAL ACTIVITY: BEYOND THE BASICS

J.A. Schrack[1,3], L. Xiao[2], V. Zipunnikov[2], T. Harris[4], L. Ferrucci[3], C. Crainiceanu[2], *1. Epidemiology, Johns Hopkins School of Public Health, Baltimore, Maryland, 2. Johns Hopkins School of Public Health - Biostatistics, Baltimore, Maryland, 3. National Institute on Aging, Baltimore, Maryland, 4. National Institute on Aging, Bethesda, Maryland*

Accurately quantifying sex-differences in active and sedentary behaviors is vital to understanding changes in activity with age and preventing functional decline. We modeled the associations among age, sex, and objectively measured activity in 611 BLSA participants (50% male, mean age 67, range 32-93), specifically examining the accumulation, intensity, and complexity of activity over the course of a day. Our results indicate women were less sedentary than men but with lower intensity of movement, suggesting women are more likely to engage in low levels of activity similar to those associated with activities of daily living and not typically classified as “physical activity.” Further, complexity of activity over the age spectrum was gradually lower with age in women, compared to a steep age-related drop in men. Future studies assessing activity in older adults should consider intensity and complexity of movement that may provide meaningful insight into sex differences in functional decline.

EVALUATING A SEX DIFFERENCE IN ACCELEROMETER COUNTS DURING WALKING IN OLDER ADULTS

A. Koster[1], D.R. Van Domelen[2,6], P. Caserotti[3], K.Y. Chen[4], R.J. Brychta[4], N.Y. Arnardottir[5], G. Eiriksdottir[5], T. Harris[6], *1. Maastricht University, Maastricht, Netherlands, 2. Emory University, Atlanta, Georgia, 3. University of Southern Denmark, Odense, Denmark, 4. National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, Maryland, 5. Icelandic Heart Association, Kopavogur, Iceland, 6. National Institute on Aging, Bethesda, Maryland*

Accelerometers have emerged as a useful tool for measuring free-living physical activity in epidemiological studies. Validity of activity estimates depends on the assumption that measurements are equivalent for males and females while performing activities of the same intensity. In an earlier comparison of a standardized 6-minute walk test, we found that, despite the fact that men walked only 7.2% faster than women, they had 13.4% greater vertical axis counts even accounting for gait speed and step length. We recently have been given access to gait data to further assess this issue to see if men have more ‘bounce’ than women per step which would lead to an excess of intensity counts while women have more lateral rotation. These data should help to address a potentially serious issue in the analysis of objective monitoring data that could confound free-living activity estimates.

MEN AND WOMEN’S WORK: SEDENTARY BUT UNEQUAL?

T. Harris[1], D.R. Van Domelen[2], K.Y. Chen[3], R.J. Brychta[3], P. Caserotti[4], A. Koster[5], *1. National Institute on Aging, Bethesda, Maryland, 2. Emory University, Atlanta, Maryland, 3. National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, Maryland, 4. University of Southern Denmark, Odense, Denmark, 5. Maastricht University, Maastricht, Netherlands*

The level of sedentary behavior in our society is rising as a proportion of the average day. This is a new exposure that may be important for the health of older persons in the future. Using data from the NHANES Study (2003-2004), we examined objective monitoring data for the total weartime counts and proportion sedentary time for men and women aged 20-60. Sedentary jobs were identified from occupational codes and the King classification system. Men working full-time in sedentary jobs spent 57% of their total time sedentary; for women the proportion was 58%. However, when not sedentary, men were generally more active, with a greater percentage of time that was lifestyle or moderate to vigorous active, 15% versus women, 11%. Thus, sedentary work appears to affect men and women equally, while non-work activities appear to be greater in men.

SEX DIFFERENCES IN PHYSICAL RECOVERY AFTER HEART SURGERY: A MINUTE-BY-MINUTE-BY-YEAR APPROACH

A. Eloyan[1], V. Zipunnikov[1], T. Harris[3], P. Green[2], M. Maurer[2], C. Crainiceanu[1], *1. Biostatistics, Johns Hopkins University, Baltimore, Maryland, 2. Columbia College of Physicians and Surgeons, New York, New York, 3. Intramural Research Program of NIA, Laboratory of Epidemiology and Population Sciences, Bethesda, Maryland*

Wearable devices allow detailed quantification of activity at the minute level, which may be useful when assessing physical activity before and after surgery in older populations. Motivated by a clinical trial that compares standard surgery with a minimally invasive alternative, we compare the recovery of circadian patterns of activity of men and women. In this study, 50 patients (20 female and 30 male, average age = 87.7 with standard deviation = 6.21) who underwent heart surgery wore accelerometers that monitored the activity continuously before surgery and at multiple visits for several months after surgery. We will investigate whether there are baseline differences in activity levels between men and women and investigate whether recovery and treatment effects are different between men and women. We will investigate the changes in circadian rhythms of activity as well as in the short-term day-to-day variability in the circadian rhythms of activity.

SESSION 1930 (SYMPOSIUM)

SHOULD COGNITION BE INCLUDED IN THE ASSESSMENT OF FRAILTY?

Chair: R. Varadhan, *Geriatric Medicine, Johns Hopkins Center on Aging and Health, Baltimore, Maryland*
Co-Chair: Q. Xue, *Geriatric Medicine, Johns Hopkins Center on Aging and Health, Baltimore, Maryland*
Discussant: M. Carlson, *Bloomberg School of Public Health, Johns Hopkins University, Baltimore, Maryland*

Frailty is generally characterized as a state of health signified by an increased vulnerability to adverse health outcomes in the face of stressors. It is recognized as an important health issue in older adults. Despite the explosion in frailty research over the past decade, translation of frailty into clinical and public health practice has been very limited. A major obstacle has been the lack of consensus on a precise definition and on how to assess frailty. There is also no agreement on the domains of frailty assessment (e.g., physical, cognition, and social). Nearly half of the frailty instruments include some aspect of cognition in the assessment. However, the most-cited frailty instrument, the frailty phenotype (Fried 2001), does not assess cognition. The main objective of the symposium is to discuss the rationale for and against the inclusion of cognition in the assessment of frailty. There will be 5 presentations: (1) an overview of the types of cognitive items used in the current frailty instruments and the motivation for such inclusion, (2) results from the Women's Health and Aging study (WHAS) looking at cross-sectional correlations between cognition and physical frailty, (3) results from the WHAS looking at longitudinal relations between dementia and physical frailty, (4) results from the Gait and Brain Study on memory impairment and executive dysfunction predicting mobility decline. Together these talks highlight the importance of careful attention to the construct of frailty so that the content of the frailty instrument matches its intended use.

LONGITUDINAL ASSOCIATION BETWEEN PHYSICAL FRAILTY AND DEMENTIA: THE WOMEN'S HEALTH AND AGING STUDY II

Q. Xue[1,2], T. Wang[3], S. Yasar[1,2], M. Albert[1], L.P. Fried[4], M. Carlson[5,2], *1. Johns Hopkins University School of Medicine, Baltimore, Maryland, 2. Johns Hopkins Center on Aging and Health, Baltimore, Maryland, 3. Eli Lilly and Company, Indianapolis, Indiana, 4. Columbia University Mailman School of Public Health, New York, New York, 5. Johns Hopkins University Bloomberg School of Public Health, Baltimore, Maryland*

This study assesses the interrelationship between incident dementia and incident physical frailty. The analytic sample contains 387 women aged 70-79 years who were free of dementia and frailty at baseline and were followed up for a maximum of 9 years. Of the 387, 18% and 24% developed frailty and dementia, respectively; 17% had dementia onset before frailty; and 14% had frailty onset before dementia. Using discrete-time Cox model, we found that, after adjusting for baseline age, race, education, and diseases, women who developed frailty first were twice as likely as those who didn't to subsequently develop dementia ($p=0.009$). In contrast, women who developed dementia first were 3.2 times as likely as those who didn't to subsequently develop frailty ($p<0.001$). These findings suggest that frailty may be a risk factor for dementia and vice versa, which challenges the prevailing view of cognition as part of the frailty construct.

INTERSECTION OF DOMAIN-SPECIFIC COGNITIVE IMPAIRMENT AND FRAILTY: FINDINGS FROM WHAS-II

A.L. Gross[1], R. Varadhan[2], M. Carlson[1], Q. Xue[2], *1. Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland, 2. Johns Hopkins School of Medicine, Baltimore, Maryland*

Previous studies have reported correlations between cognitive impairment and physical frailty. To evaluate the association of particular cognitive domains with physical frailty, we used 9 years of data from the Women's Health and Aging Study (WHAS-II, N=424, 6-visits). We applied clinical cutoffs on Trail-Making A and B, and immediate and delayed word-list recall. Of N=424 women, N=73 (17%) developed frailty. Using generalized estimating equations (GEE) to characterize interactions between time and impairment in cognition predicting frailty status, baseline impairment in Trails A (OR=9.2) and B (OR=5.2), and word-list learning immediate (OR=2.8) and delayed recall (OR=5.1) were associated cross-sectionally with frailty (p's<0.01), but none of the associations became stronger with time ($p>0.3$). In GEE Markov transition models, cognitive impairment was not associated with incidence of frailty (p's>0.05). Findings suggest physical frailty and cognitive impairment are related cross-sectionally but not longitudinally, possibly reflecting distinct constructs with common underlying age-related processes.

COGNITIVE DOMAINS AND ITEMS ASSESSED IN FRAILTY INSTRUMENTS

B. Buta, J.G. Godino, M. Park, A.L. Gross, R. Varadhan, *Center on Aging and Health, Johns Hopkins University, Baltimore, Maryland*

This talk provides an overview and description of the domains of cognitive function (e.g., memory) and the types of cognitive items (e.g., Mini-Mental State Examination (MMSE)) used in frailty instruments. Our literature review identified 47 unique frailty instruments. Of these, 20 (43%) used some cognitive items. Cognitive domains (and related items) in these instruments include: mental status (MMSE; Modified Mini-Mental State (3MS) examination; Short Portable Mental Status Questionnaire), psychomotor speed and attention (Trail-Making Test Part B; questions on attention and identifying the current day/month/year/time), visuospatial ability (Clock Drawing Test), memory loss / forgetfulness, presence of vascular or Alzheimer's disease, and reasoning ability. Mental status was the most common cognitive domain (35%) assessed in these instruments. We will discuss the motivation provided by authors for the inclusion of cognition in frailty instruments. We will also discuss the implications for the link between physical frailty and cognitive function.

COGNITIVE FUNCTION IS ASSOCIATED WITH MOBILITY DECLINE AND PRE-FRAIL STATUS. RESULTS FROM THE GAIT AND BRAIN STUDY

M. Montero-Odasso, S.W. Muir, K. Gopaul, M. Speechley, *Medicine, Division of Geriatric Medicine, University of Western Ontario, London, Ontario, Canada*

It is still unknown if there is a "motor signature" associated with cognitive dysfunction and which cognitive domains affect mobility and gait. Previous studies have found that executive dysfunction is constantly associated with slower gait and futures falls. The "Gait and Brain Study" is a cohort study following non-disable seniors with cognitive complaints with the aim to determine predictors of cognitive and mobility decline and frailty status. Results: One hundred fifty older participants, mean age 77+6 y/o and 57.6% female without disability were included for this analysis. Univariate analysis showed that cognitive dysfunction specifically executive dysfunction and episodic memory dysfunction were associated with gait disturbances and mobility disability. These findings remain significant after adjusting by age, gender, history of falls, physical activity and comorbidities. Conclusions: Cognitive dysfunction, specifically episodic memory impairment and executive dysfunction predicts gait disturbances and mobility disability and prefrail status in a cohort of non disable seniors with cognitive complaints.

SESSION 1935 (SYMPOSIUM)

LIVEWELL: DEVELOPING INTERVENTIONS TO IMPROVE HEALTH AND WELLBEING IN LATER LIFE

Chair: S. Moffatt, *Institute of Health & Society, Newcastle University, Newcastle upon Tyne, United Kingdom*
Discussant: C. Jagger, *Institute of Ageing & Health, Newcastle University, Newcastle upon Tyne, United Kingdom*

Additional life expectancy must be accompanied by good health and wellbeing in later life. The aim of the LiveWell Programme is to develop and pilot behavioural and social interventions to improve health and wellbeing through retirement transitions. Our objectives were to: identify intervention opportunities; identify intervention features associated with effectiveness; design and pilot a suite of acceptable interventions; and develop sensitive outcome measures. In this symposium, LiveWell researchers with backgrounds in four complimentary fields (social gerontology, health psychology, sociology, nutrition) will present the outcome of three steps in a research process that connects evidence production in academic spaces (qualitative research and systematic reviews) through evidence synthesis (co-design, intervention and outcome development) to the piloting of a functioning multimodal lifestyle intervention platform in the community. Presentations will cover: (i) qualitative data on retirement transitions; (ii) conceptualisations of 'later life' and 'wellbeing' with implications for intervention development; (iii) the integration of research evidence (qualitative analysis, 3 systematic reviews) through a co-design process with older people, and the production of a working intervention prototype; (iv) development of sensitive and appropriate outcome measures to assess wellbeing; (v) the use of a healthy ageing phenotype (panel of outcome measures) in piloting the prototype in a community sample. We conclude by describing challenges in the development of an integrated platform intended to facilitate preventative medicine in a particularly diverse population of older adults. Discussion will include the acceptability and feasibility of the intervention platform for assessment in a definitive randomised controlled trial.

NARRATIVES ON WELLBEING AND LATER LIFE IN RETIREMENT: IMPLICATIONS FOR INTERVENTION DEVELOPMENT

B. Heaven[1], N. Hobbs[1], E. Evans[1], M. White[1], T.D. Meyer[3], J.C. Mathers[2], S. Moffatt[1], *1. Institute of Health and Society, Newcastle University, Newcastle upon Tyne, Tyne and Wear, United Kingdom, 2. Institute for Ageing and Health, Newcastle University, Newcastle upon Tyne, United Kingdom, 3. Institute of Neuroscience, Newcastle University, Newcastle upon Tyne, United Kingdom*

Retirement presents an opportunity to intervene to improve outcomes in later life, as individuals adjust wellbeing-associated behaviours. Social relationships, physical activity and diet all influence wellbeing, but there is little evidence about: which social components to target; how wellbeing and later-life are defined by people around retirement; how to effectively intervene given the diversity of retirement transitions. Methods employed were: (i) a systematic review and (ii) qualitative study (n=45, focus groups, interview) using thematic analysis. Provision of 'social roles' was identified as a way to wellbeing for those looking for structure and purpose in retirement. Resources such as good health, wealth, and rewarding social relationships underpin wellbeing. However the 'capability' to mobilise resources to achieve outcomes was key in participants' accounts of wellbeing-in-practice. 'Later life' was conceptualised as a period of decline in an uncertain future. Assistance with building capability to achieve desired outcomes may be an effective intervention strategy.

INTEGRATING MIXED-METHODS DATA TO DEVELOP A BEHAVIOUR CHANGE INTERVENTION IN RETIREMENT

N. Hobbs[1], B. Heaven[1], E. Evans[1], S. Moffatt[1], P. Moynihan[2], J.C. Mathers[2], M. White[1], *1. Institute of Health and Society, Newcastle University, Newcastle upon Tyne, United Kingdom, 2. Institute of Ageing and Health, Newcastle University, Newcastle upon Tyne, United Kingdom*

Behaviour change interventions should be theoretically sound and evidence-based. How usable and engaging they are plays an important role in their effectiveness. Key stakeholders (older adults, potential providers, commissioners and researchers) were involved in intervention development and optimisation through a process of co-design. Co-design methods were used to integrate the evidence base from qualitative research and systematic reviews to develop and prototype new intervention ideas to promote health and wellbeing in retirement. An internet-based intervention was built and subjected to an iterative process of testing and optimisation. The intervention comprises five interrelated modules (work transitions, time planning, physical activity, eating well and social roles) and a virtual mentor supports the experience. The intervention provides users with behavioural self-regulation and practical tools to help them adopt a healthier and happier lifestyle. Users can access the resources when they wish and they receive weekly email prompts to revisit the intervention regularly.

MEASURING THE OUTCOMES OF LIFESTYLE INTERVENTIONS IN RETIREMENT: PSYCHOSOCIAL WELLBEING

E. Evans, B. Heaven, J. Lara, N. Hobbs, S. Moffatt, J.C. Mathers, T.D. Meyer, *Newcastle University, Newcastle upon Tyne, United Kingdom*

To evaluate the effectiveness of lifestyle interventions to promote wellbeing in retirement, change-sensitive, reliable and valid outcome measures are required. We aimed to identify markers of psychosocial wellbeing in retirement, and determine measures to best capture these markers. Methods employed were an international workshop on the 'Healthy Ageing Phenotype', a systematic review of psychosocial wellbeing interventions, and a concept-mapping exercise linking extant tools with wellbeing domains. Markers of psychosocial wellbeing included emotion, life satisfaction, meaning and purpose, social connectedness and social roles. Measurement challenges included diverse and overlapping wellbeing constructs, inconsistently-used terminology and lack of theoretically-derived instruments. Absence of mental illness was frequently erroneously conflated with psychosocial wellbeing. We assembled a battery of the best existing measures and developed a new measure of social roles. Psychosocial wellbeing is multidimensional, presenting measurement challenges. However, using a mixed-methods approach we produced a comprehensive, psychometrically-sound instrument battery to assess psychosocial wellbeing in retirement.

A PILOT RCT OF AN INTERNET-BASED LIFESTYLE INTERVENTION FOR PEOPLE AROUND RETIREMENT

J. Lara[2,1], E. Evans[3,1], B. Heaven[3,1], N. Hobbs[3,1], A.C. Munro[2,1], M. White[3,1], J.C. Mathers[2,1], *1. Newcastle University, Newcastle upon Tyne, United Kingdom, 2. Human Nutrition Research Centre, Institute for Ageing and Health, Newcastle upon Tyne, United Kingdom, 3. Institute for health and Society, Newcastle upon Tyne, United Kingdom*

There is growing interest in developing lifestyle interventions around the retirement period. We have undertaken a pilot randomised controlled trial evaluating a newly-developed internet-based lifestyle intervention (Living, eating, activity and planning through retirement (LEAP)). Ninety men and women within two years of retirement from full-time work were randomised to LEAP or to a control group using a NHS-website providing general lifestyle information. The intervention lasted two months. Participants of this study were regular internet users living in the Northeast of England. Physical activity levels, dietary habits, and a set of functional outcomes directed to assess the healthy ageing phenotype (HAP), including physiological, physical capability, cognition, and psycho-social wellbeing, were evaluated at baseline and at 2-month follow-up. Results on primary outcomes (feasibility and acceptability of the intervention and the HAP assessment), and secondary outcomes (early indicators of change in dietary, physical activity and HAP outcomes) will be presented and discussed.

SESSION 1940 (SYMPOSIUM)

TACKLING THE CHALLENGES OF LONGITUDINAL AGING RESEARCH: INTEGRATIVE ANALYSIS OF LONGITUDINAL STUDIES OF AGING (IALSA)

Chair: G. Muniz Terrera, *Lifelong Health and Ageing, Medical Research Council, London, United Kingdom*
Discussant: J. Rodgers, *Vanderbilt University, Dept of Psychology, Nashville, Tennessee*

A major feature of the IALSA network is the evaluation of the reproducibility of results from longitudinal studies. The replication of longitudinal research is challenging as there are multiple ways that results can differ including features of the sample and study design and choice of statistical analysis (selection of covariates, retest effects, attrition, mortality selection within and across studies). An ongoing aim of the IALSA network is to examine the impact of alternative statistical models (Piccinin et al., 2011) on the interpretation and replicability of study results. Several projects within IALSA are evaluating the impact of statistical models on questions and conclusions regarding associations between health and cognition. Although age is often employed as a time metric to model change, its use may not be optimal and time in study may be more adequate to describe change in samples of older individuals. Analysis of change in the presence of time varying covariates is challenging as many methods can be considered, each addressing a different question. In ongoing studies, understanding the power necessary to detect rates of change is highly relevant. Particularly in the study of older adults, missing occasions and dropout due to illness and death are a big issue as is mortality selection in initial sample selection as individuals who have died are no longer available to be sampled. In this symposium, we critically evaluate alternative statistical approaches for these major issues and consider best practice for analyses of longitudinal data that will lead to reproducible research findings.

DEMYTHIFYING THE USE OF AGE AS THE “NATURAL” METRIC TO MODEL CHANGE IN AGING STUDIES

A.M. Piccinin[1], G. Muniz Terrera[2], S.M. Hofer[1,3], *1. Psychology, University of Victoria, Victoria, British Columbia, Canada, 2. MRC Unit for Lifelong Health and Ageing, London, United Kingdom, 3. Oregon Health & Science University, Portland, Oregon*

Age is often regarded as the “natural” metric with which to model aging-related change. However, when used in growth models fitted to age heterogeneous samples, assumptions about convergence of cross sectional and longitudinal age effects are often made without testing. Due to age differences at study entry, a decision regarding placement of the intercept is required, such as centering at the average baseline age, although alternative proposals exist. This impacts other model parameter estimates, including the association of level and rate of change with risk factors. Alternatively, when modelling change as a function of time, less arbitrary decisions about intercept placement are required and weaker assumptions and extrapolations are made. In this talk we discuss advantages, limitations and consequences of using chronological age or time since study entry as metrics of time in studies of aging, and illustrate them presenting results from studies affiliated with the IALSA network.

ON THE ROBUSTNESS OF RESULTS FROM LONGITUDINAL OBSERVATIONAL STUDIES: A WITHIN-STUDY REPLICATION EXPERIMENT TO EXAMINE THE CONSISTENCY OF RESULTS ASSOCIATED WITH INCREASES IN NUMBER OF OCCASIONS AND STUDY DURATION

S.M. Hofer[1,2], P. Rast[1], G. Muniz Terrera[3], A. Kelly[1], A.M. Piccinin[1], *1. Psychology, University of Victoria, Victoria, British Columbia, Canada, 2. Oregon Health & Science University, Portland, Oregon, 3. MRC Unit for Lifelong Health & Ageing, London, United Kingdom*

The central aim of the Integrative Analysis of Longitudinal Studies of Aging (IALSA) research network (NIH/NIA P01AG043362) is to optimize reproducible research on longitudinal and life course studies. This is achieved by evaluating comparable conceptual and statistical models at the construct-level. However, replicability of results is also a challenge within each longitudinal study as the number of assessments and overall study duration increases. While longer studies with more occasions have higher power to detect change as more within-person information becomes available, study dropout and mortality-selection must be carefully considered and the models of change shift from difference scores (2 waves) to linear change (3-4 waves) to non-linear change (5+ waves). We will discuss methodological issues related to the robustness of within-study results in regards to the selection of measures and measurement models, study design factors (number of occasions, study duration), and statistical models (linear/nonlinear change) and implications for cross-study comparison.

ANALYSIS OF CHANGE IN THE PRESENCE OF TIME-VARYING COVARIATES

A. Robitaille[1], G. Muniz[2], A.M. Piccinin[1], S.M. Hofer[1], *1. University of Victoria, Ottawa, Ontario, Canada, 2. University College London, London, United Kingdom*

Longitudinal studies allow researchers to model interindividual differences in intraindividual change using growth models. Time-invariant covariates are commonly included to predict between-person differences in the intercept and slope. Still, many variables treated as time-invariant are, in reality, variables that change across time, and could therefore be treated as time-varying covariates. The current presentation will discuss approaches to modelling time-varying covariates using longitudinal data from studies affiliated with the IALSA network. The results from models examining the relationship between health indicators and cognitive functioning will be presented to illustrate growth modeling with time-varying covariates. After attending this presentation, participants will have a better understanding of the questions that can be answered with longitudinal models that include time-varying covariates. We hope this presentation will also inform participants about the importance of examining time-varying covariates in their own longitudinal data.

MISSING DATA DUE TO DEATH: A DISCUSSION OF LIMITATIONS, CHALLENGES AND ADVANTAGES OF EXISTING APPROACHES

G. Muniz Terrera[1], S.M. Hofer[2], A.M. Piccinin[2], *1. University College London, London, United Kingdom, 2. University of Victoria, Dept. of Psychology, Victoria, British Columbia, Canada*

Attrition and dropout in longitudinal studies is a given. In ageing studies, death also plays a considerable role reducing the number of individuals included in the follow up samples even further and introducing biases in estimates of change. Several methods have been proposed in the literature to account for missing data due to death in longitudinal ageing studies. Methods include, amongst others, the use of indicators of whether individuals die during the study’s follow up time, indicators of survival up to each follow up occasion, modelling scores as a function of time to death, and jointly modelling the longitudinal process and the risk of death. In this talk, we will present each approach and discuss their advantages and limitations. To illustrate their application and compare inferences resulting from each modelling approach, we will present results from fitting the different models to data from studies affiliated to the IALSA network.

SESSION 1945 (SYMPOSIUM)

VA GRECC SYMPOSIUM: THE ROLE OF EDUCATION IN IMPLEMENTATION SCIENCE

Chair: B. Kramer, *VA Greater Los Angeles Healthcare System, Los Angeles, California, David Geffen School of Medicine at UCLA, Los Angeles, California*
Co-Chair: J.L. Howe, *James J. Peters VA Medical Center, Bronx, New York*
Discussant: M.K. Goldstein, *VA Palo Alto Health Care System, Palo Alto, California*

Educators in geriatrics and gerontology are being challenged to move beyond traditional teaching and learning models for increasing knowledge and skills and to explore the role of education in the transformational field of implementation science. If education is necessary —- but not necessarily sufficient —- to implement best practices, how are we positioning continuing education and professional development to connect with healthcare professionals, researchers and quality managers in optimizing patient outcomes? What are the practical, evaluation, and theoretical implications for educators? Are new models developing in connecting educational and organizational research in testing or adopting new clinical processes of care? If "one size doesn't fit all," just how many sizes are there? This symposium explores VA GRECC education and training initiatives that have been integrated into health services research, clinical demonstrations or implementation of best practices in the areas of dementia/ delirium, polypharmacy, palliative care and primary care.

USING THE PARIHS FRAMEWORK TO PLAN EDUCATION INTERVENTIONS

S.A. Trudeau[1,2,4], K.J. Horvath[1,3,4], L. Radwin[5], E.S. McConnell[6,7], *1. Edith Nourse Rogers Memorial VAMC, Bedford, Massachusetts, 2. Tufts University, Department of Occupational Therapy, Medford, Massachusetts, 3. Northeastern University, Bouve College, Boston, Massachusetts, 4. New England Geriatric Research Education and Clinical Center, Boston, Massachusetts, 5. Manchester VAMC, Manchester, New Hampshire, 6. Durham VAMC, Durham, North Carolina, 7. Duke University School of Nursing, Durham, North Carolina*

The PARIHS (Promoting Action on Research implementation in Health Services) conceptual framework posits that Successful Implementation is a function of the nature and quality of the Evidence, characteristics of the Context, and Facilitation strategies. It is best employed as a two-stage process where the elements of Evidence and Context, and the respective sub-elements, are assessed in order to design the most appropriate Facilitation (education) strategies. Thus, the education goal in implementation research often focuses more on organizational processes and culture, and learner values than topical content. Our data is derived from the developmental formative evaluation conducted to initiate the implementation study of an evidence-based Home Safety Toolkit for persons with dementia of the Alzheimer's type. Stakeholder interviews and the Organizational Readiness to Change Assessment tool are used to construct an evaluation schema that identifies the types of educational interventions that will best facilitate implementation this new intervention into clinical practice.

COMBINING QUALITY IMPROVEMENT AND GERIATRICS TRAINING: THE NURSING HOME POLYPHARMACY OUTCOMES PROJECT

C.L. Bell[1], B.K. Tamura[1], J. Davis[1], L. Mee-Lee Nakamoto[2], G. Gatchell[2], W. Iwasaki[3], K. Masaki[1], *1. Geriatric Medicine, University of Hawaii John A. Burns School of Medicine, Honolulu, Hawaii, 2. VA Pacific Islands Health Care System, Honolulu, Hawaii, 3. Healthways, Honolulu, Hawaii*

We examined the sustained effects of repeating an educational quality improvement (QI) project on medication safety and cost-effectiveness. In October 2007 and August 2008, facility leadership and geriatrics faculty identified all patients receiving ≥9 medications (polypharmacy cohort) in a 170-bed teaching nursing home and taught Geriatric Medicine fellows (n=12 in 2007, 11 in 2008) to: 1) systematically collect medication data; 2) generate medication recommendations (stop, taper, or continue) based on expert criteria (Beers Criteria) or drug-drug interaction programs; 3) discuss recommendations with patients' attending physicians; and 4) implement approved recommendations. Over the two projects, the polypharmacy cohorts demonstrated decreased potentially inappropriate medications (odds ratio (OR) 0.78, 95% confidence interval (95%CI) 0.69-0.88, $p<0.001$), contraindicated medications (OR=0.63, 95%CI=0.47-0.85, $p=0.002$) and medication costs (OR=0.97, 95%CI=0.96-0.99, $p<0.001$). Our findings suggest that programs planning educational QI projects for trainees may benefit from a multi-year approach to maximize both clinical and educational benefits.

FORMATIVE EVALUATION OF A MULTI-COMPONENT, EDUCATION-BASED INTERVENTION TO IMPROVE PROCESSES OF END-OF-LIFE CARE

K.L. Burgio[1,2], B.R. Williams[1,2], L.L. Woodby[1,2], F. Bailey[1,2], *1. Birmingham/Atlanta Geriatric Research, Education, and Clinical Center, Department of Veterans Affairs, Birmingham, Alabama, 2. Medicine, University of Alabama at Birmingham, Birmingham, Alabama*

A multi-component palliative care education-based intervention was implemented in six VA Medical Centers to promote update of best practices for end-of-life care. The intervention included on-site staff training plus supporting written materials, installation of an electronic order set, and follow-up consultation. Training included large group didactic presentations, small group clinical demonstrations, and one-on-one consultations. The intervention strategy was targeted broadly to hundreds of hospital providers, including physician, nursing, and ancillary staff. The purpose was to train staff in identifying actively-dying patients and implementing best practices of home-based hospice care. A formative evaluation was conducted using semi-structured telephone interviews with key informants from each site. Qualitative data analysis revealed processes that facilitated or impeded uptake of the intervention and perspectives on preferred training strategies. Results can be used to optimize future implementation of education-based interventions to improve adoption of best practices for end-of-life care within acute care settings.

A MULTI-SITE CLINICAL AND EDUCATIONAL DEMONSTRATION PROGRAM TO SERVE RURAL VETERANS (GRECC-CONNECT)

W.W. Hung[1,2], B. Kramer[3], J.G. Hennon[7], T.V. Caprio[8], L. Moo[4], S.E. Espinoza[5], S. Barczi[6], J.L. Howe[1,2], *1. Geriatrics, Mount Sinai School of Medicine, New York, New York, 2. James J Peters VA Medical Center, Bronx, New York, 3. VA Greater Los Angeles Healthcare System, Los Angeles, California, 4. Bedford VA Medical Center, Bedford, Massachusetts, 5. South Texas Veteran Healthcare System, San Antonio, Texas, 6. Madison VA Geriatrics Research Education and Clinical Center, Madison, Wisconsin, 7. VA Pittsburgh Healthcare System, Pittsburgh, Pennsylvania, 8. Canandaigua VA Medical Center, Canandaigua, New York*

GRECC-Connect was established to provide geriatric consultation to rural VA community-based clinics through telehealth modalities with a goal to improve healthcare for rural older Veterans. Seven Geriatric Research, Education and Clinical Centers (GRECCs), which are centers of excellence in geriatric care, serve as the resources for geriatric consultation for clinics located in the Northeast, Northwest, Midwest and Southwest. Based on their variable resources and expertise, each of these GRECCs and clinics has evolved a unique combination of programs to accommodate local needs. Approaches to educate and assist rural providers in providing geriatric care included educational approaches using a case-based conference format and team huddles through teleconferencing, and clinical approaches using video telehealth and chart consultation. The multi-site collaborative provided opportunities for rapid update of successful educational strategies, but the variability in approaches is a challenge for measuring the impact of the education in improving processes of care and patient outcomes.

MULTIMODAL TRAINING TO ENHANCE THE CARE OF VETERANS WITH DELIRIUM

D.M. Kresevic, B. Heath, E.F. Smilovich, P. Chen, A. Jennings, *grecc, va, Cleveland, Ohio*

Delirium is a prevalent condition associated with profound clinical outcomes including, increased institutionalization and lengths of stay, medication use, falls, restraints, and mortality. (Witlox, 2010). Implementation of non- pharmacological evidenced based interventions into clinical practice such as enhanced communication, mobility, nutrition and meaningful activities continues to lag despite traditional educational programming. (Ely, 2001; Inouye, 2003; Foreman, 2001) Barriers to this implementation appear to be multifactorial and include attitudes, knowledge and skills. (Ely, 2004). To address these gaps a multimodal educational program was developed that included the use of video's, case studies, simulation training and bedside mentoring by a delirium resource team. Following bedside consultation and mentoring by a delirium resource team including nurses and physicians using pocket cards, patient outcomes demonstrated improvements in mortality rates, nursing home placement, readmission rates, and emergency room visits. Training programs using case studies were well attended and were highly rated for relevance and effectiveness.

SESSION 1950 (PAPER)

ACUTE CARE II

HOSPITAL PROVIDERS' PERCEPTION OF TRANSITIONS TO SKILLED NURSING FACILITIES: PROCESSES AND BARRIERS

B.J. King[1], A.L. Gilmore-Bykovskyi[1], J. Porter[3], K.A. Kennelty[2], T.J. Roberts[2], B.J. Bowers[1], A. Kind[3], *1. Univeristy of Wisconsin, School of Nursing, Madison, Wisconsin, 2. William S. Middleton Veterans Hospital, Geriatric Research, Education, Clinical Center (GRECC), Madison, Wisconsin, 3. University of Wisconsin, School of Medicine and Public Health, Department of Medicine and Geriatrics, Madison, Wisconsin*

Hospital discharge to a Skilled Nursing Facility (SNF) is one of the strongest predictors for experiencing a 30-day rehospitalization. In order to design effective hospital-SNF transitional care interventions to reduce these rehospitalizations, common processes and barriers to high quality transitions within the sending (hospital) end of these transitions must be better understood. This qualitative study utilized Grounded Dimensional Analysis, a variant of grounded theory methodology. Hospital staff including nurses, case managers, discharge planners, physicians and health unit coordinators (N=53) employed at 3 hospitals in Wisconsin participated in focus groups with in-depth interviews. Data were analyzed using open, axial and selective coding. Hospital staff identified several factors that contribute to unsafe/ineffective hospital-to-SNF transitions. Factors specific to the inter-hospital setting included inconsistent layers of communication within and across provider teams, a limited sense of accountability from hospital staff regarding post-discharge care or outcomes and lack of awareness of the SNF environment. Salient intra-setting barriers included difficulty identifying the appropriate frontline provider. Conditions that improved transitions included discharging nurse knowledge of patient (i.e. consistent assignment) and having an established relationship between hospital and SNF. Overall, hospital staff conceptualized transitions as a discharge process and expressed limited awareness of the concept of bridging care transition from one setting to another. Lack of hospital staff awareness of basic principles of transitional care and SNF setting likely contribute to poor hospital-to-SNF transitions and may increase re-hospitalization risk for older adults who frequently utilize SNF services.

EFFECT OF HOSPITALIZATION ON PHARMACOTHERAPEUTIC MANAGEMENT OF ATRIAL FIBRILLATION FOR NURSING HOME RESIDENTS

S.K. Dutcher[1], I.H. Zuckerman[2], *1. Pharmaceutical Health Services Research, University of Maryland School of Pharmacy, Baltimore, Maryland, 2. IMPAQ International, Columbia, Maryland*

Objective: Stroke prevention is a cornerstone of pharmacotherapeutic management of individuals with atrial fibrillation (AF). Older nursing home (NH) residents are at high risk for stroke and hospitalizations based on their age and poorer health status. This study describes the effect of hospitalization on quality of stroke prevention in NH residents with AF. Methods: Using a retrospective cohort design with Medicare administrative claims linked to the Minimum Data Set and Online Survey Certification and Reporting data, older (≥65 years), long-stay NH residents with AF were identified. Individuals were followed for all months with NH residence and Medicare coverage following the first observed AF diagnosis between 1/1/2007-12/31/2009. The effect of a hospitalization on use of warfarin and receipt of international normalized ratio (INR) monitoring in the following month was determined using hierarchical generalized linear mixed models. Results: The cohort (n=16,174) was predominantly female (76%), white (88%), and aged ≥85 (54%). Individuals were followed for a median of 12 months (range 1-36). The average monthly prevalence of warfarin use was 37.4%, and

84.3% of those receiving warfarin had INR monitoring in the month. In adjusted analyses, a hospitalization increased the odds of using warfarin in the following month by 28% (99% CI 1.11-1.46) but had no effect on subsequent INR monitoring (OR 0.98, 99% CI 0.87-1.09). Conclusion: A hospitalization may increase awareness of the need for stroke prevention in older NH residents with AF. Future interventions should aim to improve awareness earlier in order to avoid unnecessary hospitalizations.

MEDICATION DISCREPANCIES BETWEEN HOSPITAL AND COMMUNITY PHARMACIES POST-DISCHARGE FOR OLDER ADULT PATIENTS

K.A. Kennelty[1,2], A. Kind[1,2], B. Chewning[2], T.J. Roberts[1,2], R. Roiland[1,2], A.L. Gilmore-Bykovskyi[2], D.H. Kreling[2], *1. William S. Middleton Memorial VA Hospital, Madison, Wisconsin, 2. University of Wisconsin- Madison, Madison, Wisconsin*

Background: Medication discrepancies that occur at time of hospital discharge are well documented sources of patient safety issues that threaten the health and lives of older adults. However, little is known about the patterns and sources of these discrepancies at community pharmacies. Objective: The purpose of this study was to 1) determine when hospitalized patients fill their prescriptions post-discharge, and 2) examine whether medications prescribed at hospital discharge reconciled with those on file at patients' community pharmacies. Methods: Patients 65 years and over (n=50) hospitalized for pneumonia, myocardial infarction, or heart failure and discharged back into community care were recruited from a Midwest hospital's transitional care program from February to December 2013. Patient medication records were retrieved from the hospital health system and community pharmacy. Medication discrepancies were identified and categorized as omission, addition, discrepant dose, frequency mismatch, or duplication. Results: Most patients (74%) visited their community pharmacy before having a follow-up provider visit. Of the 461 prescription medications examined, 30.2% were discrepant. The most frequent type of discrepancy was omissions (18.0%). Cardiovascular (24.9%), hormones (14.3%), and central nervous systems agents (12.6%) comprised over half of all medication discrepancies. Conclusions: This study suggests that medication discrepancies are prevalent between the hospital discharge medication list and the medications on file at patients' community pharmacies post-discharge. Since many patients visit their community pharmacies relatively soon after discharge, community pharmacies should be included in care coordination procedures upon discharge. Future research is needed to better understand the causes of these medication discrepancies.

EVALUATING THE RAPID EMERGENCE OF GERIATRIC EMERGENCY DEPARTMENTS (GEDS)

J. Schumacher[1,2], J. Hirshon[2], E. Couser[2], P.D. Magidson[2], *1. University of Maryland, Baltimore County (UMBC), Baltimore, Maryland, 2. Univesity of Maryland, Baltimore, Baltimore, Maryland*

Older adults (>65 years) made over 20.4 million out of 136 million emergency department (ED) visits in 2009. These older ED patients are heterogeneous presenting with numerous co-morbid conditions, medication complexity, decreased functional reserve, and atypical symptoms. The first Geriatric Emergency Department (GED) opened in 2008 and now GEDs exist in over 50 hospitals nationwide. This research examined the structure and process of care provided by these Geriatric Emergency Departments. Data collection used a mixed-methods approach including telephone surveys, content analysis of GED websites, and in-depth ethnographic observation of three GEDs. Descriptive statistics and a grounded theory approach were used for analysis. Results suggest nationwide GEDs are highly heterogeneous in terms of design, physical environment, staffing, policies, and procedures. No single GED standard has yet emerged. GEDs are clustered geographically, in the East Coast and Midwest, with over 50% associated with a single healthcare system. In terms of the physical environment, remodeling or building dedicated GED space appears to be a key discriminator. Over 90% of GEDs report training nursing staff in geriatric care with less training/education of ED physicians. The majority of GEDs report limited hours of operation (e.g., 9-5pm) rather than 24 hour care. Common challenges involved GED admission criteria, after hours care, and follow up care. GEDs remain a healthcare delivery model with an unknown trajectory. Standards and guidelines are needed to provide direction to those considering its implementation. Systematic measurement of GED outcomes and efficacy are called for.

INJURY DEATHS AMONG ADULTS AGED 65 AND OVER: UNITED STATES, 2000-2011

E. Kramarow, L. Chen, H. Hedegaard, M. Warner, *National Center for Health Statistics, Hyattsville, Maryland*

Injury deaths are a large burden on society, and many of these deaths are preventable. Injury deaths are classified by intent (e.g., unintentional, suicide, homicide) and by mechanism (e.g., motor vehicle traffic, firearm, fall, suffocation). Unintentional injuries are the ninth leading cause of death among adults aged 65 and older in the United States, resulting in about 40,000 deaths per year. This research describes the magnitude of injury deaths among adults aged 65 and over in the United States using mortality data from the National Vital Statistics System. Trends in unintentional injury deaths are shown for 2000-2011, and detailed descriptions of unintentional injury deaths by age, sex, race/ethnicity and urbanization in 2010-2011 are presented. We highlight the five leading causes of unintentional injury death among the U.S. population aged 65 and over: falls, motor vehicle traffic accidents, suffocation, poisoning, and fire or flame. Analyses show that slightly more than half of all unintentional injury deaths among adults aged 65 and older were due to falls, and the rate of fall injury deaths has been increasing. Death rates from motor vehicle traffic accidents among older adults were 1.7 times higher in non-metropolitan areas than in metropolitan areas. The rate of death due to fire or flame for older non-Hispanic blacks was more than twice as high as the rates among non-Hispanic whites and Hispanics. Possible explanations for these patterns and trends are discussed.

SESSION 1955 (SYMPOSIUM)

USING INNOVATIVE RESEARCH METHODOLOGIES FOR UNDERSTANDING THE CONTEXT OF AGING AND DISABILITY

Chair: N. Ruggiano, *School of Social Work, Florida International University, Miami, Florida*
Discussant: P. McCallion, *University at Albany - SUNY, Albany, New York*

Over the next several decades, the population of older adults with disabilities and chronic illnesses is expected to increase significantly. Despite policy and service responses aimed at meeting the health and social needs of this population, there are still significant barriers to promoting independent living, successful aging, person-centeredness, self-management, and self-determination among older adults with chronic conditions. One specific barrier includes the vast, growing diversity of this population. Older adults with chronic conditions include: individuals with a variety of conditions; individuals who experienced their disability during later life and individuals whose onset of disability occurred at an earlier age; and individuals from varying cultural backgrounds with different understandings of disability and implications from chronic conditions. Responding to demographic trends, scholarship focused on aging and disability has increased over time, and has become increasingly complex. Scholars in this area are examining the context of aging and disability by examining diverse samples, applying novel theoretical perspectives, developing new measures, and using cutting edge methodologies. Such research in critical to informing health and supportive services for this population. This session highlights several innovative methodological approaches currently being used to understand the context of aging and disability. The individual presentations will represent qualitative and quantitative approaches to inquiry by both senior and beginning investigators. Participants will initiate a dialogue about how research methodology can promote the health and social well-being of older people with disabilities, with a specific focus on the implications of current research on the health and social service systems.

USING ERIKSON'S THEORY TO UNDERSTAND HEALTH SELF-MANAGEMENT: FINDINGS FROM TWO FIELD STUDIES

N. Ruggiano[1], T. Perry[2], N. Shtompel[1], L.A. Hassevoort[2], *1. School of Social Work, Florida International University, Miami, Florida, 2. Wayne State University, Detroit, Michigan*

According to Erik Erikson's theory on human development, psychosocial crises are often revisited later in life. This is especially true for adults experiencing disabilities and chronic illnesses who are self-managing their physical and mental health later in life. This research integrated data from two qualitative studies on health self-management to examine how self-managing physical and mental health changes later in life relates to Erikson's epigenetic principle of human development. It was found that older adults (1) reasserted autonomy by initiating creative problem solving; and 2) applied skills gained from productive activities earlier in life to new health-related problems that arise later in life. The paper will discuss policy and practice implications of these findings. It will also discuss the process and value of integrating multiple qualitative data sets and using Eriksonian theory as a methodological approach to studying chronic conditions later in life.

CONTENT ANALYSIS: SEARCHING FOR LONG-TERM SERVICES & SUPPORTS FOR PERSONS AGING WITH DISABILITY IN SCIENTIFIC LITERATURE AND AT GSA ANNUAL MEETINGS

M. Putnam, *School of Social Work, Simmons College, Boston, Massachusetts*

Although there is an emerging body of knowledge about long-term services and supports (LTSS) for persons aging with long-term disability acquired in early or mid-life, it is difficult to locate. The size and scope of the literature is unknown. This presentation provides two examples of how content analysis (CA) methods were applied as part of a broad scoping review to identify existing LTSS research. CA methods were used to review 9 years of program abstracts (2004-2013) from the Gerontology Society of America annual meetings to identify the amount and themes of annual presentations related to this topic. CA was also employed in a literature review of LTSS that used diagnostic conditions to identify subgroups of the aging with disability population to assess the scope of research available in this area of study. Findings for each CA are reported. Utility of the CA method for this work is discussed.

MEASUREMENT DEVELOPMENT, EVALUATION AND RESEARCH FOR MINORITY ELDERS

K.T. Chan[1], T. Tran[2], *1. University at Albany SUNY, Albany, New York, 2. Boston College, Chestnut Hill, Massachusetts*

With alarming rates of growth in minority aging, gerontological researchers are increasingly aware of the need for meaningful, appropriate, and practical research instruments for their populations. To ensure the quality of data collection and validity of outcomes, gerontologists conducting cross-cultural work must have both reliable and valid research measurements. Using scales that lack comparable psychometric properties can lead to biased results. Measurement equivalence is a fundamental issue in ensuring the fidelity of research and evaluation in our diverse society. This workshop aims to provide an overview of issues and techniques of cross-cultural measurement research, and provide a step-by-step approach to developing, adopting, or adapting instruments for minority aging populations. Special attention will be placed on examining the measurement of disability and psychological distress. This workshop will include an overview of reliability and confirmatory factor analysis, along with measurement invariance tests and test of Tau equivalence using Lisrel, MPlus, and Stata.

SOCIAL SUPPORT IN OLDER HEMODIALYSIS PATIENTS: ASSOCIATIONS WITH SELF-MANAGEMENT AND A CONFIRMATORY FACTOR ANALYSIS OF THE SIX ITEM LUBBEN SOCIAL NETWORK SCALE

T.R. Washington[1], S. Zimmerman[2], *1. University of Georgia, Athens, Georgia, 2. University of North Carolina, Chapel Hill, North Carolina*

Older hemodialysis (HD) patients are at risk for social isolation, yet factors associated with social support are understudied, and measures of social isolation have yet to be validated with this population. The purpose of the current study was to 1) examine the relationship of social support to self-management behaviors; and 2) examine the factor structure of the Lubben Social Network Scale - 6 (LSNS-6) using data provided by 107 community-dwelling HD patients aged 50 and older. Advance directive status ($p = 0.01$), cognitive symptom management ($p = 0.02$), communication with physicians ($p = 0.03$), and weekly exercise time ($p = 0.02$) were associated with social support. The LSNS-6 demonstrated good fit as reflected in the CFI (0.977) and TLI (0.941) scores. HD patients reporting low social support practice fewer self-management behaviors, and the LSNS – 6 is valid for use of rapid assessment of social isolation in older HD patients.

SESSION 1960 (SYMPOSIUM)

TRAINING ON PERSON-CENTERED PLANNING AND PARTICIPANT-DIRECTION

Chair: K.J. Mahoney, *Graduate School of Social Work, Boston College, Chestnut Hill, Massachusetts, National Resource Center for Participant-Directed Services, Chestnut Hill, Massachusetts*

Discussant: L. Gerhard, *US Administration on Aging, Washington, District of Columbia*

Person-centered planning and participant or self-direction are basic elements in the Affordable Care Act, but a recent survey shows that staff in Area Agencies on Aging have little preparation and desire more training. The New York Community Trust (NYCT) has funded the Council of Social Work Education together with the National Resource Center for Participant-Directed Services to work with nine Social Work Programs to develop modules for infusing these approaches into clinical and macro social work courses. Each social work program is partnered with a community-agency (typically an Aging and Disability Resource Center) to provide grounding for the curriculum and field experiences for the students. The first paper will present research on training needs from a survey of Area Agency on Aging directors and staff holding social work positions. The second paper will review research and experience in curriculum infusion and preliminary findings from the NYCT project in preparing social work students with PC/PD competencies. The third paper will discuss the advantages of working with agencies in curriculum building as a form of participatory action research. Finally, Lori Gerhard from the Administration on Community Living will discuss future needs for such training and how it relates to planning at the federal level.

WORKFORCE COMPETENCIES IN THE AGING NETWORK: A SURVEY OF AAA DIRECTORS AND STAFF

M. Sciegaj, *Penn State University, University Park, Pennsylvania*

This paper describes a national survey of Area Agency on Aging (AAA) administrators and of staff who hold information and assistance service positions. This 18-month study sought to determine the extent competency-based workforce initiatives and needs within the Aging Network in the areas of gerontology, diversity, person-centered practices, and participant-directed services. The survey collected information on the extent of competency based performance in the network, perceived training needs related to competency based performance expectations, and the extent of influence of educational background and professional training on the presence of workforce competencies in the above areas. Paper discusses implications of findings on training for both the current and future workforce in aging and disability services.

PREPARING SOCIAL WORK STUDENTS FOR PERSON CENTERED AND PARTICIPANT DIRECTED OCCUPATIONS

N.R. Hooyman, *University of Washington, Seattle, Washington*

To address the need for workforce development in PC/PD, this paper will present findings from a national project funded by the New York Community Trust to prepare social work students with PC/PD competencies to work effectively within the Aging and Disability Network as well as community-based long-term services and supports funded by the ACA. The project partners nine schools of social work with nine aging and disability network agencies for the purposes of articulating and infusing PC/PD competencies into social work curriculum. Effective strategies to infuse such competencies into required curriculum will be discussed, and examples of teaching resources (e.g., lectures, case studies, modules) and measures of student competency attainment presented.

BUILDING THE COMMUNITY-BASED PARTNERSHIP

C. Morano, *Silberman School of Social Work at Hunter College, New York, New York*

As a part of the Partners Project, Hunter College and the Visiting Nurse Association of New York City have collaborated in the formulation of a competency-based curriculum for social work students. The goal of the curriculum is to train social work students in the areas of person-centered practices and participant-directed services so that they will be able to work effectively within the Aging and Disability Network (and avoid the need for on-the job training). As such, this partnership reflects the basic tenets of participatory action research—the collection and use of information so that it benefits the people it directly affects. This presentation describes the process of engaging our community based partner in a collaborative process, effective strategies to infuse such competencies into required curriculum, and measures of student competency attainment will be presented

SESSION 1965 (SYMPOSIUM)

INTERDISCIPLINARY TEAMWORK TRAINING AND PRACTICE IN GERIATRICS: CHALLENGES AND OPPORTUNITIES FOR THE FUTURE

Chair: P.G. Clark, *Program in Gerontology, Univ Rhode Island, Kingston, Rhode Island*

Discussant: R. Kaiser, *Veterans Affairs Medical Center, Washington, District of Columbia*

Interdisciplinary teamwork (IDT) is an essential component of providing quality care to older adults with complex and chronic health care needs. Health care professionals need to be trained in the essentials of interprofessional education (IPE) to be adequately prepared for clinical practice. The Partnership for Health in Aging (PHA), a coalition of over 30 health professional organizations supported by the American Geriatrics Society, has recently published a "Position Statement on Interdisciplinary Team Training in Geriatrics," and the task is now to implement its recommendations. Although past history of IDT efforts indicates that this goal is fraught with substantial challenges, the current context offers new opportunities. This symposium presents a comprehensive discussion of what strategies might be most effective in moving the IDT agenda in geriatrics forward. The first paper summarizes the background and important insights from the recent utilization of the curriculum, the Geriatric Interdisciplinary Team Training (GITT) Kit, which was developed as a national model for IDT education. The second paper summarizes the lessons learned from the successful continuation of a GITT and other similar programs at a university medical center. The third paper describes current and future initiatives within the Veterans Administration (VA) health care system in support of IDT utilization and training. Finally, the last paper develops a force-field analytical framework assessing the positive and negative forces and factors underlying the development and continuation of IPE. Implications for developing, implementing, and sustaining interdisciplinary geriatric teamwork education and practice to meet future health care needs will be developed.

THE EVOLUTION AND DISSEMINATION OF GERIATRIC INTERDISCIPLINARY TEAM TRAINING (GITT)

T. Cortes, S.A. Greenberg, Y. Bazile, *New York University, New York, New York*

Responding to the need for national models for interdisciplinary team (IDT) training in geriatrics, in the mid 1990s the Hartford Foundation invested in the development of IDT demonstration projects. NYU was funded to develop a Resource Center to serve as a clearinghouse for disseminating curriculum and training materials, and the GITT kit was born. It is comprised of an Implementation Manual, a Curriculum Guide, DVDs/CDs portraying team conferences, and a Preceptor Guide. The Hartford Institute for Geriatric Nursing (HIGN) at NYU has sampled those who have ordered the kit to determine if and how they are using this resource. This paper reports on a qualitative analysis describing how organizations have used the kit to enhance the knowledge and value of interprofessional practice in geriatric care, as well as to develop and continue IDT programs. Results are interpreted in the context of the challenges of developing and sustaining IDT.

INITIATING AND SUSTAINING IDT IN DIVERSE SETTINGS: SOME STRATEGIES FOR SUCCESS

S. Lapidos, *Rush University Medical Center, Chicago, Illinois*

Requiring participation in interprofessional learning and practice experiences has increasingly emerged as a fundamental part of didactic and clinical training for students entering health professions at a growing number of academic institutions. Rush University Medical Center has capitalized on its entry into interprofessional education that began nearly two decades ago to expand its commitment to diverse and innovative interprofessional initiatives. From its successful development and continuation as one of the original Geriatric Interdisciplinary Team Training (GITT) sites funded by the Hartford Foundation in the mid-1990s, this paper will describe how Rush University has used its GITT Program to launch at least six other interprofessional education and team-based clinical care projects, as well as online programs. The factors leading to the successful launch of these initiatives will be presented, as well as strategies for overcoming barriers and challenges to implementing interprofessional programs at large academic medical institutions.

IDT IN THE VA: CURRENT PLANS AND FUTURE PROSPECTS

K. Shay[1], R. Tsukuda[2], C. Hojlo[3], S. Shreve[4], T. Edes[3], N. Quest[3], R.M. Allman[3], *1. Department of Veterans Affairs, Ann Arbor, Michigan, 2. Department of Veterans Affairs, Portland, Oregon, 3. Department of Veterans Affairs, Washington, District of Columbia, 4. Department of Veterans Affairs, Lebanon, Pennsylvania*

The Interdisciplinary Team Training in Geriatrics Program in the Department of Veterans Affairs (VA) was offered at 12 sites and provided education and consultation throughout the VA. The VA's 2010 introduction of the patient-centered medical home was accompanied by renewed emphasis on teams in primary care. A 2012 system-wide survey of VA-delivered programs in geriatrics and extended care found widespread self-identification of programs (including Community Living Center, In-Patient Geriatric Evaluation and Management, Palliative Care, Home-Based Primary Care, Adult Day Health Care, and Geriatric Primary Care) as "interdisciplinary teams," although the source and recency of formal team training varied widely. VA's system of Geriatric Research, Education, and Clinical Centers was the most commonly-cited source of prior training, but accounted for less than a quarter. As VA focuses increasingly on "veteran-centric" care and services, there will continue to be demand for interdisciplinary team training, although the form it will take remains uncertain.

PROMOTING INTERPROFESSIONAL TEAMWORK EDUCATION IN GERIATRICS: THE DEVIL IS IN THE DETAILS

P.G. Clark, *Program in Gerontology, Univ Rhode Island, Kingston, Rhode Island*

Though the need for effective interprofessional collaboration for older adults with complex chronic conditions is increasingly recognized as essential for high quality care, the preparation for teamwork of future health care professionals is often limited or non-existent. Understanding the reasons for this situation demands an assessment of the factors and forces promoting and opposing a change in the educational status quo. This paper presents a force-field analysis of the development and continuation of interprofessional education (IPE) for teamwork in geriatric settings. These factors include (1) structural barriers, e.g., separate departments or schools for different professions, (2) cultural factors, e.g., loyalties to one's own professional identity or perspective, (3) power differentials, e.g., status and resource inequities, and (4) logistical challenges, e.g., scheduling. Strategies utilizing external pressures, such as accreditation, to move IPE forward will be considered, and recommendations for both the development and the continuation of teamwork education will be explored.

SESSION 1970 (SYMPOSIUM)

ENGAGEMENT OF THE FAMILY IN PALLIATIVE CARE

Chair: C.S. Berkman, *Fordham University Graduate School of Social Service, New York, New York*
Co-Chair: K.B. Hirschman, *University of Pennsylvania School of Nursing, Philadelphia, Pennsylvania*

Engaging families in the planning and care of older adults with palliative needs is critical to positive outcomes for both the older adult and the family's well-being. The purpose of this symposium is to describe and examine engagement of family in various aspects of palliative care including caring for patients, advance care planning, preference discussions, and loss. First, Buck, Harness and Wion will discuss their systematic review of older caregiver's engagement in heart failure symptom management and the inconsistencies in relation to types of symptom management and gaps in knowledge. Second, Reinhardt, Boerner and Downes will present findings from their study in which they found that more frequent discussions with family members of nursing home residents about end-of-life treatment goals and preferences about life-sustaining treatments were associated with greater satisfaction with care. Third, Shulz & Boerner will discuss their findings that engaging in advance care planning was associated with greater preparedness for death, which in turn predicted lower levels of post-death depression among caregivers of long-term care residents. Fourth, Berkman, Ko, and Roh will discuss the discordance between adult children and their community-dwelling older adult parents on preferences for end-of-life treatment and decision making. Finally, Morrissey will present her findings of the influence of the loss of family or community on the experience of pain, discomfort or distress among older adults in nursing and hospital facilities.

OLDER ADULT HEART FAILURE CAREGIVERS AS CO-PROVIDERS OF CARE: A SYSTEMATIC REVIEW OF CAREGIVERS ENGAGEMENT IN SYMPTOM MANAGEMENT

H.G. Buck[1], K. Harkness[2], R. Wion[1], *1. Penn State, University Park, Pennsylvania, 2. McMaster University, Hamilton, Ontario, Canada*

Symptom management is a major component of palliative care. The purpose was to conduct a systematic review of older caregiver's (CGs) engagement in heart failure (HF) symptom management. PRISMA criteria were used with terms heart failure and caregiv* in MEDLINE®, EMBASE, CINAHL®, the Cochrane Library and ClinicalTrials.gov databases for studies published between 1948-2012. Inclusion criteria: informal CGs of adult HF patients published in English. Studies were abstracted/confirmed by two members. 40 papers met criteria. 1318 patients and 1625 caregivers in 8 different countries were involved. More is known about CG's role in symptom management related to: following a plan of care (n=14 studies), health surveillance (n=14), treatment implementation (n=12), maintaining a healthy lifestyle (n=7), than in symptom recognition (n=1), symptom evaluation (n=2), or treatment evaluation (n=2). There are significant gaps in what is known about CG's engagement as co-providers in HF symptom management while equally old and potentially frail.

PLANNING MATTERS: IMPORTANCE OF DISCUSSING END-OF-LIFE TREATMENT PREFERENCES FOR SATISFACTION WITH CARE

J. Reinhardt[1], K. Boerner[1], D. Downes[2], *1. Research Institute on Aging, Jewish Home Lifecare, New York, New York, 2. Jewish Home Lifecare, New York, New York*

Conversations about end-of-life healthcare choices regarding treatment goals, preferences about life-sustaining treatments, and advance care planning are important, especially in nursing homes, where progressive decline in end-stage disease, including dementia, is compounded by co-morbidities and acute events (e.g., pneumonia). Participants were 90 family members of nursing home residents with advanced dementia. Semi-structured interviews were conducted at baseline and 6 months later. The effects of specific health care discussions with clinical staff (e.g., around comfort care, resuscitation, use of artificial hydration) on family members' care satisfaction were examined with multiple regression analyses. Results showed that having more frequent discussions about preferences (e.g., hydration) had significant, positive associations with both concurrent care satisfaction and increased satisfaction over time. The importance of having these discussions is discussed.

A PROSPECTIVE STUDY OF PREPAREDNESS FOR DEATH AND ADJUSTMENT TO BEREAVEMENT

R. Schulz[1], K. Boerner[2], *1. U. of Pittsburgh, PIttsburgh, Pennsylvania, 2. Jewish Home Lifecare, New York, New York*

Data from a two-group randomized controlled trial testing the efficacy of a six month psychosocial intervention for 217 informal caregivers whose recipients resided in a long-term care facility were used to examine the role preparedness for death ("If your loved one were to die soon, how prepared would you be for their death?") as a predictor of post-bereavement depression (CES-D) and complicated grief. 89 care recipients died during the 18 month follow-up. In multivariate models controlling for baseline sociodemographics, group assignment, and care recipient functional status, we found that preparedness for death was associated with lower levels of post-death depression. Similar models testing predictors of complicated grief showed a significant association between preparedness and complicated brief, which became non-significant when controlling for baseline depression. Factors associated with being prepared for a loved one's death included lower baseline CES-D scores and engaging in advance care planning.

DISCORDANCE IN PREFERENCES FOR COMMUNICATION AND ADVANCE CARE PLANNING FOR END OF LIFE AMONG KOREAN AMERICAN OLDER ADULTS AND THEIR CHILDREN

C.S. Berkman[1], E. Ko[2], S. Roh[3], *1. Graduate School of Social Service, Fordham University, New York, New York, 2. San Diego State University School of Social Work, San Diego, California, 3. University of South Dakota Department of Social Work, Sioux Falls, South Dakota*

Adult children are often involved in decision-making with and for parents regarding end of life treatment. Relatively little is known about the extent to which children know and/or agree with the parent's preferences for end-of-life treatment. This pilot study included 38 Korean American older adults and one of their adult children. Responses for older adults and their child were discordant on whether the older adult: would want medication to prolong life if there were bad side effects; would want medication to relieve bad pain even if they shortened life; would want treatment to stay alive even if the older adult were comatose with no hope of waking up; and the older adult wanted to know about a diagnosis of incurable cancer. Older adults were more likely than the children to delegate decision-making to the family. The implications of this discordance is discussed.

INCREASING EFFECTIVENESS OF PALLIATIVE CARE AS A SOCIAL PARADIGM: THE INFLUENCE OF FAMILY CAREGIVING RELATIONSHIPS AND PRESENCE ON OLDER ADULTS' PAIN AND DISTRESS

M.E. Morrissey, *Fordham University Graduate School of Business Administration, New York, NY, New York*

Essential to palliative care is providing patient- and family-centered social support and counseling, and facilitating conversations about goals of care. In a qualitative study of pain, suffering and decision making among older adult patients in nursing and hospital facilities (n=20) using phenomenological data analysis, patients' descriptions of their own experience in unstructured in-depth interviews revealed that loss of family or highly-integrated community influenced their experience of pain, discomfort or distress in 100% of cases. Variation in types of pain and forms of suffering, including types of distress, reported by patients ranged from unbearable pain from complex wounds, serious injuries, and advanced disease processes to disabling conditions such as being restricted to bed and not being able to walk, and forms of dependency and near total helplessness. The implications of the study findings for the design of "total palliative environments" will be discussed.

WORLD ELDER ABUSE AWARENESS DAY (WEAAD): A CALL FOR EVALUATION

E. Podnieks, *Ryerson University, Toronto, Ontario, Canada*

With the growth of the worldwide elder population, and the ongoing strain of economic challenges, it is clear that World Day must serve as a spring board for continuous activities to enlist public support in the fight against elder abuse. In 2011, the United Nations officially designated June 15th as WEAAD. Much has been accomplished as the 10th anniversary of WEAAD approaches in 2015: governments, corporations, organizations and other funders have committed generous funding to promote World Day activities. It is now critical to evaluate the strengths and weakness of programs: what worked, what didn't work, what people thought about the programs, what was actually accomplished. The objectives of this session are to report on evaluation methods from regions of Africa, Asia, Europe, Latin America, North America and Oceania. Participants will also define the elements of a global evaluation framework to be launched at the First World Summit on Elder Abuse to be held June 15th, 2015.

SESSION 1975 (SYMPOSIUM)

THE "VILLAGE" MODEL: STRENGTHENING CONNECTIONS WITH PEERS, PROGRAMS, AND PLACE

Chair: A.E. Scharlach, *Social Welfare, University of California, Berkeley, California*
Discussant: J. Pynoos, *University of Southern California, Los Angeles, California*

In a climate of declining public and family support, increased attention is being given to underutilized human and social resources that have the potential to foster positive health and social outcomes for older adults. One initiative that has received a great deal of attention is the "Village" model - grassroots community-based membership associations that claim to promote aging in place by fostering stronger supportive connections between older adults and their peers, younger community members, and local service providers. This symposium presents the first outcome data regarding the potential effectiveness of the Village model in achieving these aims. The first paper identifies the core characteristics of the Village model, describes its proliferation, and examines potential pathways through which Villages may impact members' health and well-being. The second paper presents findings regarding the effects of Village membership on social engagement, social support, and perceived ability to age in place, based on retrospective and prospective studies with a total of 420 Village members in California. The third paper examines the effects of Village membership on physical and psychological well-being, service access, and health services utilization, drawing upon a 12-month longitudinal study of California Village members. The fourth paper examines the impact of "Village Connections," a volunteer-based care coordination program implemented by Capitol Hill Village in Washington, DC. Finally, implications of these findings for future efforts to develop community-based interventions for enhancing supportive connections will be discussed, along with recommendations for future research.

THE VILLAGE MODEL: CONNECTING ELDERS, CONNECTING COMMUNITIES

C. Baldwin, *1. Capital Impact Partners, Arlington, Virginia, 2. Village to Village Network. LLC, Arlington, Virginia*

The Village model is emerging across the US and internationally providing an intersection of community development with services and programs to provide a comprehensive mechanism for older adults to age in the community setting of their choice. Villages are person-centered, community-based membership organizations that empower older adults to remain active and engaged in their communities. Built upon cooperative principles, Villages facilitate the opportunity for members to develop, own and operate an organization that facilitates their independence and choice. The Village to Village Network, a nationally based peer to peer network, was launched to support the replication and scaling of the Village model. This peer to peer network was developed in response to the need to support capacity building of Village founders at the local level and to identify key intersections through research of the social impact of the Village model to inform publically supported aging services.

THE IMPACT OF VILLAGE MEMBERSHIP ON SOCIAL ENGAGEMENT AND AGING IN PLACE

C. Graham, *UC Berkeley School of Social Welfare, Berkeley, California*

In a study of 282 members from 5 Villages, 80% agreed that they knew more people as a result of Village membership, and 59% felt more socially connected, a factor known to promote aging in place. Multivariate analysis showed higher social impact scores were associated with more frequent use of Village transportation services, volunteering for the Village, use of companionship services, and more frequent participation in Village social activities. Longitudinal data capturing 138 members at intake and 12-months post enrollment showed significant increases in feelings of belonging to a community (p<.001); frequency of talking to friends or neighbors (p<.05); and a significant decrease in the number of members who were considering moving to alternative housing (p<.001). Villages represent a promising new model that may ameliorate social losses as people age and increase confidence aging in place, but questions remain about their ability to serve seniors as they age over time.

THE IMPACT OF VILLAGE MEMBERSHIP ON HEALTH AND SERVICE ACCESS

A.E. Scharlach, C. Graham, *Social Welfare, University of California, Berkeley, California*

This paper presents the first empirical evidence regarding the potential effect of Village membership on older adults' physical and psychological well-being, service access, and health services utilization, drawing upon data from a longitudinal study of 138 California Village members during their first 12 months of Village membership. Significant increases were observed in the ability to get help when needed (p=.003), as well as reductions in unmet needs (p=.03), home safety problems (p=.01), and falls (p<.001). While there were no other statistically significant changes in health or functioning, the study found increases in the use of health care services, including 911 calls (p=.005), hospitalizations (p=.000), and ER visits (p=.000). These findings help to clarify the potential health and well-being impacts of Village membership, and the mechanisms through which those outcomes might be achieved. In doing so, the findings may have important implications for developing effective community-based aging services interventions.

LEVERAGING COMMUNITY CAPACITY TO PROVIDE VOLUNTEER-BASED CARE COORDINATION

J. Maggioncalda, *Capitol Hill Village, Washington, District of Columbia*

Many communities are struggling with the logistics of supporting older adults with chronic conditions and functional limitations as they age-in-place. For these individuals, staying healthy at home not only requires that they know what resources exist, but also have the capacity to successfully engage with these resources and coordinate the care between multiple agencies in order to ensure that all of their needs are met. In the spring of 2013, Capitol Hill Village launched Village Connections, a volunteer-based care coordination program that pairs older adults who are at risk of institutionalization with a trained volunteer. Maximizing the impact of a single staff person or professional, the Village Connections program ensures that those who have the most difficulty accessing resources are not left out of the support system. Village Connections provides a promising programmatic model for communities seeking to create a system of support for frail older adults by leveraging the strengths of the community and the power of neighbors helping neighbors.

SESSION 1980 (PAPER)

LONG TERM SERVICES AND SUPPORTS: HOME-BASED CARE

LONG-TERM CARE: WHERE HAVE YOU GONE, WHERE ARE YOU GOING?

R. Applebaum, S. Mehdizadeh, I.M. Nelson, J. Straker, *Miami University, Oxford, Ohio*

From its name to the type and setting of care provided, the world of long-term services and supports has changed dramatically in the last two decades. Using 20 years of longitudinal data from the state of Ohio this presentation describes how the long-term services system is different from the one that existed in the early 1990's. Data come from ten biennial surveys of all Ohio nursing homes and residential care facilities and comprehensive resident and home care participant data on user characteristics and utilization rates. Findings show large changes in where services are provided and who receives services. For example, Ohio, as has most other states, has changed the ratio of its older population using Medicaid long-term care, going from 91% nursing home in 1993, to 55% nursing home in 2011. At the same time the sheer number of admissions to Ohio nursing homes increased from 70,000 to more than 220,000 painting a picture of today's nursing home as a short-term care provider. These massive changes indicate an industry in transition. What will this mean for the future of the home care and nursing home industries? What will tomorrow's system of long-term services and supports look like? Building on these two decades of findings the presentation will tackle the question of where long-term care has gone, and where it is going.

COMMUNITY TRANSITION FROM NURSING HOMES: WHAT DELAYS THE PROCESS?

J. Robison[1], N. Shugrue[1], M.A. Porter[1], A. Kleppinger[1], M. Lynch[1], D. Lambert[2], *1. University of Connecticut Health Center, Farmington, Connecticut, 2. Connecticut Department of Social Services, Hartford, Connecticut*

Since 2009, Connecticut has transitioned over 2000 people from nursing homes and other institutions to home and community-based settings through its Money Follows the Person Rebalancing Demonstration (MFP). The time from program referral to community transition varies widely, from 1 day to almost 3 years, with a mean of 142 days and a median of 76 days for transitions in 2012 and 2013. The program's goal is to transition everyone within 180 days, but 25% of transitions take longer than 180 days and 10% take longer than 1 year. Examining transitions in 2012 and 2013, the CT MFP Evaluation team developed a predictive model using linear regression models to identify the most salient factors influencing time to transition. A longer stay in the facility, younger age, male gender, having diabetes, a lack of engagement in the process, issues with spouses or other family members, and a need for housing modifications all contribute significantly to a longer time to transition. An interactive, web tool based on these model results is now an integral part of the CT MFP transition planning process, allowing care managers to predict a targeted discharge date and build an action plan around that date. Early identification of factors that likely slow the transition process allows the transition team to design interventions and process improvements that impact those factors and ideally will lead to shorter transition times and best practices.. The interactive tool will be demonstrated at this paper presentation and policy implications will be discussed.

MEASURING LONG TERM CARE PREFERENCES

J. Guo[1], R. Konetzka[2], E. Magett[2], W. Dale[2], *1. American Institutes for Research, Washington, District of Columbia, 2. University of Chicago, Chicago, Illinois*

Current policies reorienting long-term care (LTC) delivery from institutional care to home- and community-based services are being made in the absence of crucial evidence on the quality of life (QOL) associated with these options. Prior studies indicate that the shift to home care is generally not cost-saving but may be cost-effective; thus, a rigorous assessment of social preference and QOL is sorely needed in order to evaluate policies incenting home care investment. This study extended the traditional Time Trade-off (TTO) method to elicit QOLs associated with the receipt of different modes of LTC services, conditional on health states defined by varying levels of functional and cognitive impairment. User's LTC preferences are quantified as differential QOL between different LTC options. Among 81 eligible participants who were age 55 or above, we find that although preferences for home care over institutional care are statistically significant under most conditions, the elicited LTC preferences depend significantly on levels of disability. Home care preference is quantified as 0.30 QOL when people only need help with one daily living activity and could be translated to a gain of $15,000-$30,000 per year. However, the preference for home care is weaker or nonexistent once the need for help became greater. Thus, people do not consistently prefer home care over institutional LTC as previously assumed. In order to provide cost-effective care, the target population should be identified for different LTC options. The extension of TTO methods to questions of policy provides a promising avenue for more rigorous policy decision-making.

THE SOCIAL EXCLUSION OF LGBT SENIORS IN HOME AND COMMUNITY CARE SERVICES

J. Watkins, *University of Toronto, Toronto, Ontario, Canada*

In this paper I present a qualitative analysis of the personal experiences of a politically and socially marginalised population in order to examine the current provision of home and community care services, and the extent to which these services reflect, reinforce or ignore the social exclusion of lesbian, gay, bisexual and transgender (LGBT) seniors in Toronto, Canada. In-depth, semi-structured interviews were conducted a total of 30 key participants who fell into two categories: 1) LGBT seniors (age 60+) who had personal experiences receiving home and community care (H&CC) services, 2) front line care managers who represent H&CC service agencies. Interviews with LGBT seniors focused on personal experiences with the health care system, with H&CC services, and perceptions of social inclusion/exclusion. Interviews with H&CC providers examined the potential impact on the health care system of providing culturally appropriate H&CC to LGBT seniors (e.g. HHR, training, funding) as well as suggestions and recommendations at the organization and state level. Results indicate that LGBT seniors' experiences of social exclusion condition their responses to H&CC care and include both avoidance of services and patterns of self-advocacy. At the organization level there is a clear lack of awareness about the needs of LGBT seniors, and a near total absence of organizational mandates that include LGBT "friendly" care. I discuss the implications of these gaps for individuals, organizations and governmemnts.

A COMPARISON OF FEELINGS OF USEFULNESS AND DEPRESSIVE SYMPTOMS AMONG RESIDENTS LIVING IN A CCRC VS. CONGREGATE SENIOR HOUSING

N. Klinedinst, B. Resnick, *University of Maryland Baltimore, Baltimore, Maryland*

Residents in long-term care facilities are at high risk for not feeling useful due to a philosophy of care where daily tasks are completed 'for' instead of 'with' residents. In community dwelling older adults, low feelings of usefulness are often associated with depressive symptoms. The purpose of this descriptive study is to compare feelings of usefulness and depressive symptoms among two samples of older adults in different residences: 29 residents in subsidized congregate senior housing (SH) and 147 independent living residents in a continuing care retirement community (CCRC). All participants completed a one-time survey. One-way ANOVA was used to compare groups. SH participants were 74.48±8.52 years old and 66% female and 72% African American. CCRC participants were 86.39±6.25 years old and 74% female and 98% Caucasian. Three percent (n=2) of SH residents and 32% (n=41) of CCRC reported feeling useful either never or rarely. Nine percent (n=14) of CCRC residents 4% (n=1) of SH residents had high rates of depressive symptoms (PHQ-2 $\leq$3). Residents of SH are significantly younger (F=77.21, df=1, p<.001) and feel more useful (F=41.19, df=1, p<.001) than CCRC residents. There were no significant differences in rates of depressive symptoms (F=.24, df=1, p=.62). While age, race, and wealth may be important confounders, the philosophy of care in which daily tasks such as housekeeping and meal preparation are performed for residents in a CCRC setting may contribute to low feelings of usefulness for these residents.

SESSION 1985 (SYMPOSIUM)

FROM CELLS TO SOCIETY: NIA AT 40 – PAST, PRESENT, AND FUTURE

Chair: M. Bernard, *National Institute on Aging, Bethesda, Maryland*

The National Institute on Aging at the National Institutes of Health was established in 1974 with a mission to support and conduct research on aging processes, age-related diseases, and special problems and needs of the aged. Shortly thereafter, the Institute was designated by Congress as the lead research agency in Alzheimer's disease. During this symposium, NIA's scientific leadership and grantees will reflect on major accomplishments to improve the health of older individuals over the past 40 years and look to the future of the NIA and aging research. This two part symposium will begin by describing progress in research in aging biology, neuroscience, behavioral and social research, and geriatrics and clinical gerontology through NIA extramural support. The second part of the symposium will provide highlights from NIA's Intramural Research Program, followed by a discussion of new directions in aging research from the viewpoint of the Institute director. Among the speakers will be Steve Austad, Eileen Crimmins, Neil Buckholtz, Luigi Ferrucci, and Richard Hodes. The symposium will conclude with a panel discussion including the NIA director, scientific director, and division directors. At the completion of the symposium, participants will be able to 1) discuss major accomplishments in aging biology, neuroscience, behavioral and social research, geriatrics and clinical gerontology; 2) discuss projected future aging research developments; 3) answer questions posed to NIA senior leadership regarding plans for future research and grant funding.

NEUROSCIENCE AT NIA

M. Bernard, N. Buckholtz, *National Institute on Aging, Bethesda, Maryland*

The Division of Neuroscience (DN) supports a broad spectrum of research and training aimed at obtaining a better understanding of age-related normal and pathological changes in the structure and function of the nervous system and how such changes affect behavior. The mission of DN is to expand knowledge on the aging nervous system to allow improvement in the quality of life of older individuals. This includes basic and clinical studies of the nervous system, clinical trials of therapies, and epidemiologic research to identify risk factors and to establish prevalence and incidence estimates of pathologic conditions. A major focus within DN is on Alzheimer's disease (AD). DN supports research on the etiology, treatment, and diagnosis of cognitive decline, mild cognitive impairment (MCI), and AD as well as treatment and prevention clinical trials. An emerging focus is how the processes of aging and age-related cognitive decline intersect with the development of AD.

INTRAMURAL RESEARCH AT NIA

M. Bernard, L. Ferrucci, *National Institute on Aging, Bethesda, Maryland*

The Intramural Research Program of the National Institute of Aging is located in Baltimore, in part because it evolved around the Baltimore Longitudinal Study on Aging. Many different aspects of aging are addressed with a translational perspective that spans from studies of single molecules, animal models, observational and intervention studies in humans. The global aim is understanding normal aging in different physiological system and tissues, and discover genetic and environmental factors affects trajectories of aging and transitions from normal aging to diseases. The NIA/IRP contributed substantial knowledge on changes in physiology that occur with aging across physiological systems. Recently, there has been emphasis on pathophysiology, early diagnosis and potential new treatment of age-related diseases particularly burdensome to older persons, such as diabetes and Alzheimer. Intervention that potentially slow-down or lessen the development of phenotypical manifestation of aging, such as caloric restriction are also studies.

NIA FACING THE FUTURE

M. Bernard, R. Hodes, *National Institute on Aging, Bethesda, Maryland*

The National Institute on Aging at the National Institutes of Health has led aging and Alzheimer's disease research for 40 years. As the Institute considers the next 40 years, there are a number of ongoing projects that may signal what that future may be. Richard Hodes, NIA Director since 1995, will review the latest findings from funded research and discuss anticipated initiatives over the next several years. This discussion will be followed by the opportunity to query Dr. Hodes and the NIA research leadership regarding their visions for the future.

FORTY YEARS IN THE BEHAVIORAL AND SOCIAL SCIENCES AT NIA

M. Bernard[1], E. Crimmins[2], *1. National Institute on Aging, Bethesda, Maryland, 2. University of Southern California, Los Angeles, California*

Forty years ago, NIA research focused on age differences in activity and social integration. Under Matilda White Riley, there was a focus on the integration of the process of aging with the age stratification and cohort changes in society. Over the subsequent three decades the promise of cells to society has been achieved. A general social science model of health change over the life cycle has developed which includes inputs from sociology, psychology, economics, biology and public health. Health outcomes have broadened to include mental health and well-being and cognitive as well as physical health. Studies of differences in health across countries, within the U.S., and changes over time have clarified the major input of behavior to health and the importance of understanding how to incentivize behavior that promotes healthy aging.

GERIATRICS AND CLINICAL GERONTOLOGY

M. Bernard[1], K. High[2], *1. National Institute on Aging, Bethesda, Maryland, 2. Wake Forest University School of Medicine, Winston Salem, North Carolina*

The NIA's Division of Geriatrics and Clinical Gerontology (DGCG) supports inquiry on health and disease in the aged and research on aging over the human lifespan. These goals are accomplished through three major research areas: Geriatrics, Clinical Gerontology, and Clinical Trials. In addition to supporting paradigm-shifting research by individual investigators, the Division has fostered an important focus on health span and maintaining independence through its Claude D. Pepper Older Americans Independence Centers, invested in critical longitudinal cohorts that are widely shared among the investigative community, and led important public-private collaborations that have broken new ground in research training and career development through the Paul B. Beeson Scholars and GEMSSTAR awards. These accomplishments and the future focus of Divisional activities including a burgeoning partnership with the CMS-sponsored Patient Center Outcomes Research Initiative will be reviewed.

SESSION 1990 (SYMPOSIUM)

RISK FACTORS FOR SUSCEPTIBILITY TO DYSFUNCTION IN THE ELDERLY

Chair: C.A. Peterson, *University of Kentucky, Lexington, Kentucky*

Aging is associated with increased variability in response to exercise, nutritional supplements and drug treatment, likely influenced by an individual's genetic makeup, as well as by environmental stimuli. This session will highlight new information related to individual variability in the elderly. Jingzhong Ding, Wake Forest University, will present his work on "Transcriptomics of aging and related diseases"; Sarah Hilmer, University of Sydney, will discuss "Altered susceptibility to drug hepatotoxicity in ageing"; and Janko Nikolich, University of Arizona & Ben Zaniello, University of Washington will present new results on "Lifelong CMV infection, aging and protective immunity: basic mechanisms and clinical implications".

LIFELONG CMV INFECTION, AGING AND PROTECTIVE IMMUNITY: BASIC MECHANISMS AND CLINICAL IMPLICATIONS

B. Zaniello[1], J. Nikolich-Zugich[2], *1. University of Washington, Seattle, Washington, 2. University of Arizona, Tuscon, Arizona*

The loss of immune responsiveness to antigens in the elderly is a key obstacle to healthy aging but its cause is poorly understood. Epidemiologic research suggests that cytomegalovirus (CMV, a β-herpesvirus) seropositivity in the elderly is associated with greater mortality and morbidity and laboratory data indicate one possible mechanism may be chronic CMV reactivation and its impact on the immune system. We will discuss what is known about this mechanism via existing animal models and clinical studies. Topics will include CMV-mediated immune system changes (the high percentage of CMV-specific T-cells vs. naïve T-cells, i.e. "memory inflation"), CMV-induced inflammation, and the influence of the virus on vaccine and infection response.

AGING-RELATED TRANSCRIPTOMIC CHANGES AND DISEASE IMPLICATIONS: THE ROLE OF MITOCHONDRIAL FUNCTION

J. Ding[1], L.M. Reynolds[3], J.R. Taylor[1], K. Lohman[3], S.B. Kritchevsky[1], D.M. Herrington[1], I. Hoeschele[2], Y. Liu[3], *1. Gerontology, Wake Forest School of Medicine, Winston-Salem, North Carolina, 2. Virginia Tech Carilion School of Medicine, Roanoke, North Carolina, 3. Public Health Sciences, Wake Forest School of Medicine, Winston-Salem, North Carolina*

Aging-related transcriptomic changes may have important clinical implications in aging-related diseases. A number of genome-wide transcriptional analyses of various tissues including the brain and skeletal muscle across human, rat and mouse have demonstrated that mitochondrial genes are down-regulated with increasing age. Our transcriptomic data in purified human monocytes from 1,264 community-based men and women aged 55-94 years support the notion that under-expression of mitochondrial genes is a cellular feature of aging, rather than merely reflecting changes in the composition of the cell population. We further show that transcriptional profiles of mitochondrial genes, especially related to oxidative phosphorylation, are positively associated cognitive function at a genome-wide significance level (false discovery rate<0.05). These findings are consistent with transgenic studies in mice that suggest a potential causal role of mitochondrial dysfunction in aging-related pathologies. Evaluation of transcriptional changes in disease-relevant human cells holds great promise to unravel molecular mechanisms underlying aging-related diseases. Objectives: After attending this activity, participants will be able to explain aging-related transcriptional changes and discuss the role of mitochondrial dysfunction in cognitive decline.

ALTERED SUSCEPTIBILITY TO DRUG HEPATOTOXICITY IN AGEING

S. Hilmer, *Royal North Shore Hospital, Kolling Insitute of Medical Research, University of Sydney, St Leonards, New South Wales, Australia*

Drug hepatotoxicity is the commonest cause of acute liver failure. It increases with age in pharmacovigilance studies for reasons that are unknown. We investigated the age-related risk of hepatotoxicity after treatment with acute toxic doses of acetaminophen/vehicle, or isoniazid/vehicle, and characterised potential pharmacokinetic and pharmacodynamic mechanisms in young adult and old male Fischer 344 rats. Old age was not associated with an increased risk of hepatotoxicity with either drug on histology, and young animals had higher serum concentrations of transaminases (markers of hepatotoxicity). We found differences with age in pharmacokinetics (transfer across the liver sinusoidal endothelium and hepatic enzyme function) and pharmacodynamics (inflammatory and cell death pathways). Calorie restriction prevented acetaminophen hepatotoxicity in all age groups. These findings have implications for potential therapeutics to prevent and treat drug hepatotoxicity, as well as for understanding the response to toxins and other stressors in old age.

SESSION 1995 (SYMPOSIUM)

A COMPREHENSIVE CONTINUUM TRAINING MODEL TO BUILD CAPACITY IN GERIATRICS

Chair: J.L. Howe, *Bronx GRECC at James J. Peters VAMC, New York, New York, Brookdale Department of Geriatrics and Palliative Medicine, Mount Sinai School of Medicine & JJ Peters VAMC, Bronx, New York*

The Geriatric Education Rural-urban Alliance (GERA) is a partnership of six programs funded by the VHA Office of Rural Health that provide a teaching-learning continuum from healthcare trainees to seasoned healthcare providers. This approach enhances VA's opportunity to retain and attract well-trained providers. Training for licensed healthcare professionals is based on the philosophy of competency-based continuous professional development and includes distance, experiential, team-based, and intensive face-to-face learning; focused specialist consultation to primary care providers; and facilitated practice change. GERA healthcare trainees are mentored by licensed providers and have rural clinical rotations, exposure to telehealth modalities, weekly seminars, reflective activities, documented self paced web- based learning, and weekly seminars. While each component has distinct outcomes at learner and team levels, the overall evaluation is replication in other healthcare settings.

ACTION LEARNING FOR THE CARE OF RURAL OLDER VETERANS WITH COMPLEXITY AND COGNITIVE IMPAIRMENT

C. Cigolle[1,2], K.K. Phillips[1], J.A. Wagner-Felkey[1], D. Scarpace[1], *1. VA Ann Arbor Healthcare System (VAAAHS) Geriatric Research, Education and Clinical Center (GRECC), Ann Arbor, Michigan, 2. University of Michigan, Ann Arbor, Michigan*

The VA Ann Arbor Healthcare System (VAAAHS) Geriatric Research, Education and Clinical Center is leading the Action Learning for the Care of Rural Older Veterans with Complexity and Cognitive Impairment, to train and support rural VA providers/teams. The project tailors and disseminates to rural sites content regarding complexity and cognitive impairment in older adults (prioritization of healthcare conditions/interventions, dementia, caregiver burden). It emphasizes use of accessible tools, algorithms, and templates (screening tools, medication reconciliation tools). An innovative component is action learning for rural providers/teams. This learning is nested in a model of collaborative care between rural providers and the VAAAHS outpatient geriatric multidisciplinary team, with ongoing consultation and collaboration using e-consults, phone consults, televised visits, etc. Rather than adding to rural providers' burden in caring for complex older Veterans, this model leverages and disseminates multidisciplinary expertise and support from VAAAHS to facilitate and assist with time-intensive care at rural sites.

PARTNERING WITH RURAL COMMUNITIES TO PROVIDE EDUCATION ABOUT VETERAN RESOURCES

R. Rupper[1,2], B.L. Hicken[3], *1. Salt Lake VA GRECC, Salt Lake City, Utah, 2. Medical University of South Carolina, Salt Lake City, Utah, 3. Veterans Rural Health Resource Center, Salt Lake City, Utah*

A disproportionate percentage of veterans are both rural and older. However, rural community resource providers often are unaware of benefits that may assist these veterans; and, VA providers may be similarly unaware of community specific resources. We present a portfolio of coordinated initiatives, funded by the VA Office of Rural Health, and implemented with support from the Salt Lake City GRECC, that educate VA and community providers about complementary resources that address the needs of older rural veterans. We include updates about: a program designed to train options counselors at Aging and Disability Resource Centers and to connect them to VA community based outpatient clinics, a pilot to electronically communicate with contract home health providers, and a program to develop rural community partnerships that include the VA. These programs exemplify how education and communication between the VA and communities can improve the coordination of resource provision to older rural veterans.

TAILORING EDUCATIONAL SUPPORT TO THE NEEDS OF VETERAN PATIENTS

J.M. Butler[1,2], R. Rupper[1,2], M. Supiano[1,2], *1. Division of Geriatrics, University of Utah, Salt Lake CIty, UT, Utah, 2. Salt Lake VA GRECC, Salt Lake City, Utah*

The Salt Lake City VHA Geriatrics Research Education and Clinical Center (GRECC) in partnership with the Salt Lake VHA Center of Excellence (COE) in Musculoskeletal (MSK) Health is leading a Rural Provider and Staff Training Initiative (RPSTI) funded by the VHA Office of Rural Health (ORH) . This program, Patient-Centered Education for Rural CBOC Providers, supports providers and staff in rural areas caring for geriatric Veteran patients within Community Based Outpatient Clinics (CBOCs). The cornerstone of the Salt Lake City RPSTI is educational content that is tailored to areas of clinical need, identified by ongoing review of the clinical characteristics of CBOC providers' patient panels and receive personalized recommendation for educational support in polypharmacy/medication management, dementia diagnosis and management, multimorbidities, end of life care (advance directives), and musculoskeletal examination. Our program also provides educational training using multiple modalities including webinars, decision support tools, and expert consultations.

VA GRECC SYMPOSIUM: GERIATRICS EDUCATION FOR VA HEALTH CARE PROVIDERS IN RURAL AREAS

J.M. Butler[1,2], R.M. Allman[3], *1. University of Utah, Salt Lake CIty, UT, Utah, 2. VA Salt Lake City, Salt Lake City, Utah, 3. Veteran's Health Affairs, Washington DC, District of Columbia*

The Veteran's Health Administration (VHA) network of Geriatric Research Education and Clinical Centers (GRECCs) were conceived to care for the aging veteran population. A central component of the GRECC mission is education for health care providers to assist them in caring for aging patients. Most Veterans in rural areas areas of the United States are over 65. Many providers in rural areas are primary care providers who have limited training in Geriatrics and Gerontology and limited access to specialty care clinicians. Thus, there is a critical need for education for rural providers caring for Veterans. In response to this need, several VHA GRECCs have generated innovative programs to provide education for many levels of providers caring for Veterans in rural areas. These programs include multiple learning modalities from hands on training experiences, to distance learning seminars, to educational interventions tailored to demonstrated clinical needs. In this symposium, we will present the educational efforts coordinated by multiple GRECCs across the country. Educational innovations will be stressed. Implications for future interventions and needed research support will also be addressed.

SESSION 2000 (SYMPOSIUM)

THE HOMEBOUND ELDERLY AND HOME-CENTERED PRIMARY CARE: MEASUREMENT, QUALITY AND OUTCOMES

Chair: K. Ornstein, *geriatrics, mount sinai, New York, New York*
Discussant: P.H. Feldman, *Visiting Nurse Service of New York, New York, New York*

The homebound elderly are a highly vulnerable population with significant functional impairment, multiple chronic illnesses, and complex care needs. Through our current era of healthcare reform, programs are increasingly being developed to better address the healthcare needs of the homebound elderly. In order to effectively meet the complex care needs of this uniquely underserved population, the homebound population needs to be well-characterized and quantified. Furthermore, we need to understand how we can improve outcomes for this population and to define what constitutes quality of care for this population. The four papers in this symposium define and describe the homebound elderly population and their environment and explore ways in which home-centered care may address their primary and palliative care needs. Two papers aim to examine what it means to be homebound using a nationally representative sample. The first presentation uses data from the National Health and Aging Trends study (NHATS) to determine a range of national prevalence estimates of the homebound living in the community. Using these definitions of homebound, the next presenter uses data from the NHATS study to examine environmental and social correlates of inability to leave the home. With data from a prospective cohort study, the third presentation provides evidence on the role of home-centered care in reducing hospital admissions for the homebound. The final presentation will describe the development of quality indicators for home-centered primary care. Our discussant, Penny Feldman, will give perspective on long-term care policy implication of research findings.

DETERMINING THE PREVALENCE OF THE HOMEBOUND ELDERLY IN THE U.S

K. Ornstein[1], B. Leff[2], L. Roberts[2], K. Covinsky[3], A. Federman[1], C. Ritchie[3], S. Szanton[2], *1. geriatrics, mount sinai, New York, New York, 2. Johns Hopkins, Baltimore, Maryland, 3. UCSF, San Francisco, California*

As the complex care needs of the growing population of elderly homebound are increasingly being recognized, new programs are being developed to support them. Yet there are currently no population estimates of the prevalence of homebound in the U.S. Using the National Health and Aging Trends Study(NHATS), we developed several definitions of homebound status and applied analytic weights to determine national prevalence estimates of the community-dwelling elderly over age 65 (n=7609). Homebound prevalence estimates ranged widely. Using our most conservative definition, "individuals who never left the house in the last month", 1.12% of the population is homebound. 2.56% "never went out or had a lot of difficulty doing so." 17.88% of the elderly population could be considered homebound based on inability to go out independently or difficulty going out alone. A better understanding of the epidemiology of being homebound is critical to providing high quality care for this underserved population.

HOME BUT STILL ENGAGED: FUNCTIONAL AND SOCIAL CORRELATES OF BEING HOMEBOUND

S. Szanton[1], L. Roberts[1], B. Leff[1], A. Federman[3], K. Covinsky[2], C. Ritchie[2], C.L. Seplaki[4], K. Ornstein[3], *1. Johns Hopkins University, Baltimore, Maryland, 2. University of California San Francisco, San Francisco, California, 3. Mount Sinai Medical School, New York, New York, 4. University of Rochester, Rochester, New York*

Lack of national data identifying the homebound and the resultant knowledge gap of homebound population's characteristics has created challenges in designing relevant services. Using the most stringent definition of homebound in the NHATS dataset, those who never left their home in the last month, we examined correlates of being homebound. Those who are homebound are much more likely than their counterparts in the overall sample to: report difficulty with self care (e.g. 80% vs. 14% for bathing), report more depressive symptoms ($B=1.88$, $p<0.001$) and to have fallen recently ($OR=2.25$, $p<0.05$). Although homebound persons never left home in the past month, 6% provide care for others, 37% say it is important to them to visit family and friends, and 40% endorse going to religious services as important. This underserved population has unmet care needs yet still seeks to be involved in family and community life. These findings provide potential intervention targets.

HOSPITAL ADMISSIONS BY HOMEBOUND ADULTS IN PHYSICIAN OR NURSE HOME VISIT PROGRAMS IN NEW YORK CITY

A. Federman[1], A. Wajnberg[1], D. Russell[2], J. Ross[3], *1. Medicine, Icahn School of Medicine at Mount Sinai, New York, New York, 2. Visiting Nurse Service of New York, New York, New York, 3. Yale University School of Medicine, New Haven, Connecticut*

We compared the effects of physician (MD) and nurse (RN) home-visit programs on hospitalizations among homebound older adults. The study included English and Spanish speakers ≥65 years meeting Medicare criteria for homebound and newly enrolled in a MD home visit program (n=103) or a RN directed long-term home visit program (n=77). Hospitalizations were assessed monthly by patient or proxy self-report. We estimated the incidence rate ratio in multivariable models with matching by propensity for MD program participation. Overall, 41% had ≥1 admission within 3 months of program enrollment. Total hospitalizations were 51 (mean person-days of observation, 318, sd 121) and 49 (person-days 265, sd 134) for the MD and RN programs, respectively. Hospitalization rate for MD program patients was lower (adjusted IRR 0.65, 95% confidence interval 0.41-0.71). MD home visits may reduce hospitalizations among homebound elders compared to RN home care alone. Randomized trials are needed to confirm these findings.

DEVELOPMENT OF HOME-CENTERED PRIMARY CARE QUALITY INDICATORS

B. Leff[1], C. Ritchie[2], *1. Johns Hopkins University School of Medicine, Baltimore, Maryland, 2. University of California San Francisco, San Francisco, California*

Home-centered medical practices face a practice environment in which there are no valid, reliable, recognized or appropriate measures for their patients. Most of these practices, at least in part because of the inappropriateness of current measures, don't engage in quality improvement efforts or performance reporting. They lack methods to benchmark the quality of care they provide against other practices, and are encouraged to use measures for quality reporting and performance bonus payments that are not suitable for their patients. This may drive inappropriate health service use and put patients at risk of adverse events. This lack of appropriate quality measures is especially critical in the context of policy and payment. In this symposium, we will describe the work of the Home-centered Primary/Palliative Care Network to develop quality indicators for these practices, as well as efforts to develop a national practice-based registry to facilitate real-time practice-based quality improvement efforts.

SESSION 2005 (SYMPOSIUM)

AGING WELL AS A MATTER OF TRUST

Chair: L. D'Ambrosio, *AgeLab, MIT, Cambridge, Massachusetts*
Co-Chair: F. Oswald, *Goethe University, Frankfurt, Germany*
Discussant: A. Mahmood, *Simon Fraser University, Vancouver, British Columbia, Canada*

The concept of aging well has largely been focused on what individuals can do to maintain their physical and cognitive health, what kinds of technology should be developed, or what changes in the environment could make it easier for people to live in their physical space. When trust has been considered, it has often been in the context of interpersonal trust, social capital and trust in technology. Yet trust is a multifaceted concept, encompassing the environment, physical, social and institutional systems, and technology, in addition to interpersonal trust. The focus of this symposium is to explore how trust, in social, physical and institutional environments, might be relevant to aging well. First, Annette Franke will provide a brief overview of the concept of trust. Chaiwoo Lee will examine how different concepts of trust affect older adults' willingness to adopt and use technologies. Birgit Kramer traces the role of trust for well-being around technology use in dementia care among caregivers at home. Adopting a biographical qualitative approach, Nadine Konopik presents the appearance of trust-related topics in self reports on health literacy processes. Using survey data, Dana Ellis will report on the ways in which different concepts of trust contribute to older adults' well-being. Finally, Atiya Mahmood will serve as the session's discussant.

THE ROLE OF TRUST IN THE CONCEPT OF HEALTH LITERACY IN LATER LIFE

N. Konopik, I. Himmelsbach, F. Oswald, *Goethe-University, Frankfurt am Main, Germany*

The aim of this study is threefold: (1) Using a person-environment interaction perspective to better understand how and why older people practice health promotion within the context of ageing in place. (2) Exploring how the experience of one's own health and health literacy develops over the life-span as well as how these perspectives are integrated into biographical narratives. (3) Identifying topics of trust across different domains of health literacy. Data are drawn from biographical in-depth interviews with 12 older women and men who participated in a survey on health literacy of older adults (using the European Health Literacy Survey Questionnaire HLS-EU-S-Q) with 463 community-dwelling elders from three urban districts (Frankfurt, Germany). Findings show that trust matters in autobiographical narratives with respect to health literacy processes of "access", "understand", "appraise", "apply", and the role of the neighborhood. In sum, the findings shall help to optimize existing health literacy programs and services.

A QUESTION OF TRUST: AN INTRODUCTION TO CORE CONCEPTS

A.A. Franke, *Network Aging Research, Heidelberg University, Heidelberg, Germany*

Trust is an important, versatile but also somewhat vague concept in ageing well. Related to other concepts as reliability, confidence and integrity it represents a core element of belief and understanding in the environment and relationships between people, or between people and social institutions. These multiple dimensions of trust lead over to an increased awareness in various disciplines as sociology, psychology, and economics. In academic literature trust is declared as a process and an outcome, mental state and attitude, which predict acceptance of measures or technological appliances (Castelfranchi & Falcone 2010; Luhmann, 1979; Misztal 1996; Rotter 1971). Recently, the use of the term trust reflects an increasing interest in the adaption of older individuals in the context of modern societies (globalization, reflexivity, technological developments). This abstract as an introduction for the proposed symposium highlights core concepts and approaches towards trust in social, physical and institutional environments.

IMPLEMENTING NEW TECHNOLOGIES IN DEMENTIA CARE - THE ROLE OF TRUST

B. Kramer, *Network Aging Research, Heidelberg University, Heidelberg, Germany*

New technologies in dementia care can contribute to well-being in two ways: reducing caregiver burden and helping people with dementia to stay longer in their familiar environment. Here we provide results concerning trust from an interview-study with 105 caregivers that examined technology acceptance in dementia care at home in Germany. We found the topic of trust in different facets during the interviews: First, there needs to be trust in the technology itself. Also important is the trust in people who suggest the use of technologies, and in those who install and maintain the technology. Crucial is the trust in oneself - caregivers need to feel capable of using the technology. Last but not least is trust in the environment– it's important that the use of technologies in care is socially acceptable. These findings underscore the importance of trust from different dimensions when introducing and implementing new technologies in dementia care.

THE ROLE OF TRUST IN OLDER ADULTS' ADOPTION AND USE OF TECHNOLOGY

C. Lee, *Massachusetts Institute of Technology, Cambridge, Massachusetts*

Older adults' adoption and use of technology is a multidimensional topic that is affected by a range of technical, individual and social characteristics. As older adults engage in making decisions around accepting and using new technologies, various factors can act to facilitate or hinder adoption. An important characteristic of such adoption factors is that they ultimately rely on the how they are perceived and understood by older adults. Furthermore, the perceptions and attitudes toward the new technologies are again influenced by the degree to which they trust the related information and organizations as well as the technologies themselves. This presentation will explore and describe how various concepts of trust influence older adults' perceptions, attitudes and behaviors around adoption and use of new technologies. The results of a survey on technology adoption and use, conducted with over 600 adults in the United States, will be discussed with quantitative and qualitative data.

THE EFFECT OF DIFFERENT ASPECTS OF TRUST ON HEALTH, WEALTH, AND NAVIGATING OLD AGE

D. Ellis, J. Coughlin, L. D'Ambrosio, *AgeLab, MIT, Cambridge, Massachusetts*

While medicine, technology, education and public health have yielded a longevity bonus, this has come at some cost. In part, aging in the modern world brings with it more complex questions and high-risk issues than ever before, as family members may live at a distance and people have retirement as a new phase of life to plan for. Older adults thus face a myriad of choices and options. Trust has been one way to cut through complexity of these numerous choices to decide on the right product, service, store, advisor, or physician. A combination of technological advancements and recent events, however, has contributed to declining levels of reported trust in others and in institutions. This paper explores which facets of trust have declined and which have strengthened, and the implications of this trust on older adults' well-being, wealth management, and navigation of old age.

SESSION 2010 (SYMPOSIUM)

UNDERSTANDING THE ROLE AND CLINICAL UTILITY OF READINESS TO CHANGE IN WELL-BEING OUTCOMES FOR INDIVIDUALS WITH DEMENTIA AND THEIR FAMILY CAREGIVERS

Chair: K. Judge, *Psychology, Cleveland State University, Cleveland, Ohio*
Co-Chair: E. Shelton, *Psychology, Cleveland State University, Cleveland, Ohio*
Discussant: K. Judge, *Psychology, Cleveland State University, Cleveland, Ohio*

Guided by the Transtheoretical Model of Stages of Change, the proposed symposium examines the role and clinical utility of the construct Readiness to Change (RTC) as applied to a sample of individuals with dementia (IWDs) and their caregivers. RTC is comprised of five distinct stages (Precontemplation, Contemplation, Preparation, Action, and Maintenance) that reflect an individual's readiness to engage in behavioral, cognitive, and attitudinal changes. Few studies have applied this framework to understand how IWDs and their caregivers may vary in their respective levels of readiness to address dementia-related care issues. Furthermore, RTC may provide useful information for understanding the illness experience of each care partner and facilitate intervention development. The first paper examines how RTC as measured by Precontemplation and Action were significant in predicting caregiver's level of anxiety and quality of life, respectively. Discussion highlights how RTC can be used to facilitate effective interventions for dementia caregivers. The second paper found RTC to significantly moderate both IWD's and caregiver's depression based on the level of distressed they experienced due to IWD's memory loss. Discussion focuses on understanding the underlying mechanisms along with how to develop dyadic interventions. The third paper examines how caregivers who completed a dyadic intervention protocol scored on RTC. Using case study methodology, this paper highlights how RTC can be used to tailor caregiver interventions. The discussant will explore how this line of research fits within the current field and outline next steps needed to further understand the research and clinical utility of RTC.

THE IMPACT OF READINESS TO CHANGE AS A KEY PREDICTOR OF PSYCHOSOCIAL OUTCOMES IN DEMENTIA CAREGIVING

M.N. Scruggs[1], K. Judge[1], S. Yarry[2], *1. Psychology, Cleveland State University, Cleveland, Ohio, 2. VA Healthcare System, New York, New York*

Understanding the unique challenges and dynamics of providing care for individuals with dementia has become increasingly important. The current study investigated the impact of caregiver's readiness to change in addition to age, gender, race, and difficulty and distress of IADLs on the psychosocial outcomes of anxiety, depression, and quality of life. Separate regression analyses (n=118) were conducted for readiness to change stages of Precontemplation and Action. Results found caregivers with higher amounts of distress caused by IADLs and lower amounts of Precontemplation had greater anxiety, while caregivers with higher Action scores experienced greater quality of life. Greater difficulty and distress caused by IADLs also were significant indicators of lower quality of life. These findings highlight the importance of including readiness to change. Discussion will focus on how to use this information when working with caregivers in an attempt to improve quality of life and reduce anxiety in caregivers.

READINESS TO CHANGE: CLINICAL APPLICATIONS FOR PSYCHOSOCIAL INTERVENTIONS WITH DEMENTIA CAREGIVERS

S. Yarry[1], K. Judge[2], *1. VA New York Harbor Health Care System, Brooklyn, New York, 2. Cleveland State University, Cleveland, Ohio*

Readiness to change (Prochaska & DiClemente, 1983) may be a meaningful component of dementia caregivers' participation in psychosocial interventions (Yarry, Judge, & McCallum, 2009). Strength-based interventions (Judge, Yarry, & Orsulic-Jeras, 2009) are well-suited to tailor skills to fit caregivers' unique needs, including stage of readiness to change. In a sample of 58 caregivers enrolled in a psychoeducational intervention (Judge, 2007), no caregivers were classified into the Precontemplation stage and the majority of participants indicated a willingness to change caregiving behaviors to varying degrees (Contemplation: n = 7, Preparation, n = 15, Action: n = 20, and Maintenance: n = 16). Guidelines for tailoring intervention protocols to fit participants' unique care needs based on readiness to change will be discussed. The benefit of a strength-based approach incorporating readiness to change in designing psychosocial interventions will be illustrated using a case study methodology.

MEMORY IMPAIRMENT AND THE MODERATING EFFECT OF READINESS TO CHANGE

E. Shelton[1], K. Judge[1], S. Yarry[2], *1. Cleveland State University, Cleveland, Ohio, 2. VA Palo Alto Health Care System, Palo Alto, California*

The Transtheoretical Model (TTM) of behavior change outlines a five-stage categorization of an individual's readiness to alter a behavior. This model has been used as a basis for understanding the behavioral change process and for tailoring interventions (e.g., smoking cessation and weight management). Little research exists, however, applying the TTM to behaviors among individuals with dementia (IWDs) and their caregivers (CGs). The present research examined the moderating effect of readiness to change on psychosocial outcomes. Findings indicate that readiness to change is an especially strong moderator of the relationship between memory related distress and depression among both the CG and the IWD. The moderation effect was such that high levels of memory related distress and high readiness to change in IWDs was predictive of high levels of depression in both IWDs and their family CG. The possible mechanisms underlying this relationship and the use of targeted intervention strategies are discussed.

SESSION 2015 (SYMPOSIUM)

LIFE SATISFACTION AND ITS PREDICTORS IN VERY OLD AGE: FINDINGS FROM THE SECOND HEIDELBERG CENTENARIAN STUDY

Chair: D.S. Jopp, *Psychology, Fordham University, Bronx, New York*

Despite the fact that more and more individuals reach very old age, research on what contributes to well-being at this advanced age is still limited. Increasing the understanding on predictors of well-being was a central research goal of the population-based Second Heidelberg Centenarian Study (N = 113). Findings indicate that despite suffering from limitations and loss in all central life domains, over 80% of the centenarians reported being satisfied with their life. Only a few health (e.g., subjective health, vision), social (e.g., loneliness) and environmental aspects (e.g., living with others) were significantly correlated to life satisfaction. By contrast, all assessed psychological strengths (i.e., self-efficacy, optimistic outlook, meaning in life and will to live) had significant correlations to life satisfaction. Regression analysis showed that being optimistic was the strongest independent predictor, followed by living with others and self-efficacy, highlighting the role of psychological strengths for well-being in very old age.

INTERGENERATIONAL AMBIVALENCE: CARE CHALLENGES FACING PORTUGUESE CENTENARIANS

O. Ribeiro[1,2,3], L. Teixeira[1], L. Araújo[1], N. Duarte[1], D. Brandão[1], I. Martin[1,3], C. Paúl[1], *1. ICBAS - Institute of Biomedical Sciences Abel Salazar, UNIFAI, Porto, Portugal, 2. ISSSP, Porto, Portugal, 3. University of Aveiro, Aveiro, Portugal*

Intergenerational ambivalence in later life is not a new theme in gerontology but it has rarely been studied within the context of centenarians' family ties, which are often characterized by internalized social norms of filial responsibilities. This paper presents findings from the Oporto Centenarian Study and considers informal caregivers who provided continuous care to a centenarian living in the same household. A total of 60 dyads were assessed on the overall caregiving experience with direct and indirect measures of intergenerational ambivalence and of psychological well-being. Caregivers were then clustered in three distinct groups: "extremely burdened", "mostly satisfied with the role" and "ambivalent". Main findings revealed that the demands of care tend to be surpassed by the existence of an overall rewarding experience, and that both ambivalence and satisfaction with the role were related to higher levels of well-being of the caregiver and the centenarian.

PHYSICAL, SENSORY, AND COGNITIVE FUNCTIONING AMONG CENTENARIANS: A COMPARISON BETWEEN THE TOKYO AND GEORGIA CENTENARIAN STUDIES

P. Martin[1], Y. Gondo[2], Y. Arai[3], Y. Ishioka[4], L. Poon[5], N. Hirose[3], *1. Iowa State University, Ames, Iowa, 2. Osaka University, Osaka, Japan, 3. Keio University, Tokyo, Japan, 4. Tokyo Metropolitan Institute of Gerontology, Tokyo, Japan, 5. University of Georgia, Athens, Georgia*

Centenarians are seen as survivorship champions but their level of functioning is often compromised. The purpose of this study was to compare centenarians in the United States with centenarians in Japan on cognitive, sensory, and physical functioning. The sample of U. S. centenarians was recruited from the Georgia Centenarian Study and included 287 centenarians. The sample of Japanese centenarians was recruited from the Tokyo Centenarian Study and included 304 centenarians. Cognitive functioning was assessed with a mental status questionnaire, sensory impairment by general assessments of vision and hearing, and physical function was by activities of daily living. The results suggest that centenarians from the Georgia study showed higher levels of functioning when compared to the Tokyo sample. A structural equation model yielded stronger associations between cognitive and sensory impairment with physical function for the Tokyo sample. Different care patterns in each country may explain the results.

SENSORY IMPAIRMENTS IN CENTENARIANS: PREVALENCE AND LINKS TO WELL-BEING

V. Cimarolli[1], D.S. Jopp[2], K. Boerner[1,3], *1. Jewish Home Lifecare, New York, New York, 2. Fordham University, Bronx, New York, 3. Icahn School of Medicine at Mt. Sinai, New York, New York*

The purpose of this study was to document the prevalence of self-reported vision, hearing, and dual sensory impairment and to explore how these impairments are linked with well-being. In-person interviews with a sample of centenarians (N=119) included self-ratings of quality of vision and hearing ability and an assessment of depressive symptoms. Based on self-report ratings, 17% of participants could be classified as having a visual impairment only, 18% as having a hearing impairment only, and 38% with both a visual and hearing impairment (dual sensory impairment). A One-way ANOVA showed that dual sensory impaired centenarians had significantly higher depression levels when compared to those without impairments and those with a hearing impairment only. This study indicates that sensory impairments - especially dual sensory impairment - are prevalent in the oldest-old and that having a dual sensory impairment is related to less optimal well-being.

PREDICTORS OF SUBJECTIVE WELL-BEING AMONG JAPANESE CENTENARIANS

T. Nakagawa[1], Y. Gondo[1], Y. Masui[2], H. Inagaki[2], Y. Arai[3], N. Hirose[3], *1. Osaka University, Suita, Osaka, Japan, 2. Tokyo Metropolitan Institute of Gerontology, Itabashi, Tokyo, Japan, 3. Keio University, Minato, Tokyo, Japan*

Adverse situations such as decline of physical function are inevitable in very old age. However, a few studies indicate that subjective well-being remains relatively stable even in the oldest-old. By using the data of Tokyo Centenarians Study, the current study investigated predictors of subjective well-being in extremely old age. We targeted 59 centenarians who answered self-reports and were cognitively intact. Multiple regression analyses were conducted to examine the role of demographic, social, health, and psychological resources. Results indicated that only low neuroticism predicted high morale. Additional analyses suggested that predictors could differ among subfactors of morale. For attitude toward own aging, living with someone was related with higher morale. For dissatisfaction, heart disease linked to lower morale. We note that the present study contained methodological limitations; selective mortality and selection bias. Participants who answered self-reports were more independent than those who didn't. Longitudinal study and selectivity analyses should be conducted.

WELL-BEING AND HEALTH IN CENTENARIANS: FINDINGS FROM GERMANY, JAPAN, PORTUGAL, AND THE USA

D.S. Jopp[1], C. Paul[2], *1. Psychology, Fordham University, Bronx, New York, 2. UnIFai, ICBAS, Universidade do Porto, Oporto, Portugal*

Increase in the number of very old individuals, including centenarians, in developed countries is a worldwide trend. Ensuring quality of life at this advanced age therefore has become a global, 21th century challenges. Given that countries are characterized by different cultures (e.g., views on aging or attitudes towards formal care), investigating which person factors as well as aspects of the immediate social and wider environmental setting contribute to quality of life is an important research question in order to find out similarities as well as differences in the predictive value of these factors. This symposium presents findings on well-being and health from five centenarian studies. Specifically, Martin and colleagues investigate physical and sensory health, and cognition in the Georgia Centenarian Study and the Tokyo Centenarian Study. Cimarolli and Jopp report prevalence of sensory impairment and their links to depression in the Fordham Centenarian Study. Ribeiro and colleagues examine the role of intergenerational relationship quality for the well-being of centenarians and their advanced age children caregivers within the Oporto Centenarian Study. Nakagawa and colleagues investigate the role of demographic, social, health, and psychological resources on well-being within the Tokyo Centenarian Study. Finally, Jopp and colleagues present findings on predictors of life-satisfaction using data from the Second Heidelberg Centenarian Study. In sum, findings from centenarian studies from around the world highlight the importance of person (e.g., health, psychological strengths), social (e.g., relationship quality) and wider environmental aspects (e.g., living with others) for ensuring quality of life in very old age.

SESSION 2020 (SYMPOSIUM)

THE CONTEXTS OF RAISING GRANDCHILDREN: BODIES, FAMILIES, SCHOOLS, POLICIES AND COUNTRIES

Chair: L. Yancura, *University of Hawaii at Manoa, Honolulu, Hawaii*
Co-Chair: M.L. Dolbin-MacNab, *Virginia Tech, Blacksburg, Virginia*
Discussant: E. Fuller-Thomson, *University of Toronto, Toronto, Ontario, Canada*

As evidenced by the theme of this year's GSA conference, From Cells to Societies, successful aging is influenced by many interconnected contexts, ranging from the intrapersonal to the broader sociopolitical. The presentations in this symposium will examine the variety of contexts in which grandparents raising grandchildren are embedded, with a focus on the experiences and well-being of custodial grandparents. The first presentation, by Ryder, will focus on the physical health of grandmothers with chronic health conditions. These women reported neglecting their own health in order to focus on grandchildrens' needs. The second presentation, by Lee, will use qualitative data from both grandparents raising grandchildren and school staff to examine role conflict and expectations associated with grandparents' experiences in school settings. This study found heterogeneity in cultural expectations for grandchildrens' learning among grandparents and staff. In the third presentation, Lent and Butts will describe successful advocacy efforts for policies that support grandfamilies on local, state, and federal levels in the United States. The final presentation, by Dolbin-MacNab and Yancura, will focus on grandfamilies in global contexts, examining how cultural and sociopolitical contexts around the world influence grandparents' reasons for caregiving as well as the needs and experiences of their families. This examination will be supported with detailed case studies of grandfamilies in South Africa and China. Taken together, the presentations in this symposium highlight the multiple contexts in which grandparents are raising grandchildren are embedded and how the interconnections among these various contexts profoundly impact grandparents and grandchildren alike.

GLOBAL PERSPECTIVES ON GRANDPARENTS RAISING GRANDCHILDREN: INFLUENCES OF SOCIOPOLITICAL CONTEXTS

M.L. Dolbin-MacNab[1], L. Yancura[2], *1. Human Development, Virginia Tech, Blacksburg, Virginia, 2. University of Hawai'i at Manoa, Honolulu, Hawaii*

Globally, grandparents are often primarily responsible for providing care to children who cannot be cared for by their parents. While grandparents raising grandchildren is common in both industrialized and developing nations, it is most common in Asia, Sub-Saharan Africa, and South America. In this presentation, we will discuss grandparents raising grandchildren from a global perspective, with an emphasis on examining how cultural and sociopolitical contexts influence grandparents' reasons for caregiving as well as their needs and experiences. We will also address social policy initiatives and intervention programs available to assist grandparent caregivers and their grandchildren. To aid our presentation, we will offer in-depth discussions of grandparents raising grandchildren in South Africa and China, among other countries. These in-depth discussions, which will illustrate the importance of viewing custodial grandparents contextually, will also serve as basis for providing suggestions related to future directions for research, practice, and policy.

GRAND ADVOCACY: USING RESEARCH TO SUPPORT BETTER POLICIES FOR GRANDFAMILIES

J.P. Lent, *Generations United, Washington, District of Columbia*

Research and awareness are growing about the importance of keeping children with grandparents or other relatives when they cannot safely remain with their birth parents. Strategic advocates have used this increased evidence base along with powerful anecdotes to back successful efforts to secure federal and state policies to better support these families, known as grandfamilies. This presentation will demonstrate how resulting supportive policies have led to more effective practices and increased services for grandfamilies through Area Agencies on Aging, legal aid programs, academic institutions, child welfare agencies, and nonprofit organizations. It will highlight outstanding policy barriers and challenges to effective implementation of relevant legislation. The presenter will discuss strategies to approach these barriers including relevant legislation, new collaborations among aging and children's advocacy organizations, grassroots engagement and efforts to build the advocacy capacity of organizations serving grandfamilies.

CULTURAL UNDERSTANDING OF THE EXPERIENCES OF GRANDPARENTS RAISING GRANDCHILDREN IN SCHOOL CONTEXT

Y. Lee, *Social Work, Binghamton University, Binghamton, New York*

Purpose: Twenty three grandparents and five school employees were interviewed for the purpose of exploring and better understanding the shared experience of grandparents raising grandchildren. Design and Methods: A total of twenty three grandparents raising grandchildren (12 White, 10 African American, and 1 Hispanic) and five school faculty/ staff (4 White and 1 African) participated in individual interviews. From the sample of 28, data analysis was conducted in three steps: (1) open coding, (2) axial coding, and (3) selective coding. Results: The following major themes emerged from the interviews: (1) finding purpose in life from raising grandchildren, (2) lack of communication with teachers/staff and understanding from school about the intergenerational caregiving situation, and (3) heterogeneity between White grandparents and grandparents of color in their perception of raising grandchildren and associated needs in relation to the school system. Implications: Intergenerational families will benefit from culturally competent teaching and practice.

SESSION 2025 (SYMPOSIUM)

LOST IN TIME METRICS: THE TIME DIMENSION IN CURRENT LIFE-SPAN AND GERONTOLOGY THINKING AND RESEARCH

Chair: H. Wahl, *Heidelberg University, Heidelberg, Germany*
Discussant: J. Baars, *University for Humanistic Studies, Haarlem, Netherlands*

Discussions related to time dimensions and time metrics lie at the heart of life-span and aging research. Birren's (1959) statement that "Chronological age is one of the most useful single items of information about an individual, if not the most useful" still resonates across the different disciplines within gerontology, ranging from biology to psychology and the humanities. Despite this focus on chronological aging, different time metrics have informed gerontology. For example, subjective time metrics and personal views on aging may be of greater importance for aging individuals than declining biological functioning. Furthermore, perceived personal life time (future time) or calendar time until death are driving forces of development in later life. Overall, an impressive body of conceptual, methodological, and empirical research has accumulated that supports the importance of all of these and other time. But how can we gain a coherent and organized view of the role of time in human development and aging? Should we let these time metrics simply stand next to each other without an organizing conceptual model? Or frame the issue only as an empirical one and test the explanatory power of different time metrics against each other? This symposium discusses possible ways of not getting lost in time metrics. We will address calendar age (Settersten), future time perspective (Carstensen), distance to death (Smith), and subjective interpretations of aging (Wahl & Diehl), as well as methodological issues (Ram). The discussion provides an overall view from a social science and life course perspective (Baars).

GERONTOLOGY'S UNEASY RELATIONSHIP WITH CHRONOLOGICAL AGE

R.A. Settersten, *Human Development & Family Sciences, Oregon State University, Corvallis, Oregon*

Gerontology has an uneasy relationship with chronological age. On one hand, chronological age is viewed as inherently tied to aging as a property of people and social systems. It is automatically included in models. As a continuous variable, it is assumed to reflect maturation or be a proxy for a variety of statuses. Age-based standards of "normal" aging are available for many health indicators. As a categorical variable, it is assumed that members of an age group share a set of experiences that are distinct from adjacent groups. On the other hand, gerontologists have difficulty distinguishing between age and aging, and between aging and age-related disease. They are quick to point to heterogeneity and the fallibility of chronological age as an index, and they perpetuate the message that successful aging is about transcending age. Thought experiments and illustrations are used to critically examine the uses of chronological age in research.

TAKING TIME SERIOUSLY IN LIFE-SPAN DEVELOPMENT

L.L. Carstensen, *Psychology, Stanford University, Stanford, California*

Age is a powerful predictor of a range of important outcomes, including disease and death, but offers little in the way of explanation. There remains a great deal to be learned about experience-based changes related to age. It appears also that many phenomena, long presumed to be rooted in chronological age and related experience, reflect perceived time horizons independent of age or experience. Socioemotional selectivity theory is grounded in the uniquely human ability to appreciate their own mortality and, at both conscious and subconscious levels, estimate time remaining in life. A good deal of evidence testing related hypotheses shows that when time horizons are experimentally manipulated or vary in response to naturally occurring phenomena, preferences, goals and cognitive resources also vary systematically. Eliminating age in predictions about long-term outcomes will advance the science of aging.

DISTANCE-TO-DEATH: CONCEPTS OF TIME IN END-OF-LIFE TRAJECTORIES OF AGING AND DYING

J. Smith, *University of Michigan, Ann Arbor, Michigan*

Advances in statistical techniques in the last 20 years have enabled researchers to model and compare age-related and death-related functional change. Findings highlight the heterogeneity, asynchrony, and plasticity of change over time. The speed of processes of aging and dying may be slow, delayed, or accelerated as a function of a multitude of interacting bio-psycho-social factors and interventions. In addition, substantial differences are observed in the shape of trajectories of aging and dying. The time is ripe for theoretical advances to complement and guide future study design and analyses. Conceptually, attention should be given to the life course timing, context, and cause of death and to the role of selective mortality on study sampling and participation.

SUBJECTIVE AGE AS A WAY OF CLOCKING LIFE

H. Wahl[1], M.K. Diehl[2], *1. Heidelberg University, Heidelberg, Germany, 2. Colorado State University, Fort Collins, Colorado*

Human individuals have the unique capability to interpret and construct their own development and aging. Given the traditionally strong biological and functional view on aging, research supporting how relevant subjective views on aging and subjective awareness processes are for major developmental outcomes have been critical in gerontology at large. What is chronological age really telling us, if adults consistently and even in late life report feeling younger? Furthermore, a body of data points to the predictive role of felt age and perceptions of aging for health, well-being, and mortality. In the light of a volume of the Annual Review of Gerontology and Geriatrics on subjective aging that we currently prepare, this presentation highlights conceptually and empirically the role of subjective time dimensions for the understanding of aging. We will also use our work on the construct of awareness of age-related change to underscore the relevance of subjective aging time metrics.

LONGITUDINAL METHODS IN THE STUDY OF HUMAN AGING: IT'S TIME TO SPEED UP THE PROCESS

N. Ram[1], B. Reeves[2], *1. Pennsylvania State University, University Park, Pennsylvania, 2. Stanford University, Stanford, California*

Advances in data mining and dynamic time-series modeling are providing for tailored information search, document retrieval, and item recommendation in a wide variety of industries and business sectors. Novel dynamic algorithms that use historical behavior reports are facilitating provision of time-sensitive recommendations to individual consumers. Computer-based games that connect avatars' behaviors in the virtual-world with individuals' behaviors in the real-world are shaping perceptions, thoughts, feelings, and actions in work, leisure and home contexts. Notions of TIME are changing. We argue that chronological age, and all the other "time" variables at the core of current best practices in longitudinal analysis, will become increasingly irrelevant in the study of aging. Data collection and analysis will soon proceed in real-time, with theoretical models playing less and less of a role as focus shifts toward provision of individualized service and shaping of context-specific behavior through an increasingly large pool of quickly updated empirical evidence.

SESSION 2030 (SYMPOSIUM)

DYADIC MODELS OF HEALTH IN LATE LIFE MARRIAGE

Chair: J. Monin, *Yale School of Public Health, New Haven, Connecticut*

Discussant: D. Almeida, *The Pennsylvania State University, University Park, Pennsylvania*

It is important to take into account the social context, especially marriage, when examining the physical and psychological health of older adults. Spouses' feelings, behaviors, and thoughts are often interdependent and transactional, especially in late life. In this symposium we will discuss four papers that examine spousal interrelations in terms of coping, health behaviors, and cognition that have implications for individual-level and couple-level physical and psychological health. The first two presentations will discuss the benefits of dyadic coping as older spouses are faced with health-related stress. Specifically, the first presentation will describe a time-sampling study of older couples showing how communal coping and spouse dissimilarity in specific health symptoms, such as aches, low energy, and digestion problems, relate to changes in each spouses' positive affect over time. The second presentation will discuss the association between spousal involvement in medical decisions and older adults' self-perceived health, showing that involvement is differentially related to health when considering effects of relational quality and injury. The second two talks will discuss antecedents and consequences of spouse similarity in physical activity. Specifically, the third presentation will discuss findings concerning the congruence between husbands and wives on social cognitive variables (self-efficacy, goals, barriers, plans, and outcome expectancies) and how it is related to individual-level and couple-level physical activity. The final presentation will describe findings from a large, longitudinal study of older married couples showing that greater physical activity in husbands and wives seems to be protective specifically for husband's psychological health in terms of less depressive symptoms.

SPOUSAL DISSIMILARITIES IN PHYSICAL SYMPTOMS AND COMMUNAL COPING ARE ASSOCIATED WITH POSITIVE AFFECT IN OLD AGE: EVIDENCE FROM A TIME-SAMPLING STUDY WITH COUPLES

C.A. Hoppmann[1], H.M. Schade[2], D. Gerstorf[2], *1. Psychology, Univ. of British Columbia, Vancouver, British Columbia, Canada, 2. Humboldt University, Berlin, Germany*

Spousal similarities in levels and long-term longitudinal changes in health and well-being are well documented. Yet, such spousal similarities do not preclude the possibility that there are also considerable differences within a given couple. In fact, spousal dissimilarities in health might be a precondition that the help of the spouse is invoked in coping with health problems. Using up to 27 simultaneous, daily-life assessments from 49 older adult couples (M age = 72 years; M relationship duration = 42 years), this study shows that aches, eating or digestion problems, and low energy were associated with concurrent decreases in positive affect. Interestingly, within-couple dissimilarity in eating and digestion problems was associated with increased positive affect but only in couples reporting high communal coping. In contrast, within-couple similarity in low energy was related to increased positive affect. Overall, findings suggest that the functions of spousal dissimilarities are domain-specific.

SPOUSAL INVOLVEMENT IN MEDICAL DECISIONS: IMPLICATIONS FOR PERCEIVED HEALTH OF OLDER ADULTS

L.R. Bangerter[1], A.R. Heid[2], S.H. Zarit[1], K. Fingerman[3], *1. Penn State University, State College, Pennsylvania, 2. The Polisher Research Institute, The Madlyn and Leonard Abramson Center for Jewish Life, North Wales, Pennsylvania, 3. The University of Texas at Austin, Austin, Texas*

Dyadic coping theory purports the benefits of couples jointly responding to stressors. In late life, a time of increased health problems, involving a spouse in medical decision-making may be particularly beneficial. Using a sample of 90 married adults aged 65 to 95, we use multiple regression to examine the association of spousal relationship quality, the presence of a recent injury, and involvement of spouses in medical decision making on older adults' perceived physical health. Results indicate that the association between relational quality and perceived physical health is moderated by both the presence of a recent injury and spousal involvement in medical decision making ($B = -1.14$, $p = .002$). Findings support the differential effects of strong marital bonds and spousal joint medical decision making on older adults' perceived health.

THE ASSOCIATION OF SPOUSAL CONGRUENCE ON SOCIAL COGNITIVE VARIABLES WITH INDIVIDUAL-LEVEL AND COUPLE-LEVEL PHYSICAL ACTIVITY

B.J. Ayotte[1], J. Margrett[2], *1. Psychology, University of Massachusetts Dartmouth, North Dartmouth, Massachusetts, 2. Iowa State University, Ames, Iowa*

Individual and spousal characteristics are important predictors of physical activity among middle-aged and older adults. This study examined how congruence between spouses on several characteristics (enjoyment, self-efficacy, outcome expectancies, goals, plans, and barriers) were related to couple-level and individual-level physical activity. Age, length of marriage, and marital satisfaction were also included in the models. Couples were coded as congruent (+/- 1SD of overall couple-level mean) or incongruent. Results indicated that couples who were congruent on planning, goal setting, and self-efficacy reported higher levels of couple-level physical activity compared to incongruent couples. Individual-level analyses indicated that congruence in self-efficacy was related to increased physical activity in both partners, while congruence in enjoyment was related to increased physical activity for husbands. Finally, congruence in barriers was related to less physical activity for both partners. These results may have implications for dyadic physical activity interventions that focus on both husbands and wives.

SPOUSAL ASSOCIATIONS BETWEEN PHYSICAL ACTIVITY AND DEPRESSIVE SYMPTOMS: LONGITUDINAL FINDINGS FROM THE CARDIOVASCULAR HEALTH STUDY

J. Monin[1], B. Levy[1], R. Schulz[2], S. Stahl[2], B. Chen[1], T.R. Fried[3], T. Kershaw[1], *1. Yale School of Public Health, New Haven, Connecticut, 2. University of Pittsburgh, Pittsburgh, Pennsylvania, 3. Yale School of Medicine, New Haven, Connecticut*

This study examined in the context of late-life marriage whether each spouse's leisure-time physical activity would predict their own and their partner's depressive symptoms using the Actor Partner Interdependence Model. Gender differences were also examined. Each spouse within 1,260 married couples (at baseline) in the Cardiovascular Health Study completed self-report measures of leisure-time physical activity, depressive symptoms, socio-demographics, social support, and disability at baseline (1989–1990), wave 3 (1992–1993), and wave 7 (1996–1997). Results revealed that husbands' physical activity predicted their own decreased depressive symptoms. There was also a marginally significant effect such that wives' physical activity predicted less depressive symptoms for husbands. Finally, husbands' physical activity predicted wives' physical activity, and husbands' depressive symptoms predicted wives' depressive symptoms but not vice versa. Findings suggest that one's own and one's partner's physical activity may be more important for husbands' mental health than wives' mental health.

SESSION 2035 (SYMPOSIUM)

METHODOLOGICAL CHALLENGES IN BEHAVIORAL INTERVENTION RESEARCH: CONNECTING INTERNATIONAL EXPERIENCES

Chair: S. Metzelthin, *CAPHRI School for Public Health and Primary Care, Maastricht University, Maastricht, Netherlands*
Co-Chair: G. Zijlstra, *CAPHRI School for Public Health and Primary Care, Maastricht University, Maastricht, Netherlands*
Discussant: L.N. Gitlin, *Johns Hopkins University, Baltimore, Maryland*

A series of public health problems in older adults, such as chronic diseases, disability or psychosocial difficulties, are not responsive to pharmalogical or medical interventions. Particularly for these problems behavioral interventions are needed to promote a healthy lifestyle, to reduce symptoms or facilitate coping with them. However, behavioral interventions research is complex and time-consuming. Developing and testing of behavioral interventions involve an incremental and iterative process to build a robust body of evidence that initially supports feasibility and safety of the intervention, then efficacy and effectiveness has to be proven, and subsequently translation, implementation, and sustainability in the real-world context has to be promoted. This symposium discusses several challenges in the progress of behavioral intervention research based on four research projects form the US and the Netherlands that focus on the improvement of community-based care in frail older people. The first presentation will be about the development and pilot testing of a multidimensional home-based care coordination intervention. The second presentation will focus on the evaluation of the treatment fidelity of a bio-behavioral-environmental intervention. Next, the economic evaluation of an interdisciplinary primary care approach will be addressed. The focus of the fourth presentation will be on the implementation of multicomponent fall-related program. Our discussant Laura Gitlin will reflect on the different phases in behavioral intervention research and will facilitate a discussion on-site.

REFLECTIONS ON DEVELOPMENT OF A NOVEL, MULTIFACETED DEMENTIA CARE COORDINATION PROGRAM: MIND AT HOME

Q. Samus, B.S. Black, D.M. Johnston, P. Rabins, C. Lyketsos, *Johns Hopkins University School of Medicine, Baltimore, Maryland*

The Maximizing Independence at Home (MIND at Home) program is a promising new community-based approach to systematically identify and address the multidimensional medical and supportive care needs of elders and families affected by Alzheimer's disease and other cognitive disorders through dementia care coordination implemented by an interdisciplinary team (e.g. non-clinical community workers, nurse, physician). Findings from a recent 18-month randomized controlled pilot trial of 303 elders in the Baltimore region showed MIND significantly delayed time to transition from home and improved patient and caregiver outcomes compared to a usual care group. To illustrate several key considerations and challenges in development of complex interventions, an overview of MIND's conceptualization and pilot testing will be provided, paying particular attention to theoretical underpinnings, intervention protocol and delivery model development, community-academic integration, and hybrid and adapative trial design considerations to maximize utility and value of the development/pilot testing phase.

FIDELITY CHALLENGES AND OPPORTUNITIES IN A BIO-BEHAVIORAL-ENVIRONMENTAL INTERVENTION: CAPABLE STUDY

S. Szanton, L.N. Gitlin, *Johns Hopkins University, Baltimore, Maryland*

Behavioral interventions with older adults often have multiple components that present varied treatment fidelity challenges. We present fidelity components, challenges, and opportunities implementing CAPABLE (Community Aging in Place, Advancing Better Living for Elders) a bio-behavioral environmental trial (planned N=300) to reduce disability in low-income older adults. CAPABLE consists of up to 10 home visits across 4 months from a nurse, an occupational therapist, and $1200 of handyman services. Fidelity strategies include interventionist training, recorded visits, a secure share site to enhance charting communication, clinical case conferences with interventionist feedback, cost and mileage tracking and shadow visits. Challenges include necessary tailoring to individual participants, complexity of the intervention, multiple interventionists, participants' refusals to be recorded and sheer amount of fidelity data. A major intervention opportunity is using fidelity checks to strengthen the intervention itself, such as comparing the participants' level of engagement and individual goals across the disciplines to enhance engagement.

HOW MUCH DOES IT COST? CHALLENGES IN ECONOMIC EVALUATIONS OF BEHAVIORAL INTERVENTIONS

S. Metzelthin[1], E. van Rossum[2,1], M.R. Hendriks[4,3], L. de Witte[2,1], G.I. Kempen[1], *1. CAPHRI School for Public Health and Primary Care, Maastricht University, Maastricht, Netherlands, 2. Zuyd University of Applied Sciences, Heerlen, Netherlands, 3. VU University Medical Centre, Amsterdam, Netherlands, 4. Maastricht University NUTRIM School for Nutrition, Toxicology and Metabolism, Maastricht, Netherlands*

There is increasing interest in cost-effective interventions for community-dwelling frail older people. However, economic evaluations in this field are scarce likely due to challenges in measuring healthcare utilization. Embedded in a cluster randomized trial among 12 general practitioner practices an economic evaluation was performed from a societal perspective with a time horizon of 24 months. Therefore a combination of different methods was used to overcome the challenges of data collection. Over 24 months frail older people in the intervention group, receiving an interdisciplinary primary care approach (n=193) used more primary care services than people in the control group receiving usual care (n=153). However against our expectations there was no decline in more expensive institutionalized care. Furthermore there were no significant effects ($p \geq 0.05$) on disability and quality of life. Total costs over 24 months tended to be higher in the intervention group than in the control group (€26,503 versus €20,550, $p=0.08$).

IMPLEMENTATION OF A MULTICOMPONENT FALL-RELATED PROGRAM INTO PRACTICE

G. Zijlstra[1], J. van Haastregt[1], M.F. Du Moulin[2], M.C. de Jonge[3], A. van der Poel[3], G.I. Kempen[1], *1. Maastricht University, Department of Health Services Research, CAPHRI School for Public Health and Primary Care, Maastricht, Netherlands, 2. Zuyd University of Applied Sciences, Heerlen, Netherlands, 3. Trimbos Institute, Program Mental Health, Utrecht, Netherlands*

"A Matter of Balance" (AMB) is a multicomponent cognitive behavioral program that showed to reduce psychosocial and behavioral adverse aspects related to falls, i.e. concerns about falls and related activity restriction in daily life. In the Netherlands the Dutch version of AMB (AMB-NL) was nationwide implemented in homecare organizations according to an implementation strategy including 4 phases, i.e. pre-condition, pre-implementation, implementation, and maintenance, and evaluated in a pre-test post-test study. After the pre-condition and pre-implementation phase, which included challenges with recruitment strategies of participants and training of 53 facilitators for the program, AMB-NL was implemented in 16 of the 64 homecare organizations (25%) in a two-year period. The program ran 19 times reaching 178 participants that significantly ($p<0.05$) benefited regarding concerns about falls and related activity avoidance. Despite the systematic implementation strategy not all targeted homecare organizations were reached and further actions for implementation and maintenance of AMB-NL are recommended.

SESSION 2040 (PAPER)

DEMOGRAPHY OF AGING II

CROSS NATIONAL COMPARISONS OF EARLY LIFE CONDITIONS AND OLDER ADULT HYPERTENSION, DIABETES, HEART DISEASE AND OBESITY IN LOW AND MIDDLE INCOME COUNTRIES

M. McEniry, J. McDermott, *Institute for Social Research, University of Michigan, Ann Arbor, Michigan*

Mounting evidence suggests that poor early life conditions can have long term consequences on older adult health such as heart disease, diabetes, obesity and hypertension. These consequences are particularly relevant for low and middle income countries where life expectancy during the 20th century (1930s-1960s) dramatically improved as a result of reductions in infant and child mortality from public health interventions and medical technology but largely in the absence of improvements in standard of living. A larger pool of survivors of poor early life conditions born in these settings may now be exposed to higher risk of chronic conditions and other risk factors increasing their mortality risk. Using data from the recently compiled RELATE (Research on Early Life and Aging Trends and Effects) cross national data on over 147,000 older adults (50 years and older) in 20 low, middle and high income countries from Africa, Asia, Latin America, Europe and the US, the paper examines the association between early life conditions (parental SES, height, rural residence, caloric intake) and adult health (mortality, measured hypertension, obesity, heart disease and diabetes based on biomarkers where available), controlling for adult SES, lifestyle and health (smoking, functionality), and utilization of health services. Being born in a rural area and in a country with poor caloric intake increased the risk of diabetes, heart disease, obesity and hypertension. The results suggest the importance of early life nutritional and infectious disease environment and a critical period in utero, early infancy or childhood with consequences for older adult mortality.

REGIONAL VARIATION IN SELF-RATED HEALTH AND LIFE SATISFACTION: A LIFE COURSE PERSPECTIVE

A. Bardo[1], J.K. Chahal[1], J. Brown[1], S.M. Lynch[2], *1. Miami University, Oxford, Ohio, 2. Duke University, Durham, North Carolina*

A vast quality-of-life literature has documented how individuals come to conclusions about their perceived health and happiness. Gerontological research has found that such conclusions are sensitive to age and cohort effects. For example, subjective measures of health (e.g., self-rated health [SRH]) generally have a negative association with age, whereas subjective well-being (e.g., life satisfaction) tends to have a positive relationship with age, while the Great Depression has been found to have a life-long negative impact on such evaluations for its formative cohorts. Life satisfaction and SRH are both influenced by similar personal characteristics (e.g., age, race, sex, SES) and an individual's physical and social environment, which varies geographically. However, these two subjective quality-of-life measures are rarely examined in conjunction, and little is understood about the relationship between the two. The present study utilizes a life course perspective to examine the role of geography in shaping life satisfaction and SRH outcomes. Previous research that has examined the role of social and cultural resources in shaping such outcomes has typically engaged these issues within relatively small geographic units (e.g., neighborhoods, counties), and age/cohort effects have generally been neglected. We utilize multiple waves of repeated cross-sectional data (BRFSS 2005-2010) to explore the role of age and cohort in shaping the relationship between life satisfaction and SRH among the 9 US Census regions. Findings indicate that the life satisfaction/SRH relationship varies by region, and is particularly weaker in the South; this relationship decreases with, and is strongest for the baby boomer cohorts.

REGION OF SOCIALIZATION VS. REGION OF CURRENT RESIDENCE AND MID-TO-LATE ADULTHOOD HEALTH OUTCOMES IN THE US

S.M. Lynch, J. Brown, *Sociology, Princeton University, Princeton, New Jersey*

Region of residence is usually included in demographic models of health outcomes only as a control variable. However, region represents a rich combination of structural and cultural factors that may influence health. The Health and Retirement Study (HRS) asks respondents not only where they live at the time of interview, but also where they were born and where they lived during adolescence. The HRS also measures numerous health outcomes. This breadth of measurement on both region and health provides considerable leverage with which to disentangle the effects of early childhood socialization and current structural constraints and opportunities on different dimensions of adult health. In this paper, we use data across 8 waves of the HRS to investigate the relative effects of early life region and current region on a number of health outcomes, including self-rated health, cardiovascular disease, cancer, obesity, diabetes, depressive symptoms, mortality, and healthy life expectancy measures based on these outcomes. Next, we incorporate time-specific, region level measures in an effort to explain the region effects. We present results of analyses based on the complete sample and based on the subset of approximately 30% who move between adolescence and later adulthood.

THE ROLE OF JOB HISTORIES AND WORK CHARACTERISTICS IN DIFFERENTIATING TRAJECTORIES OF PHYSICAL AND MENTAL HEALTH IN LATER LIFE

M. Engelman, *Sociology, University of Wisconsin-Madison, Madison, Wisconsin*

While survival to and health in older ages have been linked to measures of socioeconomic position throughout the life course, the mechanisms that predispose individuals to particular patterns of health declines and functional impairments are not well understood. This study aims to characterize heterogeneous trajectories of physical and mental health among older Americans and, particularly, to examine the role of employment histories and job characteristics in differentiating these trajectories over time. Using the nationally representative Health and Retirement Study, I examine the work and health trajectories of American men and women between 1992-2010. Job histories are assigned cumulative psychosocial and physical exposure scores using a work exposure matrix. To account for the heterogeneous trajectories of impairment, I use a latent class framework to examine change over time in four dimensions of physical and mental health, including disability (difficulty performing primary or instrumental activities of daily living), physical functioning, depressive symptoms, and cognitive impairment. I first estimate distinct trajectories within each health outcome, considering the onset, progression, and overall level of health problems as people age. Next, I incorporate time-varying covariates to show how changes over time in employment and retirement status, health conditions, and social support interact to define these health trajectory classes. Finally, I analyze the association of these trajectories with race/ethnicity, education, income, occupational categories (at baseline and for the longest-reported occupation), and cumulative job characteristics exposure scores to better understand the mid-life factors that predict differential patterns of physical and mental health declines in the post-retirement years.

LONG-TERM BMI PATTERNS, EXERCISE, HEALTH, AND MORTALITY IN OLDER ADULTS

A. Zajacova, *University of Wyoming, Laramie, Wyoming*

Background. The relationship between body mass index (BMI) and health develops over the life course. There is increasing interest in modeling long-term changes in BMI and identifying distinct BMI trajectory types in the population rather than linking one-time BMI to outcomes. Objective. The aim is to identify clusters of long-term BMI curves using a novel nonparametric functional-data approach, and to determine how these BMI clusters predict mortality among older adults beyond differences in baseline health and physical activity. Methods. Data are from the Health and Retirement Study (N=9,893), a nationally-representative panel survey of older adults. BMI, collected in up to 10 waves between 1992 and 2010, is analyzed using hierarchical clustering of functions estimated via the PACE algorithm, a powerful, cutting-edge nonparametric approach for longitudinal data. Proportional-hazard models estimate all-cause mortality as a function of the BMI clusters, physical activity, and baseline health. Results. Three BMI trajectory clusters emerged for each gender: normal stable, overweight gaining, and overweight losing. Mortality was highest in the overweight losing cluster; the overweight gaining cluster had similar (women) or significantly lower (men) mortality risks compared to the normal stable group, even when baseline health and exercise levels across the clusters were taken into account. Conclusions. BMI trajectories among older adults cluster into distinct types, with systematically different exercise levels, health, and mortality risks. The findings highlight the importance of understanding long-term changes in BMI rather than one-time BMI level, in order to solve the mortality paradox and understand processes relevant to obesity and health.

SESSION 2045 (PAPER)

HEALTH OUTCOMES AND LONG-TERM CARE

PAIN AMONG NEW LONG-TERM SERVICES AND SUPPORT RECIPIENTS OVER TIME

K.B. Hirschman, A.L. Hanlon, M.D. Naylor, *School of Nursing, University of Pennsylvania School of Nursing, Philadelphia, Pennsylvania*

Among older adults receiving long term services and supports (LTSS) in their homes (HCBS), assisted living facilities (ALF) or nursing homes (NH), the report of having pain can vary considerably. In this NIA/NINR supported (R01AG025524) prospective, longitudinal study we examined the self report of experiencing pain among 470 English and Spanish speaking older adults who, at the time of enrollment, were new recipients of LTSS. We found in multivariable GEE modeling that the odds of older adults in ALFs reporting having pain was 46% less than those receiving HCBS (p=0.006) and only 17% less than older adults in NHs (p=0.33). The odds of older adults in NHs reporting pain was 35% less than those receiving HCBS (p=0.03). LTSS recipients reporting pain in the prior 3 months were 69% more likely to enroll in hospice than those not reporting pain in the prior 3 months (p=0.04). Reporting pain was higher with lower self reported mental and physical health ratings (OR=0.97; OR=0.92; p<0.001, both). LTSS recipients reporting pain was associated with higher negative affect–quality of life (OR=1.28; p=0.008) and less cognitive impairment (OR=1.03; p=0.03). Reporting pain was higher for LTSS recipients with fewer years of education (OR=0.95; p=0.02). LTSS recipients with fewer years of education had a higher proportion with pain (OR=0.95; p=0.02) and it increased over time where as LTSS recipients with more years of education had a steady lower proportion of having pain over time (p=0.01). Future directions for research and the implications of these findings will be discussed.

STAR-VA: AN INTERDISCIPLINARY, BEHAVIORAL INTERVENTION FOR CHALLENGING BEHAVIORS IN DEMENTIA

M. Karel[1], B. Karlin[1,6], E. McConnell[5,3], S.M. McCurry[2], S. Visnic[4], L. Teri[2], *1. Department of Veterans Affairs, Washington, District of Columbia, 2. University of Washington, Seattle, Washington, 3. Duke University, Durham, North Carolina, 4. Department of Veterans Affairs, Ann Arbor, Michigan, 5. Department of Veterans Affairs, Durham, North Carolina, 6. Education Development Center, New York, New York*

STAR-VA is an interdisciplinary, behavioral intervention that promotes effective management of challenging behaviors in residents with dementia in Department of Veterans Affairs (VA) Community Living Centers (CLC). This approach entails collaboration between a CLC psychologist or psychiatrist and CLC nurse leader working with care staff to: (1) identify and change activators and problematic consequences of challenging behaviors; (2) increase personally-relevant and meaningful pleasant events; and (3) have realistic expectations of and effective communication with individuals with dementia. In 2013, the STAR-VA expanded implementation initiative entailed completed training of teams in 17 CLCs over six-months, enrolling 71 Veteran participants. Target behaviors clustered into six categories: agitation, resistance to care, vocalization, aggression, wandering, and other. Average intervention duration was 35.8 days (SD = 16.1). The mean rated frequency and severity of target behaviors, each rated on a 1-5 point scale, decreased 45%, from 3.4 (SD = 0.8) to 1.8 (SD = 1.2), effect size (d) = 1.2, and 64%, from 3.1 (SD = 0.8) to 1.1 (SD = 1.1), d = 1.6, respectively. Depressive symptoms on the CSDD decreased 46%, from mean of 12.6 (SD = 5.6) to 6.8 (SD = 3.9), d = 1.3. Anxiety symptoms on the RAID decreased 51%, from mean of 13.5 (SD = 7.8) to 6.6 (SD = 5.0), d = 1.0. Agitation symptoms on the CMAI-SF decreased 28%, from mean of 28.7 (SD = 6.7) to 20.8 (SD = 4.9), d = 1.0. Successes and challenges for real-world implementation of this systemic intervention are discussed.

LONGITUDINAL EXAMINATION OF PRESSURE ULCER RATES IN VETERANS HEALTH ADMINISTRATION NURSING HOMES

C.W. Hartmann[1,2], M. Shwartz[2,1], S. Zhao[1], J.A. Palmer[1], D. Berlowitz[1,2], *1. CHOIR at Bedford & Boston VA Medical Centers, Bedford, Massachusetts, 2. Boston University, Boston, Massachusetts*

Pressure ulcers result in significant health and economic consequences. Yet nursing home studies consistently demonstrate lapses in pressure ulcer care, and pressure ulcer rates remain unacceptably high. Identifying sites with significantly improving and declining rates is a first step in developing effective interventions. The Veterans Health Administration (VHA) houses the U.S.'s largest integrated nursing home system. A retrospective longitudinal examination of 109 VHA nursing homes' pressure ulcer rates was conducted using Minimum Data Set (MDS) data from FY 08-11. Pressure ulcer development was defined as a stage 2 or larger pressure ulcer on an MDS assessment with no pressure ulcer on the previous assessment. A risk adjustment model was developed using 105,274 MDS observations to predict the likelihood of pressure ulcer (c statistic = 0.72). A Bayesian hierarchical model, which adjusted for differences in the reliability of pressure ulcer rates from facilities of different sizes, was used to calculate smoothed risk-adjusted (sra) rates of pressure ulcers for each facility. Over the 4 year period, median sra pressure ulcer rates were fairly consistent at approximately 4%, though the range in sra rates declined from 14.8% to 10.1%. Some facilities had significantly improved sra rates (e.g., declined steadily from 5.5% to 3.9%) and some had significantly worsening sra rates (e.g., increased steadily from 5.1% to 7.9%). This study represents the most recent longitudinal investigation of VHA nursing home pressure ulcer rates. The significant variation found suggests room for quality improvement efforts. Further investigation of differences could aid in intervention development.

POLYPHARMACY AND PERSON CENTERED CARE IN THE SKILLED NURSING FACILITY: INTERVENTION PLANNING AND EXECUTION

J. Rabig, *NASH, Niskayuna, New York*

The session will describe the program process and outcomes of a comprehensive interdisciplinary medication review initiative implemented in four skilled nursing facilities. The program was one component of a larger person centered holistic wellness initiative associated with the implementation of the small house model of skilled nursing care. The goals of the medication review program included a comprehensive review of medication regimes targeting polypharmacy, especially unnecessary medications, medication redundancy,untoward therapeutic outcomes, medications not consistent with advance directives, pill burden, medication crushing practices and medication pass frequency. The challenges of the program included facilitating the necessary physician, nurse and family and resident paradigm shifts regarding medications, the maintenance of achieved results, managing the time consuming nature of the review process and identifying and tracking outcomes that related to quality of life and quality of care.

SESSION 2050 (PAPER)

HISPANIC CARE-GIVING AND SUPPORTS

THE MOST PREFERRED AND MOST LIKELY CHILDREN CAREGIVERS IN MEXICAN AMERICAN FAMILIES

Z. Cong, Y. Pei, *Human Development and Family Studies, Texas Tech Univ, Lubbock, Texas*

This study examines which children are the most preferred and which children are the most likely caregivers for older adults in Mexican American families. The sample derived from a convenient sample of Mexican American elders with at least one living child in a city in West Texas. Our working sample included 329 parent-child dyads of 82 elder parents. We used fixed effects logistic regression to examine children's likelihoods of being named the most preferred caregivers and being named the most likely caregivers. Although daughters were more likely to be named the most likely caregivers, they were not more preferred by parents. This might be related to the culture in Mexican American families where patrilineal tradition is relatively strong. In addition, emotional closeness with parents is the shared predictor for children being named as the most preferred and most likely caregivers. Moreover, parents' nomination of the most preferred and most likely caregivers seems to be marginally affected by financial help from parents. Finally, children who lived closer were more likely to be named as the most likely caregivers, but not necessarily the most preferred caregivers. We discussed our findings within the contexts of Mexican American families.

LATINA DEMENTIA CAREGIVERS: THE ROLE OF SOCIAL CAPITAL, GENDER, AND ETHNICITY IN CONCEPTIONS OF WELLBEING

E. Apesoa-Varano, *Betty Irene Moore School of Nursing, UC Davis, Sacramento, California*

Up to 70 percent of individuals suffering from dementia in the U.S. are cared for at home and approximately 9.8 million family members take on this responsibility. Dementia caregivers are at risk for poor quality of life and declining mental and physical health. Latina caregivers report higher levels of burden and depression compared to other ethnic groups. The purpose of this qualitative study was to examine how social capital and ethnicity shape dementia Latina caregivers' experiences over time. A purposive sample of 15 Latina dementia caregivers was recruited in the Sacramento region. Caregivers completed three in-depth interviews, along with structured questionnaires to assess physical and mental health. Data from in-depth qualitative interviews were analyzed thematically from a social constructivist approach. We found that Latina caregivers' experiences are influenced by changes in available social capital. Perceptions of wellbeing were closely tied to the availability and use of that social capital. Social capital use patterns were, in turn, shaped by caregivers' views of the role of women in the home and the family in the context of Latino dominant values. For example, caregivers describing a lack of social resources (e.g. characterized by conflicts dispelling the ideal of familismo) were more apt to express less traditional feminine views of women as caregivers and report a higher sense of wellbeing. This information is significant for advancing our understanding of caregiver burden and rewards beyond the dyad in order to build socio-culturally tailored models to support dementia Latina caregivers in the clinical and community settings.

FAMILY SUPPORT AND HEALTH OUTCOMES FOR OLDER MEXICAN RETURN MIGRANTS

S. Mudrazija[1], M. Lopez-Ortega[2], W.A. Vega[1], W. Sribney[3], *1. Roybal Institute on Aging, University of Southern California, Los Angeles, California, 2. Instituto Nacional de Geriatría, Mexico City, Mexico, 3. Third Way Statistics, Dorset, Vermont*

While a large literature focuses on health and behaviors of Mexican immigrants in the United States, our knowledge about later-life resettlement in Mexico remains fragmentary. This is an important gap given the potential impact of circular migration on support systems. This study examines differences in family time and financial support and their relationship with health for aging return migrants. Migrants experience disrupted family ties; therefore we test the supposition that return migrants receive less family support in old age than non-migrants, and these differences increase with age when health problems peak. Data come from the 2001-2012 waves of the Mexican Health and Aging Study and the sample consists of 13,363 individuals of whom 1,585 were U.S. migrants. Generalized estimating equations are used to test whether family support is predictive of health status over time. Preliminary findings suggest that, unlike financial support, time support received from family differs between return migrants and non-migrants. Controlling for age and sex, older return migrants who suffer from ADL limitations in 2003 and/or 2012, but had no such limitation in 2001 are 21-24 percentage points less likely to receive time support from family, and a similar pattern is observed for support with chronic conditions. Return migrants who receive family time support in 2001 experience significantly slower functional declines by 2012. The information from this study can contribute to improved integration and coordination of publicly supported policies for aging vulnerable populations including home assistance, partial day care, and nursing services with family support capacity.

BEHIND HISPANIC FAMILY CAREGIVING FOR ELDERS: TRADITIONAL FILIAL VALUES OR DYADIC MUTUALITY

H.S. Kao, *School of Nusing, The University of Texas at El Paso, El Paso, Texas*

Filial values have long been considered the motive for elderly care. Do the values still hold true while younger Hispanic generation is rapidly acculturated? Besides the traditional 'family above individual', do Hispanics give to their families to receive some favors back should they subsequently in need? Such mutuality explains the family dynamics behind elderly care has been theorized. Mutuality is the accrued impact of supports provided by elders to their family, which is, in turn, evaluated for care given to them by the family. This study is to theoretically and empirically analyze filial values and mutuality in Mexican American (MA) families. Methodology. A correlational design with a convenience sample of 193 MA adult caregivers of elders was used to test the association between filial values (by the Expectations of Family Loyalty Scale of Children toward Elderly Relatives; EFLOCTER) and mutuality (by Mutuality Scale; MS). Results. Theoretically, a link between mutuality based on Social Exchange Theory and filial values derived from Investment Thesis was argued. Empirically, while acculturation was marginally significant ($r = .21$, $p < .05$), MS scores were even strongly correlated ($r = .45$, $p < .001$) to EFLOCTER. Discussion. Whether the mutuality binds the filial values or the filial values strengthen the mutuality between the dyad remains a chicken-and-egg question. Yet, Social Exchange Theory suggests a return on investment made earlier by elders is also indicated by filial Investment Thesis in preparing for a rainy day. Hence, mutuality and filial values have common theoretical and empirical ground.

SUPPORT TRANSFERS TO OLDER ADULTS IN LATIN AMERICA: A NETWORK PERSPECTIVE

E. Storelli, *Boston College, Alexandria, Virginia*

This research examines social support transfers and networks among older adults (aged 60+) in five countries in Latin America: Argentina, Brazil, Chile, Mexico and Uruguay. Latin American countries are aging rapidly and, compared to Western Europe and North America, have had a relatively short amount of time to accommodate to their aging population. While families have traditionally served as the primary support network of older adults in the region, current demographic, social and economic changes have cast doubt on the future viability of these informal supports. Relatively little is known about support to older adults throughout the region. This paper presents findings on how network structure is associated with the receipt and provision of financial and instrumental support among older adults in Latin America. Data are from the Survey on Health, Well-Being, and Aging in Latin America and the Caribbean (SABE), which includes information on over 7,000 older adults living in urban centers throughout the region. Multi-level analyses also use data on over 50,000 members of older adults' household and family networks. Study findings confirm the importance of network structure for the receipt and provision of support among older adults in Latin America, highlighting regionally unique patterns. They also suggest a dynamic perspective of support provision throughout region, where network members jointly navigate motivating factors to provide support to older adults in need. Findings provide an important step in understanding elder support in Latin America, and offer a strong foundation for future assessments.

SESSION 2055 (PAPER)

CAREGIVING FOR GRANDCHILDREN

PERCEIVED ANGER TOWARD CUSTODIAL GRANDCHILDREN'S BIRTH PARENTS: SPILLOVER AND CROSSOVER EFFECTS ON THE MENTAL HEALTH OF CUSTODIAL GRANDPARENT DYADS

N. Toyokawa, G.C. Smith, K.E. Cichy, *Kent State University, Kent, Ohio*

Custodial grandparents' (CGP) commonly feel anger toward adult offspring whose irresponsible behaviors (e.g., drug abuse; incarceration) have caused them to assume full-time care of a grandchild. Yet, little is known regarding the impact of such anger on CGPs' mental health, including how it may impact relationship dynamics within married CGP dyads. Specifically, we tested a path analysis model with 193 CGP marital dyads where CGPs' anger was hypothesized to spill over to their depressive symptoms via their perceptions of burden and changes in marital relationship because of their unexpected caregiving responsibilities. Each spouse's sense of burden and perceived changes in their marital relationship was also hypothesized to cross over mutually within dyads. We found (CFI = 1.00) that the spillover of custodial grandmothers' (CGMs) anger to their own depressive symptoms was mediated by their sense of caregiving burden and perceived changes in their marital relationships ($\beta = 2.95$, $p = .003$). The spillover effect of custodial grandfathers' (CGFs) anger on their depressive symptoms was also significant, but mediated only by their sense of burden ($\beta = 2.46$, $p = .014$). The crossover effect of CGFs' anger on CGMs' sense of burden ($\beta = 2.50$, $p = .013$) and CGMs' perception of negative changes in the marital relationships on CGFs' higher depressive symptoms ($\beta = 2.30$, $p = .022$) were significant. We concluded that CGPs' anger toward birth parents has spillover effects on their own, as well as a crossover effect on their spouses', psychological and relationship distress. [Funded by R01-MH-66851]

WEB-BASED RESOURCEFULNESS TRAINING FOR GRANDMOTHER CAREGIVERS

C. Musil, J.A. Zauszniewski, J. Russek, P. Thongterm, *Case Western Reserve University, Cleveland, Ohio*

Resourcefulness is a repertoire of cognitive-behavioral skills for coping with adversity that involves the ability to perform daily responsibilities independently (personal resourcefulness) and to seek help from others (social resourcefulness) when needed. Resourcefulness is believed to bolster one's capacity to manage stress. Resourcefulness training (Zauszniewski) has been provided in face to face situations, which limits access. We developed and tested a web-based delivery of resourcefulness training using an online resourcefulness training video and online journaling rather than the previously used face-to-face training and pencil and paper journaling. Resourcefulness training was provided in a 30-minute online video with examples and resourcefulness skills applications tailored to grandmother caregivers for grandchildren. The pilot sample of grandmother caregivers (n=12) ranged in age from 39 to 77 (M=57.3) years and was recruited online and through a grandmother support group and community library notices. Subjects completed the baseline questionnaire that included measures of intra-family strains, self-rated and general health, family functioning, depressive symptoms, social support and demographics. Eleven grandmothers completed the 6-week follow-up of the same measures. Measures showed comparable reliabilities to pencil and paper administrations. We examined acceptability, feasibility and fidelity, and compared data on those who completed journaling with those who did not. Content of the journals was also examined. Results from this pilot support proof of concept and are encouraging for larger scale applications. Implications for online resourcefulness training and other interventions with grandmothers raising grandchildren and others are discussed.

INSIGHTS INTO THE SACRIFICES AND REWARDS OF LAKOTA GRANDPARENTS RAISING GRANDCHILDREN ON THE RESERVATION

M. Dennis, *University of Kansas, Lawrence, Kansas*

This presentation aims to reveal the unique experiences of American Indian elder caregivers of children living on the reservation. American Indian grandparents have a long history of providing physical, emotional and cultural care and instruction to their grandchildren. To date, there has been little research on American Indian grandparents and their experiences of caring for their grandchildren. Through in-depth qualitative interviews with 25 Lakota elders living on the Pine Ridge Indian Reservation, this study explored the experiences health and well-being across the lifespan. In these narratives, all of the Lakota elders reported raising grandchildren at some point in their lives. The next generation's well-being is always on the mind of the elders as they worry and provide financial and emotional support for their children and grandchildren and the grandchildren in the broader community. The Lakota elders shared the physical, emotional and spiritual strain of raising their grandchildren who were managing their own feelings of abandonment and loss of their parents. The elders were willing to sacrifice their own well-being and physical comfort for the success of their grandchildren, especially those grandchildren who were attending college and working towards positive goals. Investing in the future generations is a cultural value in which many of the elders served their families in hopes the grandchildren will have opportunities for a good life where they can support themselves and their families. The social work implications for working with elders, children and students who may be impacted by having an elder caregiver will be described.

GRANDPARENTS RAISING ADOLESCENT GRANDCHILDREN: A DYADIC ANALYSIS OF PARENTING INTERACTIONS

M.L. Dolbin-MacNab[1], K.A. Kopko[2], R.E. Dunifon[2], *1. Human Development, Virginia Tech, Blacksburg, Virginia, 2. Cornell University, Ithaca, New York*

For grandparents raising grandchildren, parenting is a defining feature of the caregiving role. In fact, the quality of grandparents' parenting has been linked to their well-being and to their grandchildren's emotional and behavioral problems. For grandparents raising adolescent grandchildren, parenting has been identified as one of their most significant stressors. Nevertheless, research has yet to explore, in any type of in-depth fashion, grandparents' actual parenting behaviors. Research on grandfamilies has also failed to capture the reciprocal nature of parenting – that grandchildren's behavior impacts their grandparents' parenting behavior. Thus, the primary purpose of this study was to examine grandparent and grandchild behavior that arises during interactions related to grandchild discipline, rules, and expectations. A secondary purpose was to examine major parenting issues that confront grandparents raising adolescent grandchildren. To address our research questions, we utilized data from a community sample of 53 grandparent-adolescent grandchild dyads. Dyads engaged in conversations about a topic of disagreement; the transcripts of the interactions were analyzed qualitatively. Findings suggest that major parenting issues include grandchildren's use of technology, peer relationships, responsibilities and privileges, and the generation gap. In responding to these parenting issues, grandparents engaged in a variety of positive, negative, and hostile parenting behaviors. They also shared their wisdom and experiences and invoked the potential future consequences of their grandchildren's behavior. Grandchildren responded to their grandparents' parenting behaviors by taking their grandparents' perspectives, working toward solutions to conflicts, challenging their grandparents, and managing their emotional reactivity and tension. Implications for parenting interventions will be addressed.

RACE AND ETHNIC DIFFERENCES IN GRANDCHILD CARE AND FINANCIAL TRANSFERS IN MULTIGENERATIONAL FAMILIES: AN INTERSECTIONAL RESOURCE APPROACH

Y. Lee[1,2], M. Silverstein[1,2], *1. Syracuse University, Syracuse, New York, 2. The Aging Studies Institute at Syracuse University, Syracuse, New York*

Grandparents often form the first line of defense in support of their adult children, particularly during difficult economic times. Support provided by grandparents to adult children most often takes the form of grandchild care for young children and provision of economic assistance. We examined whether care provided to grandchildren and money transfers to and from younger generations were differently related among older adults based on their race/ethnicity. Resource scarcity and immigrant adaptation theories suggest that time and money are more likely to be interchangeable resources and exchanged reciprocally in minority and less acculturated Hispanic families than in white non-Hispanic families. Data derived from 12,235 grandparents participating in the 2008 Health and Retirement Study, with reports about 25,378 adult children who were parents. Using logistic regression, results revealed that compared to white non-Hispanics, (1) Hispanic grandparents—particularly those preferring Spanish language—who provided financial support to adult children were less likely to provide grandchild care, and (2) African American grandparents who received financial support from adult children were more likely to provide grandchild care. We conclude that grandparents provide resources to their grand-families and receive resources from them in ways that suggest an adaptation to cultural conditions.

SESSION 2060 (SYMPOSIUM)

THE IMPACT OF SLEEP ON HEALTH IN AGING: MECHANISMS, NOVEL RISK FACTORS, AND OUTCOMES ACROSS MULTIPLE LEVELS

Chair: K.L. Stone, *Research Institute, California Pacific Medical Center, San Francisco, California*

Discussant: M.V. Vitiello, *Univesity of Washington, Seattle, Washington*

Introduction: Sleep is central to healthy aging, quality of life, and longevity. Recent large-scale epidemiological studies have investigated the genetic, sub-clinical, and behavioral correlates and mechanisms involved in differentiating sleep outcomes and their downstream health effects. Objective: In this symposium we present findings from population-based studies which examine specific sleep factors in relation to depression, mortality, and health care utilization. Sleep is highly health relevant and multi-factorial. Our presentations therefore span multiple levels of analyses, coinciding with the theme of the conference "Making Connections: From Cells to Societies." Attendees will be provided with specific, novel evidence linking specific sleep characteristics to health outcomes Presentations: We begin by presenting an investigation of the relationship between circadian gene polymorphisms and depressive symptoms. Next, we examine whether Circadian Rest-Activity Rhythms are a risk factor for increases in depressive symptoms. Third, using records obtained from Medicare/HMOs we examine whether and how sleep disturbances are related to increased inpatient health care utilization. Finally, we investigate how inflammatory burden, a sub-clinical marker, may mediate associations between objectively measured sleep disturbances and mortality. Discussion: These presentations span multiple levels of analysis and highlight the complexity and centrality of sleep in aging. Several unanswered questions which arise from each of our investigations will be discussed.

CIRCADIAN REST-ACTIVITY RHYTHMS PREDICT FUTURE INCREASES IN DEPRESSIVE SYMPTOMS AMONG COMMUNITY-DWELLING OLDER MEN

S.F. Smagula[1], S. Ancoli-Israel[2], T. Blackwell[3], R. Boudreau[1], M.L. Paudel[4], K.L. Stone[3], J.A. Cauley[1], *1. Epidemiology, University of Pittsburgh Graduate School of Public Health, Plainsboro, New Jersey, 2. Departments of Psychiatry and Medicine, University of California San Diego, San Diego, California, 3. Research Institute, California Pacific Medical Center, San Francisco, California, 4. Division of Epidemiology & Community Health, University of Minnesota, Minneapolis, Minnesota*

Objective: To examine longitudinal associations of circadian rest-activity rhythms (CARs) with depressive symptoms among community-dwelling older men. Methods: We examined associations of CARs (measured with actigraphy over a mean of 4.8 days) with depressive symptoms (measured with the Geriatric Depression Scale) among 2997 community-dwelling older men (mean age: 76.3 +/- 5.5) from the MrOS Sleep Study. Symptom change scores were calculated after an average follow-up of 1.2 (+/- 0.32) years and examined as mean change scores: >1 standard deviation (SD) and >2 SD increases. Results: Cross-sectional associations between rhythm amplitude (height) and mesor (mean) were independent of chronic diseases, lifestyle, sleep, and self-reported physical activity covariates. Longitudinally, low CAR robustness (being in the lowest quartile of the pseudo-F statistic) was independently associated with having a >2 SD (≥4 symptom) increase between visits (AOR=1.73, 95% CI 1.04-2.88, p=0.04). Conclusion: Low CAR robustness independently contributes to the risk of worsening depression symptomology.

SLEEP, INFLAMMATION, AND MORTALITY

J.A. Cauley[1], S.F. Smagula[1], K.L. Stone[2], S. Redline[3], S. Ancoli-Israel[4], E. Barrett-Connor[5], N.E. Lane[6], *1. Dept of Epidemiology, Graduate School of Public Health, University of Pittsburgh, Pittsburgh, Pennsylvania, 2. Research Institute, California Pacific Medical Center, San Francisco, California, 3. Division of Sleep Medicine, Brigham and Women's Hospital and Beth Israel Deaconess Medical Center, Boston, Massachusetts, 4. Departments of Psychiatry and Medicine, University of California San Diego, La Jolla, California and Department of Veterans Affairs San Diego Center of Excellence for Stress and Mental Health (CESAMH), LaJolla, California, 5. Division of Epidemiology, Department of Family and Preventive Medicine, University of California, San Diego, San Diego, California, 6. Aging Center, Medicine and Rheumatology, University of California at Davis School of Medicine, Sacramento, California*

Inflammation burden may mediate associations between sleep and mortality, however no prior investigations have tested this hypothesis. We assessed whether the associations of objectively measured sleep characteristics and mortality are mediated by inflammatory burden. Participants from the MrOS Sleep Study (n=2531) were an average age of 76.3 (5.5 s.d.) years at baseline and mortality was measured over an average follow-up time of 7.4 (1.9 s.d.) years. Significant indirect effects (through inflammatory burden) explained 22-43% of associations between the following sleep factors and mortality: spending ≥10% total sleep time with blood oxygen desaturation <90%, short sleep duration (<5 hours), and sleep latency ≥60 minutes (all p<0.001). Inflammatory burden may therefore biologically mediate associations between the above mentioned sleep characteristics and mortality risk. Associations between severe blood oxygen desaturation and sleep fragmentation persisted after accounting for inflammatory burden, therefore future research is needed to examine the mechanisms linking these factors to death.

THE IMPACT OF SLEEP/WAKE DISTURBANCES ON INPATIENT HEALTH CARE UTILIZATION IN OLDER WOMEN

M.L. Paudel[1], B. Taylor[1,2], J. Schousboe[3], S. Ancoli-Israel[4], K.L. Stone[5], S. Redline[6], K. Yaffe[7], K. Ensrud[1,8], *1. Division of Epidemiology and Community Health, University of Minnesota, Twin Cities, Minneapolis, Minnesota, 2. Center for Chronic Disease Outcomes Research, VA Medical Center, Minneapolis, Minnesota, 3. Park Nicollet Institute for Research and Education, Minneapolis, Minnesota, 4. UCSD, Department of Psychiatry, La Jolla, California, 5. California Pacific Medical Center, San Francisco, California, 6. Brigham and Women's Hospital, Boston, Massachusetts, 7. UCSF, Department of Psychiatry, San Francisco, California, 8. VA Medical Center, Department of Internal Medicine, Minneapolis, Minnesota*

The extent to which poor sleep impacts health care utilization(HCU) in older community-dwelling women is uncertain. We examined 2,103 women (mean(SD) age of 84.2(3.9) years) enrolled in the Study of Osteoporotic Fractures. Sleep disturbances were assessed at the visit 8 exam using wrist actigraphy for a mean(SD) of 4.2(0.7) nights and by self-report(Pittsburgh Sleep Quality Index(PSQI)). Inpatient HCU assessed using Medicare and/or HMO data. Risk of hospitalization and rate-ratio of inpatient days was estimated using Logit-Poisson Hurdle Models. 1,157(55%) women were hospitalized during an average 2.8(0.6) years of follow-up. In age-adjusted models, sleep/wake disturbances were associated with a 20-50% increased rate of inpatient days. Results were attenuated and no longer statistically significant after adjusting for health-related factors and disability. Poor sleep quality(PSQI>5) was not associated with inpatient HCU. Older women with sleep disturbances have greater inpatient HCU, which was largely explained by a greater burden of comorbidities and disability.

CIRCADIAN GENE POLYMORPHISMS AND DEPRESSIVE SYMPTOMS IN OLDER ADULTS

G.J. Tranah[1,3], J.E. Maglione[2], S. Ancoli-Israel[2], S. Redline[4], K. Yaffe[3], K.L. Stone[1], *1. Research Institute, California Pacific Medical Center, San Francisco, California, 2. University of California, San Diego, San Diego, California, 3. University of California, San Francisco, San Francisco, California, 4. Harvard Medical School, Boston, Massachusetts*

Depression is common in older adults and associated with poor outcomes. Circadian dysfunction has been implicated in depression; however, the relationship between circadian genes and depressive symptoms in older adults is unclear. We performed a genetic association study of 529 SNPs representing 30 circadian genes in two population-based cohorts: Osteoporotic Fractures in Men Study (n=1270, 77±5.6 years) and the Study of Osteoporotic Fractures in women (n=1740, 84±3.5 years) and a meta-analysis was performed. Depressive symptoms were assessed with the Geriatric Depression Scale. There were associations meeting multiple testing criteria for significance between several PER3 SNPs and one RORA SNP and the development of mild and more severe depressive symptoms. Additional work to be presented will make use of several methodologies to assess genome-wide pleiotropic effects on sleep and depression and to identify genetic variation that mediates the effect of sleep disturbance on depressive symptoms.

SESSION 2070 (SYMPOSIUM)

HIP REHAB: A RANDOMIZED TRIAL OF A HOME-BASED EXERCISE PROGRAM AFTER HIP FRACTURE REHABILITATION

Chair: N. Latham, *Health and Disability Research Institute, Boston University School of Public Health, Boston, Massachusetts*
Co-Chair: A. Jette, *Health and Disability Research Institute, Boston University School of Public Health, Boston, Massachusetts*
Discussant: J. Magaziner, *Dept of Epidemiology and Public Health, University of Maryland School of Medicine, Baltimore, Maryland*

Most people continue to have significant mobility limitations for at least two years after a hip fracture. Supervised, intensive exercise programs to extend the benefits of traditional hip fracture rehabilitation improve function, but the benefits of less-supervised home-based programs were unclear. The aim of the HIP Rehab randomized controlled trial (n=232) was to investigate whether a 6-month functionally-oriented home exercise program (i.e. HIP Rehab) which required minimal contact with a physical therapist (PT) improved function after traditional hip fracture rehabilitation ended, compared with an attention-control group. Primary outcomes were function at 6-months, as measured by the Short Physical Performance Battery (SPPB) and Activity Measure for Post-Acute Care (AM-PAC) Mobility and Daily Activity. The intervention group showed significant improvement relative to the control group at 6 months (SPPB P<0.001; AM-PAC Mobility P=0.03; AMPAC Daily Activity P=0.026). Significant between group-differences persisted 9 months after randomization for all functional measures. This symposium will explore the findings of this trial and is comprised of five presentations. First, the study background, methods and primary findings will be presented. Second, the impact of the intervention on pre-specified subgroups of patients will be explored and the specific adaptations that the PTs made to the exercise program for different subgroups of patients will be described. Factors that mediated functional change will be explored with psychological factors explored in the third presentation and physical impairments in the fourth. Finally, in the fifth presentation the implications of this research and proposed new research will be discussed.

DESIGN AND PRIMARY FINDINGS OF THE HIP REHAB TRIAL OF HOME EXERCISE AFTER HIP FRACTURE

N. Latham[1], B. Harris[2], J.F. Bean[3,4], P. Ni[1], D.M. Heislein[5], T. Heeren[6], A. Jette[1], *1. Health and Disability Research Institute, Boston University School of Public Health, Boston, Massachusetts, 2. MGH Institute of Health Professions, Boston, Massachusetts, 3. Spaulding Rehabilitation Hospital, Boston, Massachusetts, 4. Department PM&R, Harvard Medical School, Boston, Massachusetts, 5. College of Health and Rehabilitation Sciences: Sargent College, Boston University, Boston, Massachusetts, 6. Department of Biostatistics, Boston University School of Public Health, Boston, Massachusetts*

The aim of this randomized controlled trial was to determine the efficacy of a 6-month home exercise program to improve function after formal hip fracture rehabilitation ended. Older adults (n=232) with recent hip fracture were randomized to exercise or attention control. Functionally-oriented exercises were taught in 3-4 home visits by a physical therapist and performed independently over 6 months. Exercise intensity was progressed using therabands, weighted vests and steps of varying height. Physical function was assessed at baseline and 6 months by blinded assessors using the Short Physical Performance Battery (SPPB) and Activity Measure for Post-Acute Care (AMPAC). Loss to follow-up was 15.9%. The exercise group showed significant improvement relative to the control group in at 6 months for all primary endpoints (adjusted analyses (for age, gender and baseline scores): SPPB, $P<0.001$; AM-PAC Mobility Function $P=0.03$; AMPAC Daily Activity Function $P=0.026$). SPPB scores exceeded minimum clinically important differences.

THE HIP REHAB INTERVENTION: EXPLORING ADHERENCE, PROGRESSIONS AND EXERCISE MODIFICATIONS

B. Harris[1], C. Goodyear[2], D.M. Heislein[3], N. Latham[4], J.F. Bean[5,6], P. Ni[4], A. Jette[4], *1. Physical Therapy, MGH Institute of Health Professions, Boston, Massachusetts, 2. Spaulding Rehabilitation Network, Boston, Massachusetts, 3. College of Health and Rehabilitation Sciences: Sargent College, Boston University, Boston, Massachusetts, 4. Health and Disabilty Research Institute, Boston University School of Public Health, Boston, Massachusetts, 5. Department of PM&R, Harvard Medical School, Boston, Massachusetts, 6. Spaulding Rehabilitation Hospital, Boston, Massachusetts*

The intervention used in the HIP Rehab trial was a 6-month long home-based functionally-oriented exercise program taught by physical therapists (PTs) over 3-4 home visits. Older people who had completed all usual hip fracture rehabilitation were asked to exercise three times per week in their home, with a DVD for guidance. HIP Rehab included a cognitive-behavioral component; functional exercises using Theraband; and stepping exercises using steps and weighted vests. While a standardized program, PTs progressed the exercises by increasing the overload or adding more challenging exercises, or omitted/modified difficult exercises. Overall, participants adhered to 70% of prescribed exercise sessions. Most people progressed to higher levels of overload (i.e. 8% used the two most resistant exercise bands in the final week) and more challenging exercises (i.e. 60% attempted the stair and weighted vest exercises). Adherence, progressions and PT modifications will be explored by type of exercise, and by subgroups of patients.

THE MEDIATION EFFECTS OF SELF-EFFICACY ON FUNCTIONAL OUTCOMES IN THE HIP REHAB TRIAL

F. Chang[1], N. Latham[1], P. Ni[1], J.F. Bean[2,3], R. Ward[2,3], A. Jette[1], *1. Health and Disability Research Institute, Boston University School of Public Health, Boston, Massachusetts, 2. Spaulding Rehabilitation Hospital, Boston, Massachusetts, 3. Department of PM&R, Harvard Medical School, Boston, Massachusetts*

This session will examine whether self-efficacy mediated the effect of the HIP Rehab exercise program on activity limitations in older adults after hip fracture. Participants (n=232) with hip fracture were randomly assigned to the intervention (i.e. HIP Rehab, a functionally-oriented, home-based exercise program) or attention control groups. Data were collected at baseline, post-intervention (6 months), and follow-up (9 months). The mediation effect of HIP Rehab on Basic Mobility function through self-efficacy for exercise was not significant at 6 months (βindirect=0.06), but was significant at 9 months (βindirect=0.21). The mediation effect of the intervention on Daily Activity function through self-efficacy for exercise was not significant at 6 months (βindirect=0.12), but was significant at 9 months (βindirect=0.49). In subgroup analyses, the mediation effect was only significant in the younger group and in females. Self-efficacy plays a partial mediating role for the effect on longer-term functional outcomes in the HIP Rehab intervention.

CHANGES IN PHYSICAL IMPAIRMENT VARIABLES IN THE HIP REHAB TRIAL

R. Ward[1,2,3], F. Chang[2], N. Latham[2], P. Ni[2], A. Jette[2], J.F. Bean[1,3], *1. Physical Medicine and Rehabilitation, Spaulding Hospital, Canbridge, Massachusetts, 2. Health and Disability Research Institute, Boston University School of Health, Boston, Massachusetts, 3. Department of PM&R, Harvard Medical School, Cambridge, Massachusetts*

This session will focus on the physical impairment variables in the HIP Rehab trial. It will explore how these variables, which include balance; knee extension strength and reaction time, changed in response to the intervention overall and by subgroups of participants (e.g. by age and sex). Participants (n=232) had significant physical impairment at baseline (e.g. mean Berg Balance Score of 40/56 which is consistent with high fall risk). Overall, participants experienced statistically significant improvements in balance at both 6- and 9-months ($P<0.001$), but much smaller and inconsistent changes in strength and reaction time. This session will also explore whether changes in these impairments mediated the effect of the HIP Rehab exercise program on functional changes in older adults after hip fracture, as measured by the Activity Measure for Post Acute Care (AMPAC) Daily Activity domain at 6-months and 9-months post-randomization.

HIP REHAB: TRANSLATION AND FUTURE RESEARCH DIRECTIONS

A. Jette[1], B. Harris[2], J.F. Bean[3,4], P. Ni[1], N. Latham[1], *1. Health and Disability Research Institute, Boston University School of Public Health, Boston, Massachusetts, 2. MGH Institute of Health Professions, Boston, Massachusetts, 3. Spaulding Rehabilitation Hospital, Boston, Massachusetts, 4. Department of PM&R, Harvard Medical School, Boston, Massachusetts*

This session will explore implications of the HIP Rehab trial, and discuss future research directions for hip fracture rehabilitation research. The findings of the HIP Rehab study and other research suggest that following traditional hip fracture rehabilitation, people are left with residual functional limitations and disability, and that many have the capacity to improve their function beyond what usual rehabilitation provides if an appropriate program is provided. Next research steps should include exploring the effectiveness of these types of interventions in "less expert" settings, the cost-effectiveness of the interventions, and the comparative effectiveness if delivered by clinicians in lieu of more traditional forms of rehabilitation. Translation of this program to clinical settings might be most feasible if it is delivered using mobile health (mHealth) or other technology platforms which would allow care providers to efficiently monitor, coach and modify exercises without the need for in-person visits by physical therapists.

SESSION 2075 (SYMPOSIUM)

A MULTI-SITE APPROACH: COMMUNITY IMPACT THROUGH EVIDENCE BASED HEALTH PROMOTION AND CHRONIC DISEASE MANAGEMENT

Chair: C.J. Beverly, *College of Nursing, University of Arkansas for Medical Sciences, Little Rock, Arkansas*
Co-Chair: R.E. McAtee, *College of Nursing, University of Arkansas for Medical Sciences, Little Rock, Arkansas*
Discussant: T. Cortes, *New York University, New York, New York*

The population of older adults is growing exponentially requiring increased primary care services across settings that reflect evidence based age specific quality of care, better outcomes, and lower cost. Increasing numbers of older adults are entering old age healthier than in the past but as they age have a higher prevalence of one or more chronic diseases that must be managed. A multi-site system design with a primary care approach to population based health focused on promoting health, managing chronic disease and employing an inter-professional team of Gerontological specialists will be presented. A major benefit of this type design is that it serves as a conduit for disseminating clinical and education programs and is most effective through use of technology. The primary care setting is the hub for the management of chronic diseases, the prevention of avoidable functional loss through chronic disease self-management and the coordination of care as people move in and out of different healthcare settings. Access to effective primary care depends on a high functioning, inter-professional team of Gerontological specialists which utilize evidence-based practice to achieve quality outcomes. This session will address multi-site innovations developed to provide health promotion, Gerontological workforce development and chronic disease self-management for older adults through a multi-site, state wide approach in AR which is being replicated in Oklahoma. Application of telehealth technology will also be discussed. Presentations describe innovative programs that capitalize on a multi-site system that promotes workforce development, describes the process for state replication and enhanced population based education.

THE OKLAHOMA HEALTHY AGING INITIATIVE: REPLICATION AND TRANSLATION OF THE ARKANSAS AGING INITIATIVE

C. Dowers-Nichols[1], L. Rubenstein[1], A. Dentino[1], C.J. Beverly[2], T. Teasdale[1], *1. Department of Geriatric Medicine, University of Oklahoma, Oklahoma City, Oklahoma, 2. University of Arkansas, Litte Rock, Arkansas*

The Oklahoma Healthy Aging Initiative (OHAI) at the Donald W. Reynolds Department of Geriatric Medicine at the University of Oklahoma, College of Medicine was designed to establish a senior health network across the state. Modeled after the Arkansas Aging Initiative, OHAI employs a three-prong approach to improve health of older adults: 1. Increase access to interdisciplinary geriatric healthcare 2. Provide excellence in health education to health providers, seniors, and caregivers 3. Enhance health and aging policy OHAI particularly focuses on rural settings which present specific obstacles to improving health. Limited access to care and poor health literacy are only two of the challenges faced. Oklahoma's health landscape is also impacted by the number of American Indian nations and their affiliated health systems. This session will discuss the replication process as well as the current status and progress of OHAI.

A GERIATRIC TELEHEALTH PROGRAM: CONNECTING THE OKLAHOMA HEALTHY AGING INITIATIVE TO RURAL HOSPITALS

A. Dentino, C. Dowers, B.N. Ngo, C. Shaw, C. Scheideman-Miller, T. Teasdale, L. Rubenstein, *OUHSC, Oklahoma City, Oklahoma*

Objectives: 1 Attendees will become acquainted with one approach (the OHAI) in delivering geriatric services via electronic telemedicine equipment to rural communities across our state 2. Attendees will consider how their respective practices, networks or health care systems might incorporate asynchronous, teleservices to reach sectors of their constituencies not easily physically accessible The Oklahoma Healthy Aging Initiative (OHAI) has developed a Geriatric Telehealth Program (GTP) to provide interprofessional health care in a variety of rural settings (tribal health systems, Federally Qualified Health Centers, and other small primary care settings). The program has received funding from the USDA to establish twelve telesatellite systems, and has applied for additional support from the Donald W. Reynolds Foundation. The GTP is also partnering with the Oklahoma City Veterans Administration Medical Center to link these systems with local health centers serving Veterans. Clinical and educational programs are provided by and disseminated via the GTP. This presentation discusses and focuses on the challenges to rural geriatric care; to the OHAI's response to these challenges via the GTP; and to the many benefits to communities, providers, patients/families and learners by utilizing 21st century technology to bring health care to underserved regions and to lessen health disparities.

EDUCATING CAREGIVERS FOR THE OLDER ADULT HOME: REPLICATION OF A STATEWIDE PROGRAM

R.E. McAtee, C.J. Beverly, *Donald W. Reynolds Institute on Aging, University of Arkansas for Medical Sciences, Little Rock, Arkansas*

Educating a workforce to care for older adults in the home is the primary goal of the Schmieding Home Caregiver Training program. With over 12 years of experience, the curriculum has been successfully implemented in 9 sites across Arkansas and replicated in 4 states. The need is quickly expanding for quality, formally trained caregivers to care for the rapidly increasing number of older adults who wish to remain in their home as they age. This program provides education and skills training to help caregivers learn how to properly care for these adults. The program has 3 progressive certification levels; In Home Assistant (40 hrs), Home Care Assistant (60 hrs) and Dementia Training (16 hrs) providing increased knowledge and skill competencies at each level. This presentation will review the quantitative and qualitative outcomes and the operational aspects of the replication of this education program across multiple sites and states.

EVIDENCE-BASED SELF-MANAGEMENT PROGRAMS: THE IMPACT ON THE HEALTH OF COMMUNITIES

R.E. McAtee[1], K. Packard[1], T. Horton[1], C. Dowers[2], *1. Donald W. Reynolds Institute on Aging, University of Arkansas for Medical Sciences, Little Rock, Arkansas, 2. Oklahoma Health Sciences Center, Oklahoma City, Oklahoma*

Educating older adults is critical for preventing and managing chronic conditions. Chronic conditions and the untoward events that occur because of them are costing the US healthcare system billions of dollars annually. Arkansas and Oklahoma are taking a unique statewide approach to attack this growing problem. They have both created Regional Centers on Aging throughout their states that focus on the education of older adults, their families, the health care professionals that care for them, and the students of the healthcare disciplines. Many of the programs offered target self-management concepts such as classes on diabetes self-management and other programs that support the associated behaviors such as healthy cooking and exercise programs. This presentation will review how these evidence-based programs have impacted the health and quality of life of the older adults served and outline how the impact is being tracked.

SESSION 2080 (PAPER)

PHYSICAL PERFORMANCE

MOTOR DECLINE AS A PREDICTOR OF DISABILITY IN OLDER ADULTS

F. Artaud[1,2], A. Singh-Manoux[1,3,4], A. Dugravot[1,2], B. Tavernier[5], C. Tzourio[6,7], A. Elbaz[1,2], *1. INSERM U1018 Centre for Research in Epidemiology and Population Health, Villejuif, France, 2. University Versailles St-Quentin, Versailles, France, 3. University College London, London, United Kingdom, 4. Hôpital Ste Périne, Paris, France, 5. CHU Dijon, Dijon, France, 6. INSERM U897, Bordeaux, France, 7. University of Bordeaux, Bordeaux, France*

Poor motor performances predict future disability but few studies have investigated the effect of motor decline on future disability. Our objective was to examine the independent relation of baseline walking speed (WS) and change in WS with onset of disability. The analyses included 3,562 (61% women) French community-dwelling older participants (65-85y) from the Dijon centre of the Three-City cohort study with up to five WS and six disability assessments over 11 years of follow-up. We studied the relation between baseline WS, slope of change in WS, and incidence of disability, while taking into account the competing risk of death and dropout, using joint models for longitudinal and time-to-event data; models were adjusted for age, sex, and marital status. During a mean follow-up of 5.3 (SD=4.3) years, 576 (68.6% women) participants developed disability. Mean baseline WS was 154 cm/s and mean WS decline was 1.70 cm/s/y. The relative risk of disability was of 1.84 (95% Confidence Interval (CI)=1.58-2.15) per decrease of one standard deviation in baseline WS (-30 cm/s) and of 2.03 (95% CI=1.35-3.05) per decrease of one standard deviation in the slope of change in WS (-1.32 cm/s/y) when both predictors were included in the same model. Independently of baseline motor performances, decline in WS was associated with disability onset; the strength of the association was similar for baseline WS and slope of change in WS. Our results underline the interest of repeated motor assessments in older adults in order to identify those at higher risk of becoming disabled.

INTERPRETING NON-SIGNIFICANT FINDINGS: PHYSICAL PERFORMANCE MEASURES IN AN EVIDENCE-BASED PROGRAM

N.T. Dawson[1], H.L. Menne[2], *1. Cleveland State University, Sagamore Hills, Ohio, 2. Benjamin Rose Institute on Aging, Cleveland, Ohio*

Reducing Disability in Alzheimer's Disease (RDAD) is an evidenced-based dyadic intervention for individuals with dementia and their caregivers aimed at reducing the psychosocial strain of the caregiver and improving functional ability of the individual with dementia. Overall efficacy results as well as acceptability and feasibility outcomes have been published regarding the RDAD intervention; however, no specific outcome information has been published on the objective physical performance measures (PPM) of walking speed, functional reach, and balance. Data from the Ohio Replication of RDAD (n=326) was utilized to analyze the change in these three physical performance measures from enrollment to 3 months. It was hypothesized that each PPM would show change for participants who completed 3 months of the program. No significant changes were identified in 3 physical performance measures: gait speed (t=.24, p=.81), balance (t=.23, p=.82), and functional reach (t=-.55, p=.58). These results contribute to two main points of discussion. First, further research and consideration is needed as to the possible mismatch between the intervention protocol and these PPM. For example, the intervention protocol may require a sufficient dosage of intervention with respects to fundamental exercise science principles, or there may be poor adherence to principles of specificity of training. Second, use of these PPMs, which have been used successfully in large-scale studies of older adults, may not be appropriate for a sample of individuals with dementia. Discussion and interpretation of non-findings is important as we seek to improve on intervention design and methodological considerations in intervention research.

APATHY SEVERITY AS A PREDICTOR OF FUNCTIONAL STATUS AMONG PERSONS WITH ALZHEIMER DISEASE

E.D. Goris[1], D.L. Schutte[2], *1. Hope College, Holland, Michigan, 2. Wayne State University, Detroit, Michigan*

Apathy, defined as a disorder of motivation with deficits in behavioral, emotional, and cognitive domains, is a prevalent behavioral symptom among persons with Alzheimer Disease (AD). Apathy occurs across the disease trajectory and is associated with serious complications, including physical deconditioning, uncooperativeness with care, and social isolation. This work examines the extent to which severity of apathy influences functional status in persons with AD, after adjusting for AD severity. Sixty-six participants were recruited as part of a larger project to examine apathy, genetics and functional status among persons with AD. Apathy, as measured by the Neuropsychiatric Inventory Apathy subscale (NPI-Apathy), was present among the majority of participants (53.0%, n=35), with a mean age of 85.83 (SD=7.35) years. Participants demonstrated moderately compromised cognition with a mean total Severe Impairment Battery (SIB) score of 50.66 (SD=39.09; range: 0-100). Severity of apathy, controlling for cognition (SIB total score), significantly predicted 50.7% of the variance in function as measured by Functional Assessment Staging Test (FAST) score (F=27.774, p<.0001). Additionally, apathy severity as measured by the NPI-Apathy, controlling for cognition, significantly predicted 26.6% of the variance in function as measured by the Functional Abilities Checklist (FAC) Self Care subscale (F=2.513, p<.0001) and 48.8% of the variance in function as measured by the FAC Cognitive Status subscale (F=25.766, p<.0001). Controlling for cognition, severity of apathy remained a significant predictor of function among persons with AD. Study findings may contribute to a risk profile for identifying individuals most at risk for functional decline based on apathy severity.

SESSION 2085 (SYMPOSIUM)

INTEGRATION OF RESEARCH, EDUCATION, AND PRACTICE TO IMPROVE PAIN MANAGEMENT IN OLDER ADULTS

Chair: T. Monroe, *Nursing/Institute of Imaging Science, Vanderbilt University, Nashville, Tennessee*
Discussant: W.G. Chen, *National Institute on Aging, Bethesda, Maryland*

Throughout its history, the Gerontological Society of America has aspired to be a professional organization that links research, education, and practice. Despite this laudable goal, many critics have argued that these three essential components of the equation have had only limited success in achieving real integration. Reasons for this disconnect range from cultural differences between the research, education, and practice communities, differing values and goals, funding limitations, and different reward systems in each sector. Practitioners experience the need for a core belief in the effectiveness of their work, while researchers are driven by a value of disbelief and thus want to evaluate whether a program or practice works. Although interest of practitioners in evidence-based practice in their work with older adults has increased since the 1990s, the work of practitioners, researchers, and educators often lacks integration. The Research, Education, and Practice Committee (REP) of GSA is committed to the identification and dissemination of examples of projects that have successfully linked these components. There are important pockets of success in which research, education, and practice have become integrated in their efforts to improve the health and well-being of older adults, and these examples should be highlighted. This symposium includes presentations by three individuals who have dedicated their careers to the improvement of pain detection and management in older people with and/or without dementia. Their pain initiatives provide substantive examples that showcase successful integration of research, education, and practice.

ONE SCHOLAR'S JOURNEY TO IMPACT QUALITY PAIN CARE FOR OLDER ADULTS

K.A. Herr, *College of Nursing, University of Iowa, Iowa City, Iowa*

Over the past 25 years, Dr. Herr has developed a program of research and scholarly contributions with the goal of improving pain care in older adults. Fueled by personal circumstances and commitment, the speaker shares career development activities that contributed to growing influence and impact on the science and practice of pain assessment and management in the US and beyond. Early research efforts focused on establishing the problem of pain in older persons and improving pain assessment self-report techniques. Advancing strategies for assessment in nonverbal populations followed, along with improving use of evidence-based practices in different care settings. Building an evidence-base and dissemination of new knowledge are key elements for practice improvements. The speaker illustrates the linking of research, education and practice in increasing impact to improve pain care for older adults.

IMPROVING QUALITY OF LIFE FOR OLDER ADULTS: A FOCUS ON RELIEVING PAIN

A. Horgas, *College of Nursing, University of Florida, Gainesville, Florida*

Dr. Horgas' career has focused on interdisciplinary aging research, focusing on strategies to improve the health and functioning of older adults. Her program of research has focused primarily on pain management in persons with dementia. As a gerontological nurse, she observed suboptimal pain management among nursing home residents. This launched her interest in understanding factors that contribute to poor pain management and to develop strategies to assess pain in vulnerable populations, such as people with dementia. Dr. Horgas will discuss this program of research as well as her complementary research activities that forged an academic career aimed at improving the quality of life for older adults, particularly in the area of pain management.

UNEQUAL BURDENS AND UNHEARD VOICES: ONE SCHOLAR'S PURSUIT FOR HEALTH AND PAIN CARE EQUITY

C.R. Green, *University of Michigan Health System and Medical School, Ann Arbor, Michigan*

Dr. Green developed a health disparities and policy-relevant research program that focuses on the role that race, ethnicity, gender, age, and class play on access, assessment, and quality of care. Her scholarly contributions on clinician and patient variability in pain management decision-making have influenced national policy. Dr. Green worked in the U.S. Congress as a health policy analyst and was instrumental in writing the National Pain Care Policy Act and the IOM report. Her work is fueled by patient care and the power of narrative. Specifically, the unequal burden of pain and previously unheard stories led to her commitment to act locally and on the national level. Dr. Green will share important crossroads in her career, career development activities, and her journey. The speaker will link clinical practice, research, education and policy to improve pain care for all, especially older minority men and women who may be vulnerable and underserved.

SESSION 2090 (SYMPOSIUM)

EMPOWERING PERSON-CENTERED CARE: INNOVATIVE SOLUTIONS FOR DEMENTIA CARE DELIVERY

Chair: A. Holzapfel, *The Global CEO Initiative on Alzheimer's Disease, Devon, Pennsylvania*
Discussant: J. Beck, *Home Instead Senior Care, Omaha, Nebraska***Discussant:** R. Shih, *RAND Corporation, Washington, District of Columbia*

The G8 has pledged to identify a cure or disease-modifying therapy for dementia by 2025. While an ambitious goal that will no doubt have positive implications for future generations, today there are more than 44.4 million people suffering from the disease worldwide. With a staggering 7.7 million new dementia cases reported each year and costs of care already exceeding $600 billion, the urgency behind accelerating innovations in care delivery for today's dementia victims cannot be overstated. Our symposium will address the critical need for increased attention and resources for dementia long-term services and support (LTSS). Symposium participants will gain new insight into the intersection of dementia and LTSS, key challenges in improving dementia LTSS, associated costs and best practices of informal and formal long-term care, as well as innovations in person-centered care delivery. Specifically, the RAND Corporation will present its cutting-edge research to be released in 2014 that provides a qualitative assessment of perspectives from nearly 30 stakeholders on potential policy solutions. The Global CEO Initiative on Alzheimer's Disease (CEOi) will provide ways to create comprehensive, interdisciplinary care practices that champion the needs, health, safety, and wellness of both the patient and caregiver. The Leaders Engaged on Alzheimer's Disease (LEAD) Coalition will address how changing demographics and advances in dementia science are altering public attitudes and government policy-making. A fourth presentation from HomeInstead will address the need for the development of a longer view of Alzheimer's disease – from pre-symptomatic to end-of-life –, an ecosystem for care delivery and dementia-friendly communities. Submitted by: Drew Holzapfel dholzapfel@highlanterngroup.com

IDENTIFICATION OF POLICY OPTIONS FOR DEMENTIA LONG-TERM CARE THROUGH STAKEHOLDER ENGAGEMENT

R.A. Shih, T.W. Concannon, J.L. Liu, E. Friedman, *RAND Corporation, Arlington, Virginia*

Recent national policy and research strategies have focused on dementia or long-term services and supports (LTSS) individually, but none have focused attention on the intersection of LTSS and dementia. In a qualitative study, we engaged stakeholders representing patients, providers, purchasers, payers, policymakers, and principal investigators. Key informant interviews with these stakeholders solicited policy options that address gaps in the LTSS system for persons with dementia and their caregivers. We evaluated the policy options against 14 criteria and summarized the options by expected impact, feasibility, dementia stage, and stakeholder group. Stakeholders identified 45 policy options that may help decision-makers improve the LTSS delivery system, workforce, and financing for persons with dementia and their caregivers. Our evaluation identified 13 policy options that could be undertaken more immediately with the strongest impact. These policy options serve as a foundation upon which stakeholders of many types can prioritize, plan, implement and evaluate policy change.

ADVANCES IN DEMENTIA TREATMENT RESHAPING POLICY LANDSCAPE

I. Kremer, *Leaders Engaged on Alzheimer's Disease (LEAD) Coalition, Herndon, Virginia*

Presenter: Ian Kremer, Esq. Executive Director LEAD Coalition Changes in the demographic, economic and social landscape of Alzheimer's disease and related disorders (ADRD) are interacting with advances in research to address ADRD detection, diagnosis, prevention, treatment and care. Leaders Engaged on Alzheimer's Disease (LEAD Coalition) will examine how these forces are altering the political environment and government policy-making both domestically and internationally.

INTEGRATING PERSONALIZED, NON-MEDICAL IN-HOME CARE INTO THE CARE CONTINUUM

J. Beck, *Home Instead Senior Care, Omaha, Nebraska*

The economic and social challenges brought on by the world's rapidly aging population require scalable, sustainable solutions to transform this perceived peril into promise. At the same time, global aging presents opportunities for societies and individuals alike – if approached with solutions that meet the needs of this demographic cohort and their caregivers. As the aging demographic shift creates growing demand for elder care services, development and expansion of flexible and affordable options for increasing the world's capacity to care will be required. Both governments and businesses have a role to play in creating new models of care that anticipate future demographic needs. Alzheimer's provides an opportunity to redefine the care ecosystem and provide solutions for many neurodegenerative diseases and age-related chronic conditions. A key to success will be the adoption of a longer-term view of aging, brain health and care support in the community.

ESTABLISHING INTERNATIONAL NORMS FOR ALZHEIMER'S CARE DELIVERY: A GLOBAL PRIORITY

G. Vradenburg, *The Global CEO Initiative on Alzheimer's Disease, Washington, District of Columbia*

Most nations have not taken the most basic steps in developing a response to the challenge of Alzheimer's and Dementia. For example, only 13 nations of the 194 members of WHO have a dementia plan. Absent a set of international norms, countries are unable to determine whether and to what extent the steps they are taking are adequate or effective. To truly make strides, experts and diverse stakeholders need to align and develop international norms for nations to assess their readiness and capacity to address the challenge of Dementia in their societies. Such norms should be viewed as an international learning system and not as a 'grade' or as 'punitive' in nature. The Global CEO Initiative on Alzheimer's Disease will discuss its efforts to serve as a convener during 2014 to identify these norms, highlight best practices and work with leading international organizations to respond to the challenge of Alzheimer's.

SESSION 2095 (SYMPOSIUM)

PHYSICIAN EXTENDERS IN NURSING HOMES: CONTEXTUAL FACTORS AND IMPACT

Chair: R. Weech-Maldonado, *Health Services Administration, University of Alabama at Birmingham, Birmingham, Alabama*
Discussant: K. Hyer, *University of South Florida, Tampa, Florida*

Nursing homes are increasingly using physician extenders (PE) (physician assistants and nurse practitioners) as a staffing strategy, with the proportion of nursing homes using a PE almost doubling from 2000 (19.8%) to 2010 (37.1%). PEs can increase the provision of primary care, and improve the management of acute illnesses as well as care coordination with physicians and nursing staff. As such, PEs may result in lower hospitalizations and rehospitalizations and improved resident outcomes. Furthermore, Medicare reimburses nursing facilities for PEs at 85% of the physician fee schedule for similar services. Therefore, PEs may be a cost-effective staffing strategy to improve nursing home quality. However, further research is needed to examine the contextual factors associated with use of PEs by nursing homes, and their potential impact on quality and financial performance. The papers in this symposium examine longitudinal data (2000-2010) of a national sample of nursing homes. Data sources include: LTCFocus, Online Survey, Certification and Reporting (OSCAR), Medicare Cost Reports, and the Area Resource File (ARF). The first presentation explores the resident, organizational, and market characteristics of nursing homes associated with use of PEs. The second presentation examines the relationship between use of PEs and hospitalization and rehospitalization rates of nursing homes. The third presentation analyzes the relationship between use of PEs in nursing homes and RN staffing, costs, and financial performance. This symposium will allow participants to understand the factors behind the growth of PEs in nursing homes, and the potential implications of the use of this staffing strategy.

PHYSICIAN EXTENDERS IN NURSING HOMES: IMPLICATIONS FOR RN NURSE STAFFING, COSTS, AND FINANCIAL PERFORMANCE

R. Weech-Maldonado[1], R. Pradhan[2], S. Gupta[1], *1. Health Services Administration, University of Alabama at Birmingham, Birmingham, Alabama, 2. University of Arkansas Medical Sciences, Little Rock, Arkansas*

The use of physician extenders in nursing homes has the potential to increase Medicare revenues from billable services. PEs may also reduce nursing home costs as a result of lower medication rates, better resident outcomes, and greater RN efficiency. The combination of higher revenues and lower costs may result in better financial performance. Using longitudinal data (2000-2010), this study examines the relationship between use of PEs and RN staffing, costs, and financial performance. Data sources include: LTCFocus, OSCAR, Medicare Cost Reports, and ARF. The dependent variables are RN staffing intensity (RNs per 1000 resident days), operating costs per inpatient day, operating margin, and total margin. The primary independent binary variable identifies the use of PEs. Control variables consist of: size, for-profit status, chain affiliation, payer mix, occupancy rate, case mix, and competition. Data are analyzed using a panel regression with facility and year fixed effects to control for unobserved factors.

USE OF PHYSICIAN EXTENDERS IN NURSING HOMES: RESIDENT, ORGANIZATIONAL, AND MARKET FACTORS

S. Gupta[1], N. Patidar[1], J. Epane[2], R. Weech-Maldonado[1], *1. The University of Alabama at Birmingham, Birmingham, Alabama, 2. University of Nevada Las Vegas, Las Vegas, Nevada*

The study examines the resident, organizational, and market factors that may influence nursing homes' decision to have PEs. Longitudinal data (2000-2010) was derived from LTCFocus (N=16,341). The binary dependent variable represented nursing homes' decision to have PEs. The independent variables included resident, organizational, and market characteristics. A panel logistic regression with facility random effects and state and year fixed effects was used for analysis. Significance was determined by p-values < 0.05. Results show that nursing homes operating in markets with higher competition and higher Medicare managed care penetration are more likely to have PEs. Moreover, larger, multi-facility, for-profit facilities, and those with higher occupancy rate and higher hospital admissions are more likely to have PEs. In contrast, nursing homes in counties with higher proportion of residents whose primary support is Medicaid and greater number of hospital-based facilities, and those with more female residents are less likely to have PEs.

THE IMPACT OF PHYSICIAN EXTENDERS ON NURSING HOME HOSPITALIZATION AND REHOSPITALIZATIONS

R. Pradhan[1], S. Gupta[2], R. Weech-Maldonado[2], *1. University of Arkansas for Medical Sciences, Little Rock, Arkansas, 2. University of Alabama at Birmingham, Birmingham, Alabama*

The objective of this study was to understand the impact of physician extenders (PE) on nursing home hospitalizations and rehospitalizations. Hospitalizations are defined as number of Medicare hospitalizations per 365 residents in a year while readmissions are proportion of hospital patients admitted to the nursing home readmitted to a hospital within 30 days. The Long-term Care focus data set was used and the analysis was panel regression with state and year fixed effects, adjusting for clustering at the provider level (2000-2010). The dependent variables were hospitalization and rehospitalization rates with presence of P.E. as the independent variable. Control variables included case-mix index, percent female, nurse staffing, size, payer mix, chain affiliation, profit status, and Herfindahl-Hirschman index. Results suggest that PE lower hospitalizations (p<.01) with no significant impact on rehospitalizations. Percent female, size, and chain affiliation were associated with lower rates of both hospitalization and rehospitalization. Managerial and policy implications are discussed.

SESSION 2100 (SYMPOSIUM)

AN OVERVIEW OF NATIONAL DATA COLLECTION EFFORTS THAT INCLUDE NURSING HOME RESIDENTS

Chair: K. Robinson, *Administration for Community Living, Washington, District of Columbia, Social & Scientific Systems, Inc., Silver Spring, Maryland*
Co-Chair: R. Hornyak, *Administration for Community Living, Washington, District of Columbia*
Discussant: D. Potter, *Agency for Healthcare Research and Quality, Rockville, Maryland*

In 2012, approximately 1.3 million people age 65 and over lived in nursing homes or skilled nursing facilities. While there are complexities involved in collecting data from people living in nursing homes (e.g., moderate to severe cognitive impairment, short tenure, administrative barriers, etc.), several national data collection efforts have found innovative ways to overcome these issues. The Health and Retirement Study and the National Health and Aging Trends Study are two longitudinal studies that follow respondents into nursing homes and continue to interview them with modified survey instruments. The American Community Survey collects important demographic, economic, and disability data on nursing home residents as part of its goal to represent all U.S. residents. Finally, as the agency that administers health care coverage for 100 million Americans, the Centers for Medicare and Medicaid Services, oversees several administrative databases and surveys that collect information on the institutionalized population. These data collection efforts help to fill a critical data gap, not only by ensuring high quality care, but also by monitoring changes in physical and cognitive functioning, relationships with family members, and overall quality of life as these individuals move from their homes into institutional settings. In this symposium, experts from these data collection efforts will discuss the strengths and challenges involved with collecting data from the institutionalized population, explain the different types of data their studies collect, and demonstrate how to access these data sources to provide researchers, program staff, and policymakers with the most recent data available.

COVERAGE OF NURSING HOME RESIDENTS IN THE HEALTH AND RETIREMENT STUDY (HRS)

M. Ofstedal, D. Weir, K.M. Langa, *Institute for Social Research, University of Michigan, Ann Arbor, Michigan*

The HRS is a nationally representative longitudinal survey of individuals over age 50 in the United States. The survey, which has been fielded every two years since 1992, was established to provide a national resource for data on the changing health and economic circumstances associated with aging at the individual and population levels. Although baseline interviews are conducted with community dwelling persons only, participants who move to nursing homes after baseline are retained and interviewed. The number of nursing home respondents has exceeded 450 in most waves. Among sample members who are found in nursing homes, interviews are obtained for about 90 percent. A self-interview is obtained for one-quarter to one-third of nursing home participants, the rest are interviewed by proxy (almost always a family member). Beginning around 2000, the HRS sample has well represented the US nursing home population. Nursing home residents are weighted separately from community dwelling participants.

NURSING HOME DATA COLLECTION IN THE AMERICAN COMMUNITY SURVEY

J.G. Belton, *American Community Survey Office, Bureau of the Census, Washington DC, Maryland*

In January 2006, the American Community Survey (ACS) was expanded to include the population living in Group Quarters (GQ). GQs are places where people live or stay, in a group living arrangement that is owned or managed by an entity or organization providing housing and/or services for residents. Examples of GQs include such places as nursing facilities/skilled-nursing facilities, college/university student housing, and correctional facilities for adults. The ACS conducts data collection at approximately 4,200 nursing/skilled nursing facilities each year. While the response rate at the GQ level for nursing/skilled-nursing facilities is relatively high, the ACS struggles with obtaining quality data at the resident level for this GQ type. The preferred data collection method is a face-to-face personal interview with sampled residents because it allows for a more complete interview. However, because of the uniqueness circumstances at nursing/skilled-nursing facilities, administrative records are often utilized and the use of administrative records impacts data quality

FACILITY INTERVIEWS IN THE NATIONAL HEALTH AND AGING TRENDS STUDY

L. Branden, S. Genoversa, *Westat, Rockville, Maryland*

This presentation will focus on conducting interviews in residential care and nursing homes for the National Health and Aging Trends Study (NHATS). NHATS is a national longitudinal study of Medicare beneficiaries age 65 and older. Baseline interviews were conducted in 2011 with about 8,000 sampled persons with annual interviews conducted in 2012, 2013, and 2014. Sampled persons who enter residential care facilities are interviewed if they are able to participate; otherwise a proxy interview is conducted. Issues covered will include training, contacting and locating procedures, gaining access to the sample person, determining whether the sample person can participate, and identifying proxy respondents if needed. Contact procedures and interviews with facility staff about the sample person will also be discussed. In Round 3 of NHATS, approximately 13% of the NHATS sampled persons resided in a facility. The NHATS interviews include collection of cognitive measures and physical performance measures.

INTEGRATING DATA FROM THE FEDERAL NURSING HOME SURVEY AND CERTIFICATION PROCESS AND CLINICAL ASSESSMENT DATA TO INFORM THE PUBLIC AND IMPROVE NURSING HOME QUALITY: THE NURSING HOME COMPARE WEBSITE AND THE FIVE-STAR QUALITY RATING SYSTEM EXPERIENCE

D. Andersen, J.M. Freedlander, I. Kramer, E. Mortimore, *CMS, Baltimore, Maryland*

Each month, multiple data sources are integrated for display on the Nursing Home Compare website to inform consumers and to create Five-Star Quality Ratings in three domains, plus an Overall Five-Star Rating. Data for approximately 16,000 nursing homes, including resident-level data, are collected daily as part of the ongoing federal process of survey and certification conducted by the Centers for Medicare and Medicaid services. Nursing home deficiency data, including resident interview responses and redacted narratives, reported by nursing home inspectors are displayed on Nursing Home Compare and form the basis for the Five-Star Quality Rating System. Additional data collected as part of the detailed clinical assessments of residents captured on the

Minimum Data Set (MDS) are used to create and display clinical quality measures and for case-mix adjusted staffing calculations.

DIRECT INTERVIEWS OF NURSING HOME RESIDENTS

D. Saliba[1,2,3], M. Pratt[4], *1. UCLA/JH Borun Center for Gerontological Research, Los Angeles, California, 2. VA GLAHS GRECC, Los Angeles, California, 3. RAND Health, Santa Monica, California, 4. Division of Chronic & Post Acute Care, Office of Clinical Standards and Quality, Centers for Medicare & Medicaid Services, Baltimore, Maryland*

In October 2010, all Medicare certified nursing homes in the US began collecting version 3.0 of the Minimum Data Set (MDS). For the first time, the MDS included items based on resident-self report. This more resident-centered approach included items that assessed resident mood, pain, preferences and desire to speak to someone about return to community. The inclusion of resident voice in the assessment represented a significant shift. National testing showed that resident interviews improved efficiency, reliability, validity and user-rated clinical relevance of the assessment. The MDS is collected on all residents in Medicare certified NHs and in VA Community Living Centers, thus providing important insights into resident's needs. We will discuss the advantages and challenges of using interviews to complete this core resident assessment.

SESSION 2105 (SYMPOSIUM)

DIFFERENT APPROACHES TO CROSS-NATIONAL AND INTERNATIONAL RESEARCH ON AGING

Chair: P. Sauer, *Miami University, Oxford, Ohio*
Co-Chair: E. Gonzales, *Boston University, Boston, Massachusetts*
Discussant: S.R. Kunkel, *Boston University, Boston, Massachusetts*

Cross-national and international research on aging poses many interesting challenges to students, emerging and experienced scholars alike. Therefore, ESPO's International Task Force would like to illustrate how a diverse panel of junior and senior researchers approaches this type of research. The four panelists will present their work on understanding late-life volunteerism cross-nationally, the impact of social healthcare insurance on low-income older Mexicans, the association between working hours and happiness across the Confucian culture zone including China, Japan, Korea and Taiwan, and the relationship between national healthcare infrastructure and older adults' care preferences across European countries. Following these presentations, there will be ample opportunity to engage in discussion with the audience about the challenges of this type of research (e.g., methodological approaches, international datasets, lessons-learned).We aim to increase awareness and scholarship of international aging research in preparation for IAGG's World Congress of Gerontology and Geriatrics in 2017 which will be hosted by GSA.

LATE LIFE VOLUNTEERING ACROSS COUNTRIES: DEFINITIONAL DIFFERENCES

H. Chen, N. Morrow-Howell, *Washington University in St. Louis, St. Louis, Missouri*

This study aims to compare the definition of volunteering and examine how definitional differences influence volunteer rates and type of volunteer services provided by older adults. Data derive from two sources: census data available from national public agencies; and the published literature on older volunteers in North America, Europe, and East Asia. Data revealed substantial variation in definitions of volunteering across countries. These variations likely contribute to the wide range in volunteer rates, with a high of 24.4% in the US and a low of 2.4 % in Spain. Recreational activities were included in social democratic countries (like Finland, Sweden), whereas service-oriented activities are the focus in liberal and corporatist states (like United States, Canada). In transitional democratic countries (like China), union membership and government mandated events were considered as volunteer work. Cross-country comparison of volunteer rates by older adults is challenged by inconsistent and broad definitions of formal volunteering.

NATIONAL HEALTHCARE INFRASTRUCTURE & CARE PREFERENCES AMONG OLDER ADULTS WITH CHRONIC DISEASE IN EUROPE

C.A. Mair[1], A.R. Quinones[2], M. Pasha[3], *1. Dept. of Sociology and Anthropology, University of Maryland, Baltimore County, Baltimore, Maryland, 2. Portland VA Medical Center & Oregon Health & Science University, Portland, Oregon, 3. Columbia, New York, New York*

Older adults with chronic illness face physical and financial health burdens that may shape their preferences for old age support. Cross-nationally, older adults' preferences for old age support may also be shaped by national funding availability for public health, disability/sickness, and long term care. We use multilevel modeling to examine individual-level health burden and nation-level healthcare infrastructure as predictors of older adults' preferences for family- or state-based support in 14 European nations using data from the Survey of Health, Ageing and Retirement in Europe (SHARE) and the Organisation for Economic Cooperation and Development (OECD). We find that older adults with chronic disease who have high financial health burdens or who live in a nation with stronger national healthcare infrastructures prefer state-based support over family care. We discuss these findings in light of older adults' financial strain and the future role of specialized health support programs, such as long term care.

THE IMPACT OF SOCIAL HEALTH INSURANCE IN THE USE OF PREVENTIVE CARE AMONG OLDER LOW-INCOME MEXICANS

M. Rivera-Hernandez, V. Mor, O. Galarraga, *Brown University, Providence, Rhode Island*

Diabetes and hypertension in older adults are substantial and growing global health problems, with racial/ethnic minorities suffering from increased prevalence, inadequate control and elevated mortality [1,2]. To minimize health inequalities, the Mexican government passed a major health care reform and Seguro Popular [SP; insurance for the poor] was introduced in 2001. However, there is limited evidence on how SP has impacted health outcomes and health care utilization for older adults. We examined the impact of SP on the use of diabetes and hypertension screening among poor older adults in Mexico using repeated cross-sectional data from the Encuesta Nacional de Salud y Nutrición (ENSANUT) 2000, 2005-2006 and 2012 surveys. To adjust for endogenity biases, we conducted an instrumental variable estimation. The results suggest positive increase in the use of preventive care for SP enrollees compared to the uninsured (29% for hypertension and 32% for diabetes).

ARE EAST ASIANS HAPPY TO WORK MORE OR LESS? AN ANALYSIS OF CHINA, JAPAN, SOUTH KOREA AND TAIWAN

T. Yamashita[1], A.R. Bardo[2], D. Liu[1], *1. University of Nevada, Las Vegas, Las Vegas, Nevada, 2. Miami University, Oxford, Ohio*

The present study analyzed the internationally representative 2010 East Asian Social Survey to examine the association between working hours and happiness across the Confucian culture zone including China, Japan, Korea and Taiwan. Results showed that working hours were only associated with happiness in Japan and Taiwan, but not in China or South Korea despite their shared cultural values. Findings from this study indicate that happiness is likely influenced by complex social forces, such as level of economic development, culturally guided work-family balance, degree of assimilation to Western values, and other sociodemographic trends in East Asia. In addition to the shared Confucian value system, each East Asian nation seems to form their own perceptions of happiness according to their unique historical, economic, and social backgrounds. Findings from the present study could be useful for developing culturally sensitive public policy to promote the happiness of workers in East Asia.

SESSION 2110 (SYMPOSIUM)

PERSPECTIVES ON THE HOUSING AND HEALTH STATUS OF OLDER HOMELESS ADULTS

Chair: L. Thomas, *Social Work, University of North Carolina at Charlotte, Charlotte, North Carolina*
Discussant: J.G. Gonyea, *Boston University, Boston, Massachusetts*

The negative health, mental health, and social outcomes associated with homelessness are exacerbated for homeless adults over the age of 50 as the impacts of homelessness interact with and accelerate aging processes. Despite a complex and daunting combination of issues to address, permanent supportive housing (PSH) effectively ends homelessness and has been linked to improved physical and mental health outcomes and reduced health service utilization among formerly homeless adults. Less is known, however, about the impact of PSH on older homeless adults and the challenges faced as they enter housing and age in place. This panel presents new findings on the impact of PSH on older homeless adults and explores issues related to their health and tenancy. The first paper examines factors that predict housing in a cohort of older homeless adults and differing health and health utilization outcomes between those who were housed and those who were not. The second paper compares three groups of older veterans in order to examine the impact of PSH on Veterans Administration health and behavioral health services utilization. The third paper uses mixed-methods to examine the role of age and other factors in housing outcomes and as well as the challenges of working with a population aging in PSH. The fourth paper examines predictors of perceived health and mental health among older and younger homeless adults in PSH. The final paper explores how older homeless adults view themselves and how their identity may be shaped by their housing status.

HEALTH OUTCOMES OF OBTAINING HOUSING AMONG OLDER HOMELESS ADULTS

R.T. Brown[1], Y. Miao[1], S.L. Mitchell[2], M. Steinman[1], *1. Division of Geriatrics, University of California, San Francisco/San Francisco VA Medical Center, San Francisco, California, 2. Hebrew SeniorLife Institute for Aging Research, Boston, Massachusetts*

Housing appears to improve health status and reduce acute care use among subgroups of the homeless population, such as those with severe mental illness. Little is known about the health outcomes of obtaining housing in the growing population of older homeless adults. We conducted a 12-month prospective cohort study of 250 homeless adults aged 50 and older recruited from shelters in Boston. At 12 months, 41% of participants had obtained housing. Participants who reported using a clinic as their usual source of healthcare (versus an emergency department) were more likely to obtain housing. Compared to participants who remained homeless at follow-up, those who obtained housing were less likely to have worsened depressive symptoms (Patient Health Questionnaire 9) at follow-up compared to baseline. Obtaining housing was associated with less emergency department use and fewer hospitalizations. Older homeless adults who obtain housing may experience improved health status and reduced acute care use.

ESTIMATING COST SAVINGS ASSOCIATED WITH HUD-VASH PLACEMENT FOR OLDER HOMELESS VETERANS

T.H. Byrne, *School of Social Policy and Practice, University of Pennsylvania, Philadelphia, Massachusetts*

This study assesses the extent to which the placement of older homeless Veterans (ages 55+) in a joint HUD-VA permanent supportive housing program (HUD-VASH) is associated with reductions in the cost of VA health services utilization. We used a difference-in-difference approach to compare changes in VA service use pre/post HUD-VASH move-in for HUD-VASH tenants to changes in VA service use over the corresponding time period for both homeless and housed matched Veteran comparison groups. Among HUD-VASH tenants, VA health services costs decreased by $13,128 from 1-year before move-in to 1-year after move-in relative to the homeless Veteran comparison group. Additionally, there were no significant differences in the cost of VA health services between HUD-VASH tenants and their housed counterparts in the 1-year period following HUD-VASH move-in. These findings suggest that for older homeless Veterans, HUD-VASH placement may generate substantial health care cost savings.

AGING IN PLACE IN PERMANENT SUPPORTIVE HOUSING

B. Henwood[1], T. Gilmer[2], M.L. Katz[3], *1. Social Work, University of Southern California, Los Angeles, California, 2. University of California San Diego, San Diego, California, 3. VA Greater Los Angeles Healthcare System, Los Angeles, California*

This mixed-methods study explores whether and how permanent supportive housing (PSH) can support successful aging in place. Quantitative analysis using a state level database of 67 PSH programs showed that as opposed to those who are younger (n=4927), older adults (n=3758) spent significantly fewer days homeless pre-enrollment. Still, older adults spent significantly less time homeless 1 year post- versus pre-enrollment partially due to increases in days living in an apartment and days living in congregate settings. Qualitative case study analysis of a program that exclusively served older adults revealed that limited mobility, depression, and lack of social support were viewed to be a bigger issue than substance abuse. End-of-life care was also regarded as the “elephant in the room” that providers were not prepared to address. These findings show that PSH is an effective way to end homelessness yet programs need additional supports and/or trainings to support aging in place.

PERCEIVED HEALTH AMONG OLDER HOMELESS ADULTS IN PERMANENT SUPPORTIVE HOUSING

L. Thomas[1], M. Clapsadl[1], J. Shears[2], *1. Social Work, University of North Carolina at Charlotte, Charlotte, North Carolina, 2. University of North Carolina at Greensboro, Greensboro, North Carolina*

Homeless adults have poorer health and mental health than the general population. Those over the age of 50 are particularly vulnerable, experiencing high rates of chronic health, mental health, and geriatric conditions. This longitudinal study examined the perceived health and mental health among older and younger homeless adults before and after entering a permanent supportive housing (PSH) program. Although older PSH tenants had more disabling conditions at baseline than did younger tenants, no difference was found between the age groups in their perceived physical or mental health. Across both groups, a positive correlation was found between general quality of life at baseline and perceived mental health at six months. Perceived social support from friends and number of disabling conditions were predictors of perceived mental health, but not physical health. This study expands research on older adults in PSH and offers insight into factors that may be associated with health outcomes.

HOUSING STATUS AND SELF-IDENTITY: MANAGING THE STIGMA OF BEING OLD AND HOMELESS

K. Melekis[1], J.G. Gonyea[2], *1. University of Vermont, Burlington, Vermont, 2. Boston University, Boston, Massachusetts*

While research is emerging on the pathways into, and the lived experiences of, homelessness in later life; there is no research exploring how older adults who find themselves homeless negotiate their identities in a society in which both “the homeless” and “the elderly” are negatively perceived. Using a symbolic interactionist approach, this qualitative study explored the social space in which 20 urban older homeless adults negotiated their identities and sought to protect their self-concepts despite membership in low status groups. Findings illustrate the range of strategies in which they engaged to manage stigma. The data underscore the role of reactive identity work, as participants engaged in self-disidentification to manage the discrepancies between internal identification and external ascription. Findings highlight the relationship between housing status and self-identity, and have implications for the importance of permanent housing not only in terms of the provision of shelter and security, but for positive self-concept.

SESSION 2115 (SYMPOSIUM)

A STATE SCORECARD ON LONG-TERM SERVICES AND SUPPORTS FOR OLDER ADULTS, PEOPLE WITH PHYSICAL DISABILITIES, AND FAMILY CAREGIVERS: SECOND EDITION

Chair: S.C. Reinhard, *AARP Public Policy Institute, Washington, District of Columbia*

In the ever-evolving long-term service and supports system and with the constant challenges in data availability, state performances vary widely. Even more important is how performances change over time. That is why The AARP Public Policy Institute (PPI), in collaboration with its partners at The SCAN Foundation and The Commonwealth Fund, will release the second edition of the State LTSS Scorecard in June, 2014. Based on a multi-dimensional approach and engaging a team of national advisors, this new edition of the State LTSS Scorecard features a new dimension, and revisits state performance across four other key dimensions of LTSS system performance including: affordability and access; choice of setting and provider; quality of life and quality of care; and support for family caregivers. This Scorecard features collaborations with several aging and disability research experts, including Dr. Joe Coughlin (MIT AgeLab), Dr. Vince Mor (Brown University), Dr. Lauren Harris-Kojetin (Center for Disease Control), Dr. Carol Irvin (Mathematica Policy Research), and Dr. Kevin Mahoney (Boston College.) Their data allowed us to rank states on nursing home quality, effective transitions, participant-directed services, and assisted living unit counts. Each researcher will present on the challenges they faced in adapting their data to rank states on individual indicators, as well as gaps they encountered in state and national data collection.

MEASURING EFFECTIVE TRANSITIONS IN LONG-TERM CARE

C. Irvin[1], A. Houser[2], R. Borck[1], L. Ruttner[1], *1. Mathematica Policy Research, Cambridge, Massachusetts, 2. AARP, Washington, District of Columbia*

The second edition of the State LTSS Scorecard includes a new dimension that captures state performance in transitions among long-term care settings. Two of the six indicators that make up the Effective Transitions dimension include: (1) nursing home stays lasting 100 days or more and (2) nursing home stays of 90+ days that end by a transition to the community. Using the 2009 Chronic Conditions Warehouse Timeline file, we find that 20 percent of the 755,454 million Medicare beneficiaries who started a nursing home stay in 2009 eventually became long-term residents of nursing homes. Approximately 8 percent of the nearly 1.4 million Medicare beneficiaries in nursing home care for 90+ days successfully transitioned to the community that year. The results suggest variability in state performance on both measures. The derived state rankings for each are not highly correlated ($r2=0.31$), suggesting the measures capture different aspects of state long-term care systems.

NATIONAL STUDY OF LONG-TERM CARE PROVIDERS: 2012 NATIONAL AND STATE RESULTS ON FIVE MAJOR SECTORS

L. Harris-Kojetin, M. Sengupta, L.L. Dwyer, C. Caffrey, E. Park-Lee, R. Valverde, V. Rome, *National Center for Health Statistics, Hyattsville, Maryland*

NSLTCP is a groundbreaking, biennial initiative by CDC's National Center for Health Statistics to monitor the diverse long-term care services industry. NSLTCP uses survey data on adult day services centers and residential care communities (RCCs); and administrative records data on home health agencies, nursing homes, and hospices. NSLTCP findings provide national and state benchmarks that may be useful for the State LTSS Scorecard. NSLTCP topics include Medicaid participation; capacity; services provided; staffing; practices such as depression screening; and provider-level distributions of users' demographics, need for assistance in activities of daily living, selected medical conditions, and hospitalizations. Differences exist by sector and state on a variety of characteristics. For example, among sectors, national daily use rates per 1,000 persons aged 65 and over were highest for nursing homes, although in 12 states the nursing home rate was equal to or lower than the RCC rate. Additional state-level findings will be presented.

ASSESSING THE PRESENT AND FUTURE OF PARTICIPANT DIRECTION: FINDINGS AND METHODOLOGICAL CHALLENGES

K.J. Mahoney[1], E.K. Mahoney[1], S. Barrett[1], C. Bouzan[1], S. Crisp[1], M. Sciegaj[2], S. Suzuki[1], K. Wang[1], *1. Graduate School of Social Work, Boston College, Chestnut Hill, Massachusetts, 2. Pennsylvania State University, University Park, Pennsylvania*

The purpose of the 2013 National Resource Center for Participant-Directed Services (NRCPDS) National Inventory was to collect information on trends and program characteristics of over 250 publicly funded participant-directed long-term services and supports (PD-LTSS) programs across the United States. Data reflect the overall growth, current condition, and state to state variations in PD-LTSS programs nationwide. Measurable outcomes evaluated include flexibility, accessibility, and integrity of PD-LTSS programs. Emerging shifts include assimilation into managed care and increasingly variable reporting systems. Capturing National Inventory information has proven crucial in identifying challenges in not only PD-LTSS expansion, accessibility, and quality nationwide but also in identifying barriers to collecting this type of data. The NRCPDS National Inventory will continue to serve as a unique tool by informing ways to improve participant choice and control through policy and research.

SESSION 2120 (SYMPOSIUM)

CHRONIC PAIN AND SUFFERING IN OLDER ADULTS: SCIENTIFIC EVIDENCE AS GROUND FOR A MORAL IMPERATIVE

Chair: M.E. Morrissey, *Fordham University Graduate School of Business Administration, New York, New York*

Persistent pain and unbearable suffering in older adults are unrecognized public health and clinical problems across diverse communities that demand the urgent attention of policy makers, legislators and scientists (Institute of Medicine, 2011). These problems are made more urgent by loss and grief in old age, and the needs and distress experienced by family caregivers who are often performing complex medical tasks for their loved ones (Reinhard & Levine, 2012), as well as providing social support in the absence of clear, comprehensive policy. This symposium will address interdisciplinary science perspectives in health and aging, public health, nursing, medicine, and gerontological social work, to inform and guide policy, research, practice interventions, and workforce development. The first and second presenters will frame the theoretical and policy foundations for these important discussions, drawing on international human rights conventions, human science frameworks, public health ethics, and government policies. The third presenter will review current scientific evidence and gaps in geriatric pain and palliative care research, making recommendations for workforce development, including education and training for health professionals and pre-professionals. The fourth and fifth presenters will focus on clinical practice interventions targeting chronic pain, loss and grieving among older adults and their family caregivers. Finally, presenters will respond to the overarching question as to whether persistent, unrelieved pain and pain disparities in the older adult population present a moral imperative supported by robust scientific evidence across the domains of policy, research and practice, that call for immediate steps in advocating for a national pain agenda.

CHRONIC PAIN AND CHRONIC ILLNESS: THE PUBLIC HEALTH RESPONSE TO ELDER SUFFERING

M.E. Morrissey, *Graduate School of Social Service, Fordham University, White Plains, New York*

Research evidence continues to mount about the twin health problems that most aging Americans will face in their later years: chronic illness and chronic pain. Recent studies highlight the prevalence of chronic illness and chronic pain, and a positive association between pain and chronic illness burden among older adults. In first person narrative accounts of frail elders themselves, descriptions of chronic pain, suffering and traumatic losses experienced in living with chronic illness were salient. In light of this growing body of evidence of elder suffering, this presentation will focus on rights to palliative care and pain management for diverse elders under legal and regulatory frameworks, as well as the relationship between the right to health and human rights. Recommendations will be made regarding fashioning appropriate policy responses to the chronic pain public heath crisis, including pubic health approaches to integration of palliative care across health systems in diverse communities.

THE ROLE OF POLICY IN ENSURING ACCESS TO CONTROLLED SUBSTANCES IN THE TREATMENT OF PAIN

J. Cleary, *1. UW School of Medicine and Public Health, Madison, Wisconsin, 2. Pain and Policy Studies Group, Madison, Wisconsin*

"The medical use of narcotics "continues to be indispensable for the relief of pain and suffering….adequate provision must be made to ensure the availability of narcotic drugs for such purposes" (Preamble, Single Convention of Narcotic Drugs, 1961). The WHO defines morphine as an essential medicine, now included in the Essential Medicines List for Pain and Palliative care. In order to ensure their medical use, the "principle of balance" is applied, ensuring that these medicines are accessibility for medical purposes while working to reduce misuse, abuse and diversion. While opioids are readily available in the United States, there are still many barriers to their accessibility. These barriers can be defined according to 1) laws and policies, 2) medicine availability and 3) clinician education. Many US States have had significant barriers to opioid availability in their laws of policies. Based on efforts based in palliative care and end of life initiatives, State Report Cards in Pain Policy have been constructed over the last 10 years. Most states have shown improvement in these policies. However at the same time, deaths associated with opioid use have increased. While there is no denying the major increase in opioid use in the US, and that there is still a great need for clinician pain education analysis of this data indicates that most of the deaths are associated with a combination of opioids, sedatives and alcohol and 1/3 are associated with Methadone which only represents 3% of pain prescriptions. This data will be reviewed particularly from the perspective of those among the 100 million Americans suffering with pain, including the elderly, who may benefit from these essential medicines.

QUALITY CHRONIC PAIN CARE FOR ALL OLDER ADULTS: CURRENT PRACTICE, GAPS AND RECOMMENDATIONS

K.A. Herr, *College of Nursing, University of Iowa, Iowa City, Iowa*

Persistent pain is a long-recognized problem in older adults across care settings that has a profound effect on function and quality of life. For over two decades research has improved the science on which to base clinical care decisions for this vulnerable population. Yet, after years of increased awareness and efforts to build an evidence base to improve quality of care, inadequacies in our health care system are evident. This presentation will highlight current evidence on implementation of assessment and treatment best practices, noting gaps that must be addressed. The state of science to guide assessment and treatment of chronic pain in older adults will be addressed. Recommendations are provided for strategies to address the imperative to improve the quality of pain care for all older adults, including future workforce development and research priorities.

INTERPROFESSIONAL TEAM APPROACH TO PAIN ASSESSMENT AND MANAGEMENT: IMPLICATIONS FOR HIGH QUALITY PERSON-CENTERED CARE

T.V. Caprio, *1. Medicine/Geriatrics & Aging, University of Rochester, Rochester, New York, 2. Visiting Nurse Hospice, Webster, New York, 3. Rochester-Canandaigua VAMC, Canandaigua, New York*

The development of pain as the "Fifth Vital Sign" has raised pain assessment to the level of a quality of care metric, yet marked inconsistencies remain in the quality of pain screening efforts and in the development of pain care plans across clinical settings including outpatient practices, nursing homes, hospitals, hospice, and home care. Clinical teams are often poorly equipped with appropriate training in pain assessment and there has been a reductionist approach to pain screening simply by capturing a self-report on a numeric pain rating scale. A comprehensive approach to clinical pain management requires an interprofessional and person-centered approach which is appropriately captured in clinical documentation and within a team communication framework, utilizing both pharmacologic and non-pharmacologic approaches to improve quality of life. This presentation will discuss this interprofessional team approach to pain management, highlighting the areas for effective communication and documentation, and developing a approach for assessing pain for those with dementia.

CHRONIC PAIN: ISSUES OF LOSS AND GRIEF FOR OLDER ADULTS AND THEIR FAMILY CAREGIVERS

N.R. Hooyman, *School of Social Work,, Seattle, Washington*

Profound feelings of loss and grief are often experienced by people who are suffering from chronic pain. But these feelings may be discounted by health professionals or misdiagnosed as depression, often resulting in additional suffering for both older adults and their family caregivers. This presentation will address types of losses frequently experienced by those suffering from chronic pain, the ways in which grief may manifest and intersect with other losses, and how types of losses experienced may vary with culture, race and gender. There is a growing body of evidence that suggests the importance of health care providers addressing the psychosocial aspects of loss and grief, not only the physical symptoms of pain. Implications for clinical practice with older adults with chronic pain will be discussed within an overall framework of culturally competent care.

SESSION 2125 (PAPER)

HOSPICE AND END OF LIFE CAREGIVING

UNDERSTANDING VARIATION IN UTILIZATION OF HOSPICE INPATIENT RESPITE CARE

A. Pozniak[1], M.R. Plotzke[1], K.E. Lucas[2], *1. Abt Associates, Cambridge, Massachusetts, 2. CMS, Baltimore, Maryland*

We used 2012 Medicare hospice claims to analyze utilization of inpatient respite care (IRC). We found 3.5% (N=45,116) of hospice beneficiaries received at least one day of IRC in 2012. These beneficiaries had a total of 64,606 IRC stays associated with a total of 275,784 IRC days ("IRC stay" is defined as consecutive IRC days in the hospice claims). Among beneficiaries who had any IRC days, 77% had only one stay. The most common site of service for IRC was an inpatient hospice setting (34%), followed by skilled nursing facility (28%), LTC nursing facilities (18%), and hospitals (13%). The average length of stay for IRC was 4.3 days and varied by site of service (slightly shorter at inpatient hospitals compared to other settings). Sixty-two percent of IRC stays were 5 days; 5 days was also the mode and median. Seventy-four percent of hospice providers provided at least one IRC day in 2012. The average share of hospice days billed as IRC was 0.4%, but a small number of providers exceeded 2%. A higher proportion of older hospices provide IRC than younger hospices, and nearly all large hospices provide IRC compared to about a third of small hospices. A higher percentage of hospice providers in the Midwest and New England states provided IRC compared to hospice providers in the West or South. Variations in utilization and provider characteristics may have implications regarding the availability of short term inpatient relief for caregivers of hospice beneficiaries.

UNATTENDED SORROW IN THE WORKPLACE: CARE AIDES' GRIEF WHEN RESIDENTS DIE

S. Caspar, P.A. Ratner, A. Phinney, *University of British Columbia, Vancouver, British Columbia, Canada*

Purpose: Central to the provision of person-centred care is the development of a positive, caring relationship between care recipients and formal caregivers. The development of these meaningful relationships is essential to both the quality of care and the quality of life in residential care facilities (RCFs). The purpose of this study was to explore how the experience of grief resulting from residents' deaths influences RCF staff members' disposition to develop caring and meaningful relationships with the residents for whom they provide care. Methods: We conducted an institutional ethnography to explore the social organization of care work in RCFs. The study was set in three RCFs and included 104 hours of naturalistic observation and 76 in-depth interviews with senior administrators, management, staff, residents, and residents' family members. Results: The care aides experienced considerable grief in response to residents' deaths, which occurred frequently. They reported receiving minimal if any support from management or the institutions within which they worked as they managed their grief. The most prominent source of support provided was from fellow care aides, which was largely dependent upon the presence of positive workplace relationships. When no support was available, the care aides were reluctant to form attached relationships with the residents, whom they described as being "here to die." Implications: Management initiatives are needed to encourage the formation of caring and meaningful relationships between care aides and residents and to support care aides when a relationship ends because of the death of a resident.

DELIRIUM: ASSESSMENT AND MANAGEMENT FOR OPTIMAL END OF LIFE IN A HOSPICE SETTING

C. Luz[1], M.D. Ensberg[2], *1. Michigan State University, East Lansing, Michigan, 2. Sparrow Senior Health Center, Lansing, Michigan*

Evidence exists that delirium is not well understood in nursing homes and hospice settings. It is frequently misdiagnosed and inappropriately treated. Symptoms are seldom differentiated from dementia or depression. Rather, they may be grouped under headings such as "terminal restlessness". Pharmacotherapy is the most common response to a range of symptoms including agitation, sleep disruption, emotional lability, and hyperactivity. This represents a critical gap in best practices since delirium and depression are distinctly different from dementia in that they are potentially reversible. Appropriate assessment and management are essential as delirium compromises optimal health and quality of life. As part of a national Geriatric Education Centers' initiative, the Geriatric Education Center of Michigan developed and tested a training program for health teams working with older adults at end of life who are exhibiting symptoms of delirium, depression and dementia. It was presented to staff of a mid-Michigan in-patient hospice unit and consisted of a 2 hour didactic in-service and 10 team meetings for applied learning using actual case reviews. Content focused on understanding delirium; using an evidence-based screening tool; differentiating delirium from dementia; non-pharmaceutical interventions, and effective interdisciplinary care planning. 45 staff members representing 6 disciplines participated. Pre-posttests indicated significant knowledge gain; team meeting notes and care plans indicated transfer of knowledge into clinical practice; staff expressed improved satisfaction; and organizational changes are being made to sustain the program goals. Follow-up focus groups are being conducted and plans are underway to replicate and evaluate the program in other hospice settings.

EXAMINING PALLIATIVE CARE IN NURSING HOMES

N. Castle[1], J. Engberg[2,1], *1. University of Pittsburgh, Pittsburgh, Pennsylvania, 2. RAND, Pittsburgh, Pennsylvania*

Many studies have explored clinical and economic effects of palliative care consultations in the acute care inpatient setting. In general, these acute care studies have identified that palliative care results in an improved patient experience with cost savings or cost neutrality. Palliative care practices have diffused into nursing homes, particularly for special populations such as for residents with advanced dementia, but they are far less prevalent than in acute settings. Identifying potential cost savings (and quality improvements) may be an effective means of changing policy to further diffuse palliative care practices into nursing homes. In this study, a simulation analysis of the potential cost savings and quality changes applied to nationally representative groups of nursing homes with varying policy, resident, and payor mixes is presented. Information for this simulation study came from a case study of palliative care in four facilities, a literature review, and cost information from nursing home billing/reimbursement systems. The potential impact to a facility, residents, Medicare, and Medicaid when implementing palliative care is discussed.

FLORIDA ASSISTED LIVING FACILITY END-OF LIFE DIRECT CARE STAFF TRAINING: THE IMPACT ON RESIDENT HOSPICE AND PALLIATIVE CARE UTILIZATION

S.J. Brande, D. Dobbs, *Aging Studies, University of South Florida, Tampa, Florida*

According to the national hospice figures 116,000 of the 1.6 million decedents who received hospice care in the United States received it in assisted living (AL) settings, an increase from 2011. Given the growing demand for end-of-life care in AL, there is interest in direct care staff training patterns related to end-of-life care and whether it affects the use of hospice. This study examined the amount of direct care staff trained and hospice use in AL. A pilot sample of licensed ALs in Florida (N=48) were surveyed between 2009-10 about end-of-life training practices for direct care staff and hospice use in the past three months. The eligible facility sample (N=48) represents 2,526 residents. Fifty-six percent were 75y≤; 81.69% were white, and 84.87% were female. Two multivariate analysis of variance models were conducted, one with small ALs (10–55 residents) and the other with large ALs (55< residents) using a three level covariate of the percent of trained staff (1=0, 2=1-59% and 3=60-100%) and the number of residents who used hospice (past three months) as the outcome. The MANOVA model of large ALs had a main effect of resident hospice use, Roy's Largest Root= .431, F(2,17) = 3.660, p=.048, partial eta squared=.301. The number of residents who used hospice (M=6.30, SD=5.314) and 60%-100% trained direct care staff resulted in a significant between-subjects effect, F(2)=3.607, p=.049, partial eta squared=.298. End-of-life staff training programs in AL could potentially increase hospice care for AL residents in larger ALs with more staffing resources.

SESSION 2130 (SYMPOSIUM)

A NATIONAL PERSPECTIVE ON PARTICIPATION IN VALUED ACTIVITIES: RESTRICTIONS AND POSITIVE INFLUENCES

Chair: J. Kasper, *Health Policy and Management, Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland*
Discussant: E. Agree, *Johns Hopkins University, Baltimore, Maryland*

The National Health and Aging Trends Study (NHATS) was developed as a resource for the study of late life disability trends and dynamics in older people in the US. As a nationally representative study of Medicare beneficiaries ages 65 and older, NHATS provides data on functioning across the spectrum and, in addition to assessments of activities of daily living, incorporates information on participation in social, generative, productive activities. Attention to participation allows for study of important aspects of quality of life for older adults beyond the realm of self-care. The papers in the session examine health factors that potentially restrict participation, the role of core social networks in participation, and favorite activities of older adults. Two papers in this session focus on the relationship of two highly prevalent problems at older ages – pain and sleep disturbances— to ability to participate in valued activities. A third paper investigates the relationship of participation to core social networks, and discusses whether bolstering participation in valued activities could improve the social networks of older adults. A final paper explores favorite activities reported by older adults and variations by gender, health and other characteristics. Together these papers contribute to a developing literature on factors that influence participation, and provide new national estimates of the productive activities that older adults value and engage in. A brief overview of NHATS will be provided and a discussant will identify themes and promising future directions for research.

IMPACT OF PAIN ON SOCIAL PARTICIPATION AMONG OLDER ADULTS IN THE UNITED STATES

K. Patel, D. Turk, *University of Washington, Seattle, Washington*

Chronic pain is common in older adults and is associated with decreased physical capacity; however, few studies have investigated the impact of pain on restricting participation in valued social activities (e.g., visiting with friends; attending clubs). We analyzed data from the 2011 National Health and Aging Trends Study (N=7,307). Prevalence of participation restriction was higher among older adults reporting pain (26.8%) than in those without pain (9.6%) [adjusted Prevalence Ratio=2.65 (95% Confidence Interval: 2.34-3.01)]. Participation restriction increased with greater anatomic sites of pain (15.3%, 21.6%, 26.1%, and 39.0% among those with 1, 2, 3, and ≥4 pain sites, respectively; P<0.001). Although adjustment for physical capacity, depressive symptoms, social network size, and other demographic/health characteristics attenuated the association, the number of pain sites remained strongly associated with participation restriction (P<0.001). In summary, social participation is substantially reduced among older adults with pain, representing an important outcome to target for interventions.

INSOMNIA SYMPTOMS AND PARTICIPATION IN VALUED ACTIVITIES IN U.S. OLDER ADULTS: THE NATIONAL HEALTH AND AGING TRENDS STUDY

A.P. Spira[1], C.N. Kaufmann[1], J. Kasper[1], M.M. Ohayon[2], G. Rebok[1], E. Skidmore[3], J.M. Parisi[1], C. Reynolds[4], *1. Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland, 2. Stanford University School of Medicine, Stanford, California, 3. University of Pittsburgh, Pittsburgh, Pennsylvania, 4. University of Pittsburgh Medical Center, Pittsburgh, Pennsylvania*

Few studies have investigated the association between insomnia symptoms and participation in valued activities among older adults. Using data from 6,050 adults aged ≥65 in the National Health and Aging Trends Study, we determined the association between number of insomnia symptoms (0, 1, or 2) and functional outcomes, including restricted participation in four valued activities. After adjustment for demographic characteristics, medical conditions, body mass index, psychiatric symptoms, cognitive performance, and sleep medication use, insomnia symptoms were associated with a greater odds of restricted participation in ≥1 valued activity (1 symptom vs. 0, odds ratio (OR)=1.32, 95% confidence interval (CI) 1.07, 1.65; 2 symptoms vs. 0, OR=1.58, 95% CI 1.19, 2.11), and in specific valued activities (going out for enjoyment, attending religious services). Insomnia symptoms may be a risk factor for restricted participation in valued activities in community-dwelling older adults, and warrant greater investigation as a potential cause of functional decline.

VARIATIONS IN SIZE AND COMPOSITION OF CORE SOCIAL NETWORKS: ASSOCIATIONS WITH SOCIAL PARTICIPATION

D.L. Roth, L.J. Samuel, J. Huang, E. Tanner, J. Wolff, *Johns Hopkins University, Baltimore, Maryland*

Social contact and participation are established predictors of health, longevity, and well-being among older adults. Community-dwelling NHATS participants (N = 6680) were asked to name up to 5 "core" social network members with whom they talk about important matters. The size and composition (e.g., family vs. non-family) of these core networks were analyzed in relation to demographic variables and social participation (e.g., volunteerism, religious attendance). Older age was associated with having fewer non-family core network members. Men listed fewer core network members than women, although married men were more likely than married women to name their spouse. Religious service attendance was associated with having more family and non-family network members, whereas engaging in volunteer work was associated with having more non-family network members only. The correlates of social network size and composition suggest avenues for interventions aimed at reducing social isolation and increasing social participation in specific demographic subgroups.

OLDER ADULTS' FAVORITE ACTIVITIES

S. Szanton[1], R. Klimmek[1], L. Roberts[1], R. Thorpe[1], J. Wolff[1], E. Agree[1], L.N. Gitlin[1], C.L. Seplaki[2], *1. Johns Hopkins University, Baltimore, Maryland, 2. University of Rochester, Rochester, New York*

While much is known about staying engaged to stay healthy at older ages, we know little about the activities that older adults actually enjoy. This is an important gap as these could be powerful intervention targets for increasing engagement. We analyzed the favorite activity accomplished in the last month among NHATS community dwelling, cognitively-intact participants. Four of the top five most commonly mentioned favorite activities are physical: walking or jogging (14%), outdoor maintenance (12.6%) playing sports (8.9%) and other physical activity (8.7%). The top favorite non-physical activity is reading (8.8%). These findings are consistent across age groups up until those in their 80s, where, even there, three of the top five activities are physical (walking/jogging, outdoor maintenance, and other physical activity.) These findings are similar by race, income level, and education though they do vary by self-rated health (OR=0.71, p <0.001), disability (OR=0.72, p <0.001), and gender (OR=0.52, p <0.001).

SESSION 2135 (SYMPOSIUM)

WELLBEING IN LATER LIFE: AN INTERDISCIPLINARY AND COMPARATIVE FOCUS

Chair: J. Nazroo, *CCSR, University of Mnachester, Manchester, United Kingdom*
Co-Chair: A. Marshall, *CCSR, University of Mnachester, Manchester, United Kingdom*

Wellbeing is an important aspect of healthy ageing, however, there is very little consensus, on how best to influence change in this outcome. This symposium contains five papers providing new understandings of inequalities in wellbeing in later life. The multidisciplinary symposium consists of contributions from social sciences, genetics and statistics investigating the role of the national and local context, and genetics on wellbeing at older ages. The papers exploit data from the English Longitudinal Study of Ageing and the Health and Retirement Study. The first paper explores country-specific influences on the determinants of two forms of subjective wellbeing (life satisfaction and quality of life) among older adults in England and the US highlighting different influences of education on each outcome in each country. The second paper, also adopts a US and England comparison by examining trajectories of depression and associated socioeconomic determinants after controlling for attrition and cross-national differences in the measurement of depression. The third paper considers the influence of neighbourhood deprivation and economic mixing on depression among older people in England. The fourth paper reports a genome-wide association analysis of depression using the Health and Retirement Study with new evidence for a significant association between particular genes and depression and a replication in the English Longitudinal Study of Ageing. Finally, the fifth paper considers an innovative solution to a central challenge of any study of wellbeing in later life; attrition, and, in particular, the tendency for those with poorer wellbeing to drop out of longitudinal surveys.

TABLED PRESENTATION: LOSE YOUR DREAMS AND YOU WILL LOOSE YOUR MIND. AIN'T LIFE UNKIND? DETERMINANTS OF SOCIOECONOMIC INEQUALITY IN SUBJECTIVE WELLBEING IN LATER LIFE. A CROSS COUNTRY COMPARISON IN ENGLAND AND THE US

J. Nazroo[1], S. Jivraj[2], *1. University of Manchester, Manchester, United Kingdom, 2. Institute of Education, London, United Kingdom*

Aims This paper explores the relative country-specific influences in the determinants of two forms of subjective wellbeing (life satisfaction and quality of life) among older adults in England and the US. Results Having a disability, being diagnosed with chronic conditions, or having low household wealth are strongly associated with poorer life satisfaction and quality of life. These statistical effects are consistent in England and the US. The effect of years spent in education, however, significantly varied between the two countries: educational inequalities have a greater adverse effect on subjective wellbeing in the US compared with England. Conclusions Interventions are required to counterbalance health inequalities that restrict sections of the population in England and the US from enjoying satisfying and meaningful lives in older age. Moreover, in England, the provision of welfare benefits and state funded public services may protect against the adverse effect of lower socioeconomic status on subjective wellbeing.

POOR MAN EYES A RICH MAN, DENIGRATES HIS PROPERTY. A RICH MAN EYES A POOR MAN, AND ENVIES HIS SIMPLICITY. NEIGHBOURHOOD WEALTH INEQUALITY AND THE PREVALENCE OF DEPRESSION AMONG OLDER PEOPLE

A. Marshall, *University of Manchester, Manchester, United Kingdom*

Aims This paper considers whether the extent of inequality in house prices within neighbourhoods of England is associated with depressive symptoms in the older population using the English Longitudinal Study of Ageing. We consider two competing hypotheses: first, the wealth inequality hypothesis which proposes that neighbourhood inequality is harmful to health and, second, the mixed neighbourhood hypothesis which suggests that socially mixed neighbourhoods are beneficial for health outcomes. Results Our results support the mixed neighbourhood hypothesis, we find a significant association between neighbourhood inequality and depression with lower levels of depression amongst older people in neighbourhoods with greater house price inequality after controlling for individual socio-economic and area correlates of depression. This association is strongest for the poorest individuals, but also holds among the most affluent. Conclusions Our results are in line with research that suggests there are social and health benefits associated with economically mixed communities.

WHAT A DRAG IT IS GETTING OLD: TRAJECTORIES OF DEPRESSIVE SYMPTOMS IN LATER LIFE IN THE US AND ENGLAND

B. Vanhoutte[1], J. Nazroo[1], S. Jivraj[2], *1. CMIST - School of Social Sciences - University of Manchester, Manchester, United Kingdom, 2. Centre for Longitudinal Studies - Institute of Education - University of London, London, United Kingdom*

Depressive symptoms occur commonly in later life, but the clinical diagnosis of depression is much rarer for elderly. Later life depression tends to be more somatic and contain less severe mood disturbances. Above that, there is a paradox in country levels of depression: while physical health is better in England, depression is less prevalent in the States, although physical and mental health are strongly linked. This study aims to answer this paradox by investigating the influence of social structure on depressive symptoms in a longitudinal and comparative way. Five matching waves of data originating from two longitudinal studies on ageing, the Health and Retirement Survey (HRS) and the English Longitudinal Survey on Ageing (ELSA) are analyzed in a latent growth model. While there is a small influence from measurement on both gender and country differences, these do not explain the substantial differences across age, gender and country. Similarly, selection mechanisms do play a role in the prevalence of development over time of depressive symptoms, but accounting for these does not alter our main findings. Previous instances of depression, wealth and educational differences explain away gender effects, while their country-specific function as a buffer largely explains the country disparities.

'SYMPATHY FOR THE DEVIL'. GENOME-WIDE ASSOCIATION ANALYSIS OF SUBJECTIVE WELL-BEING IN THE UNITED STATES AND UNITED KINGDOM

K. Mekli[1], J. Nazroo[1], J. Lee[2,3], C. Prescott[2], D. Phillips[2], N. Pendleton[1], *1. CCSR, University of Manchester, Manchester, United Kingdom, 2. University of Southern California, Los Angeles, California, 3. RAND Corporation, Santa Monica, California*

Aims This study adopts a genome-wide association study in order to understand the genetic factors that influence subjective well-being. We build on previous research using twin and family studies that suggest that genetic factors account for a moderate, 30-40% variance in this trait independent of environmental influences. Results The most significant genome-wide association surviving correction was for SNP rs58682566 in the intronic region of the Ectopic P-granules autophagy protein 5 homolog (C. elegans) (EPG5) gene ($p=6.28E-09$, $\beta=0.19$).

Another 11 SNPs reached the genome-wide suggestive level (below p=1E-05). Conclusion Our study provides evidence for the involvement of the EPG5 gene in subjective well-being. To support this novel finding we will conduct a replication study using common genotypic and phenotypic measures in a second representative cohort of community dwelling older adults (English Longitudinal Study of Ageing, ELSA). Findings from the replication will be available at the time of presentation.

YOU CAN'T ALWAYS GET WHAT YOU WANT: JOINT MODELS OF OLDER PEOPLE'S QUALITY OF LIFE AND ATTRITION IN BRITAIN 2002-2010

G. Tampubolon, *University of Manchester, Institute for Social Change, Manchester, United Kingdom*

Objectives: Later life in public mind is being transformed by the emerging possibility of a flourishing third age with sustained quality of life. The trajectories of life quality over some period for four different cohorts are drawn. These trajectories are refined by jointly modelling attrition, recognising the fact that older people tend to leave longitudinal study for non-random reasons. Methods: Growth curve models of CASP-19 are estimated for participants in the English Longitudinal Study of Ageing waves 1 to 4. Then joint models are estimated where individual random effects are shared in the growth curve model and the attrition model. Extensive predictors are entered in the model including demographic attributes, social and economic status, health conditions, and health behaviours. Results: Strong non-linear age trajectory of life quality is revealed where the peak is achieved in the late 60s. Then joint models uncover the peak somewhat later in time, and importantly, show secular improvement in life quality experienced by the younger cohort. Sharp estimates for many predictors of higher levels of life quality are found across the different domains of demographic, social, economic and health predictors. Conclusion: For the first time the trajectories of life quality in the third age are drawn and improvement across cohorts is demonstrated. The contributions are estimated for predictors amenable to intervention such as social capital and social support. This can help in policy discussion on improving the lives of older people in the third age.

SESSION 2140 (SYMPOSIUM)

ADVERSE LIFE CONDITIONS AND HEALTH ACROSS THE LIFESPAN

Chair: K.E. Cichy, *Human Development and Family Studies, Kent State University, Kent, Ohio*
Co-Chair: R.S. Stawski, *Oregon State University, Corvallis, Oregon*
Discussant: T.L. Gruenewald, *USC Davis, Los Angeles, California*

Across the lifespan, exposure to adverse life conditions creates a context where physiological systems and coping resources are repeatedly taxed, and these emotional and physiological assaults are hypothesized to create vulnerabilities and produce disruptions in psychosocial functioning and stress-responsive biological systems that have cascading consequences for adult mental, physical, and cognitive health. Although researchers speculate about how these processes unfold throughout adulthood, questions about the effects on health related to the type and timing of experienced adversities, remain. This symposium addresses these unanswered questions by considering how multiple sources of adversity uniquely and collectively shape a diverse set of adult outcomes. Friedman and colleagues examine how childhood adversities collectively shape three indicators of cardiometabolic health, including diabetes, heart disease, and obesity. Cichy, Li, and Woolverton examine the extent to which adult deficits in family support and strained family ties mediate associations between reports of childhood abuse and markers of cardiovascular risk. Toyokawa and colleagues explore how adverse childhood experiences and negative experiences within the parental role contribute to depressive symptoms for custodial grandparents. Fagundes and colleagues examine associations between childhood abuse, quality of life difficulties, and immune functioning among breast cancer survivors. Finally, Stawski, Fisher, Geldhof, and Wu explore how accumulating life events influence aging-related changes in depressive symptomatology. Together, these studies explore potential pathways through which adverse life experiences contribute to long-term health and well-being. Tara Gruenewald will reconcile the presentations and offer insights into how these research findings fit into and extend our understanding of adversity and health.

THE RELATIONAL LEGACY OF ADVERSE FAMILY ENVIRONMENTS AND CHRONIC DISEASE RISK

K.E. Cichy, J. Li, N. Woolverton, *Human Development and Family Studies, Kent State University, Kent, Ohio*

Early exposure to abusive, unsupportive family environments has consequences for adult health. Researchers speculate that early family adversity leads to deficits in adult social support, which intensifies the risk for cardiovascular disease (CVD). The current study examines the extent to which family support and strain mediate associations between retrospective reports of childhood abuse and markers of CVD risk (e.g. Body Mass Index (BMI)) among adults from the Midlife in the United States Survey (MIDUS II) aged 34-84 years ($N = 1255$, Mage = 55.2). Emotional abuse ($\beta = 0.11$), family support ($\beta = -0.07$), and family strain ($\beta = 0.13$) were significantly associated with BMI ($p < .05$). Results revealed that family strain, not family support, partially mediated or reduced the association between emotional abuse and BMI ($\beta = 0.08$), suggesting that the link between early family adversity and CVD risk is partially explained by increased family conflicts and demands.

CHILDHOOD ADVERSITIES AND ADULT CARDIOMETABOLIC HEALTH

E. Friedman[1], J.K. Montez[2], C. Sheehan[3], T.L. Gruenewald[5], T. Seeman[4], *1. RAND corp, Santa Monica, California, 2. Case Western Reserve University, Cleveland, Ohio, 3. University of Texas, Austin, Austin, Texas, 4. UCLA, Los Angeles, California, 5. University of Southern California, los angeles, California*

Mounting evidence shows that adverse early-life experiences, such as material deprivation or parental abuse, indelibly influence later-life health, often irrespective of adult circumstances. However, we know little about how early-life adversities collectively shape adult health (e.g., additively, nonlinearly), or whether they shape health similarly for women and men. Using MIDUS data, this study examines how childhood adversities are associated with three indicators of cardiometabolic health—diabetes, heart disease and obesity—for women and men. We test five specifications of adverse childhood experiences, and show that functional form matters. For instance, cumulative models of adversity are the best fit for heart disease and obesity and, to a lesser extent, diabetes. In addition, the association between childhood adversity and heart disease is stronger for women than men.

THE IMPACT OF LIFE EVENTS AND EDUCATION ON LONGITUDINAL CHANGES IN DEPRESSIVE SYMPTOMATOLOGY IN ADULTHOOD AND OLD AGE

R.S. Stawski[1], G.G. Fisher[2], G. Geldhof[1], C. Wu[1], *1. Oregon State University, Corvallis, Oregon, 2. Colorado State University, Fort Collins, Colorado*

Life events and education have long been known to have a considerable impact on mental, physical and cognitive health; the former having deleterious effects and the latter, protective. Less is known about whether these factors contribute to long-term changes and trajectories of depressive symptomatology throughout adulthood and old age. The current study examines whether the accumulation of life events and education influence aging-related changes in depressive symptomatology among older adults. Drawing on bi-annual longitudinal data from four cohorts of the Health and Retirement Study: HRS Cohort (born 1931-1941), AHEAD (born <1924), Children of the Depression (CODA: born 1924-1930) and the War Baby Cohort (WB: born 1942-1947), we observed significant longitudinal increases in depressive symptoms, particularly among the oldest ages and earliest born cohorts at baseline. Preliminary evidence also suggests that these effects are also exacerbated by the experience of life events, and attenuated by possessing higher levels of education.

PARENTING EXPERIENCES WITH THEIR OWN CHILDREN INFLUENCE WELL-BEING OF PRIMARY CARE GRANDPARENTS

N. Toyokawa, G.C. Smith, K.E. Cichy, *Kent State University, Kent, Ohio*

We compared individuals who reported being primary caregivers of grandchildren (PCG) to grandparents who were not to examine the cumulative effects of childhood adverse family environments and negative parenting experiences with PCGs' own children for their grandparents' psychological well-being. Out of 1,007 grandparents in the MIDUS I and II samples reporting demographic information, early adversity, and parenting experiences, four randomized comparisons were formed by gender and PCG or non-PCG status (N=50 for each group). Negative parenting experiences in the past were significantly related to female PCGs' depressive symptoms, F(2, 37)=4.84, p=.01, ΔR2=.16 and to their negative affect F(2, 37)=8.19, p=.001, ΔR2=.23, but were not significantly related to these outcomes for the other three groups. Adverse family environments during childhood were not significantly related to well-being for either PCGs or non-PCGs. Our findings suggest that negative parenting experiences are uniquely associated with negative affect and depressive symptoms in female PCGs.

SESSION 2145 (SYMPOSIUM)

AGEING IN THE ASIA-PACIFIC REGION: A LONGITUDINAL FOCUS

Chair: D. McLaughlin, *School of Population Health, The University of Queensland, Herston, Brisbane, Queensland, Australia*
Co-Chair: N.A. Pachana, *School of Population Health, The University of Queensland, Herston, Brisbane, Queensland, Australia*
Discussant: D. McLaughlin, *School of Population Health, The University of Queensland, Herston, Brisbane, Queensland, Australia*

Longitudinal studies of ageing provide unique perspectives on a range of health, emotional and social processes over time. Globally, increases in the proportion of older adults within the population make the data gleaned from longitudinal studies of increasing importance. Managing the challenges inherent in longitudinal studies of ageing participants requires flexible methodologies but provides a rich source of data which measure changes over time. The number of older people in the Asia-Pacific region is rising at an unprecedented rate and is unmatched in scale anywhere else in the world. Data in this symposium come from four large longitudinal studies located in Australia, New Zealand and Malaysia: the Australian Longitudinal Study on Women's Health (ALSWH); the Household, Income and Labour Dynamics in Australia (HILDA) Survey; the New Zealand Health Work and Retirement Study (HWR); and the Malaysian Elders Longitudinal Research study (MeLOR). Topics covered in this symposium include methodological changes over time and utilisation of administrative datasets to reduce participant burden (ALSWH); measurement of quality of life and health and linkages with government health data bases (HWR); changes in subjective and economic well-being (HILDA); establishing a new longitudinal study on ageing: challenges of recruitment, and collecting data in a multi ethnic developing country (MeLOR). This symposium offers diverse perspectives on the strengths and challenges of longitudinal studies in ageing. Objectives include (i) sharing our experiences in the pitfalls and riches inherent in longitudinal studies of ageing and (ii) describing the variety of recruiting and retention methods that these four studies have utilized.

NATIONAL HEALTH DATA-LINKAGE IN A NEW ZEALAND LONGITUDINAL AGEING COHORT

F. Alpass, C. Stephens, B. Stevenson, *Psychology, Massey University, Palmerston North, New Zealand*

The Health and Ageing Research Team's (HART) longitudinal cohort comprises a nationally representative community-based sample currently aged 52-89 years. We hold up to five biannual waves of self-reported health and well-being data for these older New Zealanders. A recent project was undertaken to link this existing data with participant health records held by the New Zealand Ministry of Health's National Medical Information Databases (including hospital admission and outpatient data, a cancer registry, pharmacy claims information, and mental health care details). Our data-linkage methodology was based on techniques employed by international studies of health and ageing, such as the Health & Retirement Study, the Australian Longitudinal Study of Women's Health and the Australian 45 & Up Study. This paper will describe the project linkage procedures undertaken, outline the challenges in securing consent from participants, and discuss the ethical concerns that such linkages bring.

MEASURING QUALITY OF LIFE AMONG A COHORT OF OLDER PEOPLE IN NEW ZEALAND

C. Stephens, F. Alpass, B. Stevenson, *School of Psychology, Massey University, Palmerston North, New Zealand*

The Health Work and Retirement (HWR) study has tracked a representative sample of older people (aged 55-70 years in 2006) for eight years as they transition from work into retirement and towards older age. The sample was selected from the New Zealand electoral roll and includes an oversample of Māori for statistical comparison purposes. Data collection is by postal questionnaire (and interviews with sub-samples). The study has focussed on Quality of Life as an outcome (QoL) and by beginning with a sample of 'young-old' New Zealanders has been able to measure a wide range of social and physical factors that are hypothesised to predict QoL in older age. The six data waves have also allowed for the inclusion and comparison of the performance of different measures of QoL and health related QoL. This paper will present and discuss comparisons between several of these measures including the WHOQoL, ICECAP, CASP-12, SF-36, SF-12, and PROMIS.

LESSONS IN PERSISTENCE AND FLEXIBILITY: FOLLOWING AN AGEING LONGITUDINAL COHORT OVER TIME

P. Gardiner[1,2], N.A. Pachana[3], D. McLaughlin[1], *1. School of Population Health, The University of Queensland, Herston, Queensland, Australia, 2. Mater Research Institute - The University of Queensland, South Brisbane, Queensland, Australia, 3. School of Psychology, The University of Queensland, Brisbane, Queensland, Australia*

The Australian Longitudinal Study on Women's Health (ALSWH) is a prospective nationwide study which has been investigating factors related to the health and wellbeing of three cohorts of Australian women since 1996. 12,432 women in the 1921-26 birth cohort participated in the original survey, when they were aged 70-75. Data were collected every three years until 2011 when, due to increasing age and declining participation, it was decided to collect data every six months. Currently 3,389 women remain in the study; 2,544 women have withdrawn and 6,499 women have died. Survey data from participants are linked to national and state-level administrative datasets which provide valuable information on health service and pharmaceutical benefits scheme use, aged and community care services and residential aged care uptake. This paper will discuss the challenges and benefits as well as translational research opportunities offered by working with an older cohort as they continue to age.

THE MALAYSIAN ELDERS LONGITUDINAL RESEARCH (MELOR) STUDY: CHALLENGES AND PRELIMINARY FINDINGS

S.B. Kamaruzzaman[1], M. Tan[1], N.N. Hairi[1], S. Jamal[2], S. Khoo[1], S. Siraj[3], N. Tey[4], A. Chin[1], *1. Faculty of Medicine,University of Malaya, Kuala Lumpur, Wilayah Persekutuan, Malaysia, 2. Faculty of Law, University of Malaya, Kuala Lumpur, Wilyah Persekutuan, Malaysia, 3. Faculty of Education,University of Malaya, Kuala Lumpur, Wilayah Persekutuan, Malaysia, 4. Faculty of Economics,University of Malaya, Kuala Lumpur, Wilayah Persekutuan, Malaysia*

The proportion of people aged > 60 in Malaysia is expected to be 22% by 2050. Western countries were already developed when challenged with their aging populations. However, Malaysia, being a developing country, has a shorter time to adjust to rapid population ageing. The Malaysian Elders Longitudinal Research (MELoR) study is a comprehensive multidisciplinary project integrating experts in the fields of Medicine, Engineering, Sports Science, Computer Science and Information Technology, Education, Economics, Sociology, Built Environment and Law. This study presents challenges of ageing and its research in a developing urban population. MELoR aims to generate a comprehensive dataset, based on feedback from older adults, on the overall needs and issues faced by them, to provide a foundation for strategic policy-making to increase quality of life and well-being of the elderly. This paper will present initial findings and discuss the challenges of recruitment, and collecting data in a multi ethnic developing country.

CHANGES IN SUBJECTIVE AND ECONOMIC WELL-BEING AMONG AUSTRALIAN BABY BOOMERS

K. O'Loughlin[1], V. Loh[1], H. Kendig[2], *1. University of Sydney, Lidcombe, New South Wales, Australia, 2. Australian National University, Canberra, Australian Capital Territory, Australia*

The Household, Income and Labour Dynamics in Australia (HILDA) Survey, a nationally representative household-based longitudinal study, conducted annually since 2001; it includes all household members aged 15 years and older. Data collection is by personal interview and self-complete questionnaire focussing on issues in three inter-related areas: income/welfare, labour market participation and family dynamics. This paper will present and discuss data on the baby boom cohort (born 1946-1965) drawn from Waves 1 to 11. The measure of self-reported overall life satisfaction will be used along with socio-demographic variables (age, gender, health, educational level, household income, marital status, home ownership), and self-rated health to examine changes in subjective and economic well-being for this cohort as they transition from middle age to early later life.

SESSION 2150 (SYMPOSIUM)

UNDERSTANDING NURSING HOME RESIDENTS' PREFERENCES FOR EVERYDAY LIVING

Chair: K. VanHaitsma, *Polisher Research Institute, North Wales, Pennsylvania*

Discussant: C.J. Whitlatch, *Benjamin Rose Institute on Aging, Cleveland, Ohio*

Understanding and honoring preferences is fundamental in the promotion of well-being for frail elders. However, research has yet to fully address how to best assess everyday preferences of individuals living in nursing homes. This symposium will examine dimensions of understanding residents' preferences in everyday living based upon findings of the study Assessing preferences for everyday living in the nursing home: reliability and concordance issues [PI: Van Haitsma; NINR:1R21NR011334-01]. First, we begin with a description of the theoretical foundation for studying preferences and background of the study. Second, drawing on cognitive interview data, we examine how an inventory to assess older adults' everyday preferences was adapted for use in a nursing home population producing a new measure called Preferences for Everyday Living Inventory (PELI). Third, the test-retest reliability of nursing home residents' everyday preferences as compared to a sample of young adults and a VA community over one week will be presented. Fourth, major domains reflecting why older adults may change their minds about the importance of their everyday preferences will be identified. Lastly, the concordance of family proxy reporters on the importance of residents' preferences will be examined, including which preferences are better understood by family members. While each presentation will capture a unique perspective of understanding older adults' preferences in everyday living in a nursing home setting, C. Whitlatch will integrate findings, highlighting implications for assessment of older adults' preferences, underscoring important future directions for research and practice.

THEORETICAL FOUNDATIONS OF PREFERENCE BASED CARE

K. Eshraghi, C. Duntzee, K. Abbott, A.R. Heid, K. Van Haitsma, *The Polisher Research Institute, The Madlyn and Leonard Abramson Center for Jewish Life, North Wales, Pennsylvania*

Person-centered care (PCC) has been embraced by policy makers and providers with the goal of providing care that addresses the needs and preferences of frail elders. This presentation explores the theoretical frameworks of PCC and how honoring preferences is the foundation of PCC. Continuity Theory addresses the need to preserve and maintain familiar arenas of life, the Competence Press Model suggests that a match between one's abilities and environment maximizes well-being, and Self-Determination Theory purports the importance of promoting autonomy, competence, and relatedness across the lifespan. The integration of knowledge about individuals' psychosocial preferences into care is related to increased satisfaction with care and positive quality of life outcomes. This presentation also introduces an ongoing study, Assessing preferences for everyday living in the nursing home: reliability and concordance issues [NINR:1R21NR011334-01], that is developing a comprehensive, reliable instrument that assesses the everyday preferences of older adults, including those with cognitive impairment.

ASSESSING RESIDENT PREFERENCES IN THE NURSING HOME: UNDERSTANDING MEANING AND LANGUAGE THROUGH COGNITIVE INTERVIEWING

K. Curyto[1], G.L. Towsley[2], K. Van Haitsma[3], *1. VA Western NY Healthcare System, Batavia, New York, 2. University of Utah College of Nursing, Salt Lake City, Utah, 3. Polisher Research Institute, Madlyn and Leonard Abramson Center for Jewish Life, North Wales, Pennsylvania*

This study adapted the Preferences for Everyday Living Inventory (PELI) for use with nursing home (NH) residents using cognitive interviewing. PELI items were administered to 31 Veteran participants and 39 non-Veteran participants who were at least 55 years of age, with moderately impaired to intact cognition, in the NH for at least one week, and medically stable. Participants rated level of importance and answered questions about their understanding and perceptions of these preferences. The majority of PELI items were retained; 25 percent of the items required wording changes, were deleted, or were added as new items. Responses from cognitive interviewing guided revisions of the PELI to include language that NH residents use and understand, reducing potential measurement error and ensuring that preferences assessed are relevant to NH residents. Individualized preference assessment using the PELI will help move clinical teams closer to the goal of providing PCC informed by individual preferences.

PSYCHOMETRIC PROPERTIES OF A PREFERENCE TOOL IN THREE SAMPLES

K. VanHaitsma, K. Eshraghi, C. Duntzee, A.R. Heid, K. Abbott, *Polisher Research Institute, North Wales, Pennsylvania*

This study sought to test the reliability of everyday preferences over one week, comparing responses of residents at a community nursing home (n = 37), residents at a VA community living center (n = 42), and university students (n = 50). Participants completed the Preferences for Everyday Living Inventory (PELI) at baseline and 5-7 days later. The overall percent perfect agreement across samples was low, with an average of 62.73% agreement across the sample on 66 preferences. When dichotomizing preference responses to "important" or "not important", percent agreement jumped from 63.73% to 84.4% for the 129 subjects in this study. The 3 samples did not show a significant difference in reliability. Qualitatively, the results suggest that there is instability in measuring everyday preferences. Age alone does not contribute to instability and further work is needed to identify if some preferences are more stable than others to inform assessment strategies.

"IT DEPENDS": REASONS WHY NURSING HOME RESIDENTS CHANGE THEIR MINDS ABOUT CARE PREFERENCES

K. Abbott, K. Eshraghi, C. Duntzee, A.R. Heid, K. VanHaitsma, *Polisher Research Institute, North Wales, Pennsylvania*

This study aims to understand and describe nursing home residents' perspectives on why their daily care preferences may change over time. Content analysis of cognitive interviews completed with 39 cognitively capable nursing home residents revealed four major domains of reasons for why nursing home residents may change their importance rating of their references. Domains include within person, facility environment, social environment, and global environment factors. Residents reflected that the importance of their preferences fluctuated "depending upon" the circumstances related to these factors or their ability to perform the preference (i.e., barriers they encountered). In order to develop formal care that matches older adults' preferences, regular assessment of both elders' preferences and the contextual factors affecting preferences is needed. However, given the changing nature of preferences, there is also a need to determine how to best balance older adults' changing preferences within care delivery environments.

DO PROXIES GET IT RIGHT? DISCREPANCIES IN REPORTING EVERYDAY PREFERENCES OF NURSING HOME RESIDENTS

A.R. Heid, C. Duntzee, K. Eshraghi, K. Abbott, K. Van Haitsma, *The Polisher Research Institute, The Madlyn and Leonard Abramson Center for Jewish Life, Merion Station, Pennsylvania*

Research demonstrates discrepancies in understanding older adults' values and preferences in family care. However, work has yet to examine how well family/friend proxies understand older adults' everyday preferences when older adults are living in nursing homes. With 88 dyads of a nursing home resident and their relative/friend, we examined the concordance of importance ratings of residents' everyday preferences across 4 domains: growth activities, leisure activities, self-dominion, and social contact. Utilizing multi-level modeling, we explored the association of individual and relationship-based characteristics with reported discrepancies. Dyads were only discrepant on the importance of growth activities for residents, with residents reporting higher levels of importance than their proxies. This discrepancy was associated with residents' hearing impairment and personality trait of openness. The findings highlight areas where proxies may be able to inform care accurately for residents in skilled nursing care, but also where further discussions might be needed.

SESSION 2155 (SYMPOSIUM)

MODIFIABLE DETERMINANTS AND TRENDS OF COGNITIVE FUNCTIONING IN COMMUNITY- DWELLING OLDER PERSONS

Chair: H.C. Comijs, *Psychiatry, GGZinGeest/VUMC, Amsterdam, Netherlands*
Co-Chair: M. Visser, *Vu University Medical Center, Amsterdam, Netherlands*
Discussant: S.M. Hofer, *University of Victoria, Victoria, British Columbia, Canada*

The Longitudinal Aging Study Amsterdam (LASA) has a long tradition of studying cognitive functioning and its decline in a population-based sample older persons. In this symposium we report about recent research from our cohort. We examined potential important determinants of cognitive functioning or cognitive decline, such as sedentary behaviour, loneliness and stress. All of these determinants are highly prevalent in older adults and are potentially modifiable. Therefore, the outcomes of these studies may offer important information for developing preventive interventions. Marjolein Visser will discuss the association between sedentary behaviour. Marja Aartsen will discuss whether loneliness mediates the relation between social support and cognitive functioning . Hannie Comijs will present data about life events, perceived stress and their relation with cognitive functioning. The last speaker, Tessa van den Kommer will present time-trend analyses to determine whether dementia prevalence changes over time. Finally, Scott Hofer will reflect on these presentations.

SEDENTARY BEHAVIOR AND COGNITION IN OLDER ADULTS

M. Visser[1,2], S. van Dongen[1], H.C. Comijs[2], *1. Health Sciences, VU University Amsterdam, Amsterdam, Netherlands, 2. VU Medical Center, Amsterdam, Netherlands*

We studied the cross-sectional association between sedentary behavior and cognitive functioning in 1,325 participants of the Longitudinal Aging Study Amsterdam, aged 60-100 years. Sedentary behavior (h/d) was assessed using a 6-item validated questionnaire (napping, reading, listening to music, watching TV, performing hobbies, talking). General cognitive functioning (MMSE), learning and delayed recall and information processing speed were assessed. After adjustment for demographics, lifestyle, depression and chronic diseases, total sedentary behavior was not associated with any cognition outcome. Napping (yes versus no, β -1.6 (95% CI -2.2 to -0.9)) and listening to music (>60 min/d versus no; -1.5 (-2.3 to -0.6)) were associated with poorer information processing speed. Reading (learning), watching TV (information processing speed and MMSE score) and performing hobbies (all domains) were associated with better cognition. The study suggests that not sedentary behavior per se, but the cognitive load during this behavior, is associated with cognitive functioning in old age.

LIFE EVENTS, PERCEIVED STRESS AND COGNITIVE FUNCTIONING IN OLDER ADULTS

H.C. Comijs[1], N. Korten[2], *1. Psychiatry, GGZinGeest/VUMC, Amsterdam, Netherlands, 2. VU University Medical Center, Amsterdam, Netherlands*

Older persons are frequently exposed to various stressors that may interfere with the system's physiological and psychological homeostasis, which may have an adverse effect on cognitive functioning. The aim of the present study is to examine the associations with life events and perceived stress and their effect on cognitive functioning. Data from the last LASA measurement will be used and include measures for executive functioning, memory and information processing speed. Next to a structured life events questionnaire, the Perceived Stress Scale was included. The first results show strong associations between the PSS and almost all domains of cognitive functioning. However, this association was mainly driven by the Perceived Self-efficacy subscale of the PSS, there was no the association between the Perceived Helplessness subscale and cognitive domains.

DOES LONELINESS MEDIATE THE RELATION BETWEEN SOCIAL SUPPORT AND COGNITIVE FUNCTIONING IN LATER LIFE?

L. Ellwardt[1], M.J. Aartsen[2], D.J. Deeg[3,2], N.J. Steverink[1], *1. University of Groningen, Groningen, Netherlands, 2. Faculty of Social Sciences, VU-University, Amsterdam, Netherlands, 3. VU-University medical center, Amsterdam, Netherlands*

Research in gerontology has demonstrated mixed effects of social support on cognitive decline and dementia: This study investigates whether subjective appraisals rather than received amounts of social support affect cognitive functioning. We expect that receiving instrumental and emotional support reduces loneliness, which in turn preserves cognitive functioning. Data are from the Longitudinal Aging Study Amsterdam (LASA) and include 2255 Dutch participants aged 55-85 over a period of six years. Respondents were measured every three years. Cognitive functioning was assessed with the Mini-Mental State Examination (MMSE), the Coding Task, and the Raven's Coloured Progressive Matrices. The analytical approach comprised latent growth mediation models. Frequent emotional support relates to reduced feelings of loneliness and better cognitive functioning. Increases in emotional support also directly enhanced cognitive performance. After ruling out the possibility of reversed causation, we conclude that emotional support relationships are a more powerful protector of cognitive decline than instrumental support relationships.

TIME TREND IN PREVALENT DEMENTIA: RESULTS FROM THE LONGITUDINAL AGING STUDY AMSTERDAM

T.N. Van Den Kommer[1], H.C. Comijs[2], D.J. Deeg[3], *1. VU University Medical Center, EMGO Institute for Health and Care Research, Department of Epidemiology & Biostatistics, Amsterdam, Netherlands, 2. VU University Medical Center, EMGO Institute for Health and Care Research, Department of Psychiatry; and GGZ InGeest, Amsterdam, Netherlands, 3. VU University Medical Center, EMGO Institute for Health and Care Research, Department of Psychiatry, Amsterdam, Netherlands*

Objective: To study whether dementia prevalence changes over time, adjusting for age and gender, and to examine possible explanatory variables. Methods: Data from the Longitudinal Aging Study Amsterdam over 10 years of follow-up were used. An age group of 68-88-year-olds was selected at each wave, including N=1,666 at baseline. Data were analyzed using logistic generalized estimating equations (GEE; 3-dependent correlation structure), with time as the main predictor. Explanatory variables were lagged one wave. Results: Dementia prevalence at baseline was 4.8% (N=71, ages 68-88), weighed according to gender and age of the Dutch population. The results showed a positive time trend for dementia prevalence (Exp(B) time (fully adjusted model)=1.045 (95% CI:1.004-1.087). Conclusion: Evidence was found for a positive time trend in dementia prevalence, i.e. an increase in dementia prevalence over time, taking into account age and sex. This time trend could not be explained by CVD, diabetes, life-style and depressive symptoms.

SESSION 2160 (SYMPOSIUM)

INCREASING RESOURCES FOR OLDER ADULTS THROUGH TECHNOLOGY FOCUSED RESEARCH AND INTERVENTIONS

Chair: S. Cotten, *Michigan State University, East Lansing, Michigan*
Discussant: S.J. Czaja, *University of Miami, Miami, Florida*

A variety of resources are being created to assist older adults in learning how to use computers, social media, and other technologies, increase health literacy, how to be safe online, and other educational and informational resources. Many of these resources are being created through technology focused research and intervention projects. The purpose of this symposium is to showcase some of the resources that have been created in recent years that are tailored to enhancing some aspect of older adults' quality of life. Researchers will detail their projects, the specific older age groups they targeted, the types of resources created, and future goals for expanding resources in these areas. Given and Given will provide details on NCI funded trials that developed and tested an AVR supported by a symptom Management Toolkit to help older patients manage symptoms and side effects that resulted from their cancer treatment. Jiang and colleagues detail a new NSF funded project focusing on understanding older adults' views on online safety and security, and the tools they use to keep themselves safe online. They also provide details on the types of technological tools older adults need to ensure their safety when online and what their project will provide. Xie and Watkins detail NIH funded projects using participatory design techniques to cultivate older adult teams to help design eHealth literacy tutorials for older adults. Cotten and colleagues detail resources created through a five year NIH funded randomized controlled trial working with older adults in assisted and independent living communities. Sara Czaja, the discussant for the symposium, emphasizes how these diverse projects with older adults provide key resources to enhance quality of life and ways to expand the creation of resources in times of less research funding.

CULTIVATING OLDER ADULT TEAMS (OATS) TO COLLABORATIVELY DESIGN EHEALTH LITERACY TUTORIALS FOR OLDER ADULTS

B. Xie[2,1], I. Watkins[1], *1. School of Information, University of Texas at Austin, Austin, Texas, 2. School of Nursing, The University of Texas at Austin, Austin, Texas*

Participatory design can empower older adults to shape the design of new technologies to make them more senior-friendly. We used participatory design to cultivate Older Adult Teams (OATs) to help design eHealth literacy tutorials for older adults. Between September 2009 and March 2014, 27 participants aged 65 and over participated in OATs. Weekly two-hour-long participatory design sessions with OATs occurred at public libraries in Austin, Texas and Hyattsville, Maryland. Working with the OATs we developed web-based multimedia tutorials for the Electronic Health Information for Lifelong Learners project, which focuses on developing and evaluating eHealth tutorials for older adults, and the Online Tutorial Overlay Presenter project, which overlays instructions on real websites to facilitate use. Forming friendships, socializing, and contributing to tutorial design were identified by OATs as key benefits derived from participation. These findings have significant implications for future research on older adult empowerment.

A RESOURCE FOR OLDER ADULTS: SYMPTOM MANAGEMENT FOR CANCER

B.A. Given[1], C.W. Given[2], *1. Michigan State University College of Nursing, East Lansing, Michigan, 2. Michigan State University College of Human Medicine, East Lansing, Michigan*

Cancer patients in active treatment have side effects and symptoms from the medication they receive. The use of an Interactive Voice

Response system (IVR) supported by a Symptom Management Toolkit to manage patients' side effects will be described. The IVR system contacted patients weekly over an 8 week period, assessed their side effects and symptoms, and based on the presence and severity of those symptoms then referred them to the Symptom Management Toolkit for guidance. This Toolkit had strategies for management of over 20 common side effects from cancer treatment. Reduction in the number of symptoms and reduced symptom side effects severity enables the older patient to continue optimal cancer treatment. The result of this resource enhances effective cancer treatment while improving the quality of life of the older patient.

ICTS AND QUALITY OF LIFE: RESOURCES

W.A. Anderson[2], S. Cotten[1], *1. Michigan State University, East Lansing, Michigan, 2. University of Alabama, Birmingham, Birmingham, Alabama*

The ICTs (information and communications technologies) & Quality of Life Study is a five-year, three-arm, randomized, controlled intervention study designed to assess the extent to which use of ICTs such as computers, the Internet, email, and social networking can increase social capital and improve quality of life among older adults living in independent and assisted living communities. In order to conduct the study, a customized, 8-week training manual was written for use by the participants. The manual included detailed instructions, screenshots, and "homework" exercises for each intervention session. In this presentation, the development and use of the manual are detailed, the manual is described, and outside resources that were used as adjunct materials (e.g., the SPRY foundation guide to evaluating health information on the Internet, assistive devices, and other materials) are discussed.

UNDERSTANDING OLDER GENERATION'S PERCEPTIONS OF ONLINE RISKY BEHAVIOR IN THE ELECTRONIC BANKING CONTEXT

M. Jiang, S. Cotten, H. Tsai, N. Rifon, B. LaRose, S. Alhabash, *Michigan State University, East Lansing, Michigan*

The study aims to understand the older generations' perceptions of online risky behavior, specifically electronic banking adoption, and the security measures they do or do not use to protect themselves online. Using Protection Motivation Theory (PMT), the researchers conduct 12 focus groups, in representation of two generational cohorts (seniors vs. older boomer) and two user groups (online banking users vs. non-users). Differences in threat appraisal and self-efficacy to perform protection behaviors were identified in different generation cohorts and user groups. Results show although older generations recognize the risks and benefits of electronic banking and self-responsibility in security protections, they expect the bank to teach them the latest security threats and protection resources. Non-users also need special training to increase technological literacy and network trust to transit from offline to online. These findings are being used to design age-tailored interventions to educate older generations to stay safe while banking online.

SESSION 2165 (SYMPOSIUM)

HEALTH, CARE, AND COMMUNITY: AN ENVIRONMENTAL GERONTOLOGY PERSPECTIVE

Chair: M. Kaup, *ATID, Kansas State University, Manhattan, Kansas*
Co-Chair: J. Norstrand, *Boston College, Chestnut Hill, Massachusetts*
Discussant: S. Golant, *University of Florida, Gainesville, Florida*

This symposium presents research on the role of different forms of community in relationship to health care access, outcomes, and general well-being for older adults both in the US as well as China. Presentations will demonstrate the application of both qualitative and quantitative research strategies that can be used to study these variables as well the proposition of new conceptual frameworks for exploring the merger of ecological models of aging with behavior models of health service use. Three individual presentations will highlight research projects which are exploring the roles and dimensions of environmental factors related to health and care outcomes. One presentation will share the outcomes of a project that examines the relationship between environmental and socio-economic community characteristics associated with health conditions of the elderly in China. A second presentation will discuss the experience of residential change from independent to assisted living in continuing care retirement communities as studied through a phenomenological lens. The final presentation will look to the future of the field of environmental gerontology and proposes a conceptual framework for a course of research that examines how neighborhood environments influence health care access, utilization, and outcomes for chronically ill elders. At the conclusion of this symposium, participants will be able to identify environmental variables that influence older adults' access to health care as well as identify methods and various forms of scholarly inquiry that can be applied to study the relationships between health, care, and community.

COMMUNITY ENVIRONMENT, HEALTH CONDITIONS AND HEALTH CARE OF THE ELDERLY IN CHINA'S COASTAL AREAS

H. Mi, Z. Ren, *Zhejiang University, Hangzhou, China*

A major criticism of economic development in China has been its negative effects on environment and health. The financial support or pension programs provided to the elderly are limited. This study examines the relationship between environmental and socio-economic community characteristics associated with health conditions of the elderly. The sample included elders in 1010 households from 36 communities. We pooled data from the Household Energy Consumption, Environment and Health Longitudinal Survey. Logistic regression models with multilevel structure were used to control for non-independence of respondents in the same community. The main results show that at the community-level, (1) environmental characteristics, such as not using fuel woods in the community, are the most significant factors to health conditions of the elderly; (2) medical and endowment insurance are not significant due to its low security level, the unbalance between urban and rural areas, and the separation of health care and elderly services systems.

DEFINING COMMUNITY IN ASSISTED LIVING: IMPLICATIONS FOR CARE AND WELL-BEING

L.L. Lien[1], M. Bruin[2], *1. University at Buffalo, Buffalo, New York, 2. University of Minnesota, St. Paul, Minnesota*

Active and supportive communities greatly impact the care and well-being of older adults. In an assisted living environment, the concept of community embodies a unique meaning, spanning physical, social, and psychological domains. This qualitative phenomenological study explored the experience of residential change from independent to assisted living among 22 older adult women residing in two different Continuing Care Retirement Communities. Themes of adaptation, socialization, memories, and satisfaction shed light on how community is defined by residents in supportive housing. Declines in health and newfound dependencies altered perceptions of self, but positively stimulated mutual support and connectedness between participants and staff and among fellow residents, thereby expanding care networks. Knowledge of how community is established within assisted living facilities provides insight into the unique needs and desires of residents, and further helps generate implications for design, policy, and research to cultivate supportive and active networks that improve care and well-being.

A CONCEPTUAL FRAMEWORK FOR EXAMINING NEIGHBORHOOD ENVIRONMENTS AND OLDER ADULTS' HEALTH CARE ACCESS

M. Ryvicker, *Center for Home Care Policy and Research, Visiting Nurse Service of New York, New York, New York*

A growing body of research has examined how older adults' health and wellbeing are sensitive to the physical and social environments of their surrounding neighborhoods. However, relatively little is known about how neighborhood environments influence older adults' access to health care, beyond geographic variations in health care supply. This paper proposes a conceptual framework for a course of research that examines how neighborhood environments influence health care access, utilization, and outcomes for chronically ill elders. The framework merges the ecological model of aging with the behavioral model of health service use to propose testable hypotheses about the health care environment, social environment, and built environment as causal and moderating factors in access to care. The model aims to facilitate analysis of within-city variation in access, with the goal of identifying environmental factors contributing to disparities in access that are not fully explained by variations in the supply of health services.

SESSION 2170 (SYMPOSIUM)

INEQUALITIES IN HEALTH AND WELL-BEING ACROSS THE LIFE COURSE: EVIDENCE FROM AMERICANS' CHANGING LIVES

Chair: A. Karraker, *Population Studies Center, University of Michigan, Ann Arbor, Michigan*
Discussant: J.A. Ailshire, *University of Southern California, Los Angeles, California*

The determinants and dynamics of health inequalities across the life course are complex and have important implications for individuals, families, communities, and society. These papers use data from the Americans' Changing Lives (ACL) to document and explicate the determinants of health inequalities across the life course. Americans' Changing Lives is the longest continuously running longitudinal study in the United States of the determinants of health and well-being and contains rich and repeated measures of health-related outcomes and related social factors. This nationally-representative sample contains five waves of data spanning from 1986 through 2011. These papers draw on ACL's rich data to explore the social, economic, psychological, and behavioral factors associated with health and well-being across individuals' lives. Papers use data from the newly-available fifth wave of data which includes several novel measures, such as sleep quality, diet, and detailed measures of health screening and preventative care. The presentations examine 1) the sociodemographic patterning of depression trajectories, 2) the connections between life course mastery and mobility-related assistive technology, 3) the relationships between chronic disease, depression and sleep problems, and 4) the social patterning of health care utilization. This suite of papers demonstrates the interrelationships between multiple dimensions of social position, health, and well-being with one another and the importance of longitudinal data in documenting cumulative (dis)advantage. The discussant will identify common themes across papers, methodological innovations, and highlight policy implications and directions for future research.

A LIFE COURSE VIEW ON DEPRESSION: TRAJECTORIES AND TYPOLOGIES OVER 25 YEARS OF AMERICAN'S CHANGING LIVES

O. Rostant[1,2], P. Clarke[3], R.J. McCammon[4], M. Sinkewicz[5], K. Zivin[2,6], *1. National Institute on Aging, Baltimore, Maryland, 2. Psychiatry, University of Michigan, Ann Arbor, Michigan, 3. Institute for Social Research University of Michigan, Ann Arbor, Michigan, 4. Department of Medicine University of Michigan Medical School, Ann Arbor, Michigan, 5. University of Michigan School of Social Work, Ann Arbor, Michigan, 6. Department of Veterans Affairs, HSR&D Center for Clinical Care Management, and Serious Mental Illness Treatment, Resource and Evaluation Center (SMITREC), Ann Arbor, Michigan*

This study investigates variations in trajectories of depressive symptomatology across the life course and examines the extent to which socio-demographic characteristics explain this variation. Data come from the Americans' Changing Lives (ACL) study, a national sample of 3617 adults (age 25+) followed over 25 years (1986-2011). Depressive symptoms were assessed across five waves of data, with a 7-item abbreviated version of the Center for Epidemiologic Studies-Depression scale (CES-D7). Results indicate that the CES-D7 was invariant across time. Two latent depression trajectories were identified across the life course; one was a normative trajectory (60% of the sample) and the other (40%) had persistently high depressive symptoms. Individuals in the high depressive symptomatology class were more likely to be female, African American, have less education and lower incomes. This study highlights the need for examining heterogeneity in depressive trajectories in order to appropriately screen and treat depression in an increasingly diverse society.

LIFE COURSE MASTERY AND MOBILITY-RELATED ASSISTIVE TECHNOLOGY USE: FINDINGS FROM THE AMERICANS' CHANGING LIVES SURVEY

K. Latham[1], P. Clarke[2], *1. Department of Sociology, Indiana University-Purdue University Indianapolis, Indianapolis, Indiana, 2. University of Michigan, Ann Arbor, Michigan*

Mastery in older ages is intrinsically linked to early-life and midlife experiences. Prior research has demonstrated that mastery is positively associated with health, and it is thought to shape health behavior including mobility device (e.g., canes, walkers, or wheelchairs) use. Using 25 years of data from the Americans' Changing Lives Survey, this research explores whether life course mastery influences the likelihood an older adult with functional impairment uses a mobility device. We used growth mixture models with a distal outcome, and examined the relationship between functional limitations and mobility device use as it varies across latent classes of life course mastery, controlling for sociodemographic characteristics and health histories. The odds of device use in the face of functional limitations was significantly higher among those with a history of persistently high life course mastery over adulthood, all other things being equal (difference in coefficients = 1.29, 95% CI = .03, 2.79).

THE IMPACT OF SLEEP DISTURBANCE ON THE ASSOCIATION BETWEEN STRESSFUL LIFE EVENTS AND CHRONIC ILLNESS WITH DEPRESSIVE SYMPTOMS

A.N. Leggett[1], S.A. Burgard[1], K. Zivin[1,2], *1. The University of Michigan, Ann Arbor, Michigan, 2. Department of Veterans Affairs, Ann Arbor, Michigan*

Sleep problems are common among older adults and may negatively impact depressed mood and its risk factors. We examine sleep disturbance as a moderator of the association between stressful life events and chronic illness with depressive symptoms in wave five of the American Changing Lives Study. On average, participants (N=1306; mean age = 63 years) experienced one chronic illness, three life events, and moderate sleep disturbance. Using linear regression, we found that chronic illness, life events and sleep disturbance were associated with depressive symptoms. Additionally we found a significant sleep disturbance by life events interaction showing that individuals experiencing many life events and severe sleep disturbance were at particularly high risk for depressive symptoms. While chronic illness, life events and sleep disturbance all impact depressive symptoms, findings indicate the stress-mood relationship is strongest at poor levels of sleep. Sleeping restfully may allow individuals the rejuvenation needed to manage stress adaptively.

THE ROLE OF INFORMAL AND FORMAL PREVENTIVE MEDICAL BEHAVIOR IN EDUCATIONAL DISPARITIES IN HEALTH

S. Burgard[1], J. House[2], P. Christine[2], K. Hauschildt[2], D.C. Brown[2], K.M. Langa[2], R. Melendez[2], R. Mero[2], *1. Sociology, University of Michigan, Ann Arbor, Michigan, 2. University of Michigan, Ann Arbor, Michigan*

Education has a very strong protective effect on health over the life course, particularly in preventing or postponing the onset of morbidity and functional impairment/disability. Improved socioeconomic attainments of better-educated people and patterns of risk or protective behaviors over the life course (smoking, alcohol consumption, total caloric consumption/body mass/obesity, and physical activity) explain part of education's effect. Using cross-sectional data from Wave 5 (20ll/12) and data from earlier waves of the ACL study, we show that less-studied factors are also strongly associated with education (and less so with income) and may help to explain some of the remaining association between education and poor health. These include health literacy, specific dietary factors (e.g. Mediterranean diet), formal preventive behaviors (e.g., screening tests for blood pressure, cholesterol, blood sugar, colon polyps, and dental or eye problems) and informal ones (e.g., supplements such as vitamins, aspirin, and calcium).

SESSION 2175 (PAPER)

DIMENSIONS OF CAREGIVING: CROSS-NATIONAL PERSPECTIVES

POSITIVE AND NEGATIVE WORK-FAMILY SPILLOVER ON PSYCHOLOGICAL AND PHYSIOLOGICAL FUNCTIONING IN MIDLIFE PARENTAL CAREGIVERS OF INDIVIDUALS WITH AND WITHOUT DISABILITIES

J.D. Wong[1], Y. Shobo[2], *1. Human Sciences, The Ohio State University, Columbus, Ohio, 2. West Virginia Higher Education Policy Commission, Charleston, West Virginia*

The influence of positive and negative work-family spillover on psychological and physiological functioning was examined in a sample of 69 parental caregivers (Mage =49.84, SD=9.66) of individuals with disabilities and 278 parents (Mage=50.88, SD=9.07) of individuals without disabilities. As a part of the National Survey of Midlife in the United States (Wave-2), parents completed interviews, questionnaires, and a Daily Diary Study. Parents also provided saliva on four of the eight Daily Diary Study days. Hierarchical regression analyses showed that parents of individuals with disabilities who reported high levels of negative family-to-work spillover had the greatest levels of negative affect than the comparison parents. Multilevel models also revealed a significant interactive effect of caregiver status and negative work-to-family spillover on bedtime cortisol level. Our findings highlight the importance of bridging research on parental demands and occupational stress to better understand the psychological and physiological impact of caregiving for individuals with disabilities in midlife.

POSITIVE ASPECTS OF FAMILY CAREGIVING: ITEM RESPONSE THEORY ANALYSES OF RACE AND GENDER DIFFERENCES

D.L. Roth[1], P. Dilworth-Anderson[2], J. Huang[1], A.L. Gross[1], L.N. Gitlin[1], *1. Johns Hopkins University, Baltimore, Maryland, 2. University of North Carolina-Chapel Hill, Chapel Hill, North Carolina*

Recent research and theory have emphasized certain positive experiences that may result from providing care to a family member with dementia. The 11-item Positive Aspects of Caregiving (PAC) scale was designed to assess this construct, and it was administered to participants in the second Resources for Enhancing Alzheimer's Caregiver Health (REACH II) clinical trial. PAC item data were obtained from 211 African American, 212 Hispanic, and 219 White family caregivers at baseline and before any REACH II interventions were provided. Item response theory models were used to assess for possible differential item functioning (DIF) by caregiver race and gender. Statistically significant ($p < .05$) and practically meaningful (odds ratio (OR) > 2) DIF was found for African Americans compared to Whites on two of the PAC items. Meaningful DIF was not found when comparing Hispanics to Whites or women to men. After controlling for the unidimensional latent construct underlying all 11 items, African Americans were more likely than Whites to agree that caregiving helped them "to develop a more positive attitude toward life" (OR = 3.12, $p < .001$) and "to appreciate life more" (OR = 2.66, $p < .001$). The 11-item PAC scale appears to contain two items that are particularly sensitive to cultural factors and caregiving expectations that are more important for African Americans than for Whites or Hispanics, and associations with observed summary scores on the PAC may be moderately impacted by this differential sensitivity. These findings reinforce considering the cultural implications of positive experiences in caregiving.

FAMILY CARE AND HEALTH BEHAVIOR AMONG MEN: DOES RELATIONSHIP QUALITY MATTER?

N. DePasquale[1], C.A. Polenick[1], D. Almeida[1], J. Bray[4], J. Hinde[5], P. Moen[3], L.B. Hammer[2], *1. The Pennsylvania State University, University Park, Pennsylvania, 2. Portland State University, Portland, Oregon, 3. University of Minnesota, Minneapolis, Minnesota, 4. Bryan School of Business and Economics, Greensboro, North Carolina, 5. RTI International, Research Triangle Park, North Dakota*

Although men now represent nearly half of family caregivers in the United States and continue to increase in number, relatively little is known about caregiving men. Given their shorter lifespans and unhealthier lifestyles compared to women, determining whether and how family care roles affect health behavior is particularly important for men. Using survey data on 370 cohabiting and married men from the Work, Family, and Health Study, we examined family care (child care only, elder care only, and multigenerational or 'sandwiched' care) correlates of self-reported sleep duration, cigarette smoking, alcohol consumption, exercise, and physical activity. We also tested the degree to which partner relationship quality moderated these associations. Findings suggest that partner relationship quality moderates caregiving men's health behavior across care situations. Evaluating health behavior and related contextual factors among caregiving men is important not only for their own health, but also for their ability to provide quality care.

DECISION ON INSTITUTIONALIZATION BY FAMILY CAREGIVERS: THE CASE OF GREECE

C. Pliakos, *1. University of Central Lancashire, Preston, United Kingdom, 2. Greek Institute of Gerontology and Urban Sociology on Ageing, Athens, Greece*

Purpose: In part of a cross-nation project between UK and Greece, on the theme of 'ageing in place' named the PATH project, this empirical study aims to identify the decisive factors of Greek family caregivers to older adults that could lead their decision to institutionalize their beloved ones. Methods: A mixed method technique in two independent samples is used by conducting an e-mail survey with structured questionnaires responded by 932 home-based family caregivers (n=932) and a qualitative study with 53 in-depth interviews conducted on 74 caregivers/decision makers (n=53) using a semi-structured questionnaire of 9 open-ended questions during the procedure of seeking a nursing or residential setting to place their relatives. Qualitative and quantitative data were analysed using Nvivo10 and SPSS10 and compared findings through methodological triangulation applied in the independent studies. Results: Findings suggested a number of 'push' and 'pull' factors for possible institutionalization with order of influence: Diminishing health status and the need for extra care, poor housing quality, lack of supportive community services, dementia related challenging behaviors, safety concerns, emotional burden and psychological stressors, changes in working conditions at the job of the caregivers, feeling of loneliness and need for socialization. Conclusions: The study develops more in-depth understanding on the reasons affecting the choice of institutionalization made by the Greek family caregivers. However, there is a need for further research with data collection on different phases of the institutionalization process and cross-nation comparisons with respect to cultural diversity issues in undertaking the caregiving role.

ELDERCARE IN TRANSNATIONAL SETTINGS: GLOBAL CARE CHAIN AND MEXICAN MIGRANT WOMEN

I. Amin, *University of North Texas at Dallas, Dallas, Texas*

With increase of transnational families and global aging, transnational elder care is becoming common. To date, global care chain analysis has predominantly focused on married women migrating to richer countries to take up domestic work leaving their dependent children, the care of whom is provided by other poorer women or often by unpaid labor. Little is known about the care chains involved in the transnational elder care practices and the delivery of physical and emotional care throughout the chain, and the influence of cultural and familial expectations on the caring arrangements for the aged. To fill this knowledge gap, using a grounded theory approach, this study analyzed transnational eldercare practices of nine Mexican migrant female care workers living in the U.S. The age of the women was between 24 and 48, and care recipients between 56 and 73. The narrated stories of the women reveal many strategies they adopt to deliver emotional care to the aged parents left behind, and in most cases at the bottom of the chain the physical as well as emotional eldercare are provided by hired domestic female labor, and other unpaid female family members. The care chain is multidirectional and the quality of care depends on factors such as, remittance sent, number of siblings, types of family, and age of the care recipient. The findings contribute to a growing body of research suggesting that international migration impacts eldercare, and by highlighting the importance of institutional policies to cater the caregiving needs of transnational families.

SESSION 2180 (PAPER)

FAMILY CAREGIVING

HOW DO FAMILY CAREGIVERS DEAL WITH CONFLICT IN LONG TERM CARE? APPLICATION OF CONFLICT THEORY

A. Petrovic-Poljak, C. Konnert, *Department of Psychology, University of Calgary, Calgary, Alberta, Canada*

Conflict between families and staff in long term care (LTC) is a daily reality that has adverse outcomes for residents, staff and families. However, to date it has not been empirically evaluated. Multiple barriers exist in examining conflict, including its sensitive nature, which may have precluded such study, as well as lack of theoretical integration. In order to examine family-staff conflict and its management in LTC, this research is merging two independent bodies of literature, that of family caregiving in LTC and organizational behavior literature on conflict. This study presents the argument that two prominent theories from the conflict literature, namely the theory of cooperation and competition (Deutsch, 1973) and the dual concern theory (Pruitt & Rubin, 1986) can be applied in the LTC context. In addition to discussing theoretical applications, the study examined conflict resolution strategies through questionnaires in a sample of family caregivers, with data showing preliminary support for the model. Results indicate that family caregivers engage in a variety of conflict resolution strategies to manage family-staff conflicts and indicate a significant role for trust, power and communication between family and staff. The implications of the conflict resolution techniques endorsed by family caregivers and the theoretical fit will be discussed. In order to effectively intervene in family-staff conflicts, it is imperative that greater understanding of conflict and its management from the point of view of family caregivers is obtained, and that conflict and conflict management models successfully used in other conflict situations are applied to family-staff conflicts.

CAREGIVER OUTCOMES FROM THE GEORGIA AND TENNESSEE REPLICATION STUDIES OF BRI CARE CONSULTATION

B. Primetica[1], D.M. Bass[1], C. Holloway[2], L. Easom[2], C. McCarthy[1], J. Wade-Whitehead[3], *1. Benjamin Rose Institute on Aging, Cleveland, Ohio, 2. Rosalynn Institute for Caregiving, Americus, Georgia, 3. Alzheimer's Tennessee, Inc., Knoxville, Tennessee*

BRI Care Consultation is an evidence-based program for older adults with physical or mental health challenges and their family caregivers. It is a telephone-based program that provides health- and care-related information, supports family and friend involvement in care, increases awareness and use of community services, and gives emotional support and coaching. With funding from the U.S. Administration on Aging's "Alzheimer's Disease Services and Support Program," BRI Care Consultation was implemented by three Area Agencies on Aging in Georgia and one Alzheimer's disease support organization serving the eastern half of Tennessee. This investigation examines changes in three categories of caregiver outcomes from enrollment to 12-months post enrollment for family caregivers in the Georgia and Tennessee programs. Outcomes included: 1) caregiver strains, 2) unmet needs, and 3) formal and informal support. Multivariate analyses of data from structured interviews with 439 caregivers indicated significant, modest-sized decreases in several types of caregiver strains over the 12-month study period, particularly for caregivers of care receivers with more cognitive and behavioral symptoms. Sizeable, significant decreases occurred for all types of unmet needs, such as with understanding memory problems, completing daily living tasks, and accessing community services. There were significant, modest-sized increases in satisfaction with informal help for care receivers and caregivers, and quality of care from physicians. Overall, results show a large-scale community implementation of BRI Care Consultation, outside of a controlled research study, was associated with improvements in a wide range of caregiver outcomes.

EXPLORING THE RELATIONSHIPS BETWEEN RESILIENCE, BURDEN, AND WELL-BEING IN FAMILY CAREGIVERS TO HOLOCAUST SURVIVORS

K.A. Anderson[1], N.L. Fields[2], *1. University of Montana, Missoula, Montana, 2. University of Texas Arlington, Arlington, Texas*

Background: Family members often draw upon resilience to help address the myriad stressors associated with caregiving. For some family caregivers, however, high levels of perceived resilience may preclude them from seeking assistance, resulting in unmet need and excess burden. Qualitative research has found that this may be the case with family caregivers to Holocaust survivors. Using quantitative methods, researchers examined the relationships between resilience and well-being in this unique group of family caregivers. Methods: Convenience sampling was used to recruit 89 (N = 89) family caregivers to Holocaust survivors. Participants completed the Resilience Scale, Zarit Burden Interview-Short Version, Center for Epidemiology Studies Depression Scale, and the Perceived Well-Being Scale-Revised. Participants were grouped as having "low-resilience", "moderate resilience", and "high resilience". ANOVA analyses with Scheffé's post-hoc tests were used to analyze the data. Results: Caregiver resilience was not significantly related to burden (F(2,86) = 0.72, ns) and there were no significant differences in mean levels of burden between the groups. Caregiver resilience was significantly related to depression (F(2,86) = 12.98, p = .000) and physical well-being (F(2,86) = 7.05, p = .001). Mean levels of depression were significantly higher and mean levels of physical well-being were significantly lower in low-resilience caregivers. Discussion: Reflective of past research, resilience appears to have a strong relationship with well-being; however, high levels of resilience may not protect family caregivers from burden and may obscure legitimate needs for assistance. These findings are explored in context to caregiving for other aging trauma survivors (e.g., combat veterans).

SHARED CARE PARTNERS INTERVENTION FOR HEART FAILURE PATIENTS AND FAMILY CAREGIVERS

M. Sebern[1], M. Sebern[3], C.J. Whitlatch[2], *1. Nursing, Marquette University, Milwaukee, Wisconsin, 2. Margaret Blenkner Research Institute, Benjamin Rose Institute on Aging, Cleveland, Ohio, 3. Milwaukee School of Engineering, Milwaukee, Wisconsin*

Heart Failure (HF) patients experience poor self-care, suffer cognitive impairment and increased mortality risk, and underutilize palliative care. This study tested the feasibility of delivering the Shared Care Partners Intervention (SCPI) to HF patients and family caregivers, hereafter referred to as care partners. The SCPI's goal is to improve HF self-care and future care planning. The SCPI adapted the effective SHARE program, which assisted partners managing dementia to develop a future care plan. A one-group quasi-experimental design was used, with eleven HF care partner pairs recruited from the community. Mean patient age was 80 years, 5 female, 6 African American. Mean caregiver age was 61, 10 female, 6 African American. Results of process and outcome evaluation supported the feasibility of the SCPI. Specifically patients had improvements in self-care maintenance (d = .39) and management (d = .48). An important finding occurred with the "Care Circles" tool where 30 self-care tasks are assigned by the patient and caregiver separately into one of three circles (caregiver, family/friends, and paid helpers). Both partners believed that the patient would prefer that the caregiver help with over 80% of self-care tasks. In subsequent joint discussion, the "full" caregiver circle and "empty" family and paid helpers circles were compelling representations of the overload that could occur. This awareness supported development of a future care plan, as well as a broader perspective on HF prognosis. Results supported our hypothesis that targeted communication facilitated self-care and care planning. We are currently enhancing the SCPI with iPad application software.

CAREGIVER BURDEN AND RACIAL DISCRIMINATION: A MIXED METHODS STUDY OF CHRONIC STRESS

D.Y. Stevens, K. Hepburn, *Emory University, Atlanta, Georgia*

Caregiver burden is a multidimensional response to the physical, emotional, and financial stressors of caring for an adult with a disabling condition. Burden has been repeatedly linked with illness, depression, and decreased quality of life. Using the Pearlin Stress & Coping framework, we examined the negative effects of chronic psychosocial stress, specifically caregiver burden and racial discrimination, on the health of African American caregivers of dementia patients (n=100). We utilized a mixed methods design with both quantitative and qualitative components. Correlation procedures and multivariate regression analyses were conducted for quantitative data analysis. A phenomenological approach was used to guide the qualitative data collection and analysis. By blending research methods, we were able to illuminate compounded challenges African American family caregivers face. Consistent with previous findings, we discovered that caregiver burden and discrimination have independent relationships with both depression and anxiety. We also discovered discrepancies between the survey data and narrative accounts of caregiver burden. We concluded that measures of discrimination (both everyday and vigilance) were added stressors for African American caregivers, significantly predicting both depression and anxiety in this sample. We also found some caregivers were more resilient and perceived low levels of burden, while others are burdened by their caregiving responsibilities. It is critical for researchers to continue to explore how multiple stressors can have a cumulative effect on minority caregivers. Researchers conducting caregiver studies involving African Americans should consider how these cultural- and societal-level determinants influence the caregiving experience.

SESSION 2185 (SYMPOSIUM)

NUTRITION AS A DETERMINANT OF HEALTHY AGING : NEW RESULTS FROM THE NUAGE STUDY

Chair: P. Gaudreau, *University of Montreal., Montreal, Quebec, Canada*
Discussant: H. Payette, *University of Sherbrooke, Sherbrooke, Quebec, Canada*

Preservation of functional capacities and autonomy represents an important challenge in our aging societies. Although the impact of modifiable determinants for example diet have gain substantial interest, longitudinal dietary data in elderly populations are still sparse. The NuAge cohort study is an observational study of 1,793 community-dwelling men and women aged 67-84 years, in good general health as well as cognitively- and functionally-intact at recruitment in 2004. Participants were drawn from a random sample stratified by age and sex, obtained from the Quebec Medicare database for the Montreal, Laval and Sherbrooke areas (QC, CA). The general hypothesis of the study was that maintenance of optimal dietary intakes throughout the senior years is associated with better physical and mental health. Here, the conference presentations are focusing on the effects of nutrients and/or dietary patterns on trajectories of physiological dysregulation, using an array of circulating biomarkers, as well as on cognition and late-life depression. Results emerging from these studies indicate that diet significantly regulates physiological trajectories during aging. Moreover, high sodium intake is detrimental to cognition in sedentary but not in physically active older individuals. Finally, a change in some micronutrients but neither in macronutrient nor energy intakes is observed in depressed NuAge participants. Altogether, these findings indicate that dietary intakes and patterns play a pivotal role in the maintenance of health in old age and suggest new avenues for dietary interventions.

INTERACTIONS BETWEEN NUTRITIONAL PATTERNS AND PHYSIOLOGICAL DYSREGULATION TRAJECTORIES DURING AGING

A.A. Cohen[1], E. Milot[1], H. Payette[1], P. Gaudreau[2], N. Malo[1], *1. Université de Sherbrooke, Sherbrooke, Quebec, Canada, 2. Centre de recherche hospitalier de l'université de Montréal, Montréal, Quebec, Canada*

We have recently proposed a method to measure physiological dysregulation (PD) during aging using an array of basic blood biomarkers. Here, we used this approach to study how dietary patterns affect trajectories of PD, using the NuAge cohort study. We found that total caloric intake predicts individual basal dysregulation level, but has no measurable effect on the individual rate of dysregulation. In contrast, dynamic dietary intake, estimated using Bayesian trajectory models, had a significant effect on the rate of dysregulation, meaning that individuals who increased their caloric intake faster during the interval also dysregulated faster. Additionally, higher baseline total score on the Canadian adaptation of the USDA Healthy Eating Index (C-HEI) and greater increase in fruit/vegetable C-HEI together predicted lower rate of dysregulation. This result implies that changing one's diet to conform to C-HEI guidelines for fruits and vegetables may actually slow the rate of aging.

DIET AND LATE-LIFE DEPRESSION: A REVERSE CAUSALITY STUDY IN COMMUNITY-DWELLING OLDER ADULTS. THE NUAGE STUDY

L. Gougeon[1], H. Payette[2,3], J.A. Morais[1], K. Gray-Donald[1], *1. McGill University, Montreal, Quebec, Canada, 2. University Institute of Geriatrics of Sherbrooke, Sherbrooke, Quebec, Canada, 3. University of Sherbrooke, Sherbrooke, Quebec, Canada*

To test the reverse causality hypothesis between diet and depression, in which becoming depressed would affect older adults' intake, we compared changes in usual intakes of depressed (75.1 ± 4.0y, n=158, 61% female) and age-sex-matched non-depressed participants (n=158) at the year prior to depression and at the year of depression (GDS≥11 or antidepressant use). In GLM mixed models, energy, protein, saturated fat, and total dietary fibre (three non-consecutive 24h-recalls) did not change significantly in those who became depressed vs. those who did not. Depressed subjects had significant lower overall intakes of folate, vitamins B6 and B12. A significant interaction of time*depression (p=0.033) was observed for B12 intake: depressed subjects declined over time compared to non-depressed, indicating incident depression only seemed to affect this one nutrient. Implications for practice and potential psychological and dietary resilience among these seniors will be discussed.

THE PROTECTIVE EFFECT OF A HEALTHY DIET ON COGNITION IS MODULATED BY PERSONAL CHARACTERISTICS AND LIFESTYLE FACTORS IN THE NUAGE STUDY

G. Ferland[1], S. Belleville[1], M. Kergoat[1], J. Morais[2], B. Shatenstein[1], C. Greenwood[3], *1. IUGM, Universite de Montreal, Montreal, Quebec, Canada, 2. McGill University, Montreal, Quebec, Canada, 3. University of Toronto, Toronto, Ontario, Canada*

A healthy diet has been linked to better cognition in older individuals, although the strength of the association has varied among studies. It has been suggested that personal characteristics [e.g. socio-economic status (SES)] and lifestyle factors (e.g. physical activity) could modulate the diet-cognition relationship in old age. We investigated the modulatory role of these factors in subgroups of individuals from the NuAge cohort (aged 67–84 years). Adherence to a healthy diet was related to better cognition at recruitment only in individuals in the upper categories of income and education, and was associated with less cognitive decline only in those with low SES. In seperate analyses, a high sodium intake was found to be particularly detrimental to cognition in sedentary, but not in physically active individuals. These findings suggest that cognition in old age is influenced by multiple personal and lifestyle factors, which interact with one another.

SESSION 2190 (SYMPOSIUM)

EVIDENCED-BASED CARE TRANSITIONS MODELS: HOW AGING AND DISABILITY RESOURCE CENTERS IMPLEMENTED MODELS TO CONNECT PEOPLE TO SUPPORTIVE SERVICES AND REDUCE HOSPITAL READMISSION RATES

Chair: C. Ryan, *US Administration for Community Living, Washington, District of Columbia*
Co-Chair: S. Jenkins, *US Administration for Community Living, Washington, District of Columbia*
Discussant: C. Ryan, *US Administration for Community Living, Washington, District of Columbia*

In 2010, The Administration for Community Living (ACL) and CMS funded 16 states to implement evidence based care transition programs through Aging and Disability Resource Center (ADRC) and hospital partnerships. Although results varied by state, preliminary findings indicate that these community/hospital partnerships have the potential to address the social determinants of health and reduce readmissions. During this symposium, participants will learn about the experience of three states that successfully implemented and evaluated ADRC transition programs. These states will share how the community based programs tracked outcomes, including readmissions and explore the impact of of person centered counseling and connection to long term services and supports on readmission rates.

FROM HOSPITALS TO THE COMMUNITY KIOSKS FOR LIVING WELL: HOW THE AGING AND DISABILITY RESOURCE CONSORTIUM OF THE GREATER NORTH SHORE, INC. IN MASSACHUSETTS LEVERAGES CARE TRANSITIONS MODELS TO PREVENT AVOIDABLE HEALTH CARE CRISES, REDUCE READMISSION RATES, AND PROMOTE GREATER COMMUNITY LIVABILITY

V. Parker Callahan, *1. Greater Lynn Senior Services, Lynn, Massachusetts, 2. Aging and Disability Resource Consortium of the Greater North Shore, Inc., Lynn, Massachusetts*

The Aging and Disability Resource Consortium of the Greater North Shore, Inc. (ADRCGNS) is an independent non-profit organization spanning nineteen diverse communities served by multiple health care systems on Massachusetts' North Shore. Dedicated to delivering person-driven supports through a "No Wrong Door" system that promotes greater consumer engagement and investment in health and well-being, the ADRCGNS has created and collaboratively implemented critical programs across the region using key care transitions principles to enhance the ways in which community-based long term support services (LTSS) more effectively address chronic disease, health care access, community inclusion, and overall consumer health and well-being. This session will review several innovative ADRCGNS initiatives including: 1) cooperative programs with hospitals, physician practices, health centers, and emergency medical service providers; 2) enhanced LTSS coordination for the Commonwealth's pilot duals demonstration; and 3) the development of the Kiosks for Living well as social magnets fostering more effective health self-management.

COMMUNITY-HOSPITAL PARTNERSHIP TO FACILITATE IMPROVEMENTS IN CARE TRANSITIONS

L. Davie, *1. Center on Aging and Community Living, Durham, New Hampshire, 2. Institute for Health Policy and Practice, Durham, New Hampshire*

Improving health care with quantifiable results requires non-traditional partnerships extending beyond traditional medical models. In 2010 Laconia New Hampshire's ServiceLink Resource Center (SLRC), an Aging and Disability Resource Center, and Lakes Region General Hospital, piloted a unique approach to enhance the Better Outcomes for Older Adults through Safe Transitions (BOOST) care transition model.

The project linked hospital discharge to community-based services, using long-standing infrastructure with a primary purpose of assisting people in finding community resources. Resources included connections with community services, increased caregiver support, early assessment of long term care needs, and working with hospital patients and their caregivers to begin long term planning. We will discuss how the program tracked outcomes explored the impact of person centered counseling on the connection to long term services and supports. The program demonstrated a lower 30 day readmission rate, even with a higher case mix.

SESSION 2195 (PAPER)

BIOLOGY OF AGING

WHY ARE "RISK ALLELES" COMMON IN GENOMES OF LONG-LIVED PEOPLE?

S.V. Ukraintseva, A. Kulminski, K.G. Arbeev, I. Akushevich, D. Wu, K. Land, P. Stallard, A.I. Yashin, *Duke University, Durham, North Carolina*

Genetic variants that have been associated with increased risks of complex health disorders, such as CHD, cancer, diabetes and Alzheimer's disease (AD), are often found in genomes of long-lived people, and do not seem to compromise longevity. Causes of this phenomenon are important to understand. Here we argue that one such cause could be that the effect of a gene variant on person's survival is not fixed but may depend on other factors and change during the life course. Specifically, the influence of a genetic variant on lifespan may be significantly modified by: (i) antagonistic effects of this variant on health and aging related traits ("genetic trade-offs"); (ii) person's age, (iii) interaction with other genes (epistasis), and (iv) gene-environment interaction, among other factors. We review current evidence in support of this hypothesis and show that the above factors can plausibly explain the common presence of so called "risk alleles" in genomes of long-lived people. E.g., an allele that increases the risk of cancer in middle age via upregulation of IGF-1, may also improve survival chances in the oldest old due to attenuation of sarcopenia and physical senescence owing the same upregulation of IGF-1, so that such allele will not necessary reduce someone's chances of becoming a centenarian. Advancing research on conditional effects of genes on phenotypes of senescence, disease and survival is crucial for better understanding the complex relationships between physiological aging, health decline and longevity, and for facilitating the progress in the area of personalized prevention.

IS CHRONIC ASTHMA ASSOCIATED WITH SHORTER LEUKOCYTE TELOMERE LENGTH AT MIDLIFE?

D. Belsky, *Center for the Study of Aging and Human Development, Duke University, Durham, North Carolina*

Background. Asthma is prospectively associated with age-related chronic diseases and mortality, suggesting the hypothesis that asthma may relate to a general, multi-system phenotype of accelerated aging. Objective. To test whether chronic asthma is associated with a proposed biomarker of accelerated aging, leukocyte telomere length. Method. Asthma was ascertained prospectively in the Dunedin Multidisciplinary Health and Development Study cohort (N=1,037) at 9 in-person assessments spanning ages 9 to 38 years. Leukocyte telomere length was measured at ages 26 and 38 years. Asthma was classified as life-course-persistent, childhood onset without persistence, and adolescent/adult onset. We tested associations between asthma and leukocyte telomere length using regression models. We tested for confounding of asthma-leukocyte telomere length associations using covariate adjustment. We tested serum C-reactive protein and white blood cell counts as potential mediators of asthma-leukocyte telomere length associations. Results. Study members with life-course-persistent asthma had shorter leukocyte telomere length as compared to sex- and age-matched peers with no reported asthma. In contrast, leukocyte telomere length in study members with childhood-onset and adolescent/adult-onset asthma was not different from leukocyte telomere length in peers with no reported asthma. Adjustment for life histories of obesity and smoking did not change results. Study members with life-course-persistent asthma had elevated blood eosinophil counts. Blood eosinophil count mediated 29% of the life-course-persistent asthma-leukocyte telomere length association. Conclusions. Life-course-persistent asthma is related to a proposed biomarker of accelerated aging, possibly via systemic eosinophilic inflammation. Life histories of asthma can inform studies of aging.

BLOOD AND MUSCLE MITOCHONDRIAL BIOENERGETICS ARE ASSOCIATED WITH PHYSICAL FUNCTION IN OLDER ADULTS

D.J. Tyrrell, M.S. Bharadwaj, C.G. Van Horn, S.B. Kritchevsky, B. Nicklas, A.J. Molina, *Geriatrics and Gerontology, Wake Forest School of Medicine, Winston Salem, North Carolina*

Background: Gait speed provides an integrated measure of physical ability that is predictive of morbidity, disability, and mortality in older adults. Energy demands associated with walking suggest that mitochondrial bioenergetics may play a role in gait speed. Here, we examined the relationship between gait speed and skeletal muscle mitochondrial bioenergetics, and further evaluated whether blood-based bioenergetic profiling might have similar associations with gait speed. Methods: Participants in this study were comprised of two subsets (n=17 per subset) and were overweight/obese (BMI, 30.9±2.37), well functioning, community-dwelling older adults (69.1±3.69yrs) without major comorbidity. Gait speeds were calculated from a fast-paced 400m walk test. Respiratory control ratios (RCR) were measured from mitochondria isolated from leg skeletal muscle biopsies from one subset. Maximal respiration and spare respiratory capacity (SRC) were measured from peripheral blood mononuclear cells (PBMCs) from the other subset. Results: Individual differences in gait speed correlated directly with RCR of mitochondria isolated from skeletal muscle (r=0.536, p=0.027) and with both maximal respiration and SRC of PBMCs (r=0.585 and p=0.014; r=0.609 and p=0.009, respectively). Conclusions: The bioenergetic profile of isolated mitochondria from skeletal muscle is an objective measure associated with physical ability in older adults. Blood-based bioenergetic profiling may provide a simpler alternative measure that is also associated with physical ability in older adults.

INTERRELATIONSHIPS BETWEEN MUSCLE ENDURANCE, SELF-PERCEIVED FATIGUE AND CIRCULATING MARKERS OF INFLAMMATION IN PARTICIPANTS OF THE COPENHAGEN AGING AND MIDLIFE BIOBANK

I. Bautmans[1,2], I. Beyer[2,1], A. Hansen[3,4], K. Avlund[3,4], H. Bruunsgaard[5], D. Molbo[3], E.L. Mortensen[3,4,6], R. Lund[3], *1. Gerontology Department (GERO) and Frailty in Aging Research group (FRIA), Vrije Universiteit Brussel (VUB), Brussels, Belgium, 2. 2Department of Geriatrics, Universitair Ziekenhuis Brussel (UZBrussel), Brussels, Belgium, 3. Section of Social Medicine, Department of Public Health, University of Copenhagen, Copenhagen, Denmark, 4. Centre for Healthy Aging, University of Copenhagen, Copenhagen, Denmark, 5. Department of Clinical Immunology, Center for Inflammation and Metabolism, National University Hospital, Copenhagen, Denmark, 6. Institute of Preventive Medicine, Bispebjerg Hospital, Copenhagen, Denmark*

INTRODUCTION Fatigue, muscle weakness and low-grade inflammation are strongly related to frailty at higher age. This study investigated whether the interrelationships between self-perceived fatigue, muscle endurance and inflammation come already to expression at midlife. If already interrelated at midlife, they might be used as early markers for frailty. METHODS 965 participants of the Copenhagen Aging and Midlife Biobank (aged 52±4 years, 536 male, 426 female) were assessed for self-perceived fatigue (20-item multidimensional fatigue inventory), muscle endurance (grip work), circulating markers of inflammation (HsCRP, IL-6, IL-10, TNF-alpha and IFN-gamma), daily physical activity (PAS-2), body composition (%body fat assessed by bio-impedance) and self-reported health status. Subjects were categorised (stratified by age and gender) according to high fatigue and/or low muscle endurance, and differences in inflammatory profile were assessed by ANCOVA (corrected for PAS-2, %body fat and presence of inflammatory conditions). RESULTS Overall, grip work, fatigue and inflammatory markers were significantly interrelated. Higher levels of HsCRP ($p<0.001$), IL-6 ($p<0.001$), IL-10 ($p=0.035$) and TNF-alpha ($p=0.028$) were observed in subjects presenting both low grip work and high fatigue. IFN-gamma was highest in those with high fatigue but normal grip work ($p=0.015$). CONCLUSIONS We found that middle-aged subjects presenting higher fatigue in combination with lower muscle endurance show higher levels of inflammation, independently from physical activity, body fat and inflammatory pathology. The underlying mechanisms as well as whether these individuals show early signs of reduced physiological reserve capacity, which at later life come to full expression by means of frailty, needs confirmation in future studies.

FROM CELLS TO SOCIETIES: A MULTIPLEX AND ELISA VALIDATION PILOT STUDY FOR ASSAYING INFLAMMATORY MARKERS IN AGING RESEARCH

S. Vasunilashorn[1], L.H. Ngo[1], J. Guess[1], S. Jastrzebski[2], J. McElhaney[2], G.A. Kuchel[2], E. Marcantonio[1], *1. Medicine, Beth Israel Medical Center/Harvard Medical School, Brookline, Massachusetts, 2. University of Connecticut Health Center, Farmington, Connecticut*

The collection of blood for clinical and population-based research has increased opportunities to examine inflammation in aging. Enzyme-linked immunosorbent assay (ELISA)-based technologies are the current "gold-standard" for measuring inflammation; however, ELISA is limited by its requirement for significant sample volume, high labor and reagent costs, and narrow detectable range. Multiplex approaches have been developed to address these limitations and enable measurement of multiple markers within the same sample. To determine the utility of the multiplex approach, we: 1) examined the reliability of concentrations obtained from a multiplex method using a Luminex-based platform (MagPix high-sensitivity [hs] cytokine kit, R&D Biosystems) to a standard-kit ELISA (R&D), and 2) compared results from the two methods. We investigated interleukin-6 (IL-6) measured at 4 timepoints (preoperatively, in the post-anesthesia care unit, postoperative day 2, and 1 month post-surgery) in patients age ≥70 undergoing non-cardiac surgery enrolled in the Successful AGing after Elective Surgery (SAGES) Study. Delirium cases and non-delirium controls (5 pairs) were matched on age, gender, surgery type, general cognitive performance, and vascular comorbidity using the Optimal Matching Procedure. ELISA and MagPix concentrations yielded acceptable coefficients of variation (CV) (about 10% for both) and low missing values (20% and 10%, respectively), with standard curves for ELISA (R2 1.00—excellent) and Magpix (R2 0.70—acceptable). MagPix and ELISA were highly correlated (Spearman's r=0.9); however, MagPix IL-6 values were consistently 30% lower. We conclude that the multiplex approach is an appropriate method for determining levels of IL-6. Additional cytokines will be investigated in future work.

SESSION 2200 (SYMPOSIUM)

FROM THE CELL TO THE GRAVE: SUCCESSFUL AGING AND DYING IN PRISON

Chair: A.J. Bishop, *Human Development and Family Science, Oklahoma State University, Stillwater, Oklahoma*
Discussant: B. Williams, *University of California-San Francisco, San Francisco, California*

Prison inmates represent the only constitutionally protected population with a right to accessible healthcare. The maintenance of individual health is assumed to be an essential element of successful aging. Yet, correctional healthcare systems across the United States are challenged by an ever-growing number of inmates who die behind bars. This has been attributed to an increasing proportion of older inmates who enter prison and must serve multiple criminal sentences over a longer period of time. More than half of these prisoners will die from an age-associated chronic illness and disease that requires long-term geriatric medical assistance in the form of end-of-life care. The purpose of this symposium is to provide theoretical and empirical evidence related to key biopsychosocial indicators that contribute to successful aging and dying in prison. Additional discussion will entail presentation of evidenced-based models and applications used to promote the well-being of aging prisoners as well as improve quality-of-care for older inmates near the end-of-life. Recommendations and implications for geriatric medical care, social work/case management, and hospice/end-of-life care involving older correctional populations will be addressed.

RELIGIOSITY AND SUCCESSFUL AGING IN PRISON: THE MEDIATING ROLE OF FORGIVENESS

G. Randall[1], A. Bishop[2], *1. Family & Consumer Sciences, Bradley University, Peoria, Illinois, 2. Oklahoma State University, Stillwater, Oklahoma*

Using data collected from 261 older incarcerated males, the current study addresses the mediating role of forgiveness between religiosity and seven outcomes of successful aging. First, we investigated the psychometric properties of the Heartland Forgiveness Scale (HFS). Rotated factor loadings supported the validity of the HFS for this sample, including three latent variables: forgiveness of self, others, and situations. Second, we investigated the mediating role of three types of forgiveness (latent variables) in the religiosity – health relationship. Outcomes included valuation of life, depressive symptoms, perceived stress, social provisions, perceived health, health conditions, and PADLs. The model fit the data well: $\chi 2$ (N=256; df=101) = 7.40; p = .014; CFI =.98; RMSEA=.04; SRMR=.03. Significant total indirect effects were found for religiosity on each outcome through forgiveness, firmly establishing the mediating role of forgiveness. Last, implications for the assessment and therapeutic role of forgiveness for successful aging in prison are discussed.

"I'M NOT AFRAID OF DYING, I'M AFRAID OF PAIN": LIVING WITH CHRONIC ILLNESS IN PRISON

R.S. Allen[1], A.R. Tackett[2,1], L. Miller[1], *1. Psychology/Center for Mental Health and Aging, The University of Alabama, Tuscaloosa, Alabama, 2. Corrections Center, Bremerton, Washington*

Thirty-two chronically ill male state prison inmates with an increased likelihood of death within two years provided responses to semi-structured in-depth qualitative interviews regarding quality of life and views of death. A two-member analysis team independently coded transcripts and developed themes using qualitative description. Emergent themes related to successful aging and dying in prison included 1) inmates receive inmate-to-inmate support for care needs and 2) inmates desire a quick, painless and peaceful death with preference to die in their sleep. Quotes describing support revealed subthemes of generativity and empathy among lifers, bartering and reciprocity, and becoming prey. Some inmates expressed that pain occurs during life in prison rather than at death: "They always talk about pain – that's before the death." Interventions designed to harness inmate-to-inmate support may enhance quality of life and death in prison by inmate skills training in dignity and forgiveness as well as hospice care.

FROM THE CELL TO THE GRAVE: A COLLABORATIVE NETWORK APPROACH TO ENHANCING PRISON END-OF-LIFE CARE

S.J. Loeb[1], J. Penrod[1], C.S. Hollenbeak[2], *1. School of Nursing, The Pennsylvania State University, University Park, Pennsylvania, 2. Penn State College of Medicine, Hershey, Pennsylvania*

Community based participatory research (CBPR) requires active collaboration between researchers and insiders across project phases. Achieving leadership buy-in, identifying staff to champion the project, and gaining prisoners' perspectives promoted shared values and built system-wide support. The purpose of this research was to explore the values, beliefs, and practices related to end-of-life (EOL) care in a state department of corrections and to develop a Toolkit for Enhancing EOL Care in Prisons. Our CBPR approach engaged 12 state level officials, 176 state correctional institution employees, 17 prisoner caregivers, and 21 prisoner patients. All relevant human subjects approvals were gained prior to recruitment. Findings regarding organizational structures, attitudes, and beliefs facilitated a deep understanding of considerations to be mindful of when deriving discrete strategies for enhancing prison EOL care. By project end, the Toolkit was developed, 24 insider co-researchers were trained in Toolkit module delivery, and the Toolkit was infused and evaluated.

THE CURATIVE EFFECT OF 'PSYCHOSOCIAL SPIRITUAL MEDICINE' ON OLDER ADULTS HEALTH AND WELL-BEING IN PRISON

T.M. Maschi, *Graduate School of Social Service, Fordham University, New York, New Jersey*

The objective of this study was to aspects of successful aging in place in prison. This study used a cross-sectional mixed methods design and a sample of 677 older adults in a northeastern state correctional system. Participants completed a mailed survey that included the Coping Resources Inventory, the Healthy Days measure, and open-ended questions about what factors helped them cope with stress in prison. Qualitative data analysis consisted of inductive and deductive content analysis methods. The findings revealed that participants' reported engaging in one or more activities that fostered their root (basic survival), physical (e.g, exercise), cognitive (e.g., positive thinking), emotional (e.g., expressing feelings), social (e.g., family contact), spiritual (e.g, praying), and participatory (e.g., leadership) well-being. Correlation analyses showed the coping resources were positively correlated with physical and mental well-being. These findings suggest areas in which successful aging in prison can be promoted in prison. Program exemplars that foster successful aging in prison are highlighted.

SESSION 2205 (SYMPOSIUM)

SOCIAL INEQUALITIES IN THE LIVES OF LGBT OLDER ADULTS: DIVERSITIES WITHIN SOCIETY'S COMMUNITIES

Chair: K.I. Fredriksen-Goldsen, *University of Washington, Seattle, Washington*
Discussant: C.A. Emlet, *University of Washington, Tacoma, Washington*

Given shifting demographics, lesbian, gay, bisexual, and transgender (LGBT) populations are aging. The emerging literature to date targets health disparities among LGBT older adults resulting from disadvantaged statutes related to sexual and gender identities. In many studies these populations are treated as homogeneous and grouped together, with limited attention to subgroup differences. Based on data from the National Health, Aging and Sexuality Study: Caring and Aging with Pride, the papers illustrate the importance of exploring diversities among LGBT older adults. In this symposium, we investigate the influences of social-structural factors that may result in social and health inequalities, including age, gender, sexual identity, and social-economic status, in order to better understand the full continuum of health and aging outcomes, Fredriksen-Goldsen and colleagues explore both similarities and differences in the configuration of protective and risk factors among LGBT midlife and older adults, and identify factors related to healthy aging by specific age groups. Kim and colleagues examine gender differences in dimensions of health-related quality of life, with sexual minority women having more physical limitations than sexual minority men, although men have more emotional role limitations. Among bisexual older adults, Shiu and colleagues present a curvilinear relationship between disclosure of sexual identity and mental health, suggesting a more complex relationship than is often assumed in existing studies. Patterns of diverse social-economic statuses and resources are explored by Muraco and colleagues, as they are linked to other co-occurring health conditions and social relations among LGBT older adults. The presentations in this symposium exemplify how social-structural factors intersect and perpetuate inequalities in aging processes and health disparities among LGBT older adults.

HEALTHY AGING AMONG LGBT MIDLIFE AND OLDER ADULTS: DIFFERING PATHS BY AGE GROUPS

K.I. Fredriksen-Goldsen, C. Shui, H. Kim, C.A. Emlet, *University of Washington, Seattle, Washington*

Evidence documents health disparities among lesbian, gay, bisexual, and transgender (LGBT) adults. Yet, much less is known about successful aging of LGBT midlife and older adults. This paper highlights findings from the National Health, Aging and Sexuality Study: Caring and Aging with Pride, with 2,560 demographically diverse LGBT adults 50 and older, conducted through community collaborations. Based on the Health Equity framework, the paper explores the relationship between quality of life (QOL) and social resources, adversity, health behaviors, SES, and background characteristics, and the moderating effects of age group differences. Younger age groups had lower levels of stigma with higher rates of disclosure and victimization. The influence of victimization was most salient among the oldest age group. The research highlights the importance of understanding differing configuration of resources and risks by age and their association with well-being and healthy aging in our increasingly diverse society.

GENDER DIFFERENCES IN DIMENSIONS OF HEALTH-RELATED QUALITY OF LIFE OF LGBT OLDER ADULTS

H. Kim, K.I. Fredriksen-Goldsen, *University of Washington, Seattle, Washington*

Gender is known to be an important social indicator of health-related quality of life (HRQOL). Still, knowledge about gender differences in HRQOL among lesbian, gay, bisexual, and transgender (LGBT) individuals in later life is limited. This study examines gender differences in dimensions of HRQOL taking into consideration socio-demographic factors and health conditions. National survey data of LGBT adults aged 50 and older (n=2,560) was analyzed, and HRQOL was measured by SF-8. After controlling for age, income, education, disability status, and chronic conditions, women showed poorer HRQOL in the domains of bodily pain, physical functioning, and physical role limitation than men. Men showed poorer HRQOL than women in the dimensions of mental health and emotional role limitations. It is important to recognize gender differences in efforts to eliminate health disparities and improve well-being among LGBT older adults.

MENTAL HEALTH AND DISCLOSURE OF SEXUALITY AMONG BISEXUAL OLDER ADULTS

C. Shiu, K.I. Fredriksen-Goldsen, *University of Washington, Seattle, Washington*

Disclosure of sexuality has positive effects on mental health among lesbian and gay men based on current literature. However, there is limited attention on the experiences of bisexual older adults. This sample of 174 bisexual older adults came from the National, Health, Aging and Sexuality Study: Caring and Aging with Pride. Mental health was measured by the CES-D 10. The index of disclosure level was computed by averaging over 12 items, asking how "out" respondents were to specific relations. Multiple-variable linear regression was used to evaluate the relationship between CES-D scores and disclosure levels while controlling for covariates. The relationship was curvilinear, and its shape approached an inverted U-shaped curve, suggesting either full or limited disclosure was related to more positive mental health among bisexual older adults. More research is needed to better understand under what conditions varying levels of disclosure are associated with mental health outcomes.

UNEQUAL LIVES: HEALTH AND SOCIAL DISPARITIES AMONG LGBT OLDER ADULTS

A. Muraco[1], C.A. Emlet[2], K.I. Fredriksen-Goldsen[3], *1. Sociology, Loyola Marymount University, Los Angeles, California, 2. University of Washington, Tacoma, Washington, 3. University of Washington, Seattle, Washington*

This study examines interview data from LGBT adults, age 50 and older, in order to understand how their socioeconomic statuses affect their experiences of aging. The study is comprised of 35 in-depth qualitative interviews with a sub-sample of CAP survey participants who lived in greater Los Angeles. Data collection occurred in 2011. Two groups emerged from the data: Haves (40%) and the Have-Nots (60%). The Haves are more likely to be in long-term relationships, have worked in professional jobs, own homes, have retirement income, and be white and male. The Have-Nots are more likely to be single, have worked in non-professional employment or have long periods of unemployment, have HIV disease or other chronic and disabling conditions, live in subsidized housing, and be of-color, female, or transgender. Results illustrate disparities in resources for these groups, particularly with respect to social support, and adequate resources to age in place.

SESSION 2210 (SYMPOSIUM)

AFFORDABLE HOUSING WITH SERVICES TO SUPPORT SUCCESSFUL AGING IN COMMUNITY: CREATING AN EVIDENCE BASE

Chair: R. Stone, *LeadingAge, Washington, District of Columbia*
Co-Chair: L. Alecxih, *The Lewin Group, Arlington, Virginia*
Discussant: R.E. Katz, *U.S. Department of Health & Human Services, Washington, District of Columbia*

The U.S. Departments of Health and Human Services (HHS) and Housing and Urban Development (HUD) supported a project exploring the potential for publicly-subsidized senior housing to serve as a platform for efficiently managing the population health of low-income older adults with various levels of physical and mental health risk. This symposium presents findings from this effort and a companion MacArthur Foundation-funded survey that examined the extent of service-enriched senior housing and its impact on resident health, quality of life and Medicare/Medicaid costs. The centerpiece of this initiative was to pilot creating a new dataset linking HUD tenant and Medicare/Medicaid claims data to compare—for the first time— the health characteristics, insurance enrollment/ subsidy status, and utilization patterns of residents in HUD-assisted properties with their community-dwelling counterparts in 12 jurisdictions across the country. Data from the services survey conducted at the property level were linked to the HUD/HHS database to facilitate an examination of types and intensity of services available and the impact of service enrichment on resident health outcomes and costs. Analyses indicate that HUD-assisted elderly residents are more likely to be dually eligible for Medicare and Medicaid, sicker and more costly to both programs than their non-subsidized peers in the community and that service enrichment can help to mitigate some costs. Presenters will review the methodological challenges with the pilot data match, describe major findings from each study, and discuss the federal and state-level health, long-term care and housing policy implications and next steps for demonstration and evaluation.

METHODOLOGICAL CHALLENGES WITH LINKING HUD AND CMS DATA

J. Marshall, L. Alecxih, *Lewin Group, Falls Church, District of Columbia*

This presentation will describe the pilot matching methods between the HUD-assisted residents and Medicare/Medicaid enrollment data. Our sample of over two million HUD-assisted housing recipients consisted of all individuals appearing in the TRACS or PIC data at any point in time during 2008 in the 12 non-randomly selected study jurisdictions. Based on social security number alone, approximately 73% of HUD-assisted housing recipients less than age 65 and 96% of recipients age 65 or older matched to Medicaid, Medicare or both. Using a more strict criteria that added date of birth and gender resulted in 69% of HUD-assisted housing recipients less than age 65 and 87% of HUD-assisted housing recipients age 65 or older that linked. We will discuss how small changes to the criteria (e.g., using month of birth rather than date) influence the match rate and challenges related to matching administrative data.

HEALTH CHARACTERISTICS AND HEALTH CARE USE AND COSTS OF HUD-ASSISTED ELDERLY RESIDENTS

J. Marshall, L. Alecxih, *Lewin Group, Falls Church, District of Columbia*

This presentation will review findings from the seminal study linking HUD and Medicare/Medicaid data to explore differences between HUD-assisted elderly housing residents and their community-dwelling counterparts. The study examined Medicare FFS beneficiaries aged 65+ receiving a HUD-subsidy and non-subsidized community-dwelling older adults in 12 jurisdictions. Two subgroups were identified—those enrolled in Medicare and those enrolled in both Medicare and Medicaid. Approximately 68% of HUD-subsidized Medicare FFS beneficiaries were dually enrolled compared to only 13% of their non-subsidized peers in the community. HUD-subsidized dual eligibles had more chronic conditions and higher Medicare-covered health care utilization and costs than their non-subsidized peers, driven by more home health, ambulatory surgery center, physician office and emergency department visits. Similar patterns were observed for Medicaid utilization and costs. The average total medical and prescription drug per member per month Medicare payment for HUD-subsidized beneficiaries was $1,479 compared to $937 for their non-subsidized peers.

EFFECTS OF SERVICE-ENRICHMENT ON HUD-ASSISTED ELDERLY RESIDENTS

R. Stone[1], A. Sanders[1], L. Alecxih[2], J. Marshall[2], *1. LeadingAge, Washington, District of Columbia, 2. The Lewin Group, Arlington, Virginia*

This presentation reviews findings from a survey on the scope and intensity of services in HUD-assisted senior housing properties. Approximately one-third of properties have a service coordinator available from part- to full-time. Almost all have some type of service provided either directly or indirectly through partnerships with health/social service providers. In-house services tend to include social activities, transportation, meals, fitness, health education, and information and referral. Relatively few properties offer through formal partnerships more intensive services (wellness nurse, personal care, medication management) and a small minority have co-located services such as adult day care or clinics. Preliminary analyses indicate that service enrichment affects health care utilization and costs. Dual eligible residents in housing properties that offer more intensive services, particularly medication management, care management through a service coordinator/nurse team are likely to have fewer hospitalizations and emergency department visits than their community-dwelling peers.

SESSION 2215 (SYMPOSIUM)

FACTORS PROMOTING RESILIENCE IN MIDDLE AGED AND OLDER WOMEN ACROSS TWO CHRONIC DISEASES: HIV/AIDS AND ALZHEIMER'S DISEASE

Chair: P.B. Harris, *Sociology & Criminology, John Carroll University, University Heights, Ohio*

The resilience process is still not well understood as it relates to managing chronic diseases. This study compares women diagnosed with two very different chronic diseases, either Alzheimer's disease (AD) or HIV/AIDS, and demonstrates how by using a resilience framework, positive promoting factors can be identified, common to both diseases. A qualitative phenomenological methodology was used comparing (N=20) case studies, 10 diagnosed with AD and 10 with HIV/AIDS, half who were resilient and half who were not. The differences between the resilient and non- resilient groups, regardless of diagnosis, lie in 3 major areas: human capital (individual differences)-acceptance of diagnosis, positive attitude/optimism, and active engagement, 2) social capital (relationship and environmental differences) - supportive social relationships and a person-centered environment, and 3) community capital - connections with community resources and supportive health care professionals. Practice implications for helping people live better with chronic disease will be discussed.

CARERS OF PEOPLE WITH DEMENTIA PERCEPTIONS OF THE FACTORS THAT STRENGTHEN RESILIENCE

K. Murphy, D. Casey, *NUI, Galway, Galway, Galway, Ireland*

Approximately 26,104 people with dementia are living in the community in Ireland being cared for by family and friends.Carers report a lack of support, information and skills. Many experience high burden, are at risk of illness and social isolation. Resilience training focuses on modifiable intra-personal skills and protective factors aimed to increase the person's 'hardiness' to remain psychologically and physically healthy (resilient) in the face of adversity. This presentation will report the findings of a descriptive qualitative study involving 28 carers' of people with dementia designed to explore carers perceptions of resilience and the factors that are important in building carer resilience. Preliminary findings indicate that internal and external factors influenced participant's resilience. These included self-esteem, coping style, knowledge, supports, activities, social networks, connection to, and learning from, other carers, humour and time for self. This study concludes that resilience can be strengthened if supports are in place.

PEOPLE WITH DEMENTIA'S PERCEPTIONS OF THE FACTORS THAT STRENGTHEN RESILIENCE

D. Casey, K. Murphy, *National University of Ireland Galway, Galway, Ireland*

Resilience is a 'behavioral process' built by strengthening personal attributes and external assets (Windle 2011). However despite the recognized potential of resilience the extent to which resilience exists or can be cultivated and nurtured in people with dementia is relatively unknown. This presentation shares the findings of a descriptive qualitative study involving people with dementia (n=8), designed to explore their understanding and experience of resilience and the factors that strengthen same. Windle's framework was used to develop the interview guide and the CORTE interviewing framework was used to guide the interview process as a way of maximizing the voice of the person with dementia. Preliminary findings indicate that personal factors, enduring relationships, social support and community engagement matter to strengthening resilience. This small study concludes that people with dementia have the capacity to be resilient and building resilience matters for social inclusion.

BUILDING RESILIENCE IN PEOPLE WITH DEMENTIA, HIV/AIDS, AND THEIR CAREGIVERS

P.B. Harris[1], J. Keady[2], *1. Sociology & Criminology, John Carroll University, University Heights, Ohio, 2. The University of Manchester, School of Nursing, Midwifery, and Social Work, Manchester, United Kingdom*

People face many adversities in their lives, but none may be more devastating than to receive a diagnosis, such as dementia or HIV/AIDS. Such a diagnosis has vast implications not only for the diagnosed individual, but also for their family members and their communities. Resilience, the behavioral process of being able to negotiate, manage, and adapt to various sources of stress or trauma (Windle, 2011) may provide some key factors, which can help people face such adversities and maintain some quality of life. However, this concept is just beginning to be examined in the gerontological literature. This symposium seeks to add to our understanding about resilience by applying it to two very different populations, across three different countries, and examining it from perspectives of both the individual and caregiver. Murphy and Casey using an Irish sample, examine factors that can promote resilience in people in early stage dementia and their caregivers, and identify factors that can facilitate resilience and foster the social inclusion of people and their caregivers within communities. McGee, Robinson, and Eldridge, focus on grandmothers in Malawi, who because of the HIV/AIDS epidemic, have become the main caregivers of their grandchildren. They will discuss the resilience of these grandmothers and strategies for conducting cross-cultural resilience research. With an American sample, Harris compares women diagnosed with dementia or HIV/AIDS and using a resilience framework, identifies common factors that cut across both diseases and helps people manage better. Practice and policy implications will be discussed from national and international perspectives.

RESILIENCE AND CAREGIVING IN THE CONTEXT OF THE HIV/AIDS EPIDEMIC IN MALAWI, AFRICA

J. McGee, *University of Alaska Anchorage, Anchorage, Alaska*

Malawi, Africa, is at the epicenter of the HIV/AIDS crisis where over 44,000 people die of AIDS each year with over 610,000 orphaned and vulnerable children (OVCs) as a result (United Nations Children's Fund, UNICEF, 2013). Malawian elders, most often grandmothers, typically assume the caregiving role for OVCs when their parents die. There are reports of elders caring for 8 or more OVCs often foregoing their own needs to provide for these children. Little systematic research has been conducted on the health and wellbeing of these caregivers who by antidotal reports demonstrate remarkable resilience in the context of significant adversity. In this symposium, we will describe the development of the Malawi Resilience Project (MRP) which aims to address this gap in the literature. Specifically, we will discuss our strategy for conducting cross-cultural resilience research with elders caring for OVCs in Malawi including lessons learned from the pilot.

SESSION 2220 (SYMPOSIUM)

GENE-ENVIRONMENT INTERPLAY IN A SOCIAL CONTEXT: THE IGEMS CONSORTIUM

Chair: N.L. Pedersen, *Medical Epidemiology and Biostatistics, Karolinska Institutet, Stockholm, Sweden*
Discussant: J.W. King, *National Institute on Aging, Bethesda, Maryland*

The Interplay of Genes and Environment across Multiple Studies (iGEMS) consortium of nine longitudinal twin studies was initiated to determine how genes and environments interact to influence late-life functioning. This symposium provides examples of how the influence of genetic effects on individual differences in aging related outcomes can be moderated by age, gender, and social context. The first presentation evaluates the role of marital status on measures of self-rated health. Marital status has widely differing influences on determinants of self-rated health depending on the measure, gender and age. The second presentation addresses the interplay of socioeconomic status (SEI) with genetic influences on cognitive aging. As SEI level increases, genetic contributions decrease in importance for some cognitive abilities, particularly for age cohorts 60 - 69 and 70-79. There are a variety of ways in which one can assess whether there may be an interaction of genes and environments for aging related outcomes. The third presentation uses identical twin comparisons to demonstrate gene-environment interplay. GE interplay may be more important for late life decline than for more stable mid-life periods. Whereas the first two presentations focused on interplay given specific environments (marital status and socioeconomic status), the last presentation evaluates both interplay and the role of APOE genotype in the interplay, using grip strength as an example. As a whole, this symposium is meant to provide further insights into the complex interplay of genes and social context on susceptibilities and resilience in the aging process.

MARITAL STATUS MODERATES GENDER DIFFERENCES IN GENETIC AND ENVIRONMENTAL INFLUENCES ON SUBJECTIVE HEALTH

D. Finkel[1], C.E. Franz[2], B. Horwitz[3], *1. School of Social Sciences, Indiana University Southeast, New Albany, Indiana, 2. University of California, San Diego, San Diego, California, 3. California State University, Fullerton, Fullerton, Colorado*

Subjective health (SH) taps personality and cognitive status, as well as physical health. Behavior genetics allow us to examine genetic and environmental contributions to SH. Three measures of SH are collected by 9 twin studies participating in IGEMS. Over 16,000 individuals aged 24 to 95 contributed data on 3 SH items: self-rated health (SRH), health compared to others (COMP), and impact of health on activities (ACT). Marital status, coded as either married/cohabitating or living alone, was used as a marker of environmental resources that impact subjective health perceptions. The strongest impact of marital status was found for ACT in men. Heritability of ACT was higher in single men (40%) than married men (30%) up to age 70, then the pattern reversed and heritability was higher in married men (26%) than single men (10%). Results suggest gender differences in the role of marriage as a source of environmental resources for health.

SOCIOECONOMIC STATUS AND AGE AS MODERATORS OF COGNITIVE PERFORMANCE

C. Zavala[1], W. Johnson[2], C.A. Reynolds[1], *1. Psychology, University of California, Riverside, Riverside, California, 2. The University of Edinburgh, Edinburgh, United Kingdom*

Socioeconomic status (SES) shows a robust influence on cognitive performance across the lifespan. Furthermore, evidence suggests heritability of cognitive abilities may differ across levels of SES. The current study examined the presence of GxE interaction, with harmonized household occupational status (SEI) as a moderator of cognitive performance in the IGEMS consortium of nine studies. Cognitive tasks assessed verbal, spatial, working memory, and perceptual speed abilities. Results suggested SEI moderation of genetic and environment contributions for verbal ability, memory, and perceptual speed. For example, shared environmental contributions were greater with higher SEI for verbal ability and perceptual speed, while additive genetic and unique environmental influences were smaller. For verbal ability, age group differences suggested that SEI moderation of shared environmental variance was most striking in older cohorts (60 years and later). Overall, results suggested that the relative contributions of genetic and environmental to cognitive performance vary with both SEI and age.

GENE-ENVIRONMENT INTERPLAY CONTRIBUTES TO HEALTH, WELL-BEING AND COGNITIVE PERFORMANCE IN MID TO LATE ADULTHOOD

C.A. Reynolds, *UC Riverside, Riverside, California*

Gene – environment interplay may be important across aging domains. GxE interactions were evaluated for depressive symptoms, BMI, and cognitive performance in eight IGEMS studies from Denmark, Sweden, and the US. Analyses considered mixture distributions of within pair differences among identical twins. Results for the full sample, within country, and within sex, suggested GxE for depressive symptoms ($p<1.62E-05$) and for BMI ($p<2.26E-06$). GxE was suggested across cognitive domains in the full sample ($p<5.29E-03$), and generally across country and sex. Trends over age bands (<50, 50-59, 60-69, 70-79, 80+) suggested GxE for depressive symptoms until age 80, peaking at 60-69 years. For BMI, GxE trends were nonlinear with peaks before 50 and after 70 years. For cognition, peak GxE was observed in midlife for speed but later adulthood for verbal ability and working memory. Peak periods of GE interplay in health, wellbeing and cognitive traits may coincide with salient periods of age-related change.

GENE-BY-ENVIRONMENT INTERACTION PARTLY EXPLAINS THE HAND GRIP STRENGTH LEVELS AS WELL AS DECLINE

I. Petersen[1], K. Christensen[1], M. McGue[2,1], C.A. Reynolds[3], *1. Institute of Public Health, University of Southern Denmark, Odense, Denmark, 2. Department of Psychology, University of Minnesota, Minneapolis, Minnesota, 3. Department of Psychology, University of California, Riverside, California*

Previous studies of hand grip strength have demonstrated a strong association with age and sex; males having a higher initial as well as decline of grip strength than females. Heritability studies of grip strength have estimated that genes and environmental factors each account for half of the observed variation of grip strength. However, apart from sex and age, little is known about the genetically and environmental determinants of level and decline of grip strength. Based on a pooled sample of longitudinal survey studies of Danish, Swedish and US twins (N=10,000; age-range: 34-99) we set out to examine the possible presence of gene-by-environment interaction as part of the mechanism behind initial level and age-dependent decline of grip strength. Using an analytical approach proposed by Fisher (1925) revealed evidence of heterogeneity of the distribution of the within-pair difference of growth curve parameters in monozygotic twins indicating that gene-by-environment interaction may be present.

SESSION 2225 (SYMPOSIUM)

AGING IN THE CONTEXT OF NEIGHBORHOOD CHANGE

Chair: J.A. Ailshire, *Andrus Gerontolgoy Center, Univ Southern California, Los Angeles, California*
Discussant: P. Clarke, *University of Michigan, Ann Arbor, California*

The U.S. population is aging rapidly and many factors, from the predicates of policy, to the assumptions of individuals, are heightening expectations that older adults will be able to live independent, active and engaged lives within their communities. But the dynamics of population change and resulting shifts in the local social, economic, and physical environment mean that communities change around individuals as they age. Furthermore, older adults may age in a changing context as a result of moving to a new community. Issues related to neighborhood change have largely been overlooked in studies of aging and the environment. This symposium presents research on how neighborhoods change around people and what happens when older adults change their neighborhood through a residential move. The presentations use both national and local data sources, as well as multiple methodologies, to provide insight into how neighborhoods are changing as the population ages. Data from multiple waves of the Health and Retirement Study and the Multi-Ethnic Study of Atherosclerosis are used to identify older adults who experience a residential move and how both their environments and their health and behavior change as a result of the move. The discussant will highlight common themes across the presentations, consider how the presentations extend this emerging field of study, and discuss the potential for further investigations on the topic.

SEGREGATION IN PLACE: POPULATION AGING AND NEIGHBORHOOD RACIAL CHANGE

M.D. Bader, *Sociology, American University, Washington, District of Columbia*

Nearly all research investigating the cause of racial residential segregation focuses on how residential relocation creates residential segregation. Research has largely ignored the influence of changing age structures on patterns of segregation in U.S. metropolitan areas. In this paper, I examine the role of differential rates of fertility and mortality on overall patterns of segregation. Using national age- and race-specific fertility and mortality rates, I simulate the consequences of fertility and mortality, and the resulting shift in the age composition of residents, on neighborhood racial composition. Higher chances of White mortality in integrated neighborhoods coupled with higher chances of minority births in those same neighborhoods contributes to a long-term racial re-segregation of previously integrated communities. I expect that this effect explains a non-trivial percentage of contemporary racial residential segregation in U.S. metropolitan areas. Implications of these processes for older residents aging in place are discussed.

INTEGRATING DEMOGRAPHIC AND CULTURAL APPROACHES IN THE EXAMINATION OF NEIGHBORHOOD CHANGE

N.T. Saldana, *University of Michigan, Ann Arbor, Michigan*

Demographic factors play a fundamental role in the quantification of neighborhood change. Research primarily focuses on race and socioeconomic composition of residents derived from census data. While scholars have demonstrated the importance of census-based demographic factors for understanding neighborhood change, less is known about how neighborhood-based organizations and institutions, such as local businesses, change over time. I incorporate systematic social observation, from in-person ratings and photographs, with census data to determine the level of correlation between census-based measures of demographic change and "on-the-ground" observations of the local neighborhood environment. Observations are made in several major U.S. cities (Los Angeles, New York, Chicago, Detroit, and Atlanta), providing a comparative perspective that is often absent in neighborhood change research. A major focus of this research seeks to unpack the mechanisms shaping the social construction of neighborhoods, how both real and symbolic boundaries are constructed, and implications for residents' outcomes.

CONSEQUENCES OF RESIDENTIAL MOVES AMONG OLDER ADULTS

J.A. Ailshire, *Andrus Gerontolgoy Center, Univ Southern California, Los Angeles, California*

Research on the importance of the residential environment for aging largely focuses on those who age-in-place and ignores the experience of older adults who move. Using data from multiple waves of the Health and Retirement Study (2004-2008), this study identifies adults ages 55 and older who experienced a between-wave move and the resulting change in their residential environment. Approximately 9% of respondents moved between waves. Of those who moved, 4% reported moving to a less safe neighborhood and 7% reported moving to a safer neighborhood. Neighborhood-based interactions with family and friends declined for 13% and 18% of movers, respectively. However, 15% of movers reported increased interaction with family in the new neighborhood and 25% reported increased interaction with friends; one of the primary cited reasons for moving was to be nearer relatives and friends. Older adults who move may experience a significant shift in their neighborhood environment.

CHANGE IN WALKING FOLLOWING RESIDENTIAL RELOCATION: THE MULTI-ETHNIC STUDY OF ATHEROSCLEROSIS

J.A. Hirsch[1], K.A. Moore[1], A.V. Diez Roux[3], K. Evenson[2], D. Rodriguez[2], *1. Epidemiology, University of Michigan, Ann Arbor, Michigan, 2. University of North Carolina, Chapel Hill, North Carolina, 3. Drexel University, Philadelphia, Pennsylvania*

We investigated whether moving to neighborhoods with closer proximity of destinations and greater street connectivity was associated with more walking and a greater probability of meeting the "Every Body Walk!" campaign goals (≥150 minutes/week of walking). We linked longitudinal data from 701 Multi-Ethnic Study of Atherosclerosis participants aged 48-87, who moved during 2004-2012, to a commercial walkability measure (Street Smart Walk Score®) for each residential location. We used fixed-effects models to estimate if changes in walkability resulting from relocation were associated with simultaneous changes in self-reported walking behaviors. Adjusting for relevant confounders, moving to a new location with 10-points higher Walk Score (better walkability) was associated with a 16.0 minutes/week increase in transport walking and 11% higher odds of meeting "Every Body Walk!" goals through transport walking. Change in walkability was not associated with change in leisure walking. Our findings illustrate the potential for neighborhood infrastructure to support walking.

SESSION 2230 (SYMPOSIUM)

THE IMPACT OF CROSS-CUTTING INTERVENTIONS TO PROMOTE EVIDENCE-BASED FALLS PREVENTION PROGRAMMING AND POLICIES

Chair: T. Shubert, *Center for Aging and Health, UNC Chapel Hill, Chapel Hill, North Carolina*
Co-Chair: M.G. Ory, *Texas A&M, College Station, Texas*
Discussant: M.L. Smith, *University of Georgia, Athens, Georgia*

Although falls are recognized as a major public health problem for older adults, and multi-level, multi-disciplinary interventions are strongly encouraged, more efforts are needed to understand the implementation and dissemination of evidence-based fall prevention programs. Little is known regarding what, if any, effect these efforts have on the behavior of falls free coalitions, health care providers, and older adults themselves. Through its State Falls Prevention Program, the Centers for Disease Control and Prevention has supported several major initiatives to examine the implementation and dissemination of fall prevention programs and policies. This symposium will present data from projects to highlight the impact of three different fall prevention activities on three different systems committed to addressing falls: 1) the effect of training and technical assistance provided to state-wide Fall Prevention Coalitions about current activities and future planning (presenter: Ms. Schneider); 2) the effect of a national training initiative for physical therapists to deliver the Otago Exercise Program, a home-based falls prevention program, on both clinical practice and patient outcomes (presenter: Dr. Shubert); and 3) the effect of a real-time and online curriculum on community health workers behaviors (presenter: Dr. Ory). A discussant (Dr. Smith) will describe the outcomes of these three initiatives in the broader context of disseminating evidence-based programs for older adults, emphasizing facilitators and barriers to dissemination, and sustainability of efforts. Time will be allotted to enable the audience to interact with the panelists about the dissemination of falls prevention programs and policies.

THE IMPACT OF WEBINAR TRAINING AND TECHNICAL ASSISTANCE ON POLICIES AND ACTIVITIES OF STATE-BASED FALL PREVENTION COALITIONS

E.C. Schneider[1], T. Shubert[1], M.L. Smith[2], M. Altpeter[1], M. Scheirer[4], M.G. Ory[3], *1. Center for Aging and Health, UNC Chapel Hill, Chapel Hill, North Carolina, 2. University of Georgia, Athens, Georgia, 3. Texas A&M, College Station, Texas, 4. Scheirer Consulting, Princeton, New Jersey*

The National Council on Aging (NCOA) released the State Policy Toolkit for Advancing Falls Prevention in 2012. The Toolkit provides evidence-based guidance and resources for Fall Prevention Coalitions to have the greatest impact on change. To facilitate use of the Toolkit, the NCOA hosted a one-hour webinar in 2013 and provided technical assistance to four selected states. Prior to the webinar, a survey was deployed to the 34 active state Coalitions to assess fall prevention strategies, policies, and regulations implemented to advance fall prevention. Additionally, the survey identified facilitators and barriers and documented general coalition practices and procedures. The same survey was deployed one year later to determine change. This presentation will: (1) present pre-post data to describe the impact of the Toolkit and technical assistance on policies pursued by the Coalitions; (2) identify successful strategies employed to advance evidence-based falls prevention policies; and (3) discuss future opportunities to promote state engagement in fall prevention.

EVALUATING A REAL-TIME AND ONLINE FALL PREVENTION CURRICULUM FOR COMMUNITY HEALTH WORKERS

M.G. Ory[2], J. St. John[2], C.B. Clarke[1], M.L. Smith[3], C.E. Beaudoin[2], C. Rosemond[1], D. Howell[2], T. Shubert[1], *1. Center for Aging and Health, UNC Chapel Hill, Chapel Hill, North Carolina, 2. Texas A&M, College Station, Texas, 3. University of Georgia, Athens, Georgia*

The Policies, Programs, and Partners for Fall Prevention (PPPFP) study incorporates multi-level intervention approaches to address fall prevention using several dissemination research methodologies—including training Community Health Workers (CHWs)/Promotores to deliver fall prevention messages. This presentation will discuss the evaluation of an innovative falls prevention CHW curriculum. The curriculum was developed and tested in both real time and online platforms for English and Spanish-speaking audiences. Demographic, evaluation and practice change data will be presented for the first 30 CHWs to complete the real-time training and the first 30 to complete the online training. The advantages and disadvantages of each format will be discussed as well as participants' perceptions about the impact on CHW practice and potential reach of each format.

FALL PREVENTION FOR PHYSICAL THERAPISTS: OUTCOMES FROM AN INITIATIVE TO CHANGE PRACTICE USING AN ONLINE TRAINING PROGRAM

T. Shubert[1], C.B. Clarke[1], S.A. Bomberger[1], M.L. Smith[2], M.G. Ory[3], E. Roberts[1], J. Busby-Whitehead[1], *1. Center for Aging and Health, UNC Chapel Hill, Chapel Hill, North Carolina, 2. University of Georgia, Athens, Georgia, 3. Texas A&M, College Station, Texas*

The Otago Exercise Program is an evidence-based fall prevention program delivered by physical therapists in 6 visits over a one-year period. Developed in New Zealand, few physical therapists in the United States have knowledge about the program. Through a multi-agency effort led by the Carolina Geriatric Education Center, part of the Center for Aging and Health at UNC Chapel Hill, and including the Centers for Disease Control and the North Carolina Area Health Education Centers, an online training program was developed and deployed to maximize reach and implementation of the program. This presentation will: 1) present demographic and practice change data from the first 1,000 therapists to complete the training; 2) present outcome data for 75 patients receiving Otago in a variety of settings; and 3) discuss next steps for continued Otago dissemination and implementation, which includes leveraging the efforts of physical therapists with other allied health providers.

SESSION 2235 (SYMPOSIUM)

SOCIAL CONNECTEDNESS AND RESILIENCE

Chair: J. Duyndam, *University of Humanistic Studies, Utrecht, Netherlands*
Co-Chair: A. Machielse, *Academic Centre for Social Intervention, Utrecht, Netherlands*
Discussant: P. Bos, *Radboud University, Nijmegen, Netherlands*

The central theme of this symposium is the importance of social connectedness and resilience for older people's experiences and social conditions (Berkman & Glass, 2000; Heller & Rook, 2001; Machielse, 2006; Pescosolido & Levy, 2002). Positive interpersonal attachments are conceived as the most important resources for people to their experience of a meaningful life (Baumeister, 1991; Stillman, et al., 2009). On its turn, the experience of a meaningful life has been hypothesized to strengthen a person's identity and character (Van Praag, 1997) and to protect against the damaging effects of external adversity such as lengthy caregiving, community relocation and increased chronic conditions that accompany aging (Ryff & Singer, 2009). So social connectedness contributes substantially to resilience, defined as the 'the ability to uphold humanity, i.e. principles of human decency, or promote these principles when faced with adversity or when under pressure' (Duyndam, 2012). We will compare two studies on the lived experiences of elderly people with regard to social connectedness. The first study is focusing on life-events of older adults in the Netherlands. The second study is conducted in a traditional rural community in the Netherlands. The comparison is supplemented by a third study: a philosophical investigation of conditional linkages between social connectedness and social resilience. A fourth will intersect on resilience and autonomy related to care.

AGING AND SOCIAL RESILIENCE

J. Duyndam, *University of Humanistic Studies, Utrecht, Netherlands*

Recent research results show the conditional social character of resilience, highly depending on so-called 'social ecologies' (Ungar, 2012; Duyndam, 2012; Wild et al., 2013; Randall, 2012). However, resilience still depends on the capacity of making sense of one's life events. Therefore, the study of interrelationships between social connectedness, meaning, and resilience is of great relevance. The research question of this paper contributing to this study is "How can resilience be understood, in the context of ageing well, as related to social connectedness and meaning?" The research of this subproject is conducted from a narrative perspective. It is hypothesized that the navigating to and negotiating for resources to resilience can be considered to be narrative processes. It is also hypothesized that because of its narrative character resilience can become exemplary, and inspiring to others. Accordingly, the philosophical 'method' consists of a hermeneutic reading and interpretation of relevant textual and empirical sources.

LIFE-EVENTS AND THE IMPORTANCE OF SOCIAL CONNECTEDNESS IN MODERN SOCIETY

A. Machielse, *Academic Centre for Social Intervention, Utrecht, Netherlands*

Social relationships with relatives, friends and acquaintances, which meet belongingness needs (Baumeister, 1991), are important resources for the personal functioning of people and contribute to their experience of a meaningful life. However, in late modern society such relationships have become less self-evident. As a result family relationships have become less stable and obvious and the significance of self-chosen relationships has increased, particularly friendship (Allen, 2008; Friedman, 1989; Pahl, 1998). The central research question of this paper is: "Which contribution make personal relationships for the experience of a meaningful life age after a life-event, and how might this differ between (given) relationships with family members and (self-chosen) relationships with friends?" It will be answered on the basis of data from a qualitative study conducted in the Netherlands. The study group consists of older adults (65+) who in the last year have been confronted with an age-related life-event.

AN ETHNOGRAPHIC INVESTIGATION INTO AGEING AND SOCIAL CONNECTEDNESS IN A TRADITIONAL ORTHODOX CHRISTIAN COMMUNITY IN THE NETHERLANDS

P. Bos, *Radboud University, Nijmegen, Netherlands*

With a population of 16 million people, policymakers in the Netherlands foresee 25% of 65+-people in 2040 (Avramov & Maskova, 2003). This age-imbalance concurs with fundamental social changes in Dutch society (Beck & Beck-Gernsheim, 2002; Giddens, 1990). The loss of (extended) family traditions had great impact on social connectedness. However, the Netherlands nowadays has a great number of traditional communities, with intergenerational cohabitation and other distinctive household-constellations, not determined by dominant cultural norms. This paper reflects an ethnographic study in an orthodox protestant village in central Netherlands (1600 inhabitants). The researchers approach every household on the spot, unravelling lived experiences within extended household constellations regarding ageing well and social connectedness (Warburton, Hung & Shardlow, 2013). In-depth interviews and participant observations reveal culturally determined perceptions from the perspective of aged people and their cohabitants.

RESILIENCE, AUTONOMY AND CARE

J. Dohmen, *University of Humanistic Studies, Utrecht, Netherlands*

Persons are not passive objects but ageing actors. One fundamental issue in actual philosophy of agency and ageing is about the tension between autonomy or care in relation to resilience. From a care-ethical perspective, autonomy is not a property of isolated individuals but the product of, and bound up with, relationships. Resilience is the product of care. From the perspective of autonomy, autonomy is bound up with relationships, but certainly not just the product of relations. Resilience is the product of autonomy. In my view, both moral values, care and autonomy, are of vital importance for resilience in later life. I will defend the concept of a well-integrated moral attitude for resilience in later life.

SESSION 2240 (SYMPOSIUM)

RELATIONSHIPS AND HEALTH IN ADULTHOOD: UNDERSTANDING MUTUAL INFLUENCES ON MULTIPLE TIME SCALES

Chair: S.J. Wilson, *Human Development & Family Studies, Penn State University, University Park, Pennsylvania*

Co-Chair: M. Barrineau, *Human Development & Family Studies, Penn State University, University Park, Pennsylvania*

Discussant: C.A. Berg, *University of Utah, Salt Lake City, Utah*

The ability to gather unprecedented amounts of data may facilitate our understanding of how couples impact one another's health and well-being across moments, days, months, and years. Thus, it is increasingly important for conceptual clarity and appropriate design and measurement that researchers consider how effects can be distinguished by their time course. This symposium will examine processes of variability and change in couples at various time scales and the connections between patterns of brief experiences and longer developmental trajectories. In so doing, we aim to foster discussion of how to improve conceptual models of couples and health with consideration of temporal factors. The first talk by Dr. Gizem Hulur will utilize ecological momentary assessment to examine how accurate a healthy sample of older adults is in evaluating their partner's feelings and whether individual, partner, and couple characteristics can explain individual differences. The remaining talks in the symposium will consider different time scales from a study of osteoarthritis patients and their spouses. Mary Jon Barrineau will assess emotion transmission in two different time scales within daily data. Stephanie Wilson will look at how couples' daily pain-related exchanges are associated with change in patient physical function and couple well-being across six months. Finally, Dr. Rachel Hemphill will present on whether spouses' confidence in arthritis patients' ability to be physically active predicts increases in patients' physical activity longitudinally and whether this association is mediated by spouses' involvement in physical activity.

DAILY PAIN-RELATED INTERACTION PATTERNS AND LONGITUDINAL CHANGE IN INDIVIDUAL AND DYADIC WELL-BEING

S.J. Wilson[1], L.M. Martire[1], M.P. Stephens[2], *1. Human Development & Family Studies, Penn State University, University Park, Pennsylvania, 2. Kent State University, Kent, Ohio*

Cross-sectional studies have demonstrated the relevance of chronic pain and couples' pain-related disclosure and responses for both patient and partner well-being. However, associations between daily communication patterns and later change in individual and dyadic well-being remain largely unexplored. Knee osteoarthritis patients and their spouses provided daily reports of patient pain, patient verbal pain disclosure, and spouse empathic responses to patient pain, as well as measures of physical function, pain communication efficacy, and marital satisfaction at baseline and six months later. Multilevel models revealed that the same-day covariation of patient pain disclosure and spouse empathic responses was not related to changes in patient physical function or pain disclosure efficacy. Stronger positive covariation between daily disclosure and empathic responses was related to increases in spouse pain communication self-efficacy and patient marital satisfaction. Thus, the daily linkage of pain disclosure and empathic responses may support couple communication and relational well-being.

SPOUSE CONFIDENCE AS A PREDICTOR OF CHANGE IN OSTEOARTHRITIS PATIENTS' PHYSICAL ACTIVITY ACROSS SIX MONTHS

R.C. Hemphill[1], L.M. Martire[1], M.P. Stephens[2], *1. Pennsylvania State University, University Park, Pennsylvania, 2. Kent State University, Kent, Ohio*

Research suggests that spouses' confidence in their chronically ill partners' ability to perform health behaviors has unique effects on patients' health behaviors and outcomes beyond patients' own self-efficacy. The mechanisms through which spouse confidence influences patients' health remain relatively unexplored. This study of 152 older adults with osteoarthritis and their spouses examined 1) spouses' confidence in patients' ability to be physically active as a predictor of change in patients' physical activity (PA) over time and 2) whether this association was mediated by spouses' provision of autonomy support, persuasion, or pressure for patients' PA. Results indicated that higher levels of spouse confidence predicted greater increases in patients' PA six months later, even when controlling for patients' self-efficacy and illness severity; however, this association was not mediated by spouses' support, persuasion, or pressure. Alternative mechanisms that may explain the impact of spouse confidence on patients' PA will be discussed.

DAILY EMOTION TRANSMISSION BETWEEN OSTEOARTHRITIS PATIENTS AND THEIR SPOUSES

M. Barrineau[1], L.M. Martire[1], M.P. Stephens[2], *1. Penn State University, University Park, Pennsylvania, 2. Kent State University, Kent, Ohio*

Emotion transmission occurs when emotions in one individual's daily experience have a predictive relationship to subsequent emotions in another person (Larson and Almeida, 1999). In the current study, 152 osteoarthritis patients and their spouses reported their positive and negative affect three times per day across 22 days. The multiple reports within the day allows for consideration of shorter and multiple transmission time scales. Specifically, it is predicted that negative emotion will be transmitted from patient to spouse within the day from morning to the end of the day. It is expected that positive emotion will be transmitted from patient to spouse on a shorter time scale, either from morning to afternoon or afternoon to end of day. Multi-level modeling will be used to test the transmission hypotheses along with assessing the role of moderating variables, specifically gender and marital satisfaction.

EMPATHY IN THE DAILY LIVES OF OLDER COUPLES

G. Hülür[1], N. Ram[2], H.M. Schade[1], D. Gerstorf[1,2], *1. Humboldt University, Berlin, Germany, 2. Pennsylvania State University, State College, Pennsylvania*

Empathy refers to recognizing emotions in others and is crucial for relationship satisfaction. Empathy has typically been examined by self-ratings or standardized tests. In this study, we take a different approach by obtaining information in people's daily life. Specifically, older couples (aged 70+) participated in a daily-diary study (49 observations across 7 days) where they, among others, rated their (a) own happiness at the moment and (b) their partner's happiness, both on a scale ranging from 0 to 100. Correlating self- and partner-ratings revealed that older adults were fairly accurate in evaluating whether their partner was less happy or happier than usual (r = .27). However, the absolute differences between self- and partner-ratings within a given couple was astonishingly large and amounted to an average of 0.8 SD units (or 18 scale points). We discuss factors that contribute to empathy and the role of empathy for relationship quality.

SESSION 2245 (SYMPOSIUM)

INNOVATIVE METHODS AND MODELS FOR UNDERSTANDING THE POSSIBLE HEALTH BENEFITS OF FAMILY CAREGIVING

Chair: D.L. Roth, *Johns Hopkins University, Baltimore, Maryland*
Co-Chair: W.E. Haley, *University of South Florida, Tampa, Florida*
Discussant: K.M. Langa, *University of Michigan, Ann Arbor, Michigan*

Being an informal caregiver of a family member with a chronic illness or disability is often considered to be a highly stressful experience that may adversely affect the health of caregivers. However, many studies that compare health outcomes of caregivers with non-caregiving controls have methodological limitations. These include using convenience samples, different selection procedures for caregivers and non-caregivers, insufficient matching techniques, shared (or unshared) exposures to other risk factors, and other potential biases. In this symposium, presenters will review recent advances in formulating caregiver/non-caregiver comparisons, present findings on the impact of caregiving on health and mortality, and discuss the psychological and physiological mechanisms by which caregiving activities may affect health outcomes. Using methods and data from population-based studies (Study of Osteoporotic Fractures, the Reasons for Geographic and Racial Differences in Stroke project), presenters will summarize findings that indicate lower all-cause mortality for caregivers after careful matching with suitable non-caregiving comparison groups. Caregivers in these population-based studies report relatively low levels of caregiving strain in comparison with previous convenience samples, and even those caregivers who report psychological distress have lower all-cause mortality than matched non-caregivers. Conceptual interpretations and the potential physiological mechanisms underlying these health benefits will be discussed and will provide stimulating directions for future research. Having a close family member with a disabling or deteriorating health condition can be a stressful and depressing situation, but the opportunity to help a loved one, and the related feelings of mastery, purpose, and compassion, appear to be health enhancing.

METHODS TO REDUCE POTENTIAL SELECTION BIAS AND CONFOUNDING IN STUDIES OF CAREGIVING HEALTH OUTCOMES

L. Fredman, *Epidemiology Department, Boston University School of Public Health, Boston, Massachusetts*

As a result of findings that caregivers have lower rates of mortality and other adverse health outcomes than non-caregivers, there is increased attention to ensuring that studies of caregiving health outcomes include appropriate non-caregiver comparison groups and adequately address confounding and potential selection bias. This presentation describes methods used to reduce confounding in the Caregiver-Study of Osteoporotic Fractures (Caregiver-SOF) and the REGARDS studies, such as matching non-caregivers to caregivers at the design phase. It will describe analyses to minimize confounding in the analysis phase, including analyses that account for changes in caregiver status and related health status over the study period. It will address selection bias by comparing characteristics of SOF participants who agreed to participate in Caregiver-SOF to those who were eligible but did not participate. The advantages and disadvantages of these approaches will be discussed with regard to analyzing data from existing studies compared to designing new studies.

CAREGIVERS ARE STRESSED AND DEPRESSED, BUT LIVE LONGER: FINDINGS FROM A PROPENSITY-MATCHED ANALYSIS

D.L. Roth[1], V.G. Wadley[2], W.E. Haley[3], *1. Johns Hopkins University, Baltimore, Maryland, 2. University of Alabama at Birmingham, Birmingham, Alabama, 3. University of South Florida, Tampa, Florida*

Using data from the national Reasons for Geographic and Racial Differences in Stroke project, we individually matched 3503 caregivers with 3503 noncaregivers using propensity scores derived from a logistic regression analysis of 15 demographic, health history, and health behavior covariates. Previous findings revealed an 18% reduction in all-cause mortality for the caregivers compared to the matched noncaregivers ($p = .02$). Subsequent analyses reveal that the caregivers reported more symptoms of depression and higher perceived stress scores than the matched noncaregivers ($ps < .001$). Depressive symptoms were positively related with increased mortality, an effect that was similar in magnitude to the opposing protective effect of decreased mortality associated with caregiving. Having a family member with a chronic illness or disability is associated with perceived stress and depressive symptoms, but providing care to that person appears to provide health benefits to the caregivers, as indexed by increased longevity.

A CONCEPTUAL MODEL FOR LINKING CAREGIVING BEHAVIORS TO IMPROVED SURVIVAL

S.L. Brown, *1. Psychiatry, Stony Brook University, Port Jefferson, New York, 2. University of Michigan, Ann Arbor, Michigan*

Caregiving has been linked to better health, reduced mortality risk, and well-being. However, almost no research addresses the physiological mechanisms by which a caregiver's survival may be influenced by his or her own caregiving activities. In my talk, I will present a theoretical model of a "caregiving system" which describes the neurobiological basis of the motivation to care for others, and connects features of the underlying neurobiology to physiological homeostasis, including stress regulation and reduced exposure to chronic inflammation. After a brief review of new models of inflammatory disease and cancer biology, I discuss how the caregiving system is uniquely poised to also interrupt the development of lethal forms of cancer. I will present the results of several studies that have tested the "caregiving system" model and conclude my talk with the implications for health policy and medical research.

SESSION 2250 (SYMPOSIUM)

WISDOM AND OPTIMAL AGING? THE POSITIVE (AND NEGATIVE) ASPECTS OF WISDOM IN OLD AGE

Chair: M. Ardelt, *Sociology and Criminology & Law, University of Florida, Gainesville, Florida*

Wisdom is usually assumed to contribute to optimal aging, yet not all aspects of wisdom might be beneficial. This symposium explores positive and negative aspects of wisdom in old age, using quantitative and qualitative data from Europe, North America, and China. In the first presentation, interviews with 47 older wisdom nominees and 47 older control participants from Austria revealed that when asked about difficult experiences in their life, wisdom nominees reported more reflectivity, appreciation of divergent views, and gratitude but also less control over life events and greater relativity. The second presentation investigates how positive and negative emotions work together to promote recovery and growth from challenging life events. Results of the qualitative interview study of 50 older US adults show that "achievers" defined successful aging in hedonic terms, while "seekers" were more interested in eudaimonic well-being. The third presentation uses ratings by US nominators to study differences between 524 middle-aged and older wise and creative nominees. Wisdom nominees were on average rated higher than visual artists on wisdom-related and mature personality qualities and well-being, yet only ratings of creativity were positively correlated with ratings of self-expression and zest. The fourth presentation demonstrates that different conceptualizations of wisdom (3D-WS and ASTI) relate differently to life satisfaction and general well-being in Canada, USA, Ukraine, and China, using samples of 50 older adults in each country. Finally, the last presentation is an ethnographic study that illustrates how wisdom benefits older adults in formal care settings in Ireland if their caregivers are wise.

"IN NO WAY WOULD I DARE TO JUDGE HOW OTHER PEOPLE DEAL WITH THIS": CRITICAL SELF-REFLECTION AS A POSITIVE AND NEGATIVE ASPECT OF GROWING WISER

J. Glueck[1], S. Koenig[1], J. Drewelies[2], K. Naschenweng[3], *1. Alpen-Adria Universität Klagenfurt, Klagenfurt, Austria, 2. Humboldt University, Berlin, Germany, 3. Pädagogische Hochschule Kärnten, Klagenfurt, Austria*

Wisdom is generally viewed as highly desirable. At the same time, we still debate whether wise people are happier than others. One reason why they might sometimes even be less happy is that "un-wise" people may believe that they know what is right and have control over their life, while wiser individuals are aware of the relativity of perspectives and the uncertainty of outcomes. Here, we report findings from a study comparing 47 wisdom nominees and 47 age- and gender-parallel control participants (mostly older adults, $M = 60.5$ years) with respect to difficult life experiences, life lessons, gratitude, and resources. Wisdom nominees reported higher levels of reflectivity, less control over life events, more life lessons involving relativity, more gratitude for difficult experiences, and more appreciation of divergent views. Being critical of one's own views may be painful sometimes, but it is essential for growing toward wisdom.

EMOTION REGULATION AND WISDOM IN LATER LIFE

H. Igarashi, M. Levenson, C.M. Aldwin, *School of Behavioral and Health Sciences, Oregon State University, Corvallis, Oregon*

Regulation of positive and negative affect is an essential component of resilience and successful aging in later life (Carstensen et al., 2011). However, how positive and negative emotions work together to promote recovery and growth is not well understood. Semi-structured interviews were conducted with 50 men ($n = 14$) and women ($n= 36$), aged 56 - 91 years ($M = 71.71$; $SD = 8.8$). Participants described a challenging moment in their lives, coping strategies and attendant changes. Individuals were grouped into conservers, achievers and seekers based on their affect pattern and orientation towards personal growth and environmental mastery (Helson & Srivastiva, 2001). Most individuals reported some change, changing across typologies (e.g., conservers to achievers). Achievers described successful aging in hedonic terms, while seekers used eudaimonic ones (Friedman & Ryff, 2012). Mixed methods approaches were used to examine group differences in a self-report wisdom inventory (ASTI; Levenson et al., 2005).

A COMPARISON OF TWO EXEMPLARS OF SUCCESSFUL AGING: WISDOM NOMINEES AND NOMINATED VISUAL ARTISTS

M. Ardelt[1], L. Orwoll[2], *1. Sociology and Criminology & Law, University of Florida, Gainesville, Florida, 2. Clinical Pyschologist, Ann Arbor, Michigan*

Both wise and creative older adults are often considered exemplars of successful aging, although the personality of creative artists might be less integrated and more complex. Using ratings by judges, psychologists, clerics, and visual artists randomly selected from their professional directories, this study analyzed the differences in personality qualities between 247 wisdom nominees ($M\_age=62.82$) and 277 nominated visual artists ($M\_age=64.98$). Three-way 2 (nominator group) x 2 (age group <60 versus 60+) x 2 (sex) MANOVA and follow-up t-tests revealed that both wise and creative nominees tended to age well as the nominator ratings were generally positive. Yet, wise nominees seemed to age even better than creative nominees. Moreover, ratings of the nominees' wisdom (but not creativity) were positively correlated with wisdom-related and mature personality qualities and well-being, whereas creativity ratings were positively correlated with self-expression and zest. Overall, wisdom appears to be a stronger predictor than creativity of successful aging.

CULTURAL DIFFERENCES IN THE BENEFITS OF WISDOM IN OLD AGE

M. Ferrari[1], M. Ardelt[4], C.S. Hu[1], T. Rozin[1], G. Shariff[1], R. Liu[2], E. Ivanova[3], *1. University of Toronto, Toronto, Ontario, Canada, 2. Beijing Normal University, Beijing, Hebei, China, 3. Kharkiv National University, Kharkiv, Ukraine, 4. University of Florida, Gainsville, Florida*

Our international study of wisdom in older adults (age 60-99) in Canada, USA, Ukraine, and China (50 participants per country) explores how well general well-being (GWB) and life satisfaction (LS) can be predicted by the 3 Dimensional Wisdom Scale (3D-WS) and the Adult Self-Transcendence Inventory (ASTI). Linear regressions of both measures of wisdom on life satisfaction found that the 3D-WS predicts GWB in all 4 countries, while the ASTI does not in Ukraine; by contrast, the ASTI predicts LS in all countries but Ukraine, while the 3DWS does so only in Ukraine. However, the 3D-WS and ASTI correlate differently in these 4 countries: positively in Canada and the USA, but negatively in the Ukraine and China. All participants were also interviewed about experiences of wisdom in their own lives and a narrative phenomenological analysis shows that the wisdom themes measured by these two scales are understood differently in these countries.

EMBEDDED AND CONNECTED WISDOM: IMPACTS OF WISE PRACTICES ON COMMUNAL LIVING IN LATER LIFE

R. Edmondson, *School of Political Science and Sociology, National University of Ireland Galway, Galway, Ireland*

This talk interrogates the use of ethnographic methods in exploring salient impacts of practices described by (other) participants as wise. It focuses on everyday life in two institutions in Ireland: a day-care centre for eighty users with sheltered accommodation for twenty, and a nursing home with forty residents. Commentators such as Ardelt have emphasised the significance of personal practice in wisdom; the talk seeks to complement this by tracing specific practical effects of components of wisdom traditionally associated with the social virtues. Concentrating on managers' interventions, we can track incidents involving tolerant solutions to disputes, or cases where communication is restored after difficulty. This shows that managers and nurses identified by others as wise both draw on and add to shared stocks of constructive communicative practice, enabling the achievement of shared goals: positive and pacific forms of joint living. Lastly, it assesses the significance of ethnography in eliciting these results.

SESSION 2255 (SYMPOSIUM)

POSITIVE AFFECT, HEALTH, AND WELL-BEING

Chair: J. Williams Robinette, *University of California, Irvine, Irvine, California*
Co-Chair: S.T. Charles, *University of California, Irvine, Irvine, California*
Discussant: A.D. Ong, *Cornell University, Ithaca, New York*

A large literature attests to the importance of positive affect (PA) and health. This series of presentations further unpack the associations between different aspects of PA and health and health-related constructs. Luong and colleagues investigated daily relationships between PA and health in a large sample of adults across a wide age range. They found that mean levels of PA are associated with better health, but more PA variability is associated with worse health. These associations were stronger among the oldest adults. Boehm and colleagues further examine the importance of means levels and variability in affect-related measures. They found that both average levels and variability in life satisfaction are related to mortality, and that that these two indices interact with one another. Sin et al. used a large national study of adults and found that heightened PA reactivity to positive events in one's day was associated with increased inflammation, measured by IL-6. Robinette and colleagues further examined unique associations between different types of negative affect and PA in relation to two different measures of health: self-reported health and allostatic load, a measure of cumulative physiological wear and tear. Results indicated that, although PA and anxiety are uniquely associated with self-reported health above the effects of depressive symptoms, affect was not associated with allostatic load. Together, these studies explore different aspects of affect – including both valence and variability – that have unique correlations with health. Anthony Ong, Ph.D., an expert in the determinants and consequences of PA, will integrate and summarize the findings.

AFFECT, HEALTH, AND PHYSIOLOGY

J. Williams Robinette, S.T. Charles, *University of California, Irvine, Irvine, California*

Higher levels of negative affect and lower levels of positive affect (PA) are associated with poorer health and health-related constructs. In the present study, we used a large national sample of adults 34-86 years-old to examine how symptoms of depression and anxiety and PA each are associated with two related variables: self-reported chronic conditions and allostatic load, an objective assessment of biomarkers predicting poorer health outcomes. Zero-ordered correlations reveal more depressive and anxiety symptoms and lower PA were significantly associated with more self-reported health conditions and physical symptoms. However, only anxiety and PA were significantly associated with health when all affect measures were assessed simultaneously. Greater allostatic load was associated with poorer health but was not related to the affect variables. Attendees at this presentation will learn that different health-related measures share different associations with affect-related measures.

AFFECTIVE REACTIVITY TO DAILY POSITIVE EVENTS AND INFLAMMATION

N.L. Sin[1], J.E. Graham-Engeland[2], A.D. Ong[3], D. Almeida[1,4], *1. Center for Healthy Aging, The Pennsylvania State University, University Park, Pennsylvania, 2. Department of Biobehavioral Health, The Pennsylvania State University, University Park, Pennsylvania, 3. Department of Human Development, Cornell University, Ithaca, New York, 4. Department of Human Development and Family Studies, The Pennsylvania State University, University Park, Pennsylvania*

Objective: Inflammation increases the risk of aging-related diseases, but the links between emotional responses to daily events and inflammation are unknown. We examined the associations of positive affect reactivity (i.e., changes in positive affect in response to a daily positive event) with inflammatory markers IL-6 and CRP. Methods: A cross-sectional sample of 683 adults aged 35-84 from the Midlife in the United States Study completed an 8-day diary protocol and provided blood samples. Multilevel models estimated affective reactivity slopes for each participant, which were subsequently used in regression models to predict inflammation. Results: Heightened reactivity was associated with higher IL-6, controlling for demographics, mean positive affect, percent of days with positive events, body mass index, comorbidities, and medications. Reactivity was not associated with CRP. Discussion: Affective reactivity to daily positive events is linked to higher IL-6. These findings underscore the importance of considering dynamic features of positive affect for health.

TOO MUCH OF A GOOD THING? AGE DIFFERENTIAL LINKS BETWEEN POSITIVE AFFECT, HEALTH, AND WELL-BEING

G. Luong[1], C. Wrzus[2], G.G. Wagner[3,4], M. Riediger[1], *1. Affect Across the Life Span Research Group, Max Planck Institute for Human Development, Berlin, Germany, 2. Johannes Gutenberg University, Mainz, Germany, 3. Berlin University of Technology, Berlin, Germany, 4. Max Planck Institute for Human Development, Berlin, Germany*

Older adults value emotionally meaningful goals, but often report wanting to maintain (vs. increase) their positive affect (Riediger et al., 2009). This apparent contradiction may be explained by the differential effects of mean levels of positive affect (i.e., affect intensity) versus how much people fluctuate in their momentary positive affect (i.e., affect variability) in predicting health and well-being. In an experience sampling study, 397 participants between 12-88 years of age (M = 39.87, SD = 20.48) provided momentary reports of their affective experiences. Greater positive affect intensity was associated with better physical health and well-being, and these associations were more pronounced with older age. Moreover, greater positive affect variability was associated with poorer health and well-being, and these effects were stronger with older age. In sum, the findings point to a possible explanation why older adults may prefer to maintain (vs. increase or maximize) their positive affect.

VARIABILITY MODIFIES LIFE SATISFACTION'S ASSOCIATION WITH PREMATURE MORTALITY IN OLDER ADULTS

J.K. Boehm[1], A. Winning[2], S. Segerstrom[3], L.D. Kubzansky[2], *1. Psychology, Chapman University, Orange, California, 2. Harvard School of Public Health, Boston, Massachusetts, 3. University of Kentucky, Lexington, Kentucky*

This longitudinal study investigated whether premature mortality was associated with mean levels of life satisfaction across time, variability in life satisfaction across time, and the interaction between mean life satisfaction and variability in life satisfaction. Participants were 4,458 Australians initially ≥50 years old. During the 9-year follow-up, 522 people died. Adjusting for age, increases in mean levels of satisfaction were associated with reduced risk of premature mortality (HR=0.81; 95% CI=0.75-0.88). In a separate model adjusting for age, increases in the variability of satisfaction were associated with increased risk of premature mortality (HR=1.20, 95% CI=1.11-1.29). The interaction between mean satisfaction and variability in satisfaction was significantly associated with premature mortality risk (HR=0.92; 95% CI=0.87-0.97); individuals with low mean satisfaction and high variability in satisfaction had the greatest risk of premature mortality. In combination with mean levels of life satisfaction, variability in life satisfaction is relevant for premature mortality among older adults.

SESSION 2260 (SYMPOSIUM)

PERSONALITY DEVELOPMENT IN OLD AGE: POTENTIALS AND CHALLENGES

Chair: J. Wagner, *Psychological Methods, Humboldt-University of Berlin, Berlin, Germany*
Co-Chair: D. Gerstorf, *Psychological Methods, Humboldt-University of Berlin, Berlin, Germany*
Discussant: J. Heckhausen, *University of California, Irvine, Irvine, California*

Personality development is of key interest in life-span developmental researchers. However, the nature of as well as antecedents, correlates, and consequences of stability and change in personality in the second half of life are still not well understood. The present symposium brings together a collection of empirical papers that target these questions at a number of different levels of analyses. Wagner et al. use 13-year macro-longitudinal data to examine how major personality traits change in advanced age and at the end of life and explore the role of risk and protective factors in the health, cognitive, self-regulatory, and social domains. Mroczek and colleagues make use of 40-year longitudinal data to investigate lead-lag associations between personality traits and physical health. Turiano et al. examine how the predictive effects of personality traits for 14-year mortality hazards change across adulthood and study the moderating role of particular health factors. Finally, Mejía and colleagues use micro-longitudinal daily-life data to address the role of personality traits in shaping everyday goal processes. The discussion by Jutta Heckhausen will integrate the empirical papers and emphasize the importance of looking at both personality structures and processes to understand developmental patterns into very old age. The major aim of the symposium is thus to showcase contemporary approaches to the study of personality development in an aging society and so move towards better understanding its determinants, mechanisms, and consequences.

PERSONALITY DEVELOPMENT LATE IN LIFE: ANTECEDENTS AND CORRELATES OF STABILITY AND CHANGE

J. Wagner[1], D. Gerstorf[1,2], N. Ram[3], *1. Psychological Methods, Humboldt-University of Berlin, Berlin, Germany, 2. German Institute for Economic Research (DIW), Berlin, Germany, 3. Pennsylvania State University, University Park, Pennsylvania*

Empirical evidence over the past 20 years has documented that key aspects of personality develop across large parts of adulthood. However, it is largely an open question whether and how personality changes late in life and what role key factors in the health, cognitive, self-regulatory, and social domains play. To examine these questions, we applied growth modeling to 13-year longitudinal data obtained from by now deceased participants in the Berlin Aging Study (N=462; age 70–103). Results revealed that neuroticism, on average, increases, particularly in advanced ages and at the end of life. In contrast, extraversion and openness on average decline. Over and above expected general positive effects of social inclusion, people with poor health and cognitive functioning were at risk for declines in extraversion and openness. We discuss potential pathways by which risk and resources in the health, cognitive, self-regulatory, and social domains affect personality development late in life.

DO PERSONALITY AND HEALTH INFLUENCE EACH OTHER OVER TIME? DYNAMIC ASSOCIATIONS BETWEEN TRAITS AND PHYSICAL HEALTH OVER A 4-DECADE LONGITUDINAL FOLLOWUP

D. Mroczek[1], R. Estabrook[1], B. Schalet[1], E. Kranz Graham[1], N.A. Turiano[2], A. Spiro[3], *1. Psychology, Northwestern University, Evanston, Illinois, 2. West Virginia University, Morgantown, West Virginia, 3. Boston VA Health System, Boston, Massachusetts*

Personality traits and physical health are both dynamic over the lifespan, but is this dynamism inter-related? We used multiple waves of measurement over 40 years on 2,002 participants in the VA Normative Aging Study to examine if changes in traits influenced changes in health and vice-versa. Participants had as many as 11 waves of measurement on 2 traits, extraversion and neuroticism, and on 2 physical health dimensions, seriousness of illness ratings and self-rated health. Autoregressive cross-lagged models indicated that four variables became less stable with increasing time lags. Multivariate auto-regressive models further indicated that both personality traits were related both health variables in a complex dynamic manner over time, with some evidence of bidirectionality between personality and health, as well as some evidence that changes in health may lead to changes in personality. Personality and health both change dynamically over time, and their association between them appears dynamic as well.

THE BIG FIVE PERSONALITY TRAITS AND HEALTH ACROSS THE LIFE COURSE

N.A. Turiano[1], P.L. Hill[3], B. Chapman[2], *1. West Virginia University, Morgantown, West Virginia, 2. University of Rochester Medical Center, Rochester, New York, 3. Carleton University, Ottawa, Ontario, Canada*

Personality traits are robust predictors of health and longevity. However, most research assumes that the strength of personality-health association is relatively constant over the entire life course. The current study utilized 14-year mortality data (N =6,000+; age range 25-80) from the Midlife Development in the U.S. Study (MIDUS) to test whether age moderated the effects of the Big 5 personality traits on health and longevity. Employing a proportional hazards modeling framework, significant age-interaction effects emerged for conscientiousness (HR = 1.01; CI = 1.00-1.02), openness (HR = 1.01; CI = 1.00-1.03), and agreeableness (HR = 0.99; CI = 0.98-0.99). The protective effect of conscientiousness decreased with age, the negative effects of agreeableness strongly decreased with age, and openness was a protective factor for those under 65. Sex-specific findings and other health indices will be discussed. This research highlights the importance of examining personality-health trajectories across the full life course.

DAILY AFFECT AND GOAL APPRAISAL PROCESSES: HITS AND SURPRISING MISSES WITH THE BIG 5 PERSONALITY TRAITS

S. Mejía[1], S. Choun[1], T. Pham[2], R. Metoyer[2], K. Hooker[1], *1. School of Social and Behavioral Health Sciences, Oregon State University, Corvallis, Oregon, 2. School of Electrical Engineering and Computer Science, Oregon State University, Corvallis, Oregon*

Personality is important for well-being in part by differentiating appraisals of goal achievement, where positive and negative affect signal individuals' progress towards or away from meaningful goals. In this study, we examine the coupling of positive and negative affect with older adults' daily goal progress in the health and social domains, and the extent to which personality traits of neuroticism, extraversion, openness, agreeableness, and conscientiousness heighten or dampen these associations. We used data from the Personal Understanding of Life and Social Experiences (PULSE) project, a 100-day internet-based microlongitudinal study of self-regulatory processes among older adults. Multilevel models suggest positive affect positively covaries and negative affect negatively covaries with daily health and social goal progress. Neuroticism amplified these associations in the health and social domains, as did agreeableness but only in the social domain. We discuss how personality traits may canalize behaviors that shape daily goal processes and ultimately, our well-being.

SESSION 2265 (PAPER)

HEALTH OUTCOMES AND MINORITY POPULATIONS

HIV MEDICATION ADHERENCE & AGING IN AFRICAN AMERICANS: ROLES OF HEALTH BELIEFS & SENSATION SEEKING

P. Sayegh[1], A.D. Thames[1], N.S. Thaler[1], A. Arentoft[1], S.A. Castellon[1,2], N. Bellete[3], D. Schonfeld[2], C.H. Hinkin[1,2], *1. University of California, Los Angeles - David Geffen School of Medicine, Los Angeles, California, 2. Veterans Administration, Greater Los Angeles Healthcare System, Los Angeles, California, 3. Pepperdine University - Graduate School of Education and Psychology, Los Angeles, California*

The influence of aging on antiretroviral therapy (ART) adherence in HIV-positive African Americans (AAs) and potential mechanisms underlying this relation remain greatly understudied. The current study sought to examine how health beliefs and sensation seeking influence ART adherence in a sample of HIV-positive AAs, and whether these constructs influence the association between aging and adherence. Path analyses revealed that health beliefs, specifically higher levels of perceived utility of treatment, and lower levels of thrill and adventure seeking, a component of sensation seeking, directly predicted optimal ART adherence. In addition, the influence of aging on ART adherence was partially mediated by lower thrill and adventure seeking levels. The role of depression in adherence was fully mediated by both perceived utility of treatment and thrill and adventure seeking, whereas the role of current substance abuse/dependence was fully mediated by thrill and adventure seeking. Finally, global neuropsychological test performance had a direct effect on ART adherence. These findings add to the literature by demonstrating that health beliefs and sensation seeking predict ART adherence in AAs and that age-related declines in thrill and adventure seeking may protect against poor ART adherence. Clinical implications include increasing AA patients' perceptions about the utility of their treatment, particularly among those with higher levels of depression symptoms, in a culturally-responsive fashion to improve adherence. Thrill- and adventure-seeking tendencies can be quickly assessed to identify HIV-positive AAs at risk for poor adherence. Compensatory strategies for medication management may help neurocognitively compromised AAs improve ART adherence.

DENTAL CARE UTILIZATION AND UNMET NEEDS: A STUDY WITH OLDER KOREAN AMERICANS

Y. Jang[1], H. Yoon[1], N. Park[2], D.A. Chiriboga[2], M.T. Kim[1], *1. UT Austin, Austin, Texas, 2. University of South Florida, Tampa, Florida*

Purpose: Responding to the need to address oral health disparities in older ethnic minorities, the present study explored predictors of dental care utilization and unmet dental needs in older Korean Americans. Drawing on Andersen's behavioral health model, we examined the predictive roles of predisposing (age, gender, marital status, education, and chronic medical conditions), enabling (dental insurance, acculturation, and family network), and need (self-rated oral health) variables. Methods: Using the data from 209 Korean Americans (aged ≥ 60) surveyed in Central Texas in 2013, multivariate regression models were estimated. Results: Dental care services were more likely to be used by individuals with strong family networks and fair/poor self-ratings of oral health. The likelihood of having unmet dental needs increased when participants had a lower education, no dental insurance, lower levels of acculturation, more limited family networks, fair/poor self-ratings of oral health, and fewer dental care visits. Implications: Findings suggest the vulnerability of older ethnic minorities who are culturally and linguistically isolated and lacking family resources; they highlight the importance of incorporating social and cultural factors in intervention efforts to bridge the gap between dental care needs and services.

PERCEIVED NEIGHBORHOOD AND MENTAL HEALTH IN OLDER KOREAN AMERICANS: THE INTERACTIVE ROLE OF HEALTH AND FUNCTION

N. Park[1], Y. Jang[2], B. Lee[1], D.A. Chiriboga[1], *1. University of South Florida, Tampa, Florida, 2. The University of Texas at Austin, Austin, Texas*

Purpose: Drawing on person-environment theories, the purposes of the present study were: (1) to examine how individuals' perceptions of their neighborhood (including perceived ethnic density, safety, social cohesion, and satisfaction) are associated with depressive symptoms among older Korean Americans; and (2) to further explore whether health and function (e.g., chronic medical conditions and functional disability) modify the association between the neighborhood perceptions and depressive symptoms. Method: Data were drawn from 420 older Korean Americans surveyed in the New York metropolitan area in 2010. In regression models, four sets of independent variables were sequentially entered: (1) demographics, (2) health and function, (3) perceived neighborhoods, and (4) interactions between perceived neighborhoods and health/function. Results: In the direct effects models, chronic conditions, functional disability, perceived neighborhood safety, and satisfaction with neighborhood were found to be significant predictors of depressive symptoms. In addition, significant interactions were found between chronic conditions and social cohesion (b=–.64, p< .05) and between functional disability and safety (b=.27, p< .05). That is, the beneficial effects of perceived social cohesion on depressive symptoms were greater for those with more chronic conditions while neighborhood safety had favorable effects for those with less functional disabilities. Implications: Consistent with the premises of person-environment theories, the study demonstrated that neighborhood perceptions affected depressive symptoms both directly and interactively (conditional on individual health conditions). It is noteworthy that the influence of neighborhood characteristics on individual mental health varied according to health conditions, a variation that should be considered in working with older minority immigrants.

UTILIZATION OF HEALTH CARE SERVICES AMONG OLDER ADULTS IN GHANA

Y. Kodwo-Nyameazea, J. Chaumba, *Social Work, University of North Carolina at Pembroke, Pembroke, North Carolina*

Health-seeking behavior studies have found that many older adult Ghanaians delay or do not seek health care services for their health symptoms. Self-rated health studies show that many of them experience poor health and functional disability. Morbidity data also indicate a high incidence of ill health among them. Currently numbered about one million, older adult Ghanaians are expected to increase to almost six million by 2050. Their health situation may be compounded by their increasing numbers, hence the importance of understanding their utilization of health care services. This study examined the factors that mitigate health care usage among older adults in Ghana. The study sample was drawn from the second wave of the Ghana national survey conducted as part of the World Health Organization's SAGE Project. The inclusion criteria for the study yielded an analytic sample of 3947. The analysis showed that older adults who have positive perception of their overall health status, reside in rural areas, and are members of Indigenous religion are less likely to use health care services. It also showed that the risk to health care affordability for older adults comes not from the size of their income, but from their exposure to income irregularity, high household debt, high number of dependents, and lack of health insurance. The projected increase in the Ghanaian older adult population underscores the importance of identifying those who are not using health care services when needed, and designing effective strategies and programs to better serve them.

THE GROWING BURDEN OF CHRONIC DISEASE AMONG OLDER GHANAIANS

L. Best, *Pan-African Studies & Sociology, University of Louisville, Louisville, Kentucky*

Ghana is currently experiencing shifts in the age structure of its population. Because of considerable gains in life expectancy, Ghana has one of the highest proportions of people over the age 60 in Sub-Saharan Africa. With this growing subgroup comes rising concerns regarding chronic health conditions and subsequent care. Using the Wave 1 (2007-2010) of the World Health Organization's Study on Global AGEing and Adult Health (SAGE), this paper examines the physical chronic health conditions of respondents age 50 and older. Specifically, chronic health conditions examined in the study include diabetes, hypertension, and heart disease. After initially examining descriptive statistics for these conditions, logistic regression analyses are utilized to assess whether socio-demography characteristics can account for possible differences in conditions, particularly as it relates to gender differences. Preliminary findings show that women are more likely to report health conditions, controlling for social factors. Findings suggest that women, particularly in rural areas, may be particularly vulnerable to chronic ailments.

SESSION 2270 (PAPER)

TECHNOLOGY AND AGING III

A SPATIAL ANALYSIS OF SOCIALLY AND MEDICALLY VULNERABLE POPULATIONS OF OLDER ADULTS IN SOUTH FLORIDA

E. Hames[1,2], S. Tewary[1,2], J. Stoler[3,4], C. Emrich[5,6], N. Pandya[1,2], G. Gannotta[7], *1. Department of Geriatrics, Nova Southeastern University College Of Osteopathic Medicine, Ft. Lauderdale, Florida, 2. Geriatrics Education Center, Nova Southeastern University, Ft. Lauderdale, Florida, 3. Department of Geography and Regional Studies, University of MIami, Coral Gables, FL, Florida, 4. Dept of Public Health Sciences, Miller School of Medicine, Miami, Florida, 5. Department of Geography, University of South Carolina, Columbia, South Carolina, 6. Hazards and Vulnerability Research Institute, University of South Carolina, Columbia, South Carolina, 7. Senior Intervention and Education Program (SIEP), Fort Lauderdale, Florida*

Background Older adults age 65 and above are one of the fastest growing populations in the United States. Florida contains the highest state-level percentage of older adults 65 and above (17.3%) and 85 and above (2.3%). The process of defining socially and medically vulnerable populations of any age group is complex and without consensus. Studies targeting these issues in older adults are few in number and rely heavily on self-reported data, and there is limited information on socially and medically vulnerable older adults in the tri-county area of Miami-Dade, Broward, and Palm Beach Counties. In this work, we define, map, and analyze social and medical vulnerability for older adults using spatial analytic techniques. Methods We focus on the tri-county region of Miami-Dade, Broward, and Palm Beach counties at the census tract level and utilize a large set of variables identified as specific indicators of social and medical vulnerability and originally obtained from the US Census, Florida Department of Health, HRSA, and Social Security Administration. We employ principal components analysis (PCA) to determine which factors drive social and medical vulnerability of this population, and analyze the resulting components using Geographic Information Systems (GIS) and spatial statistics. Results We observe substantial intra-county heterogeneity of socio-medical vulnerability across the study area with some spatial clustering of high-vulnerability census tracts along the inland corridor, and spatial outliers in coastal regions. We also derive key indicators from the PCA related to race, ethnicity, and socioeconomic status, and suggest an alternative vulnerability index that is maximally parsimonious. Conclusions The identification of socially and medically vulnerable populations of older adults is vital for healthcare management planning and emergency preparedness in both the public and private sectors. Analysis of geographic patterns in South Florida can improve understanding of the dynamic spatial organization of healthcare, health care needs, access to care and outcomes, and ultimately serve as an input for health care planning across our aging nation.

SOCIAL INTERACTIONS IN RETIREMENT COMMUNITIES: RESEARCH RESULTS FOR TECHNOLOGY INTERVENTIONS

C.B. Rebola, *School of Industrial Design, Georgia Tech, Atlanta, Georgia*

There are different housing options available for older adults including nursing homes, assisted living facilities, continuing care retirement communities, and naturally occurring retirement communities. Independent living retirement facilities are communities that have been designed for people who are functional and can live independently but who need or want some help, mainly with caring for a home. These communities are a viable and affordable option for the majority of older adults especially considering that by 2030, older adults will represent 20% of the total population, and that by 2050, 50% of older adults who require care will not have children. Yet to date, 2.3% of older adults are housed in independent living retirement facilities that were designed before the population they serve. Social interactions in retirement communities' shared spaces are a key component to preventing social isolation and loneliness among older adults. Given the under- utilization of these spaces, placing technologies to promote utilization of- and socialization in- shared spaces might improve independence and quality of life among older adults. The purpose of this presentation is to describe the design, development, and technology studies conducted for understanding the social interactions of older adults in retirement communities. To understand current use of shared spaces, observational studies were conducted. Moreover, interventions were implemented to evaluate the impact of designed technologies in shared spaces. Results indicate that technology interventions increases the level of traffic 23.2 % and the level of social interaction by 58.1% The technological intervention appears to increase social interaction relative to increased traffic by a factor greater than 2×, and this factor may not depend highly on pre-existing social activities. Furthermore, by providing technology of potential interest within the common area, the intervention increased use of the common areas. The results motivate the need for improving social interactions among older adults via technology interventions in retirement communities' shared common spaces.

PILOT TESTING AN INNOVATIVE TEACHING TOOL TO IMPROVE DRESSING ASSISTANCE IN NURSING HOMES

P. Tsai[1], C. Beck[1], T. Jakobs[2], M. Rettiganti[1], K. Jordan[3], S. Kitch[1], *1. University of Arkansas for Medical Sciences, Little Rock, Arkansas, 2. InvoTek, Inc., Alma, Arkansas, 3. University of Central Arkansas, Conway, Arkansas*

This pilot study tested the initial effect of an innovative technology intervention on caregivers' level of assistance (LoA) in dressing and demented patients' dressing independence. Nine dyads, assigned to either the experimental or control arms, completed the study. Both arms received a traditional one-hour education module conducted by a research assistant. The experimental arm received an additional two-hour intervention using a newly developed video simulator on a tablet computer that enabled Certified Nursing Assistants (CNAs) to practice their LoA skills. Major outcomes—CNAs' scores on appropriateness of performing dressing LoA and residents' scores on Beck Dressing Performance Scale (BDPS)—were measured before the intervention and 6 weeks after the intervention. The results showed that the two arms were not significantly different in either appropriateness of dressing LoA or BDPS (p=.25-.36). Detailed analysis showed that a lack of effort to assist and low statistical powers might explain the insignificant finding. The observed effect sizes of the experimental intervention in appropriateness of dressing LoA and BDPS were .51 and .89, respectively. Future studies should verify CNAs achieve a specific skill level and knowledge after training, and consider incorporating a strategy to improve CNAs' intention to change behavior. In addition, the training program should consider the timing of training to achieve maximum effect.

INFORMAL CAREGIVERS' WILLINGNESS TO PAY FOR TECHNOLOGY TO SUPPORT CAREGIVING

R. Schulz[1], S. Beach[1], J.T. Matthews[1], K.L. Courtney[2], A. DeVito Dabbs[1], *1. U. of Pittsburgh, Pittsburgh, Pennsylvania, 2. U. of Victoria, Victoria, British Columbia, Canada*

We report the results of a study designed to assess whether and how much family caregivers are willing to pay for kitchen and personal care technologies designed to monitor and/or provide assistance to their care recipients. A national web panel of 512 adults caring for a parent (79%), spouse (10%), or other relative (11%) participated in the survey. The primary health problems of the care recipients included Alzheimer's disease (23%), diabetes (13%), heart disease (13%), cancer (10%), arthritis (10%), and stroke (9%). Survey topics included current use of technology for caregiving, general technology use, general technology attitudes, and general acceptance and willingness to pay for technology systems under development to help monitor and/or provide assistance with kitchen tasks and personal care tasks. Caregivers were willing to pay a median of $50 per month out-of-pocket for kitchen and personal care technologies. Only 17-22% are not willing to pay anything. Multivariate models showed that those providing more hours of care per week, those with more positive attitudes toward technology in general, and those who use more technology were willing to pay more for kitchen monitoring and help systems. Individuals caring for persons with Alzheimer's disease were willing to pay significantly more than individuals caring for persons with other conditions, even when controlling for hours of care provided. About two-thirds of caregivers believe that the government should pay at least half of the cost of these technologies.

A FEASIBILITY ASSESSMENT OF AN ELECTRONIC EXPERIENCE SAMPLING TOOL FOR USE WITH OLDER ADULTS

E.W. Hagood, T.L. Gruenewald, M.R. Grossman, D. Wang, R. Rashad, K.R. Rusli, S. Kariyawasam, N. Marcione, *University of Southern California, Los Angeles, California*

The feasibility of using electronic devices for surveying the daily experiences of older individuals is an important methodological question for gerontologists seeking to use experience sampling methodologies. The current data derive from a pilot study intended to assess the feasibility of using electronic tablet devices to measure daily generative activities, affect, and cognition among a group of older adults. The present sample (n = 36) was 67% female, ranged in age from 54—90, and ranged in educational attainment from 4—20 years. Compliance over the 7-day survey period was high, with an average of 26.1 completed surveys out of 28 total surveys (4 surveys per day). Regression models examining sociodemographic predictors of compliance indicated that survey completion rates were not significantly associated with age, gender, or education, suggesting that the use of electronic tablets to measure daily experiences may be feasible across such groups. Participant responses on a tablet experience survey indicated a favorable experience in completing the electronic surveys. Responses ranked on a 5-point scale (1=definitely disagree; 5=definitely agree) were as follows: *Surveys were easily understood* (mean=4.64; SD=0.54), *enjoyable* (mean=3.86; SD=1.05), *cognitive tasks were enjoyable* (mean=4.22; SD=0.96), *survey length appropriate* (mean=4.36; SD=0.68), *cognitive task length appropriate* (mean=4.22; SD=0.87), *had concerns about privacy of survey data* (mean=1.44; SD=0.88), *willing to participate in a similar protocol in the future* (mean=4.47; SD=0.94), and *would recommend the study to a friend* (mean=4.06; SD=1.01). Together, these findings suggest that electronic sampling of daily experiences may be viable among sociodemographically diverse older adult populations.

SESSION 2275 (PAPER)

DISABILITY TRANSITIONS AND TRAJECTORIES

DISABILITY TRANSITIONS AND PSYCHOLOGICAL RESILIENCE IN LATER LIFE: LONGITUDINAL EVIDENCE FROM OLDER CHINESE

Y. Yang, *Sociology, University of Utah, Salt Lake City, Utah*

China had more than 109 million people aged 65 or older in 2010 and this number is forecasted to be more than 228 million in 2030 and 333 million in 2050. The ability of older adults to maintain health and independence is clearly of great public health concern. Limited research has explored how positive psychological resources (e.g. locus of control, self-esteem) influence the onset of functional disability in the developed societies. Few studies have examined the reciprocal aspect of this relationship, however. The purpose of this study is to examine the influence of disability transitions on change in psychological resilience across a 6-year observation period. Longitudinal residual change models are estimated using a sample of 4,162 older adults from two waves of the Chinese Longitudinal Healthy Longevity Survey (CLHLS), 2002-2008/9. Results show that transitions in disability statuses are significantly related to change in psychological resilience (measured by a five-item scale), net of baseline resilience, socio-demographic characteristics, family support, and health. More specifically, stable disability statuses in instrumental activities of daily living (IADL) items and activities of daily living (ADL) items have the effect of decreasing resilience scores by the follow-up, although only the former is statistically significant. The onset of disability in both IADL and ADL items has stronger effects on decrement in resilience scores than the stable disability statuses and the influence of each is statistically significant. In contrast, recovery from IADL disability has the effect of increasing resilience scores although the effect does not reach statistical significance.

DISABILITY TRAJECTORIES AT THE END OF LIFE: A ‘COUNTDOWN’ MODEL

D. Wolf[1], V.A. Freedman[2], J. Ondrich[1], C.L. Seplaki[3], B. Spillman[4], *1. Aging Studies Institute, Syracuse, New York, 2. University of Michigan, Ann Arbor, Michigan, 3. University of Rochester, Rochester, New York, 4. Urban Institute, Washington DC, District of Columbia*

Objectives Studies of late-life disablement typically address the role of advancing age as a factor in becoming disabled, and in some cases have pointed out the importance of time to death in explaining changes in functioning. However, few studies have addressed both of these dynamics simultaneously, and none have dealt satisfactorily with the problem of missing data on time to death in panel studies. Methods We model remaining lifetime and use it to impute time to death among right censored observations in the Health and Retirement Survey, a prominent panel study of late life functioning. We fit latent-class trajectory models of disablement using the imputed data, and employ multiple-imputation techniques to obtain final parameter estimates and standard errors. Results Our best-fitting model has three latent trajectory classes. In each class the probability of having a disability increases with age; however, the three classes reveal three different patterns of dependence on time to death. Discussion The model reveals a complex pattern of age- and time-dependent heterogeneity in late-life disablement. The techniques developed here could be applied to other phenomena known to depend on time to death, such as cognitive change, weight loss, and health care spending.

TEMPORAL TRENDS FROM 1991-2010 IN SURVIVAL AMONGST DISABLED AND NON-DISABLED SWEDES AGED 81-99

S. Angleman[1,3], G. Santoni[1], E. von Strauss[1,2], L. Fratiglioni[1,3], *1. Aging Research Center, Department of Neurobiology, Care Sciences and Society, Karolinska Institutet and Stockholm University, Stockholm, Sweden, 2. The Non-profit Foundation for the Red Cross Hospital and Red Cross University College in Sweden, Stockholm, Sweden, 3. Stockholm Gerontology Research Center, Stockholm, Sweden*

Objective: To estimate temporal trends in survival amongst older Swedish adults with and without Activities of Daily Living (ADL) disability from 1991-2010. Methods: Older adults aged 81-99 (from two population-based longitudinal studies, consecutively carried out in Stockholm, Sweden: the Kungsholmen Project and the Swedish National study of Aging and Care in Kungsholmen) were assessed on seven different occasions, with varying sample sizes (average 646, range 212-1096). ADL disability was defined as difficulty in one or more of dressing, bathing, eating, transfer, or toileting. Estimates of three-year mortality and corresponding temporal tests for trend were derived from logistic regression models stratified by ADL status. Median time lived with and without incident disability was estimated using Laplace regression. All analyses were age-stratified and sex-adjusted. Results: The proportion of non-disabled persons dying within three years decreased significantly from 1991-2010, and median survival time in those without incident disability during 2001-2007 was 1.3 years longer than for those without incident disability during 1991-96, for the two younger age groups (81-84 and 87) and was steady but suggestive of an increase for those aged 90-99. In contrast, the proportion of disabled persons dying within three years remained stable and high, and survival times after the onset of ADL disability during 1991-96 were unchanged for those with onset during 2001-2007. Interpretation: Mortality remained steady among disabled persons but decreased during this period amongst persons without disability, suggesting that increased life expectancy in the last decades may be driven by the longer lives of functionally independent people.

LONGITUDINAL ASSOCIATIONS BETWEEN PHYSICAL AND COGNITIVE FUNCTION AMONG COMMUNITY-DWELLING OLDER ADULTS

M. Tolea[1], J.C. Morris[2], J. Galvin[1], *1. New York University, New York, New York, 2. Washington University, St. Louis, Missouri*

Background: Although there is strong empirical evidence for a link between cognitive and physical functionality, their longitudinal association is less clear. The goal of this study was to assess the directionality of this association by comparing rates of decline in physical and cognitive function across groups defined by presence of cognitive and/or functional impairment at baseline. Methods: A sample of 766 participants (total of 3,090 observations) in cognitive and aging studies at the Knight Alzheimer’s Disease Research Center at Washington University in St. Louis were categorized into cognitively and functionally normal (n=218); functionally impaired but cognitively normal (n=170); cognitively impaired but functionally normal (n=158); and cognitively and functionally impaired (n=220) and compared on rates of functional (PPT score) and cognitive (global, memory, speed, executive function, and language) decline over a period of up to 8 years. Results: Rates of decline reached 20% for PPT and varied across cognitive tests. Decline in PPT score was better predicted by baseline impairment in cognition (slope=-1.24, $p<0.001$), with baseline functional impairment not contributing to further decline in functionality (slope=-0.27, p=0.240). In turn, baseline functional impairment was only marginally associated with rate of cognitive decline. Conclusion: The cognitive-functional association is likely to operate in the direction of cognitive impairment to functional decline although functional impairment may also play a role in cognitive decline/dementia. Interventions to prevent further functional decline and development of disability and complete dependence may benefit if targeted to individuals with cognitive impairment who are at increased risk.

MAKING THE TRANSITION: INFLUENCE OF SELF-REPORTED WORK DISABILITY ON LABOR FORCE CAREERS

M. Stone, J. Kelley-Moore, *Case Western Reserve University, Cleveland, Ohio*

This paper examines the relative importance of self-identified work disability, personal resources, and health and employer characteristics on labor force careers. Using five waves (10 years) of the Health and Retirement Study, a nationally-representative panel study of adults ages 50 and older, I accomplish three aims: Aim 1: Construct labor force careers for workers ages 50 to full retirement age and develop a typology of the patterns of labor force transitions. Aim 2: Estimate the likelihood of specific labor force transitions based on degree of self-identified work disability, net of employer characteristics (e.g., work accommodation), personal resources (e.g., employer-based pension) and health (chronic conditions). Aim 3: Determine if the likelihood of applying for SSDI is associated with self-identified work disability, net of current labor force status, recent labor force transitions, personal resources, health, and employer characteristics.

SESSION 2280 (SYMPOSIUM)

INTERDISCIPLINARY MODELS OF GERIATRIC PRIMARY CARE

Chair: T. Cortes, *Hartford Institute for Geriatric Nursing, NYU College of Nursing, New York, New York*
Discussant: C. Blaum, *New York University School of Medicine, Division of Geriatric Medicine and Palliative Care, New York, New York*

As the prevalence of older adults with multiple chronic conditions increases, so does the need to provide integrated and coordinated healthcare through interprofessional models of training. The development of an interprofessional workforce, particularly one focused on primary care, is to provide better care, produce better outcomes and reduce costs requires. These changes require systematic integration of interprofessional competencies in education and practice settings. Realigning care providers who support much-needed modification of standard practice to enhance integrated coordinated care requires the adaptation of interprofessional practice into the core of education. This symposium will highlight different models which educate interprofessional teams in practice and educational settings. One session will present an example of care coordination of chronic disease management, which focuses on reducing the use of acute care services by empowering community-based patients through self-management education. Another session will present an initiative to promote interprofessional collaboration, among nurse practitioners, social workers, and pharmacists, together with students from each profession, involving analyzing and modifying complex medication regimens for older adults. A third session will describe an innovative HRSA-funded Post Master's Certificate Program to increase the capacity of advanced practice nurses to provide interprofessional primary care to older adults with multiple chronic conditions. A final session will discuss Center for Medicare and Medicaid Services-funded interdisciplinary hospital initiative for clinical training education of Advanced Practice Registered Nurses, with a focus on increasing services to rural and medically underserved areas.

THE COLLABORATIVE, CONTINUOUS CARE (3C'S) MODEL FOR PRIMARY CARE

M. Giuliante, T. Cortes, *Hartford Institute for Geriatric Nursing, New York University, College of Nursing, New York, New York*

Implemented in Fall 2013 as part of a three year HRSA-funded initiative, The Collaborative, Coordinated, Continuous Care (3Cs) Model maximizes the potential of the primary health care team by implementing a geriatric-care based interprofessional model led by advanced practice nurses in community-based health care setting. This education/practice collaborative brings together students and practitioners from advanced practice nursing, pharmacy and social work to work with frail home bound older adults who are dually eligible and have complex medication regimens. The 3Cs model enhances collaboration and coordination in the care of frail homebound older adults through deliberate communication. Among the outcomes being measured are reduction in medication complexity, use of acute care services by the patients, and the professionals' perceptions of the effectiveness of the interprofessional team among health professionals. In this presentation, we will discuss the first year findings.

INNOVATIVE POST-MASTER'S CERTIFICATE APN GERIATRICS PROGRAM IN INTERPROFESSIONAL PRIMARY CARE

S.A. Greenberg, *New York University, College of Nursing, New York, New York*

As the population ages and the prevalence of those living with multiple chronic conditions increases, there is a crucial need for accessible, coordinated, and collaborative primary care for older adults. In particular, there is a need for adult advanced practice nurses to have evidence-based knowledge and skills in the interdisciplinary team management of community-dwelling older adults. This presentation will discuss an innovative post-master's certificate program for adult nurse practitioners needing gerontological didactic and clinical content in caring for older adults in collaboration with an interprofessional team. This replicable program includes shared learning with primary care medical residents, strategies involving the New York University Teaching, Technology, Teamwork curriculum, didactic, online learning modules/resources, and simulation-based interprofessional curriculum. This HRSA-funded initiative expects to increase the number of adult nurse practitioners with the gerontological competencies to provide comprehensive primary care to vulnerable, underserved older adults with multiple chronic conditions.

CLINICAL EDUCATION ACROSS THE CONTINUUM: CMS GRADUATE NURSE EDUCATION DEMONSTRATION PROJECT

M. Brewer, *Scottsdale Healthcare, Scottsdale, Arizona*

The Center for Medicare and Medicaid Services awarded a Graduate Nurse Education (GNE) Demonstration Project to five hospitals in July 2012: Hospital of the University of Pennsylvania, Duke University Hospital, Memorial Hermann-Texas Medical Center Hospital, Rush University Medical Center, and Scottsdale Healthcare. This four-year Project provides funding for clinical training education of Advanced Practice Registered Nurses (APRNs), and will increase the supply of APRNs to provide health care to the growing number of Medicare beneficiaries in a complex health care delivery system. In Arizona, the population over age 65 is increasing rapidly, and represents over 40% of hospital admissions. Arizona's GNE Project includes interprofessional clinical training education for primary and chronic care management across the care continuum with a focus on rural and medically underserved areas. Outcomes after completion of two years of the Project include development of effective APRN clinical training models, innovative partnerships, and increased numbers of graduates.

CHRONIC DISEASE MANAGEMENT FOR OLDER DUALLY ELIGIBLE ADULTS: COACH INITIATIVE

T. Smith[2], T. Cortes[1], B. Paris[2], A. Zagorin[2], S. Saviolis[2], Y. Bazile[1], *1. Hartford Institute for Geriatric Nursing, New York University, College of Nursing, New York, New York, 2. Maimonides Medical Center, Brooklyn, New York*

The Patient Protection and Affordable Care Act of 2010 (ACA) has presented an opportunity for states to realign their policies for the care of dual eligibles and placed an emphasis on coordinating and improving their care. The goal of this project is to reduce the use of acute care services by older adults through a primary care practice with an RN trained in Stanford Chronic Disease Self-Management Program. This initiative will analyze the use of Medicare dollars and Medicaid dollars in managed care models mandated for duals and define the role of care co-ordination for older adults with multiple chronic conditions. This proposal represents a partnership between a provider, Maimonides Medical Center, a payor, Healthfirst and the Hartford Institute for Geriatric Nursing.

SESSION 2285 (SYMPOSIUM)

TOWARDS THE UNDERSTANDING OF SARCOPENIA: RISK FACTORS AND ASSOCIATION WITH COMMON DISEASES

Chair: K. Norman, *Charite Research Group on Geriatrics Charite Universitätsmedizin Berlin, Berlin, Germany*
Co-Chair: I. Demuth, *Charite Research Group on Geriatrics Charite Universitätsmedizin Berlin, Berlin, Germany*
Discussant: E. Steinhagen-Thiessen, *Charite Research Group on Geriatrics Charite Universitätsmedizin Berlin, Berlin, Germany*

In the past 25 years, aging research has focused on body composition and muscle mass in particular. Sarcopenia, the age related loss of muscle mass and strength is associated with e.g. impaired physical performance and increased risk of falls. Moreover, reduced muscle mass is related to metabolic disorders including insulin resistance, rendering older adults more vulnerable to the development of diabetes or metabolic syndrome. While the etiology of sarcopenia is considered multifactorial, diagnosis, definition and classification have been the focus of ongoing debate. This symposium will start with three presentations highlighting first results from the Berlin Aging Study II (BASE-II). Meyer and colleagues have studied the relationship between telomere length as potential marker of sarcopenia and reduced appendicular muscle mass in older BASE-II participants. The link between vitamin D insufficiency and muscle mass as well as the association between vitamin D insufficiency and impaired physical performance are the topic of the second presentation by Spira and colleagues. Buchmann and colleagues have investigated the prevalence of sarcopenia in older adults with type II diabetes and/or metabolic syndrome and will discuss the association between different definitions of sarcopenia and functional and metabolic parameters considering both fat mass and fat mass distribution. The paper by Kiel and colleagues will complete the symposium by presenting results from a meta-analysis of genome wide association studies, furthering the understanding of the genetics of lean body mass. Steinhagen-Thiessen will summarize and discuss these new findings on risk factors of sarcopenia and its association with common diseases.

RELATIVE LEUCOCYTE TELOMERE LENGTH (RLTL) IS NOT A MARKER OF SARCOPENIA: DATA FROM THE BERLIN AGING STUDY (BASE-II)

A. Meyer[1], B. Salewsky[1], E. Steinhagen-Thiessen[1], K. Norman[1], I. Demuth[1,2], *1. Charité Research Group on Geriatrics, Charité-Universitätsmedizin Berlin, Berlin, Germany, 2. Institute of Medical and Human Genetics, Charité-Universitätsmedizin, Berlin, Germany*

The age associated loss of muscle mass and function, sarcopenia, has been recognized as an increasing problem in the aging society. Sarcopenia is a characteristic of frailty and associated with other features of this syndrome, such as physical inactivity, decreased mobility and increased risk of falls. The length of the chromosome ends, the telomeres, has been widely accepted as a biomarker of aging. Here we evaluated the relationship between sarcopenia and rLTL as determined by qPCR from samples of 1,245 BASE-II participants (60-83 years, 48% men, 68.09±3,58 years). As expected, rLTL decreased with age and women had on average shorter telomeres than men, which is in line with the literature on rLTL determined by the method used here. There was no association, however, between rLTL and sarcopenia when analysed in the context of different sarcopenia definitions considering muscle mass alone or including measurements of muscle function and physical capacity.

VITAMIN D AND PARAMETERS OF SARCOPENIA: DATA FROM THE BERLIN AGING STUDY II (BASE-II)

D. Spira[1], A. Meyer[1,2], N. Buchmann[1], I. Demuth[1,2], E. Steinhagen-Thiessen[1], R. Eckardt[1], K. Norman[1], *1. Charité - Universitätsmedizin Berlin; Research Group on Geriatrics, Berlin, Germany, 2. Charité - Universitätsmedizin Berlin; Institute of Medical and Human Genetics, Berlin, Germany*

Vitamin D insufficiency can have negative effects on muscle tissue and might be linked to sarcopenia. In a sample of 1263 participants from the Berlin Aging Study II (BASE-II) aged 60 years or older, we measured levels of 25-hydroxy-vitamin D and assessed appendicular skeletal muscle mass (ASM) with dual-energy X-ray absorptiometry (DEXA). Parameters of relative (ASM/body weight) and absolute (ASM/height squared) muscle mass were derived. Grip strength and the timed "Up and Go" test (TUG) were used as functional parameters. Vitamin D insufficiency, prevalent with 51.4%, was significantly associated with low ASM% (p=0.004) whereas low function was significantly associated with lower serum levels of vitamin D (p=0.018) independent of age and BMI. Low vitamin D levels may be a contributing factor to sarcopenia. With regard to our findings relative and absolute muscle mass need to be differentiated and muscle function should be considered irrespective of muscle mass.

SARCOPENIA IN DIABETES AND METABOLIC SYNDROME – DATA FROM THE BERLIN AGING STUDY (BASE-II)

N. Buchmann[1], D. Spira[1], J. Nikolov[1], I. Demuth[1,2], E. Steinhagen-Thiessen[1], R. Eckardt[1], K. Norman[1], *1. Research Group an geriatrics, 13347 Berlin, Germany, 2. Institute of Medical and Human Genetics, Charité-Universitätsmedizin, Berlin, 13347, Germany*

Earlier studies have suggested that type 2 Diabetes (T2D) and metabolic syndrome (MetS) are associated with reduced muscle mass or impaired physical function. We analyzed the relationship between T2D, MetS, muscle mass and self-reported mobility in 1043 community-dwelling old subjects (53% female; mean age 68.2 ±3.6 years). The prevalence of T2D was 13%, whereas 19.1% had MetS; sarcopenia was identified in 26.6% of the participants, using the conventional approach with reduced appendicular muscle mass/height2. Since absolute appendicular skeletal mass was significantly higher in subjects with T2D ($p<0.001$) or MetS ($p<0.001$), the prevalence of sarcopenia was lower in these participants ($p = 0.035$). However, muscle mass corrected for weight or various fat measures was significantly decreased in participants with MetS or T2D, who also reported a higher degree of limited mobility. Therefore, adjustment of muscle mass for fat mass seems necessary in order to identify sarcopenia in subjects with metabolic disorders.

DISCOVERY AND REPLICATION OF SEVERAL LOCI SIGNIFICANTLY ASSOCIATED WITH LEAN BODY MASS:A LARGE META-ANALYSIS OF GENOME WIDE ASSOCIATION STUDIES FROM THE CHARGE AND GEFOS CONSORTIA

D.P. Kiel[1,4], L. Yerges-Armstrong[2], Y. Hsu[1,4], D. Karasik[1,5], T. Harris[6], C. Ohlsson[7], S. Demissie[8], M. Zillikens[3], *1. Institute for Aging Research & Harvard Medical School, Hebrew SeniorLife, Boston, Massachusetts, 2. University of Maryland School of Medicine, Baltimore, Maryland, 3. Erasmus MC, Rotterdam, Netherlands, 4. Harvard Medical School, Boston, Massachusetts, 5. Bar-Ilan University, Safed, Israel, 6. National Institute on Aging, Bethesda, Maryland, 7. Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden, 8. Boston University School of Public Health, Boston, Massachusetts*

Genetic determinants of lean body mass are not known. We performed a meta-analysis of GWAS for total body (TBLM) (n=38,292) and appendicular lean mass (ALM) (n=28,330) adjusted for fat mass measured using DXA or bioelectrical impedance analysis. Replication was carried out in 62,880 (46,632 European ancestry) subjects for TBLM and in 44,495 (41,765 European ancestry) subjects for ALM. In Europeans, for TBLM, 5 of 13 genome wide significant (P<5x10-8) or suggestive (P<2.3x10-6) SNPs in five genes (IRS1, HSD17B11, VCAN, ADAMTSL3, and FTO) and for ALM, 3 of 8 SNPs in three genes (ADAMTSL3, IRS1, VCAN) significantly replicated. The FTO locus is known to associate with lean mass while IRS1, HSD17B11, VCAN, and ADAMTSL3 are novel findings. Some non-coding variants had potential functional roles in myoblast cells lines. One locus contained a variant expressed less in old versus young muscle. Our findings provide new insight into the genetics of lean mass.

SESSION 2290 (PAPER)

LONG TERM CARE I

WHAT MAKES A NURSING HOME A HOME? INSIGHTS FROM FAMILY MEMBERS

L.E. Weeks[1], J. Keefe[2], R. Stadnyk[3], *1. Applied Human Sciences, University of Prince Edward Island, Charlottetown, Prince Edward Island, Canada, 2. Mount Saint Vincent University, Halifax, Nova Scotia, Canada, 3. Dalhousie University, Halifax, Nova Scotia, Canada*

Identifying factors that enhance the quality of life for older adults living in nursing homes can contribute to transforming health care institutions into person-centered homes offering long-term care services. One component of a federally funded project based in Nova Scotia, Canada, focused on the quality of life in nursing homes from the perspective of the family members of the residents. A total of 397 family members completed a survey containing both open and closed-ended questions focusing on their perspectives on quality of life indicators in a nursing home environment. In addition, family members also participated in focus groups. Multiple regression analysis resulted in the identification of several factors that have a significant influence on the quality of life of nursing home residents, including that a perception of more homelikeness is related to higher resident quality of life. Focus group results provided further insights into how family members of residents felt that homelikeness can be fostered, including focusing on the physical environment (i.e. safety and security, outdoor spaces, privacy, natural light) and care provided (i.e. personalization of care, options for food and scheduling of daily activities). Upon the conclusion of the presentation, attendees will be able to identify key elements in supporting homelikeness and implications of these findings for practice within nursing home settings. Our results are relevant to planners and administrators of nursing homes in other jurisdictions who are facing challenges associated with meeting the care needs of an aging population within various environmental, financial and staffing constraints.

CHOOSING A LIVING ENVIRONMENT FOR A RELATIVE WITH DEMENTIA: VALIDATION OF A CAREGIVER DECISION-AID

M. Couture[1,2], F. Ducharme[2], *1. Centre for Research and Expertise in Social Gerontology (CREGÉS), CSSS Cavendish, Montreal, Quebec, Canada, 2. Institut universitaire de gériatrie de Montréal, Montréal, Quebec, Canada*

Many family caregivers report a lack of support from health care professionals when choosing a living environment for their relative with dementia. To further support a partnership approach between health care professionals and caregivers, we developed a tool entitled “Decision-Aid for Caregivers: Choosing a Living Environment for a Relative with Dementia (DAC-CLERD)” based on a systematic review of the literature on the decision making process of caregivers. The objective of this study was to validate the content of the decision-aid by assessing whether the chosen format, items and instructions were clear and acceptable and if the designated themes were relevant. Using open ended-questions, eight caregivers who placed their relative in a long term care institution in the past year and seven case managers having experience in supporting caregivers were interviewed. Qualitative data was analysed using Miles and Huberman’s approach. Results showed that participants (caregivers and health care professionals) appreciated the open and partnership format of the tool to stimulate dialogue. The initial version of the tool was judged easy to understand and relevant but participants made suggestions to refine questions and to add new themes to explore with caregivers such as their future role in the new living environment. To have time to reflect on the situation, participants proposed that caregivers receive the decision-aid before a scheduled meeting with the health care professional. The content validation process demonstrated that the items comprised in the decision aid as well as the partnership approach were coherent with the reality of potential users.

MEDICARE & MEDICAID EXPENDITURES PRECEDING AND FOLLOWING ENTRY INTO CALIFORNIA’S HCBS PROGRAMS

R. Newcomer, M. Ko, C. Harrington, D. Hulett, P. Chu, T. Kang, A. Bindman, *University of California, San Francisco, California*

Aims: The study examined what acute and post-acute use and expenditures are associated with the initiation of home and community based services (HCBS) for Medicare and Medicaid eligible (MME) beneficiaries, and does initiation of HCBS impact subsequent acute and post-acute events and expenditures? Methods: California Medicaid and Medicare claims are used to track recipient-specific service use for adult beneficiaries (n=62,614) who initiated HCBS in either 2006 or 2007 and who had not received HCBS in the previous year. Children, adults with developmental disabilities, and those in managed care were excluded. Acute, post-acute and HCBS use and costs were aggregated for the 12 months prior and following HCBS entry. Findings: HCBS was often initiated following a rapid increase in mean monthly expenditures for acute and post-acute care services. Total Medicare and Medicaid expenditures rose from a monthly mean of $4,000 three months prior to HCBS initiation to $6,000 at entry. Following HCBS initiation there was an equally steep decline in mean monthly total health care expenditures. These typically more than offset the mean monthly HCBS expenditures, but expenditures generally returned only to rates that prevailed three months prior to HCBS entry rather than those from earlier in the pre-entry period. Implications: The relatively high use of emergency department and hospital services, preceding and following HCBS entry suggests the need to systematically evaluate the needs of MMEs who are at higher risk for HCBS services in order to prevent avoidable health care use.

ORGANIZATIONAL CONTEXT FACTORS AND RESEARCH UTILIZATION IN GERMAN NURSING HOMES: PSYCHOMETRIC TESTING OF THREE TRANSLATED RESEARCH TOOLS

M. Hoben[1,2,3], C.A. Estabrooks[3], J. Squires[4,5], A. Kruse[6], J. Behrens[2], *1. Network Aging Research (NAR), University of Heidelberg, Heidelberg, Baden-Württemberg, Germany, 2. Institute of Health and Nursing Sciences, Medical Faculty, Martin-Luther-University Halle-Wittenberg, Halle (Saale), Saxony-Anhalt, Germany, 3. Knowledge Utilization Studies Program (KUSP), Faculty of Nursing, University of Alberta, Edmonton, Alberta, Canada, 4. School of Nursing, Faculty of Health Sciences, University of Ottawa, Ottawa, Ontario, Canada, 5. Clinical Epidemiology Program, Ottawa Hospital Research Institute, Ottawa, Ontario, Canada, 6. Institute of Gerontology, Faculty of Behavioural and Cultural Studies, University of Heidelberg, Heidelberg, Baden-Württemberg, Germany*

We lack appropriate research tools in German to study the crucial role of organizational context factors and their association with research use (RU) in German nursing homes (NHs). We thus translated three well-tested Canadian tools and assessed their psychometric properties: the Alberta Context Tool (ACT), Estabrooks' Kinds of RU items, and the Conceptual Research Utilization (CRU) scale. This presentation reports on the methods and results of the psychometric testing. Responses of 273 care aides, 196 registered nurses, 152 allied health providers, 6 clinical specialists, 129 managers and 65 nursing students from 38 German NHs were included. Confirmatory factor analyses (CFAs) confirmed the seven-factor structure of the scaled ACT items and the one-factor structure of the CRU scale. However, our results indicate a six-factor structure of the count-based ACT items rather than the three-factor structure suggested by the Canadian CFA. Reliability scores based on the CFA parameters were >0.7 in all provider groups for 9 of the 13 ACT concepts, and ranged between 0.90 and 0.96 for the CRU scale. Multiple-group CFAs suggested partial strong measurement invariance of the ACT, and partial strict measurement invariance of the CRU scale. Six structural equation models, acceptably fitting the data, revealed significant associations of various ACT concepts with RU. However, some of these associations were unexpectedly negative. Overall, the three translated tools demonstrated acceptable factorial validity, reliability and measurement invariance. More research is needed to understand the reasons for the negative associations between some ACT concepts and RU.

THE EFFECT OF SWALLOWING TRAINING PROGRAM FOR NURSING HOME RESIDENTS WITH STROKE

H. Bang, *College of Nursing, Seoul National University, Seoul, Seoul, Republic of Korea*

Background: Aging, neurologic disorders, functional status and medication are factors affecting the high prevalence of dysphagia in nursing homes. Indirect swallowing therapies such as oromotor exercise and swallowing maneuvers can be administered safely by nurses. An applicable training program for swallowing can improve swallowing capacity and nutritional status. Aim: The aim of this study was to develop a training program for swallowing and to test its effect on swallowing capacity and nutritional status in stroke residents at risk for dysphagia. Methods: A literature review, content validation by experts and pilot test were done to construct a swallowing training program. A quasi experimental pretest and posttest design was used to evaluate the effectiveness of the developed program. One institution in an urban area was selected. The subjects in the experimental group (n=16) received 30 minutes of swallowing training 3 days per week for 8 weeks Results: The swallowing training program consisted of oromotor exercise, expiratory muscle strength exercise and effortful swallow. The average age of the subjects was 77.2 years. The swallowing capacity measured by dysphagia risk and swallowing symptoms improved significantly. Tongue pressure increased significantly (p=.003). The changes in nutritional status were not significant. Conclusion: A swallowing training program was developed and its effectiveness was demonstrated. More studies are needed to identify its effect on nutritional status. It is recommended that nurses conduct a swallowing training program in long term care facilities, especially for stroke residents, to manage and prevent dysphagia and its complications.

SESSION 2295 (SYMPOSIUM)

THE AGING AND DISABILITY RESOURCE CENTER PROGRAM: RESULTS OF NATIONAL PROCESS AND OUTCOME EVALUATIONS

Chair: R.M. Bertrand, *Health Policy, Abt Associates Inc., Cambridge, Massachusetts*
Co-Chair: T. Barretto, *IMPAQ International LLC, Columbia, Maryland*
Discussant: S. Kunkel, *Scripps Gerontology Center, Miami University, Oxford, Ohio*

The Administration for Community Living (ACL) was created by the U.S. Department of Health and Human Services to serve as the Federal agency responsible for increasing access to community supports, while focusing on the unique needs of older Americans and persons with disabilities. ACL's mission is to promote the independence, well-being, and health of older adults, all persons with disabilities, and their families and caregivers. Aging and Disability Resource Center (ADRC) grants, originally co-funded by the ACL and Centers for Medicare & Medicaid Services, align with ACL's mission by serving as a coordinated, No-Wrong-Door system with access to a full range of long-term supports and services (LTSS). To assess ADRCs' effectiveness in serving as a No-Wrong-Door system and meeting the LTSS needs of the aging and disability populations, the ACL funded the first national evaluation of the ADRC program. In this symposium we will provide an overview of the evolution of the ADRC program and discuss more recent initiatives such as one-on-one options counseling, person-centered care transitions, and other programs that promote No-Wrong-Door access to LTSS. Presenters will discuss the results of the process evaluation based on data collected via a web-based survey administered to all State and Local ADRC directors and a sample of AAA directors from communities without ADRC coverage. The results of the outcome evaluation in which consumer experiences were collected via a telephone survey will also be presented. Results of the national evaluations will be discussed in terms of best practices and lessons learned.

OVERVIEW OF THE ADMINISTRATION FOR COMMUNITY LIVING-FUNDED AGING AND DISABILITY RESOURCE CENTER (ADRC) PROGRAM

S. Jenkins, *Center for Disability and Aging Policy, US Department of Health and Human Services, Administration for Community Living, Washington, District of Columbia*

The mission of the Administration for Community Living (ACL) is to support the long-term needs and well-being of older adults, people with disabilities, their families and caregivers. The Aging and Disability Resource Center (ADRC) program is an ACL initiative, originally co-funded with the Centers for Medicaid & Medicare Services (CMS) and other agencies, to offer a full range of long-term supports and services (LTSS) to people of all ages, disabilities and income levels. Since 2003, 54 out of 56 states and territories have received ADRC grants and currently there are a total of 467 active ADRC systems nationwide, covering about 70% of the US population. ADRCs assist older adults with information and referral, one-on-one options counseling, and person-centered care transitions. ADRC programs also serve as the entry point to publicly administered long-term supports, including those funded under Medicaid, the Older Americans Act, Veterans Health Administration, and state revenue programs.

ACCESS TO LONG-TERM SERVICES AND SUPPORTS: FINDINGS FROM THE NATIONAL PROCESS EVALUATION OF ADRCS

R. Varghese[1], T. Barretto[1], R.M. Bertrand[2], S. Pedersen[1], K.L. Phillips[1], S. Toor[1], S. Jenkins[3], *1. IMPAQ International, LLC, Columbia, Maryland, 2. Health Policy, Abt Associates Inc, Cambridge, Massachusetts, 3. Administration for Community Living, Washington, DC, District of Columbia*

The process evaluation of the Aging and Disability Resource Centers (ADRC) explores the range of long-term care services and supports (LTSS) provided by ADRCs, and whether ADRCs are fulfilling their mission of providing streamlined access. Data were collected via a web-based survey that received response rates of 91% (48 of 53) and 84% (472 of 559) from state- and local-level ADRCs, respectively. Ninety-five percent of ADRCs indicated an improvement in ability to provide integrated, comprehensive LTSS access after receiving an ADRC grant. Seventy-six percent provide options counseling, 68% assist clients with Medicaid LTSS financial eligibility application, and 37% provide care transition services. Nearly 78% view partnerships as the most important factor influencing their ability to provide LTSS access. These findings indicate the extent to which ADRCs provide the full range of LTSS, implement the ADRC mission of streamlined access, and utilize strategies that facilitate effective and efficient LTSS provision.

DO ADRCS MEET CONSUMER'S NEEDS FOR NO-WRONG-DOOR ACCESS TO LONG-TERM SERVICES & SUPPORTS? A NATIONAL EVALUATION

R.M. Bertrand[1], L. Goodman[1], R. Varghese[2], S. Jenkins[3], L. Buatti[1], T. Barretto[2], S. Pedersen[2], *1. Health Policy, Abt Associates Inc., Cambridge, Massachusetts, 2. IMPAQ International, LLC, Columbia, Maryland, 3. Administration for Community Living, Washington, District of Columbia*

A national evaluation was conducted to assess the efficacy of Aging and Disability Resource Centers (ADRCs) as No-Wrong-Door systems. Preliminary analyses of 496 consumers (73.5% older adults) were conducted using data from a survey developed for this project and revised based on cognitive and pilot testing. Results indicate that most consumers contacted ADRCs for personal care assistance (19%), Medicare (16%) and Medicaid (13%) questions. Nearly 80% said that they spoke with a representative on their first call, and found most representatives very knowledgeable about LTSS (75%). Fifty-six percent received services directly. Of those not receiving services directly, 52% reported receiving ADRC referral help; 43% of those said they successfully received services, and 38% reported it was too soon to tell. Results suggest that ADRCs may be achieving their goal of no-wrong-door access. Additional analyses among ADRC consumers compared to consumers in communities not served by an ADRC will be explored.

SESSION 2300 (SYMPOSIUM)

THE NEIGHBORHOOD AND PHYSICAL ACTIVITY IN OLDER PERSONS

Chair: K. Diaz Moore, *University of Kansas, Lawrence, Kansas*
Discussant: W. Satariano, *University of California, Berkeley, California*

With the World Health Organization's creation of the Age-friendly environments program, there have been increased efforts to understand the characteristics of environments to promote healthy and independent lifestyles for older adults. This symposium presents current research from three different countries exploring the role physical characteristics of neighborhood play in physical activity and mobility in older persons. The first presentation focuses on the development of a user-led neighbourhood environmental audit tool for older adults, "Seniors Walkability Audit in Neighbourhoods" (SWAN). The second presentation focuses on almost 600 older adults in Frankfurt, Germany, stratified by age, household composition and neighborhood, their mobility and its impact on neighborhood belonging. The third presentation offers a pilot retrospective analysis of the impact objective measures, such as integration and connectivity, of neighborhood walkability have on sedentary behavior and subsequent biometric (Gluteal circumference, insulin levels), physical performance (e.g. chair rise time, walking speed), and attention measures. The discussants will frame the state of the art in terms of methodology, empirical understandings and theoretical development pertaining to neighborhood, activity and older persons with and without cognitive impairments. Attendees will be able to explain the characteristics of neighborhood likely to impact independent physical activity and how that activity impacts quality of life factors such as sense of belonging.

DEVELOPMENT OF A USER-LED BUILT ENVIRONMENTAL AUDIT TOOL - SENIORS' WALKABILITY AUDIT IN NEIGHBORHOODS (SWAN): ASSESSMENT OF NEIGHBOURHOOD DISTRICTS FOR PHYSICAL ACTIVITY IN OLDER ADULTS

A. Mahmood[1], H. Chaudhury[1], F. Oswald[2], N. Konopik[2], T. Pfeiffer[2], S. Stott[1], *1. Gerontology, Simon Fraser University, Vancouver, British Columbia, Canada, 2. Goethe University, Frankfurt, Germany*

Identification of the barriers and facilitators of physical activity and mobility in the neighbourhood built environment by older adults themselves can assist them to vocalize and advocate their needs. This paper presents the development of a user-led neighbourhood environmental audit tool for older adults, "Seniors Walkability Audit in Neighbourhoods" (SWAN). This tool has been developed to collect objective built environmental data related to mobility, functionality, access and services across five domains: functionality, safety, destinations, aesthetics and social quality. The objectives of the project were: a) to develop a user-led neighbourhood environmental audit tool; b) to pilot test the tool with older adults in three districts in Frankfurt, Germany to assess the tool's usability and relevance; and c) to generate pilot data collected by older adults on micro-environmental features (e.g., width of sidewalk, street lighting, furniture) that are supportive or deterrent in mobility of older adults living in those districts.

BEING OUT AND ABOUT – ON THE RELATIONSHIP BETWEEN OUT-OF-HOME ACTIVITY, OUTDOOR MOBILITY AND NEIGHBORHOOD BELONGING IN THREE URBAN DISTRICTS

R. Kaspar[1,2], F. Oswald[1], *1. Goethe University Frankfurt, Frankfurt, Germany, 2. German Institute for International Educational Research (DIPF), Frankfurt, Germany*

This study assesses the relative importance of two major concepts of Environmental Agency (i.e. activity vs. mobility) for processes of Environmental Belonging. We assume older persons' attachment to their outdoor home environment (i.e. urban-related identity) to be positively related to out-of-home activity and negatively to outdoor mobility, but expect no such inverse pattern with more general neighborhood perceptions (i.e. cohesion, informal control). Data are drawn from a study with 595 community-dwelling elders from three urban districts (Frankfurt, Germany) stratified by age (70-79, 80-89) and household composition (living alone, with partner). We combine survey, mobility diary and GIS-coded map information to estimate individuals' propensities for out-of-home activity and mobility. Multi-Group-SEM consistently shows urban-related identity to be strongly and inversely impacted by mobility (-.59***) and activity (.51***), but also points to diverging patterns of influence on neighborhood perception in different districts. Implications for active aging and aging in place will be highlighted.

NEIGHBORHOOD CHARACTERISTICS PREDICT HEALTH AND COGNITION IN OLDER ADULTS WITH AND WITHOUT AD

A. Watts[1,2], F. Ferdous[1], K. Diaz Moore[1], J.M. Burns[2], *1. Lifespan Institute, University of Kansas, Lawrence, Kansas, 2. KU Alzheimer's Disease Center, Kansas City, Kansas*

Older adults are highly sedentary, thus at risk of disease and cognitive decline. Neighborhood walkability is important for physical activity, but little research has focused on older adults. We evaluated the role of neighborhood walkability on physical activity, cognitive performance, and health biomarkers. We hypothesized that individuals whose neighborhoods were more integrated would engage in more physical activity, have better health and cognitive performance. In 26 older adults with and without mild AD, we evaluated neighborhood walkability using GIS data. Although neighborhood integration did not predict self-reported physical activity, it predicted BMI (β=-.57, p=.04), insulin (β=-.66, p=.04), walking speed (β=-.60, p=.05), chair rise time (β=-.72, p=.01), and attention (β=.64, p=.03). Neighborhood walkability may be an important determinant of physical and cognitive health outcomes. This has implications for design and maintenance of living spaces for older adults and may be helpful in eliminating barriers to physical activity in sedentary older adults.

SESSION 2305 (SYMPOSIUM)

INTEGRATED CARE FOR OLDER ADULTS – THE POLICY LANDSCAPE

Chair: K. Zivin, *Psychiatry, University of Michigan, Ann Arbor, Michigan, Department of Veterans Affairs, Ann Arbor, Michigan*
Discussant: T. Cortes, *Hartford Institute for Geriatric Nursing, New York City, New York*

Federal legislation, including but not limited to the Affordable Care Act, has provided opportunities, guidance, and incentives to improve the overall quality of health care and well-being for older adults. Policy has been focused on person- and family-centered care, including integration of health and social service needs. Policies have an impact not only on the traditional healthcare setting, but are being developed to create a robust community-based healthcare system to promote wellness and maintain function in the increasing number of community dwelling older adults. Policies aim to expand consumer-driven health care, give individuals and their caregivers greater access to their health care information and empower self-management of chronic disease. Policies are also increasingly focusing on care coordination between multiple types of care providers to assure integration of services for holistic care of the aging population. Finally, polices aimed at preventive services need to be incorporated into care plans for older adults. This session led by Health and Aging Policy Fellows will identify several elements essential to the implementation of high-quality, integrated care for older adults. Presenters will address community and long-term care services for older adults, the importance of developing an electronic health information system that can be available to patients and their caregivers, the benefits and challenges for integrating behavioral health services into primary care, and preventive healthcare services for older adults. Presenters will explore differences between policies and identify challenges and opportunities for successful care integration from an interdisciplinary perspective, including geriatrics, nursing, and health services research.

CONNECTIONS AND DISCONNECTIONS IN LONG-TERM SERVICES AND SUPPORTS FOR OLDER ADULTS

H.L. Menne, *Margaret Blenkner Research Institute, Benjamin Rose Institute on Aging, Cleveland, Ohio*

1965 was an important year for federal legislation related to older adults: Medicare and Medicaid were created under the Social Security Act, and the Older Americans Act (OAA) was signed into law. While Medicare and Medicaid were created as health insurance programs, OAA was created to provide a range of community-based programs and services to older adults. In 2014, there are 9 million 'dual eligible' people who receive Medicare and Medicaid, and approximately 59 million Americans eligible for OAA funded services. In Congress there is a great focus on health care reform and spending, but relatively little attention is paid to the OAA services and programs which keep older adults healthy and independent in the community. This session will explore the connections and disconnections between community-based services and programs through the OAA and long-term services and supports through Medicare and Medicaid.

BRIDGING THE DIGITAL DIVIDE: FAMILY CAREGIVERS AND HEALTH INFORMATION TECHNOLOGY

J. Wolff, *JHU/APL, Baltimore, Maryland*

Consumer e-health encompasses electronic technologies that are primarily oriented toward individuals, but that intersect with health information technology that is more conventionally used in health care delivery, such as the electronic health record. By expanding access to personal health information, consumer e-health enables individuals to actively engage in their care, and may benefit chronic disease management, coordination of health information, and health outcomes. However, not all individuals are equipped to manage their health information. Ambiguity in policies to ensure the privacy and security of individual health information and variability in how policies are implemented may restrict information access by family members or trusted friends as desired by individuals. This session will discuss the challenges of implementing an integrated consumer e- health system that enables individuals and designated others to access electronic health information. Potential solutions and benefits of clarifying policies and their implementation will be discussed.

INTEGRATING PREVENTIVE HEALTH CARE FOR OLDER ADULTS INTO PRIMARY CARE SETTINGS

F. Kobylarz, *Rutgers Robert Wood Johnson Medical School, New Brunswick, New Jersey*

The Affordable Care Act established the Medicare Annual Wellness Visit (AWV) to provide personalized preventive plan services in addition to the existing Welcome to Medicare Visit (initial preventive physical exam). Older adults know little about this new benefit and healthcare providers underutilize it. Currently, most care provided to older adults is focused on the treatment of acute and chronic illnesses. The AWV is a comprehensive tool aimed at prevention and or to address existing chronic illnesses. This session will discuss this current policy and highlight the differences between the Welcome to Medicare Visit and the Subsequent Annual Wellness Visit. Challenges and opportunities to implement this policy will be discussed.

INTEGRATING BEHAVIORAL HEALTH CARE FOR OLDER ADULTS INTO PRIMARY CARE SETTINGS

K. Zivin, *1. Psychiatry, University of Michigan, Ann Arbor, Michigan, 2. Department of Veterans Affairs, Ann Arbor, Michigan*

Older adults are more often under-diagnosed and under-treated for mental disorders than any other population, and to the extent that they receive services, treatment usually takes place in primary care settings. Although traditionally treatments for mental and physical disorders have been obtained from separate providers and treatment settings from one another, accumulating evidence has demonstrated that integrated care and overall care coordination is associated with improved patient outcomes and ultimately decreased costs and improved quality of care. Medicare is the largest insurance provider of mental health services for older adults, and as such, it plays a key role in determining which providers can be reimbursed, for which services, and in which settings. This session will discuss current policy initiatives designed to facilitate integrating mental health care into primary care settings, as well as challenges and opportunities for practices and providers seeking to make this type of care transformation.

SESSION 2310 (SYMPOSIUM)

DISABILITY AND BEHAVIORAL RISK FACTORS ASSOCIATED WITH MORTALITY, NURSING HOME USE AND MEDICARE COST

Chair: W.L. Anderson, *RTI International, Research Triangle Park, North Carolina*
Co-Chair: B.S. Armour, *Centers for Disease Control and Prevention, Atlanta, Georgia*
Discussant: B. Spillman, *Urban Institute, Washington, District of Columbia*

Disability has been long associated with poor health outcomes as well as extended and expensive health care service use. Much less is known about its association with behavioral risk factors such as obesity, smoking, and drinking, and the subsequent effects on health outcomes and health care service use. This symposium presents the results of four studies sponsored by the Centers for Disease Control and Prevention to better understand these associations. The first study uses the National Health Interview Survey and mortality data over more than a decade to estimate the differential effects of different types of disability on mortality after controlling for obesity and other factors. A second study examines the relationship between disability and obesity and vice versa, finding that although disability may nominally cause obesity, comparatively, the risk of obesity causing disability is larger. The third study examines the effects of obesity and smoking on nursing home use, finding that, after controlling for disability, persons with extreme obesity or who had ever smoked had a higher nursing home risk. The final study estimates the effects of obesity, smoking, and drinking in conjunction with disability on Medicare expenditures, finding differential effects across these behavioral risks. Although smoking always leads to higher Medicare expenditures, the results are mixed for varying weight and drinking status. Brenda Spillman of the Urban Institute will be the discussant.

EFFECTS OF OBESITY AND SMOKING ON THE RISK FOR NURSING HOME USE

J. Wiener[2], W.L. Anderson[1], L. Coots[3], B.S. Armour[4], *1. Aging, Long-Term Care and Disability, RTI International, Research Triangle Park, North Carolina, 2. RTI International, Washington, District of Columbia, 3. RTI International, Waltham, Massachusetts, 4. Centers for Disease Control and Prevention, Atlanta, Georgia*

This study estimates the effects of smoking and obesity on nursing home use. Descriptive and multivariate statistics were used to analyze data from survey respondents originally living in the community age 50 years or older from the 1996-2008 Health and Retirement Study. Smoking increased nursing home use by 18%. Using three binary measures to denote obesity class, we found that the most obese respondents (Body Mass Index of 40 or higher) had 31% higher nursing home use, while less obese persons, as well as persons who were overweight but not obese, had a lower risk of nursing home use. Being underweight resulted in 43% higher nursing home use. Each additional two-year period that respondents experienced obesity resulted in 10% higher nursing home use. Understanding behavioral risk factors association with nursing home use is important for identifying ways to reduce nursing home use.

UNDERSTANDING THE CAUSAL RELATIONSHIP BETWEEN OBESITY AND DISABILITY

W.L. Anderson[1], J. Wiener[2], L. Coots[3], B.S. Armour[4], *1. Aging, Long-Term Care and Disability, RTI International, Research Triangle Park, North Carolina, 2. RTI International, Washington, District of Columbia, 3. RTI International, Waltham, Massachusetts, 4. Centers for Disease Control and Prevention, Atlanta, Georgia*

Obesity may cause disability, and vice versa. Understanding the association between obesity and disability is necessary for focusing public health initiatives. Random effects estimation was performed on 1994-2008 Health and Retirement Study data on respondents age 50 and older. A two-stage least squares approach used spousal Body Mass Index (BMI) and cognition score as instruments for obesity and disability, respectively. A one unit increase in BMI increased disability risk by 3.5 percent. Conversely, higher disability prevalence resulted in lower obesity rates when controlling for endogeneity, and no effect when not controlling for endogeneity. Each additional two-year period that respondents experienced obesity increased disability by about 11.3 percent. In descriptive statistics, the obesity rate is growing faster among people with disability than people without disability. Although disability may nominally cause obesity, comparatively, the risk of obesity causing disability is larger. Public health measures should be focused on reducing obesity.

EFFECTS OF UNHEALTHY LIFESTYLES ON MEDICARE EXPENDITURES

W.L. Anderson[1], J. Wiener[2], L. Coots[3], E.A. Courtney-Long[4], B.S. Armour[4], *1. Aging, Long-Term Care and Disability, RTI International, Research Triangle Park, North Carolina, 2. RTI International, Washington, District of Columbia, 3. RTI International, Waltham, Massachusetts, 4. Centers for Disease Control and Prevention, Atlanta, Georgia*

Unhealthy lifestyle behaviors (obesity, smoking, and excessive drinking) may lead to poor health and higher health care expenditures. The effects of unhealthy lifestyle behaviors by people with disabilities on health outcomes and health care expenditures are unknown because of opposing theories of morbidity compression near the end of life. People with healthy lifestyles may live longer, healthier lives and then die quickly due to natural aging without an extensive period of disease and disability. On the other hand, people could live longer lives and experience more disability and more expensive medical care over a longer period of time. This study estimated the effects of unhealthy lifestyle behaviors on health care expenditures over a 17-year period using the 1994 -2010 Health and Retirement Study linked to Medicare claims data. Disability was interacted with each of the unhealthy lifestyle behaviors. Differential effects on expenditures were found across the unhealthy lifestyle behaviors.

DISABILITY STATUS, MORTALITY, AND LEADING CAUSES OF DEATH IN THE UNITED STATES COMMUNITY POPULATION

V.L. Forman-Hoffman[2], K.L. Ault[2], W.L. Anderson[2], J. Wiener[3], A. Stevens[1], V.A. Campbell[1], B.S. Armour[1], *1. Centers for Disease Control and Prevention, Atlanta, Georgia, 2. RTI International, Research Triangle Park, North Carolina, 3. RTI International, Washington, District of Columbia*

This study examines the effect of different types of functional disability on all-cause mortality and cause-specific deaths over more than a decade among community-dwelling adults. Understanding mortality by disability type is necessary because different groups may need tailored interventions to reduce their mortality risk. We used Cox proportional hazard regression models to estimate the likelihood of mortality and leading causes of death for adults with and without a disability in NHIS data. Adults with any disability were more likely to die than adults without disability (19.9% vs. 10.9%). This association was statistically significant for most causes of death and for most types of disability studied. The leading cause of death for adults with and without disability differed (heart disease and malignant neoplasms, respectively). Heart disease may be the leading cause of death in the United States partly because of the high prevalence of adults with disability who die from this disease.

SESSION 2315 (SYMPOSIUM)

FILM'S ROLES IN EXPLORING ARTS ENGAGEMENT OF COGNITIVELY IMPAIRED ELDERS

Chair: H.Q. Kivnick, *School of Social Work, University of Minnesota, Saint Paul, Minnesota*
Co-Chair: R.J. Scheidt, *Kansas State University, Manhattan, Kansas*

An increasing body of research documents multiple positive outcomes (e.g., developmental; physical and cognitive function; emotional well-being) of elders' engagement in a variety of structured arts activities. Associated with this work, the GSA has long introduced the arts and humanities into Society Committee Work (e.g., Standing Committee on Humanities and the Arts), and Annual Meetings (e.g., scientific sessions on humanities and arts; showing of full-length films). Most recently, The Gerontologist has added a Humanities and Arts section and a collection, in each issue, of reviews of films on issues of aging. Leaders in these various Society endeavors present this symposium to: 1) Consider the emerging gerontological practice of arts engagement, as implemented with elders living with a wide array of cognitive impairments; and 2) Begin to explicate the unique role of film (in this case, documentary and educational film) in describing, informing, and teaching about these forms of practice. The session opens with a collection of rich film clips illustrating the medium's multiple possibilities for exploration of arts participation among cognitively impaired elders. The first presentation explicitly considers the role of film in teaching, promoting, and documenting self-expression in elders with dementia. The second refers to specific film clips to discuss developmental theory as it underlies positive outcomes of arts involvement for cognitively impaired elders and for their relationships with caregivers and families. The third uses the clips to consider artists' observations of the impact of their arts-involvement interventions with cognitively impaired elders..

VITAL INVOLVEMENT THROUGH ARTS ENGAGEMENT: PATHS TO/FROM THE "SELF" OF COGNITIVELY IMPAIRED ELDERS

H.Q. Kivnick, *School of Social Work, University of Minnesota, Saint Paul, Minnesota*

Erikson's principle of vital involvement holds that healthy psychosocial development in older adulthood rests on elders' meaningful, reciprocal engagement with the world outside the "self". While cognitively impaired elders may find "ordinary" conversation increasingly difficult, they can often participate in sensory engagement with arts materials (e.g., paint; clay; sound; movement) that open paths satisfying to themselves and meaningful to caregivers and other co-actors. The arts provide a medium for the give-and-take reciprocity that constitutes vital involvement. After summarizing the vital involvement principle, this presentation refers to selected film clips that illustrate how otherwise inaccessible aspects of elders' inner and outer expressions of "self" may be discovered and sustained through their active participation in making and appreciating the arts. It then clarifies how the same vital involvement that underlies these elders' arts participation can also enrich relations with caregivers and family members.

IMPROVISATION AND PEOPLE WITH DEMENTIA: RECONSIDERING THE POSSIBILITIES OF ENGAGEMENT

K. de Medeiros, *Sociology and Gerontology, Miami University, Oxford, Ohio*

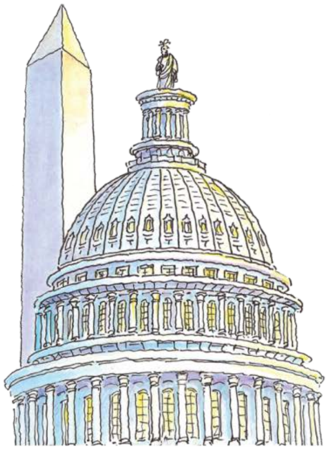
Although there is a growing body of literature pointing to benefits of the use of arts-based interventions with people with dementia, there is a lack of work that specifically explores why and how. This paper draws from the Dementia Arts Research Ensemble (DARE) research retreat attended by artists and social scientists to consider artists' perspectives on the power of the arts. An analysis of field notes from the proceedings revealed that the concept of "improvisation" — or the ability to use a newly introduced idea as a springboard for new creation — was a critical component that can be applied to traditional participatory arts as well as engagement with film clips. Considering existing literature, this paper will apply the key finding from the artist retreat to clips presented during the symposium to offer new ways to consider engaging people with dementia.

MORE THAN WORDS: USING FILM TO EXPLORE A NEW LANGUAGE OF DEMENTIA

J. Vanden Bosch, *Terra Nova Films, Chicago, Illinois*

Self expression and meaningful engagement can be challenging for persons living with cognitive impairment. Living in an environment where memory, word-speak and linear thought are the normative channels of communication makes self expression and engagement even more challenging for them. For persons living with dementia, familiar channels of cognition becoming increasingly impaired. They need help in finding new ways of social engagement and self expression. For many, being guided into more right-brain avenues of engagement provides alternative ways of expressing themselves and maintaining a sense of value, identity and belonging. As richly illustrated by the film clips shown as the first part of this symposium, this presentation will reflect on the unique ability of film/video to document and demonstrate the effectiveness of these kinds of creative engagements for persons living with dementia.

GSA 2014 ANNUAL
SCIENTIFIC MEETING
NOVEMBER 5–9, 2014
WASHINGTON, DC



2014 Late Breaker Poster Sessions

Organized by the Behavioral and Social Sciences, Biological Sciences, Health Sciences, and Social Research, Policy & Practice Sections

GSA 2014 Late Breaking Posters

The Late Breaker Poster Sessions are jointly sponsored by GSA’s Behavioral and Social Sciences, Biological Sciences, Health Sciences, and Social Research, Policy & Practice Sections. These sessions are a forum for the presentation of the newest, most pressing, and previously unreported results in aging research.

Participating posters will be grouped together in a special Late Breaker section of Exhibit Hall D of the Walter E. Washington Convention Center. The poster number on each board corresponds to the number in front of an abstract in this program. Posters will be displayed during the times listed below.

*Presenters will be at their boards during the Face-to-Face Time for each session.

Wednesday, November 5
6:00 PM to 8:00 PM
Face-to-Face Time: 6:00 PM - 7:00 PM

Thursday, November 6
11:45 AM to 2:45 PM
Face-to-Face Time: 11:45 AM – 12:45 PM

Friday, November 7
10:00 AM to 1:00 PM
Face-to-Face Time: 10:00 AM - 11:00 AM

Saturday, November 8
11:45 AM to 2:45 PM
Face-to-Face Time: 11:45 AM – 12:45 PM

*Presenters: Set-up times for poster sessions are 5:00 pm on Wednesday and upon opening of the Exhibit Hall at 9:30 am on Thursday, Friday, and Saturday. All poster presenters are responsible for the removal of their materials by the end of their presentation time.

Wednesday, November 5
6:00 PM-8:00 PM | Exhibit Hall D (CC)

264. 'How' and 'Why' Wise People Reflect on the Past: Relations Among Wisdom, Adverse Life Experience, and Self-Reflective Processing, *Nic Weststrate, University of Toronto; Judith Glück, Alpen-Adria-Universität Klagenfurt*
Objectives: To identify characteristic ways through which wise people make meaning of personal hardship in autobiographical memories.
Abstract Body: The idea that individuals accumulate wisdom through adversity is pervasive (Ardelt, 2005; Glück & Bluck, 2011). But, what makes the 'hard road to the good life' possible? This study investigates self-reflective processes that encourage growth in wisdom following personal hardship (Glück & Bluck, 2013; Staudinger, 2001). We propose that wisdom depends on 'how' and 'why' individuals reflect on the past. We hypothesize that when narrating a difficult life event, wise individuals adopt an exploratory, analytical, and growth-oriented perspective on the past, viewing the life event as an occasion to gain self- or life-insight. In contrast, we expect wisdom to be unrelated to forms of self-reflection aimed at positive emotional transformation and resolution of the event, which may instead be predictive of psychological well-being. A lifespan sample of 94 participants were interviewed about their most difficult life experience. Autobiographical memories were reliably coded for 4 self-reflective processes that loaded onto 2 uncorrelated dimensions: (1) exploratory processing (meaning-making, personal growth), and (2) redemptive processing (emotional processing, resolution). Participants completed self-report and performance measures of wisdom, a difficult life event inventory, and a measure of psychological well-being. As expected, wisdom was positively associated with exploratory processing, whereas redemptive processing was positively associated with well-being. We conclude that wise people reflect on significant life events in characteristic ways. Rather than pursue a positive ending, wise people look for deeper meaning in the past. This self-reflective tendency may play a role in the development of wisdom through adversity, whereas redemptive processing may lead to enhanced well-being.

265. "All the World's a Stage" – Bridging the Generational Gap through Theatre, *Neda Norouzi, Virginia Tech; Sarah Lyon-Hill, Virginia Tech*
Objectives: To introduce alternative approaches to fostering intergenerational bonds; Creative ways of altering preconceptions of one cohort toward other generational cohorts;
Abstract Body: The use of intergenerational theatre in forming relationships is a growing scholarly field. It offers opportunities for all generations to participate in various ways as mutual experts. Intergenerational theatre empowers participants through the process of teaching and learning new skills and knowledge from other generations. This project explored the effects of theatre on intergenerational connection among participants by studying two programs with different approaches to the goal of encouraging intergenerational engagement. The Intergenerational Learning Center (ILC) program welcomes different age groups from the St. Paul metropolitan area to collaborate in producing an annual play. Mind the Gap (MtG) in NYC invites select applicants to a scriptwriting process during which youth and elders are partnered one-on-one. For each program, we interviewed program directors and staffs, and collected over 30 participants' surveys. Results revealed theatre's ability to alter participant perceptions, encouraging intergenerational bonds. Interviewees described how participants changed their stereotypes about other cohorts by embracing a deeper understanding of each generation's unique experiences. In surveys, young respondents circled words to describe their perceptions of older adults before and after the programs. The use of positive words doubled in post-perception responses, while the use of negative words such as "boring" and "old-fashioned" decreased from 87 to 29 total responses. We noted a similar trend from older adult perceptions toward youth. Anecdotal evidence from interviews and surveys described participants learning from one another and engaging outside both programs. Interviewee and participant responses from MtG, however, referenced "self-discovery" and "reflexivity" more than those from ILC.

266. "He Said, She Said": Do Older Adults Remember Their Doctors' Advice For Lifestyle Change?, *Shoshana Bardach, Lexington VAMC; Nancy Schoenberg, University of Kentucky; Britteny Howell, University of Kentucky*
Objectives: To better understand older patients' recall for dietary and physical activity discussions in primary care.; To develop strategies for healthcare providers that might enhance older patients' recall for health consultations.;
Abstract Body: Background: Despite the known benefits of engaging in healthy diet and physical activity across the lifespan, suboptimal diet and physical inactivity are pervasive among older adults. While healthcare providers can influence patients' health behaviors, patient recall that such advice took place during a medical consultation, let alone the nature of that advice, tends to be imperfect. Moreover, providers often feel that such efforts are futile with older adults; therefore healthcare often forego such discussions. Purpose: This study sought to better understand older adults' recall of dietary and physical activity discussions in primary care. Methods: 115 adults ages 65 and older were interviewed immediately following a routine primary care visit about the interaction that had just taken place. Interview questions focused on recall of discussion pertaining to diet and physical activity. All interviews were recorded, transcribed, and analyzed with a grounded theory approach involving a constant comparison method. Findings: Most patients accurately recalled whether or not they discussed diet and physical activity. Moreover, the content of these discussions was accurate. Patients were more likely to remember

discussions involving recommendations than discussions that addressed diet or physical activity but did not involve any behavioral suggestions. For dietary discussions, patients were also more likely to recall discussions of longer duration. Implications: These findings suggest that specific recommendations and an extra minute of discussion, at least for dietary recommendations, increase the likelihood of patient recall that the discussion occurred.

267. Gender Differences in Longitudinal Trajectories of Change in Physical, Social, and Cognitive Leisure Activities, *Deborah Finkel, Indiana University Southeast; Ross Andel, University of South Florida; Nancy Pedersen, Karolinska Institutet*

Objectives: To identify and interpret gender differences in trajectories of change across three domains of leisure activities: physical, social, and cognitive.

Abstract Body: Leisure activities in multiple domains have been investigated as precursors of physical and cognitive changes associated with aging, but often in isolation. Moreover, possible gender differences in both mean leisure activity and rate of change have been largely overlooked. 1398 participants in the Swedish Adoption/Twin Study of Aging completed a brief leisure activity questionnaire up to 4 times over 17 years. Mean age at first leisure assessment was 64.9 (range = 35 to 93); 59% of the sample was female. Factor analysis of the leisure activity items identified physical, social, and cognitive factors with inter-factor correlations ranging from .12 to .15. Age-based latent growth curve models including both linear and accelerating decline were used to identify gender differences in aging trajectories in each domain of activity. Results indicated significant gender differences in both fixed effects (mean parameters) and random effects (variance around parameter estimates). Men and women reported approximately the same level of social activity until age 65, when social activity remained stable for women and declined for men. Women reported higher mean levels of cognitive leisure activity, but no gender differences in change trajectories were evident. Both men and women showed dramatic declines in physical leisure activity, with somewhat faster rates of decline for women. Variance in leisure activities increased with age; women demonstrated more variance in social activities, whereas men showed more variance in physical activities. Gender differences in social roles and physical aging likely explain differences in patterns of changes in leisure activity with age.

268. A Life Course Approach: Childhood Adversity and Age Trajectories of Frailty for the Chinese Elderly, *Zhenhua (Jessica) Xu, The Department of Sociology, University of North Carolina at Chapel Hill;   ,*

Objectives: This paper examines whether childhood adversity is associated with age trajectories of frailty.; This paper also examines whether the associations between childhood adversity and age trajectories of frailty vary by birth cohorts over the life course.

Abstract Body: Objective: This paper examines whether childhood adversity is associated with age trajectories of frailty and how it varies by birth cohorts over the life course.   Methods: Using data from the Chinese Longitudinal Healthy Longevity Survey (CLHLS), 7,382 Chinese elderly age 80 and older are observed over five waves from 1998 to 2008. Childhood adversity is measured by four indicators: inadequate access to health care, lowest quartile arm length, no schooling, and birth in rural areas during childhood. Growth curve models are employed to analyze intercohort variations of childhood adversity in age trajectories of frailty.   Results: We find that Chinese elderly with inadequate access to health care, lowest quartile arm length, and no schooling during childhood are associated with high frailty, however, those born in rural areas are associated with low frailty in late life. Among four indicators of childhood adversity, the effects of no schooling and birth in rural areas on age trajectories of frailty differ by cohorts. The education-based gap in frailty trajectories converges in successive birth cohorts. Birth in rural areas is associated with low frailty for early cohorts born before 1910, however, after 1910, birth in rural areas is more likely to have a high frailty.   Discussions: Significant rural-urban divide in China has created various socioeconomic conditions across cohort groups that affect individuals' life course trajectories over the twentieth century. Life course approaches significantly improve the understanding of the association between childhood adversity and age trajectories of frailty in China.

269. Acceptability of an Online Intervention to Motivate Adults Aged 50+ to be More Physically Active: a Pilot Study, *Elske Stolte, VU University Amsterdam; Theo van Tilburg, VU University Amsterdam; Marja Aartsen, VU University*

Objectives: Assess the acceptability of a six week online motivational program for people aged 50 and over.

Abstract Body: Goal A six week online intervention program was developed for people aged 50 and over. The goal is to motivate participants to be more physically active (PA) and to study the effect and mechanisms of e-mail prompts and cognitive antecedents of PA. Aim of the pilot is to assess the acceptability of the program. Methods Participants are randomly assigned to two groups. The first group receives an online PA plan, a PA diary, two brochures sent by mail and PA tips in the form of texts and animated video's (n = 19). The second group receives the same information (n = 14), however the PA tips are supplied using prompts, i.e. short e-mail messages, sent three times a week during four weeks. Of the participants 73% are female, the mean age is 63 years. Nineteen (58%) participants filled out the post measurement questionnaire. Results Appreciation of the program is high. Most participants (74%) report that they got more active during the program and that the program helped them to achieve this (79%). Half or more of the PA tips were viewed by 75% of the first group and 57% of the prompting group. Discussion The program is acceptable for most users who completed the program. Some participants expect more personal feedback. Usage of PA tips is lower than expected. As a result PA tips and prompts were adjusted for a new version of the program that has just been conducted.

270. Adaptive sleep and activity patterns in free-living older Icelandic men and women, *Erlingur Johannsson, Center of Sport and health Sciences, Iceland University of Education, Laugarvatn, Iceland; Robert Brychta, 2National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda Maryland, USA; Nanna Arnarsdottir, Research Center of Movement Science, University of Iceland, Reykjavík, Iceland; Vilmundur Gudnasson, Icelandic Heart Association, Kópavogur, Iceland and Faculty of Medicine, University of Iceland, Reykjavík, Iceland; Gudny Eiriksdottir, Icelandic Heart Association, Kópavogur, Iceland and Faculty of Medicine, University of Iceland, Reykjavík, Iceland; Tamara Harris, Icelandic Heart Association, Kópavogur, Iceland and Faculty of Medicine, University of Iceland, Reykjavík, Iceland; Kong Chen, National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda Maryland, USA*

Objectives: Aging is often associated with sleep qualities and physical activity declines. Ambient lighting also influences sleep patterns.; To identify cross-sectional and seasonal sleeping and physical activity patterns in a healthy, community-dwelling, aging, Icelandic population using accelerometers.; Physical activity and sleep are thought to be inter-related and both are known to play an important role in health and wellness.

Abstract Body: Objective: Aging is often associated with sleep qualities and physical activity (PA) declines. Ambient lighting also influences sleep patterns. We investigated cross-sectional and seasonal sleeping and PA patterns in a community-dwelling Icelandic healthy aging population using accelerometers. Methods: Participants (n=244, male/female 110/134, age 79.7±4.9 years, BMI 26.9±4.8 kg/m2) wore an Actiwatch Spectrum on the non-dominant wrist to assess sleep and an Actigraph GT3X on the right hip to assess PA for one week during free living. A subpopulation (n=72) performed two 7-day measurements during seasonal periods with long and short daylight (13.4±1.4 vs.7.7±1.8 hours). Results: Cross-sectionally, the length of daylight was a statistically significant predictor of sleep duration, onset latency, and rise time (all p<0.05); however, the actual within-individual differences in the repeated studies were rather subtle (< 20 minutes/day). Men had a shorter sleep duration than women (462±80 vs. 487±68 minutes, p=0.008) mainly because men had an earlier rise time and a higher number of awakenings per night (46.5±18.3 vs. 40.2±15.7, p=0.007). Daily PA was similar between men and women (134±70 and 127±62 counts/wear-time minute) and between long and short daylight (125±67 and 118±73 counts/wear-time minute). BMI, age, gender, overall PA, grip strength, and normal 6-meter walking time all predicted the variations in sleep parameters using multiple regressions. Conclusions: The sleep and PA characteristics of this unique population revealed some gender differences, but the lack of variation in response to significant daylight changes may be due to long-term physiological and/or environmental adaptations.

271. Age Differences in the Influence of Affective versus Deliberative Processes on Decision Making., *Neika Sharifian, North Carolina State University; Thomas Hess, North Carolina State University*

Objectives: To examine age differences in the impact of general affective information versus more specific numeric information on decision making

Abstract Body: Previous research with younger adults demonstrated an undue influence of affect on decision-making processes (e.g., Hsee & Rottenstreich, 2004): when decision-relevant information was presented in an emotionally evocative manner, the use of numeric information (i.e., scope) in making quantitative decisions was greatly attenuated. Our study examined whether this interaction between affective and deliberative processing changes with age, as predicted by suggestions that aging-related declines in deliberate functions will result in greater reliance on affective information (Peters, Hess, Västfjäll, & Auman, 2007). Based on this, we predicted that either the impact of numeric information would be reduced and/or the impact of affective information increased in older adults relative to younger and middle-aged adults. To test this, we replicated the methods of two of the experiments from Hsee and Rottenstreich (2004) with a sample recruited using Amazon Mechanical Turk (N=312) and community residents (N=27). Scenarios were presented examining the influence of low versus high numerical information on donating money or sentencing criminals in the presence or absence of affective information. Contrary to our hypotheses, older adults (N=101, M=69.91, SD=4.78) were not influenced by the presence of affective components, whereas young adults (N=124, M=29.65, SD=5.73) exhibited the expected scope by affect interaction, replicating the interfering effects of affect on use of quantitative information seen in Hsee and Rottenstreich (2004). Interestingly. middle-aged adults (N=114, M=52.71, SD=5.43) also demonstrated minimal influences of affect. The results suggest that specific decision contexts may interact with age in determining the impact of affective versus deliberative processes on decision-making.

272. Age group comparisons in cognitive aging: Do visual acuity criteria matter?, *James Houston, The University of Akron*

Objectives: Provide evidence for the impact of visual acuity exclusionary criteria across a substantial number of cross-sectional cognitive aging studies that employ visual stimulus presentation.; Ascertain what potential visual criteria allows for an optimal combination of participant inclusion (given that normative declines in visual acuity is experienced through the aging process) and precision (via the minimization of age-related effects that are the result of the general poorer visual acuity of older adult samples relative to paired younger adult samples).;

Abstract Body: The influence of visual capacities on cognitive performance in older adults has been frequently posited as being a driving force behind age group differences in task performance. This review of the cognitive aging literature explored the relationship between specific visual acuity criteria commonly utilized by aging researchers in order to assess the validity of concerns that a lack of consensus regarding visual acuity inclusionary criteria has had an effect on the interpretation of age comparisons. Age group comparisons in 462 studies were recorded across a wide array of cognitive domains including attention, executive function, explicit memory, language, perception, and processing speed. Resulting main effects for each study were transformed into effect sizes & age group comparisons by cognitive domain were compared across several inclusionary criteria. Across all domains of cognitive function, no planned comparisons of age differences in performance across visual acuity criterias reached significance. Results indicated that inclusionary criteria vexations in the cross-sectional aging literature is unsubstantiated based upon a significant number of articles across a variety of cognitive domains. Further efforts are needed to determine if visual functioning other than acuity (e.g. contrast sensitivity, luminance) have a more substantial impact on age differences in cognitive functioning.

273. Age Moderation of Genetic and Environmental Influences on Depressive Symptoms, *Andrew Petkus, University of Southern California; Wendy Johnson, University of Edinburgh; Chandra Reynolds, University of California, Riverside; Jenae Neiderheise, Pennsylvania State University; Nancy Pedersen, Karolinska Institutet; Margaret Gatz, Karolinska Institutet*

Objectives: Examine how the genetic and environmental influences on depressive symptoms change with age across the adult lifespan

Abstract Body: While the links between depressive symptoms and age have been well-studied, it is not yet clear how genetic and environmental contributions to individual differences in depressive symptoms vary across the lifespan. This question is important for understanding the underlying factors contributing to depression at different ages. This study is part of the IGEMS consortium, aggregating data from nine twin studies across three countries (three U.S. studies, four Swedish, and two Danish). Depressive symptom data from 16,831 individuals (including 6,437 complete twin pairs) were available. The age range of participants was 25 to 102 years (M= 63.5; SD = 13.4) and 51.9% were female. Depressive symptoms were measured in the different studies by self-reports on either the CESD scale or the CAMDEX. A harmonized score was derived to pool data across all participants. A biometrical model of depressive symptoms with linear and quadratic age moderation of the Additive Genetic, Shared Environmental, and Unique Environmental variance components was fitted. Genetic and environmental variance components differed between males and females but not among countries. For both sexes, total variance as well as unique environmental variance was greater at older ages. Males showed, quadratic age moderation, with greater genetic influences and fewer shared environmental influences with greater age. Females showed linear age moderation with magnitude of genetic influences similar over age but greater unique environmental influences. Overall these cross-sectional findings suggested that genetic and environmental contributions are not constant across the lifespan and differ by sex. [For the IGEMS Consortium, Grant No. R01 AG037985.]

274. Age, period and cohort patterns in all-cause mortality in Sweden, *Kozma Ahacic, Institute of Gerontology, School of Health Sciences, Jönköping University, Sweden/ Centre for Epidemiology and Community Medicine; Stefan Fors, Aging Research Centre (ARC), Karolinska Institutet and Stockholm University; Anton Lager, 2 Centre for Epidemiology and Community Medicine, Health Care Services*

Objectives: How one finds out whether any cohort effect is obscuring the latest overtime trend in mortality

Abstract Body: While life expectancies increased throughout the last decades, the observed health trends in old age morbidity are more ambiguous. The prevalence of certain health problems even increased. These findings are peculiar as the birth cohorts that make up the oldest segments of the population today exhibited better health in mid-life than prior generations did. These patterns imply that the later cohorts have experienced higher rates of morbidity onset during old age than previous cohorts. Sweden went through an economic crisis during the 1990s which had substantial public health consequences, particularly for the psychic health of young adults. It is possible that the crisis also had long-term consequences for another vulnerable age segment, namely the oldest old. In this study, we examine age, period, and cohort patterns in all-cause mortality in Sweden between 1900 and 2012. The analysis consists of graphical depictions of cross-tabulations between age groups, birth cohorts, and periods. Results show a substantial rectangularization of the survival curve. Moreover, with one exception, all birth cohorts experienced continuous reductions in mortality at all ages throughout the period. There were no indications of any effect of the economic crisis among the elderly. However, among the young (i.e., the generation born during 1980s) no reduction in mortality was observed during age 20-30, when compared to the cohorts born in the 1970s. This finding is striking as all other cohorts, without exceptions, showed continuous mortality reductions at all ages throughout the whole of the last century, including the great depression.

275. Aging and the Processing of Emotional Words, an Event-Related Potential Approach, *James Houston, The University of Akron*

Objectives: Contribute to the research literature on age-related differences in word recognition as they relate to processing commonly and infrequently experienced words by using a lexical decision paradigm and controlling for additional word characteristics such as; Identify differences in emotional processing at time frames that are representative of exogenous emotional processing and cognitive appraisal (early and late emotional effects, respectively) in a younger and older adult sample.; Identify behavioral and electrophysiological trends as they correspond to emotional valence and word frequency effect interactions in a younger and older adult sample.

Abstract Body: Current knowledge of human attention with emotional material suggests distinct patterns of behavior in younger and older adults regarding emotional arousal and cognitive appraisal of emotional stimuli. In the domain of written word recognition, past research has identified emotional valence effects and word frequency effects at early and late stages that are believed to correspond to pre-lexical and post-lexical processing in younger adult samples. The current study sought to identify word frequency and emotional valence effects in a lexical decision task across a sample of younger and older adults in order to reveal distinct age-related patterns in the processing of written language with an emotional connotation. Behavioral and electrophysiological data were recorded from a sample of younger and older adults while completing a lexical decision task in which emotional words and phonologically correct nonwords were presented. In younger and older adult age groups, positive words were identified more rapidly than nonwords and common words were recognized faster and more accurately than uncommon words. Event-related potential data indicated no effects involving emotional valence at pre-lexical or post-lexical stages. However, an age group by emotional valence interaction suggested greater neurophysiological activation at the post-lexical stage (400-600 ms) in the younger adult sample for high frequency relative to low frequency words with no word frequency differentiation in the older adult sample. These findings suggest an age-related difference in word recognition at a post-lexical stage and have implications for both word recognition and emotional attention literatures.

276. An Eye-Tracking Analysis of Four Female Older Adults with Normal Cognition to Identify Changes in Wayfinding Strategies in a Virtual Environment, *Brandy Alexander, Grand Valley State University; Rebecca Davis, Grand Valley State University*

Objectives: Describe how fixations on salient cues are related to wayfinding performance in older adults.; Discuss how salient cue fixations change over days of learning.;

Abstract Body: Individuals' ability to find their way, called wayfinding, has been shown to decline with normal aging. Caduff and Timpf's (2008) conceptual model suggests that salient cues capture an individual's attention which can improve wayfinding. The purpose of this study is to describe how fixations on cues influence wayfinding initially and over time in both cued and un-cued environments. Four older women (aged 68-83) were asked to find their way in two cue conditions in a virtual reality simulation of a senior residence; one environment had no salient cues (CC1) and one had multiple salient cues (CC2). Participants underwent ten trials on both day 1 and day 2 for 80 total trials. The number of fixations on cues and environmental features, the number of successful trials, as well as the latency and distance traveled for each trial were analyzed. Study results showed that the four participants had improved wayfinding in CC2 (cued) than CC1 and had improved wayfinding on day 2 of the study from day 1. Salient cue fixations decreased between day 1 and 2 in CC2, which may indicate that once the environment is learned, less attention to cues is needed for successful wayfinding. These findings give beginning support that older women fixate on salient environmental cues which help them find their way in new environments and that this learning improves over time.Through the presence of salient cues, individuals wayfinding abilities can be enhanced to improve quality of life through the maintenance of independence and greater environmental safety.

277. Analysis of lifestyle related variables to cognitive functioning in older adults, *Elizabeth Handing, University of South Florida; Brent Small, University of South Florida*

Objectives: Using an exploratory factor analysis approach, this study investigates how lifestyle factors influence cognitive functioning in older adults

Abstract Body: Research has indicated that lifestyle factors such as diet, physical activity, and health status largely contribute to risk for disease in older age, however it is unclear how these factors relate to cognitive functioning. This study examines the relationship between diet, physical activity, health status, and biomarkers (serum cholesterol, LDL, HDL, triglycerides, CRP, ferritin, fibrinogen, iron, and albumin) as they relate to cognitive functioning in 258 older adults from the National Health and Nutrition Examination Survey (Wave 2001-2002). An exploratory factor analysis was conducted, five factors were identified, and three were moderately correlated with Digit Symbol Substitution Task performance: Factor 1 (micronutrients; vitamin B12, vitamin D, vitamin E, folate, and homocysteine), Factor 2 (macronutrients; intake of protein, fat, carbohydrates, vitamin C and beta carotene) and Factor 3 (health and inflammation; self-reported health, serum iron, CRP, fibrinogen, and albumin). Inflammation and poorer health status were related to poorer cognitive performance (r= -.165, p =.008), while higher intake of micronutrients and macronutrients were associated with better cognitive performance (r= .157, p=.001; r= .192, p=.002, respectively). When these factors were examined using multiple regression controlling for gender, education, ethnicity, and total calories, macronutrients and health/inflammation factors remained statistically significant. Information from this provides a holistic view of lifestyle factors, particularly nutrition, health status, and inflammatory markers as they relate to cognitive functioning in older adults. Future research should target these mechanisms and may offer insight into ways to preserve cognitive functioning.

278. Assessing Emotional Intelligence in Older Adults: A Pilot Study, *Leehu Zysberg, Graduate School, Gordon College of Education; Anna Dr. Zisberg, The Cheryl Spencer Department of Nursing, University of Haifa; Ron Dr. Ben-Itzhak, Margoletz Psychogeriatric Center, Tel Aviv Sourasky MC; Odelyah Saad, Department of Nursing, Lev Academic Center-JCT; Jeremia Prof. Heinik, Margoletz Psychogeriatric Center, Tel Aviv Sourasky MC*

Objectives: After reading the poster conference attendees should be able to understand the concept of EI and its potential applicability in testing studying various health outcomes.; After reading the poster conference attendees should be able to consider using measures of EI in their research or interventions with older adults.

Abstract Body: Objectives: Emotional Intelligence is a concept pertaining to individuals' ability to identify emotions, integrate emotions in thought and reasoning, process complex emotions and manage emotions effectively. The concept has been associated in the literature with a broad range of health outcomes. Despite the promising evidence, the concept is yet to be assessed for its potential applications among older adults. This pilot study examined the applicability of the Audio Visual test of Emotional Intelligence (AVEI) , developed and validated in college student' samples, for use in older-adults. The AVEI was chosen for its intuitive interface, web-based, brief format. Method: Three pilot samples consisting of 75 undergraduate nursing students (mean age 21.57±2.39), 80 working adults (41.69±6.94)) and 31 older adults (73.00±11.91) took the on-line AVEI test and filled-out basic demographics (age, gender, education level, etc). The AVEI test is a 27-item computer-based audiovisual test that represents the ability-testing approach to EI. It focuses on emotion-recognition and the emotional process¬ing aspects of EI. Results: AVEI scores showed close to normal distribution in all 3 groups (students 15.69±4.16; adults 14.33±3.45 and older adults 14.69±3.59). No significant differences were found in the AVEI scores between the study groups (F(df=2)=0.45, p=0.67). Moreover, ANCOVA analysis adjusted to years of education yielded similar results. Conclusions: The pilot results suggest the AVEI can be applicable for the measurement of EI among older adults. A test utilizing perceptual modalities rather than self-report may have multiple methodological and applied benefits in future studies and interventions aimed at this specific target population. Emotional intelligence is a relatively new concept introduced to the empirical research arena. It associations with health outcomes are promising but empirical evidence have started appearing only very recently and are scarce. To date we do not know of any study focusing on EI in older adults. We aim to add to this growing body of evidence by pilot-testing the applicability of a test of EI in older adults. Our findings suggest that the AVEI test may be applicable for both future research and intervention with the target population.

279. Association Between Care Environments and Apathy in Long-Term Care Residents with Dementia, *Ying-Ling Jao, Pennsylvania State University; Donna Algase, University of Michigan; Janet Specht, University of Iowa; Kristine Williams, University of Iowa*

Objectives: To describe the significant environmental factors associated with apathy in long-term care residents with dementia

Abstract Body: Background Apathy is prevalent in dementia but often overlooked. Environment-based interventions have demonstrated positive effects on apathy in persons with dementia. However, influential components of the environment are largely understudied. This study examined the relationship between care environments and apathy in long-term care residents with dementia. Methods A sample of 40 was selected from a parent study with 185 participants from 23 facilities. Three videos from each participant were coded using the Person-Environment Apathy Rating scale to measure apathy and environmental stimulation. Data on ambiance, crowding, staff familiarity, light, and sound were extracted from the parent study. Generalized linear mixed models were used for analysis. Results and Discussion Clarity and strength of the environmental stimulation were significantly associated with a lower apathy level. An increase of 1 point on stimulation clarity corresponded to a decrease of 1.3 points on apathy score (p<.0001). Similarly, an increase of 1 point on stimulation strength corresponded to a decrease of 1.9 points on apathy score (p<.001). In contrast, crowding within 2 feet showed some effect on higher apathy level and the effect approached statistical significance (p=.06). Environmental ambiance, staff familiarity, light and sound levels did not show significant effect on apathy. This is the very first study explicitly exploring influential environmental factors on apathy. Findings suggest that care environments that contain clear and sufficiently strong environmental stimulation are significantly associated with lower resident apathy levels in persons with dementia. Findings will provide guidance for environmental design, activity programs, and individualized interventions for dementia care.

280. Can a Convenience Sample Produce Generalizable Results?, *Elizabeth Zelinski, Davis School of Gerontology University of Southern California; Ross Jacobucci, University of Southern California; Robert Kennison, California State University Long Beach; Deanah Zak, University of Southern California*

Objectives: To compare Long Beach Longitudinal Study sample participants over age 50 with the nationally representative HRS 2006 longitudinal sample on demographic characteristics using decision tree analysis and to develop sampling weights for LBLS anchored to HRS c; To analyze findings of 2006 HRS list recall and physical function measures completed by LBLS participants with and without sampling weights to compare generalizable with convenience effects.;

Abstract Body: A major limitation of longitudinal studies based on convenience samples is generalizability to the population, but which can be accomplished if population-appropriate sample weights can be identified. Long Beach Longitudinal Study participants completed the 2006 HRS cognitive and physical function measures for comparison with the HRS population sample. There were 423 LBLS and 18,469 HRS participants. Classification and Regression Trees (CART) was used to predict group association for the two studies. The rpart package in the R statistical environment was used to determine how well age, gender, race, ethnicity, and education predicted study assignment, as well as to create sample weights. Results of the analysis showed that the model explained approximately 18% of the variance. To determine whether the LBLS sample demographics were similar with and without sampling weights, a MANOVA was conducted (Wilks's Lambda = 0.874, $F_{5,744} = 21.55$, $p < .001$). Individual contrasts as well as logistic regression indicated that the most significant predictor of study membership was years of education. The sample weights were used to predict list recall from demographics and physical health measurements, with these results being compared to those without the use of sample weights. Using CART with no weights produced an R-Squared of 0.30, while entering the weights dropped the R-squared to 0.18. A similar impact was demonstrated with linear regression; 0.08 without sample weights, 0.065 with weights. These findings suggests that a convenience sample, despite biases towards higher education, can be adjusted for generalizability.

281. Change in Sitting and Stepping Behavior Across the Day After a Sedentary Behavior Intervention, *Nancy Gell, University of Vermont; Salene Jones, Group Health Research Institute; Dori Rosenberg, Group Health Research Institute*
Objectives: After attending this session participants will be able to describe changes in sitting behavior over the course of the day in response to a sedentary behavior reduction intervention in a sample of older, obese adults.; After attending this poster participants will be able to describe changes in step counts at the hourly level in a sample of older, obese adults after participation in an 8 week sedentary reduction intervention.
Abstract Body: Sedentary time increases with age and is associated with chronic health conditions. However, little is known about behavior change around sedentary behavior. We examined how sitting and stepping behavior changed across the day in overweight and obese older adults during a sedentary behavior intervention. Twenty-three participants (Age 65-85, 62% female, mean BMI: 34.1) completed an 8-week, telephone-delivered sedentary behavior reduction intervention. Time spent sitting and stepping was measured at baseline and post-intervention for 5-7 days with ActivPal inclinometers. We examined change in average minutes spent sitting and stepping across each hour of the day with start times for each participant centered to begin at Hour 1. Paired t-tests compared baseline to post-intervention sitting and stepping. At baseline, minutes spent sitting each hour gradually increased over the course of the day (37 minutes at Hour 1 to 49 minutes at Hour 15). Post-intervention, participants spent fewer minutes sitting at every hour of the day (range: 0.5-5 minute decrease) with significant decreases at Hours 3, 8, and 14 (all p-values<0.05). At baseline, minutes stepping were highest at Hour 1 (7.6 min.) and decreased across most hours of the day. Post-intervention, participants showed a higher number of minutes stepping for Hours 8-15 compared to baseline, with significant increases at Hours 8 and 9 (p-values <0.05). In this pilot study overweight and obese older adults were able to implement a significant change in sitting behavior across different hours of the day. Post intervention, time spent stepping increased significantly later in the day.

282. Childhood Adversity and Self-Rated Health: What Are the Mechanisms Throughout the Life Course?, *Abigail Howard, Purdue University*
Objectives: The present study seeks to understand how early life disadvantages impact individuals' perceptions of their health in later life and what mechanisms early life adversity may work through
Abstract Body: Childhood adversity can have long-term negative consequences for one's health throughout the life course. However, it is unclear what mechanisms exacerbate or alleviate these negative outcomes over the life course. Drawing from cumulative inequality theory, the present study seeks to understand how early life disadvantages impact individuals' perceptions of their health in later life and what mechanisms early life adversity may work through. Results reveal that the cumulative effects of early life adversity contribute to more negative views of both previous and future health. Physical abuse by mother, poor physical health at age 16, and poor mental health at 16 had the largest negative impact on self-rated health. Further, these negative views of previous and future health had detrimental effects on less subjective health measures seven years later. Smoking and Body Mass Index (BMI) over 30 also added to poorer self-rated health. The findings highlight the limits of human agency, particularly when early adversity constrains choices and opportunities.

283. Cognitive Screening and Vascular Burden among Older African American Adults in a Primary Care Setting, *Ishan Williams, University of Virginia, School of Nursing; Scott Sperling, University of Virginia, Department of Neurology; Carol Manning, University of Virginia, Department of Neurology*
Objectives: Describe a novel computerized cognitive screening tool that was used in a primary care setting among older African American adults.; Discuss the analyses of cognitive impairment among African Americans who have vascular risk factors.; Describe the policy implications for early detection of cognitive decline among older African American adults in primary care settings using computerized cognitive assessments.
Abstract Body: Despite evidence that early identification of dementia is of growing policy concern and clinical significance, limited work has been done evaluating the utility of cognitive screening measures in primary care settings. Additionally, little work has been done on understanding the systematic barriers to timely dementia diagnoses among minority older adults. The aim of this research study was to provide primary care physicians with a clinically informed dementia screening of minority patients with high vascular risk factors. The study used a novel computerized measure of cognitive functioning using a tablet, the Computerized Assessment of Memory and Cognitive Impairment (CAMCI), and the Mini Mental Status

Exam (MMSE). In a sample of 96 African American older adults, there was evidence that African American older adults coming to see their primary care providers for reasons unrelated to cognition were experiencing significant cognitive problems ($p<.01$) and that men were more likely than women to exhibit memory problems ($p < .05$). Of note, primary care providers were largely unaware of the existence or the extent of the problems. The perception that memory problems are a normal part of aging; lack of screening tools in primary care; and stigma associated with memory loss could have accounted for these findings. The complexity of vascular conditions among this minority sample may have contributed to the high levels of memory decline. Our results suggest that interventions should be developed that are aimed at facilitating timely dementia diagnoses, particularly among the minority population who is at high risk for developing dementia.

284. College Students' Retirement Expectations: A Cross-Cultural Comparison, *Janet Koposko, Oklahoma State University; Douglas Hershey, Oklahoma State University; Martha Zapata, Universidad Autónoma de Yucatán; Antonio Brito, Universidad Autónoma de Yucatán*

Objectives: After attending this session, participants will be able to identify key psychological dimensions that underlie college students' expectations of future financial planning for retirement.; After attending this session, participants will have an appreciation for the way in which childhood and adolescent learning experiences influence the likelihood of future planning and saving.; After attending this session, participants will be able to identify similarities and differences between college student attitudes toward financial planning in the United States and in Mexico.

Abstract Body: Cross-cultural studies of retirement planning are limited, and most investigations focus on working adult populations. It has been argued that college students represent an important yet understudied segment of the population, given that they will soon face significant long-range financial decisions that have consequences for quality of life in old age. Indeed, little is known about how college students perceive the task of financial planning for retirement, and how those perceptions differ across cultures. Participants were 346 American and 345 Mexican college students between 18-52 years of age ($M=20.61$; $SD=2.89$). An established psychomotivational model of financial planning (Hershey, Henkens, & Van Dalen, 2010) was tested separately for each sample. Path analysis models revealed that among students in both countries, a striking amount of variance (approximately 40%) was accounted for in expectations of future financial planning activities. However, key predictors of the outcome variable (expected planning activities) differed cross-culturally. For Americans, financial knowledge had a dominant influence on the criterion, whereas for Mexicans, future time perspective was found to be more influential. Moreover, in both countries financial lessons learned from one's parents were found to be positively related to the development of a longer future time perspective. Results reveal that despite differences in culturally-linked financial values and national retirement systems, psychological variables (e.g., goals, knowledge, personality indicators) exert a strong influence on anticipated financial planning practices, but in different ways. These findings have implications for intervention specialists who seek to understand how cultural differences shape major life planning decisions.

285. Combat exposure predicts re-occurrence and new onset of PTSD over ten years in middle and older aged males from the National Comorbidity Survey, *Natalie Sachs-Ericsson, Scientist Department of Psychology Florida State University; Thomas Joiner, Distinguished Professor, Department of Psychology, Florida State University; Jesse Cougle, Assistant Professor, Department of Psychology, Florida State University; Ian Stanley, PhD Student, Department of Psychology, Florida State University; Julia Sheffler, PhD Student, Department of Psychology, Florida State University*

Objectives: To describe the effect of early combat exposure on the persistence or development of new onset post-traumatic stress disorder (PTSD) in older adulthood

Abstract Body: Background: Combat is a risk factor for post-traumatic stress disorder (PTSD); however, little is known about how early-life exposure to combat may contribute to the re-emergence or new onset of PTSD in later life. The 'sensitization' hypothesis posits that prior exposure to trauma sensitizes people to respond more intensely to subsequent stressors. Further, aging initiates new challenges that may undermine previous coping strategies. Thus, over the life course combat-exposed veterans may be more reactive to new stressors and thus more vulnerable to PTSD. Methods: The current study draws on the National Comorbidity Survey Wave 1 and Wave 2 (10-year follow-up). Participants were male (Non-Combat $N=620$ and Combat $N= 107$) and age 50-65 years at Wave 2. At baseline, participant's exposure to wartime combat was assessed and DSM-III diagnoses, including PTSD, were obtained. At follow-up, PTSD (re-occurrence or new onset) was determined. A measure of recent stressors (12-months) was also obtained. Results: Using logistic regression analyses, baseline combat predicted PTSD at follow-up (controlling for demographics, baseline DSM diagnoses, and PTSD). Recent stressors at follow-up were associated with PTSD. Whereas there was no difference in the number of recent stressors by combat status, the effect of recent stressors on the development of PTSD was greater for those who experienced combat. Conclusion: Veterans who have experienced combat may be more reactive to new stressors, and in turn be more vulnerable to the re-occurrence or new onset of PTSD. Older veterans who have experienced combat should be regularly assessed for current stressors and PTSD.

286. Community-dwelling Older Adults' Adherence to Fall Pevention Rcommendations, *Suzanne Taylor, Virginia Commonwealth University Medical Center; E. Ayn Welleford, Virginia Commonwealth University; J. James Cotter, Virginia Commonwealth University; Constance Coogle, Virginia Commonwealth University; Al Copolillo, Virginia Commonwealth*

Objectives: Participants will understand the difference between personalized education and generalized education for fall prevention recommendations. Participants will understand how to incorporate three learning avenues to provide fall prevention recommendations for older adults.

Abstract Body: Twenty-two community-dwelling older adults participated in a randomized control group study that took place across three home visits. Participants were interviewed regarding their recent falls and perceived susceptibility to future falls and a home environmental evaluation was conducted. Treatment group participants were provided personalized education while control group participants were provided generalized education with regards to recommendations to reduce environmental fall hazards. Participants who received personalized education were more likely to follow recommendations than those who received generalized education. No statistically significant relationship was found between an individual's recent falls, nor their perceived susceptibility to future falls, with their extent of adherence with environmental fall prevention recommendations. This study suggests that providing personalized education for environmental fall prevention recommendations increases adherence with such recommendations.

287. Comparison of Staff Caregiver Burden in Two Types of Care Facilities in Japan, *Mika Kunisada, Prefectural University of Hiroshima; Yuki Sawada, Nihon Fukushi University; Hiroshi Ishida, J. F. Oberlin University; Kana Kageyama, Kyushu University*

Objectives: After attending this session participants will be able to compare the levels of staff caregiver burden between two different types of care delivery models; After attending this session participants will be able to identify 3 most commonly reported burdensome nursing activities in Japan; After attending this session participants will be able to explain a factor affecting the level of staff caregiver burden

Abstract Body: Despite research in recent years has focused on the association between care delivery models and residents' quality of life, little is known about the associations between care delivery models and staff caregiver burden. This study aims to examine and compare caregiver burden in staff caregivers of newly adopted unit-based care facilities (UBCFs) and conventional non-unit-based care facilities (NUBCFs) in Japan. Participants were 83 nursing staff members (UBCFs: n=42; NUBCFs: n=41), who were asked to rate the level of burden on a 5-point rating scale (1=no burden and 5=extremely burdensome) for each of their nursing activities, which were coded and grouped into 10 categories using "Care-Codes" created by the national government of Japan. Results indicated that the mean level of caregiver burden was significantly lower in UBCF participants (M=2.3±0.7, p<0.001) than NUBCF participants (M=2.9±0.8, p<0.001), and UBCFs had the 3 lowest, while NUBCFs had the 3 highest levels of caregiver burden. A comparison between the types of nursing activities indicated that UBCF participants had a significantly lower mean level of burden than NUBCF participants in providing assistance with bathing and personal hygiene (respectively UBCFs: 2.4±0.9, NUBCFs: 3.3±1.1; p<0.001), eating (2.1±0.9, 2.8±0.9; p<0.001), toileting (2.7±0.7, 3.3±0.9; p<0.003), position change and transfer (2.5±0.9, 3.0±0.9; p<0.008), and providing indirect care (1.9±0.9, 2.8±0.9; p<0.001), social services and activities (1.6±0.9, 2.4±1.0; p<0.032), independent support services (1.7±1.0, 2.2±1.0; p<0.071), and medical care (1.9±1.0, 2.7±1.0; p<0.027). The results suggest that the new unit-based care delivery model is associated with lower staff caregiver burden levels.

288. Control Beliefs Moderate the Longitudinal Impact of Multimorbidity on Functional Impairments and Negative Affect, *Beth LeBreton, Purdue University; Elliot Friedman, Purdue University*

Objectives: Do control beliefs moderate the relationship between multimorbidity and functional impairment?; Do control beliefs moderate the relationship between multimorbidity and psychological well-being (i.e., positive and negative affect)?;

Abstract Body: The number of adults living with multimorbidity (i.e. two or more chronic medical conditions) is estimated to rise from 60 million in 2000 to 81 million by the year 20201, an increase that is expected to result in reduced quality of life (both mental and physical) for older adults. Using data from the national longitudinal Survey of Midlife in the United States (MIDUS), this study tested the hypothesis that control beliefs (personal mastery and perceived constraints) would moderate the degree to which baseline multimorbidity was associated with two key subsequent outcomes: physical functioning and subjective well-being. The sample consisted of adults ages 28-84 years (mean age 55, n = 4020). Physical and psychological functioning were assessed by basic activities of daily living (BADLs) and positive and negative affect, respectively. Baseline multimorbidity was positively related to BADL scores and negative affect, and inversely related to positive affect 9-10 years later. Importantly, significant interaction effects showed that individuals with multimorbidity and high control beliefs had similar BADL scores as those with no chronic conditions; however, those with multimorbidity and low control beliefs had higher BADL scores. Additionally control beliefs moderated the relationship between multimorbidity and negative affect (but, not positive affect), such that those with low control beliefs and multimorbidity had increased negative affect, while those with high control beliefs and multimorbidity did not. These results highlight how psychological resources such as control beliefs may provide a buffer against diverse negative outcomes associated with chronic medical conditions in aging adults. 1Fortin, 2007

289. Creating Homelike Care Environments: The Perspective of Formal Carers, *Ryan Woolrych, Simon Fraser University; Sarah Canham, Simon Fraser University; Caitlin O'Reilly, Simon Fraser University; Mei Fan Lang, Simon Fraser University; Judith Sixsmith, Simon Fraser University; Andrew Sixsmith, Simon Fraser University*

Objectives: To identify the perceptions of long-term care staff transitioning into a home-like care setting; To discuss the implications of home-like care settings on care practices and personalised care delivery.;

Abstract Body: Increasingly, long-term care (LTC) is being organized in ‘homelike’ care settings to support independence, autonomy, and choice for older adults. Despite the benefits homelike care settings have on older adults’ health and well being, particularly those living with cognitive difficulties, relatively little is known about how these environments are viewed and experienced by LTC staff. To address this gap, we report preliminary findings from a study evaluating the impact of transitioning from a traditional care facility into a homelike care setting in Victoria, BC, Canada. Qualitative ‘pre-move’ data from 4 focus groups and 30 semi-structured interviews with LTC staff (care aides, nurses, administration, and management) were analyzed using a thematic approach. LTC staff perceived homelike care environments (e.g. those with personalized, private spaces) as likely to enhance resident health and well-being. Care staff also identified a number of factors that may facilitate or constrain care delivery in a homelike care setting, impacting resident wellness, quality of care and staff workplace wellness. Factors identified by staff as either contributing to or detracting from a successful homelike care environment included: the design of the physical environment; culture of care; care efficiency; carer-staff relationships; and freedom of decision-making. Homelike care environments represent a shift from the care facility as an institutional setting to a therapeutic environment,designed around normalized living. As we strive to develop successful homelike care environments, the needs and insights of LTC staff need to be thoroughly considered and integrated into the design of such settings.

290. Depressive Symptoms, Cognition, and Everyday Function among Community-Residing Older Adults, *Glenna Brewster, University of South Florida, College of Nursing, School of Aging Studies; Lindsay Peterson, University of South Florida, School of Aging Studies; Rosalyn Roker, University of South Florida, School of Aging Studies; Michelle Ellis, University of South Florida, School of Aging Studies; Jerri D. Edwards, University of South Florida, School of Aging Studies*

Objectives: The objective of this study was to understand the relationships among depressive symptoms, cognitive performance, and functional performance in a community-based sample of older adults

Abstract Body: Background: Depression can negatively affect cognitive performance (Raji, Reyes-Ortiz, Kuo, Markides, & Ottenbacher, 2007) and functional performance (dos Santos Gomes et al., 2014). It is unclear, however, which particular cognitive domains are more influenced by depressive symptoms and whether these domains mediate the relationship between depressive symptoms and functional performance. Method: Older adults (N=885) between 62-96 years of age from the Staying Keen in Later Life (SKILL) study completed tests of executive function, memory, and speed of processing (Clay et al., 2009; Edwards, Wadley, Myers, et al., 2005). The Center for Epidemiological Depression Scale assessed depressive symptoms (CES-D). The Timed Instrumental Activities of Daily Living Test (TIADL), a performance-based measure, was used to assess participants’ accuracy and speed in completing different visual tasks. Results: Depressive symptoms had statistically significant, but small, associations with performance across domains of executive function (ps<.001), speed of processing (ps<.001), and some indices of memory (Hopkins Verbal Learning Test, p<.001, Spatial Span Forward , p<.001). There was no significant association between depressive symptoms and instrumental functional performance (p=.12). Conclusion: Depressive symptoms in a community-based sample similarly affect cognition in multiple domains, but do not significantly impair efficiency and accuracy of functional performance.

291. Differences in Leukocyte Telomere Length across Cultural and Ethnic Groups in a Multiethnic Sample in Hawaii, *Grant Edmonds, Oregon Research Institute; Hélène Côté, University of British Columbia; Sarah Hampson, Oregon Research Institute; Joan Dubanoski, Kaiser Permanente Center for Health Research, Hawaii*

Objectives: Identify cultural and ethnic group differences in leukocyte telomere length.; Evaluate social environmental and behavioral factors linked to differences in leukocyte telomere length across cultural and ethnic groups;

Abstract Body: Large health disparities across cultural and ethnic groups in Hawaii are well documented. Identifying surrogate endpoints has diagnostic value, in that these are observable prior to morbidity and mortality. Telomeres are protein structures at the ends of chromosomes and tend to shorten with age. Leukocyte telomere length(LTL) has been proposed as biomarker of cellular aging. Differences in LTL may offer observable makers of health, and thus allow for the evaluation of behavioral and social-environmental factors that contribute to health disparities. Using data from a multiethnic sample of adults assessed in Hawaii we investigated differences in LTL across participants’ self-identified cultural and ethnic groups, and evaluated explanatory variables including BMI, smoking, and educational attainment. LTL was assessed using qPCR on DNA derived from dried blood spots collected from a venous arm draw during a half day clinic visit. Comparing means of LTL adjusted for age and gender, we found evidence for differences in LTL across ethnic and cultural groups F(7,685) = 2.90, p = .01. Participants identifying as Chinese American had the longest average LTL; those identifying as Latino had the shortest LTL. These two groups differed by one standard deviation. Post hoc analyses revealed significant differences in six of the 21 possible pairwise comparisons. Smoking did not account for differences across groups in LTL. BMI and educational attainment partially accounted for group differences in LTL. These data suggest behavioral and social-environmental factors that partially account for disparities in health across cultural and ethnic groups.

292. Directly Assessed and Self Rated Memory among Older Adults: A Comparison between China and the US based on Nationally Representative Surveys, *Qiong Wu, Peking University*

Objectives: Compare the average levels of memory functions between Chinese and US older adults aged 50+; Examine whether the association between self rated memory and directly assessed memory scores is similar across two countries; Explore whether the association between memory function and a number of key predictors including demographics and depressive symptoms is the same across countries

Abstract Body: Purpose: The current study compares memory functions of Chinese and US adults aged 50+ in three aspects: 1) average level of directly assessed (objective) and self rated (subjective) memory; 2) association between objective and subjective memory; 3) factors associated with memory scores. Method: Data were from the latest wave of the Chinese Health and Retirement Longitudinal Study (CHARLS, Year 2011) and the US Health and Retirement Study (HRS, Year 2010). Results: Chinese older adults (n=11,709) scored much worse on the 10-word immediate (mean=3.14 vs 5.43 for the US) and delayed (mean=2.36 vs. 4.41 for the US) recall tests than the US older adults (n=12,865), and the Chinese also had lower self ratings (1.92 vs 3.01 for the US on a 1-5 scale). Gaps persisted after accounting for age, gender, education, marital status and depressive symptoms. Despite the wide gap, in both countries, objective memory scores accounted for only 5% of the total variance in subjective memory. Furthermore, the two countries showed similar patterns in the association between objective memory and age, gender, education, and depressive symptoms. Quite notably, the US data revealed an interesting pattern of differentiating effects of marital status, i.e., despite higher scores in objective memory of married respondents, they had levels of subjective memory. This pattern is also consistent with the China data. Conclusion: In both China and the US, objective and subjective memory scores are weakly correlated. China may face a greater challenge in fighting against cognitive impairment among older adults than the US.

293. Disease Knowledge and Coping Behaviors of Knee Osteoarthritis for Rural Community-dwelling Older Adults, *Stephanie Yu-ching Chen, Dept. of Adult and Continuing Education, National Chung Cheng University*

Objectives: to learn the disease knowledge and coping behaviors of knee OA for community-dwelling older adults; to learn the factors which affecting the disease knowledge and coping behaviors of knee OA for community-dwelling older adults;

Abstract Body: Older patients with low literacy lacked full awareness of knee osteoarthritis (OA) and always underestimated the disease severity. This study measure disease knowledge, coping behaviors and their impact factors of knee OA for community-dwelling older adults as a basis for the subsequent development of community care model. The object of study include 210 older adults are over 55 years old, there were pain symptoms on knee in the last year, cluster randomly sampled from 20 community senior centers at Taiwan south rural area. Research tools include knee OA knowledge scale and coping scale for the older adult. It collects data by group interview at the community senior centers. The results show that over 75% education level are under primary school, average age is 74.4 years old, 66.2% had visited the doctors and 71.9% had been diagnosed as knee OA. Older adults more understand clearly about disease causes and symptoms than diagnosis and treatment. The significant impact factors of knowledge, including age, gender, education level and inhabiting situation. Most of the active coping behaviors include not standing or squatting for a long time, having a rest in the right time, having regular exercise, and not getting on and going downstairs frequently. It is necessary to care about the older adults' negative emotional coping behaviors, include feeling sad from knee pain, being afraid of disability and becoming family burden. The significant impact factor of coping behaviors just only pain awareness. Finally, this study provides recommendations for educational intervention in the future.

294. Do Neighborhood Characteristics Explain the Association Between Childhood Socioeconomic Status and Adult BMI?, *Gregory Pavela, University of Alabama, Birmingham*

Objectives: After reviewing this research, participants will be able to identify evidence of sex-specific longitudinal associations between childhood conditions and adult weight

Abstract Body: There is evidence that childhood conditions exert an influence on adult weight. Whether the influence of childhood conditions on later weight is best described using a critical period model or an accumulation of risk model is not yet settled. This research tests whether neighborhood characteristics explain the association between childhood socioeconomic status and adult body mass index (BMI). The association between childhood conditions and adult body mass index is modeled using a two and three-level hierarchical linear model framework. Data on individual childhood and adult characteristics come from waves 2000 through 2008 of the Health and Retirement Study. Data on neighborhood characteristics come from the RAND Center for Population Health and Health Disparities Data Core. Results suggest that among males, childhood conditions are not associated with adult BMI after adjustment for individual characteristics. However, among females, paternal education remains associated with adult BMI after adjustment for individual and neighborhood characteristics. Past research has typically relied on paternal occupation as an indicator for childhood socioeconomic status, but results from these analyses demonstrate the importance of including a broader range of childhood SES measures when feasible.

295. Do Social Relationships Mediate Relationships between Age and Positive Emotion?: ; A Test of Socio-emotional Selectivity Theory in Japan and the U.S., *Jun Nakahara, Japan Society for the Promotion of Science; Mayumi Karasawa, Tokyo Woman's Christian University; Carol Ryff, University of Wisconsin-Madison*

Objectives: To test the prediction that the age-related difference of the quality of social relationships (social support and strain) would mediate improvement with age in emotional experience in two different cultural contexts

Abstract Body: That positive affect improves with age, while negative affect declines with age (known as the positivity effect) has been empirically demonstrated in Japan and the U.S. This trend has been interpreted within the framework of socio-emotional selectivity theory (SST) created by L. L. Carstensen. She claims that perceived constraints on time, namely impending death, lead to an emphasis in older adults on maintaining smaller, but more emotionally satisfying, social networks and avoiding interpersonal conflict. Drawing on SST, the present study tested the prediction that the age-related difference of the quality of social relationships (social support and strain) would mediate improvement with age in emotional experience in two different cultural contexts. We use data from MIDUS II in the U.S. and a parallel survey from Japan (MIDJA). MIDUS II was conducted in 2004-2006 as 2nd wave of a national survey of Americans and MIDJA was conducted in 2008-2010 with respondents randomly selected from the Tokyo metropolitan area. We selected MIDUS II respondents (n = 1,805) available to compare to MIDJA (n = 1,027). Result of the mediation analyses using bootstrapping showed that social strain mediated the negative association between age and negative affect in both countries. Additionally, social support and strain from family members were mediators of age-related improvement of positive affect, but only in the U.S. These results supported SST in case of negative affect in both countries, whereas imply it might be difficult to interpret the age-related improvement of positive affect from the perspective of SST in Japan.

296. Effects of Individual and Workplace Factors on Person-Centered Approaches to Dementia Care, *Paulette Hunter, University of Saskatchewan; Thomas Hadjistavropoulos, University of Regina; Lilian Thorpe, University of Saskatchewan; David C. Malloy, University of Regina*

Objectives: To determine how much variance in self-reported person-centred care is accounted for by organizational factors, after controlling for demographic variables.; 2.To determine whether personal factors, including beliefs about personhood in dementia and burnout, explained additional variance in self-reported person-centred care after controlling for demographic variables and organizational factors.

Abstract Body: Very few studies have empirically assessed variables that contribute to person-centred care. To contribute to an understanding of these variables, we used hierarchical regression to analyse results from a correlational descriptive survey of 109 long-term residential care employees. Scores on five subscales of the Person-Directed Care scale (PDC; Autonomy, Knowing the Resident, Personhood, Comfort Care, and Supporting Relationships) were regressed on measures of demographic factors, organizational-environmental factors, beliefs about personhood in dementia, and burnout. After controlling for demographic variables, organizational-environmental factors explained a statistically significant increase in variance for all five PDC subscale scores: ΔR2 = .278, ΔF(3, 87) = 12.51, p < .001; ΔR2 = .168, ΔF(3, 89) = 6.21, p < .01; ΔR2 = .196, ΔF(3, 88) = 7.79, p < .001; ΔR2 = .352, ΔF(3, 87) = 8.41, p < .001; ΔR2 = .342, ΔF(3, 86) = 17.01, p < .001. After controlling for demographic and organizational-environmental factors, beliefs about personhood in dementia also explained a statistically significant increase in variance (Personhood subscale of the PDC only, ΔR2 = .08, ΔF(1, 88) = 10.02, p < .01). Finally, burnout explained a statistically significant increase in variance (Personhood and Comfort Care subscales only, ΔR2 = .08, ΔF(2, 86) = 5.52, p < .01; ΔR2 = .05 and ΔF(2, 84) = 3.83, p < .05, respectively) after controlling for all other variables. These findings suggest that organizational-environmental factors are important to person-centered dementia care. Beliefs about personhood and burnout may also be important for some kinds of person-centered care.

297. Emotions and Alzheimer's Disease: Preliminary Efforts to Develop Emotional Staging for Alzheimer's Disease, *Sean Halpin, Geriatric Research, Education, and Clinical Center, Department of Veterans Affairs; Rebecca Dillard, Emory University Center for Health in Aging; Carolyn Clevenger, Emory University School of Nursing; Bill Puentes, Emory University School of Nursing; Roxanna Chicas, Perimeter College;*

Objectives: Identify common themes regarding internal and external stimuli and their effects on emotional status and/or behavior of AD/MCI patients; Enhance our understanding as to whether various emotional responses may (or may not) coincide with specific stages in AD/MCI progression;

Abstract Body: The emotional reactions to the progression of Alzheimer's disease (AD) oftentimes present as cognitive or behavioral changes, leading to misguided interventions by caregivers. Yet, despite a rich body of literature identifying cognitive and behavioral staging of AD, the emotional changes that accompany AD have been largely ignored. Here we present preliminary findings of a study which seeks to fill this gap through one hour, unstructured interviews, with seventeen caregiver–patient dyads; patients were in various stages of mild cognitive impairment and AD. An interdisciplinary team employed grounded theory methods to detect emotional characteristics of the participants with AD. Emotional experiences were classified into depression/sadness, apathy, concern/fear, anger/frustration, and acceptance. However, the experiences did not necessarily present linearly, and instead were entwined within a set of binary (positive/negative) categories including; relationship with the informal caregiver (e.g., teamwork versus infantilzation), relationship with the formal caregiver (e.g., patient versus disengaged), coping (e.g., adaptive versus non-adaptive), and perceived control (e.g., internal versus external locus of control). An example is a person who has poor caregiver support and external locus of control may become depressed, a condition which is known to negatively affect cognitive status. Future work will further explore the emotional experiences as they relate to demographic characteristics and to the currently established cognitive and behavioral Functional Assessment Staging Tool (FAST). Understanding the emotional reactions of individuals diagnosed with AD will provide clinicians with the information needed to develop treatment modalities best suited to the emotional needs and stage of the patient.

298. Empty Nest Status of Midlife Parents: Associations with Marital Functioning and Health, *Lauren Papp, University of Wisconsin-Madison;*
Objectives: To document associations between family transitions, namely empty nest status, and midlife parents' marriage functioning and health outcomes
Abstract Body: Establishing how spouses and marriages fare during the highly normative “empty nest,” when couples live with no children after having raised one or more children together, is important because midlife functioning is a robust predictor of aging outcomes, including physical, psychological, and financial health, and mortality. This study employed secondary analysis of the Wisconsin Longitudinal Study to examine marital adjustment and personal health of adults in the empty nest as compared to adults living with grown children in the home. Findings based on 6,140 married midlife individuals indicated that empty nest status, or living without grown children, was positively associated with marital quality levels (b = .063, t = 5.44, p < .001) and negatively associated with depression symptoms (b = -1.082, t = -2.53, p = .011); empty nest status was not reliably associated with physical health ratings (b = .035, t = 1.70, p = .09). Moderator tests further revealed that the findings did not significantly differ for men versus women or for first- versus later-marriages.

299. Monocyte chemoattractant protein-1 (MCP-1): A pro-inflammatory cytokine elevated in sarcopenic obesity (SO), *Mei Sian Chong, Institute of Geriatrics and Active Ageing. Tan Tock Seng Hospital; Yew Yoong Ding, Institute of Geriatrics and Active Ageing. Tan Tock Seng Hospital; Laura Tay, Institute of Geriatrics and Active Ageing. Tan Tock Seng Hospital; Ismail NH, Institute of Geriatrics and Active Ageing. Tan Tock Seng Hospital; Audrey Yeo, Institute of Geriatrics and Active Ageing. Tan Tock Seng Hospital; Suzanne Yew, Institute of Geriatrics and Active Ageing. Tan Tock Seng Hospital; Bernard Leung, Department of Rheumatology, Allergy and Immunology. Tan Tock Seng Hospital*
Objectives: To understand the differences between sarcopenia and sarcopenic obesity and the functional implications; To understand the role of pro-inflammatory biomarker in sarcopenic obesity;
Abstract Body: Objectives: Skeletal muscle may be negatively influenced by the pro-inflammatory milieu associated with visceral fat, while the loading effect of obesity may enhance muscle anabolism. We set out to examine the association of MCP-1 with SO compared with pure sarcopenia and obesity phenotypes. Methods: We studied 151 community-dwelling, cognitively-intact, well older adults. Clinical data,physical performance measures (short physical performance battery (SPPB)) and muscle mass measurements were collected. Blood biomarker and MCP-1 levels were performed. Asian Working Group for Sarcopenia criteria and NCEP-obesity definitions were used. Multiple group comparisons and correlation analysis were performed. Results: 25.8% subjects of study subjects were normal, 13.4% sarcopenic, 48.3% obese and 11.9% SO respectively. Significant differences in age, gender and stroke disease prevalence between subgroups noted. There was an incremental increase in body fat with the 4 clinical phenotypes while appendicular lean mass was lowest with poorest physical performance on SPPB in SO. MCP-1 level was significantly different (104.9+34.8 for normal, 96.4+21.5 for sarcopenia, 118.0+50.1 for obese and 147.6+71.8 for SO subjects respectively, pg/ml, p<0.05). Modest correlation of MCP-1 was noted with body fat (Spearman’s correlation coefficient 0.16, p=0.05) with no significant correlation between MCP-1 and appendicular lean mass (correlation coefficient 0.06, p=0.49). Conclusion: SO represents a distinct phenotype (‘obesity paradox’) in older adults with performance limitations beyond sarcopenia-related lean mass alone. MCP-1 is significantly raised, suggesting a potential role of inflammatory cytokines in the pathogenic mechanism of SO. These interesting results require further confirmation in longitudinal study with potential therapeutic implications.

300. Heterochronic Parabiosis: Allowing the Dissection of the Aged Immune System, *John Davies, Department of Immunobiology and the Arizona Center on Aging, College of Medicine, University of Arizona; Heather Thompson, Department of Immunobiology and the Arizona Center on Aging, College of Medicine, University of Arizona; Vesna Pulko, Department of Immunobiology and the Arizona Center on Aging, College of Medicine, University of Arizona; Janko Nikolich-Zugich, Department of Immunobiology and the Arizona Center on Aging, College of Medicine, University of Arizona*
Objectives: Tissue mapping of the immune system in heterochronic parabiosis.; Rejuvenation of the aged immune system.;
Abstract Body: Parabiosis is the surgical union of two organisms resulting in the development of a single, shared circulatory system. When animals of different ages are conjoined (i.e. heterochronic parabiosis), investigators have shown that blood-borne factors from the younger animal beneficially affect the older animal and recapitulate the youthful phenotype and function in their target tissues. However, the effect of heterochronic parabiosis on the aged immune system remain unexplored. An important question to be answered is whether the cellular defects involved in the aged immune system are due to intrinsic defects or if they can be rescued by extrinsic factors. This experimental technique is ideal to test cellular

migration patterns, interrogate the mechanisms driving migration defects that occur with aging, if these defects can be rejuvenated and which molecules are targets for intervention. Finally, T cell ontogenesis is known to diminish drastically with age due to thymic involution, but there are also defects in lymphopoiesis that affect early T cell precursors. The heterochronic parabiosis model allows one to test the contributions of the aged thymus, the aged pre-T cells (thymic seeding progenitor cells) or the aged systemic environment are involved in the defect in thymic output with age. Thus far, the preliminary data hint at differential migration patterns of T cells, B cells and neutrophils. Of interest, while young pre-T cells can adequately seed the old thymus and undergo thymopoiesis, the opposite is not true, indicating that there may be a defect in old pre-T cell generation or migration to the thymus.

301. Effect of Aging and Exercise on Irisin and BAIBA in Humans, *Sangeeta Ghosh, University of Texas Health Science Center San Antonio; Hanyu Liang, University of Texas Health Science Center San Antonio; Helen lum, The University of Texas Health Science Center San Antonio; Jose De Jesus Garduno Garcia, The University of Texas Health Science Center San Antonio; Raweewan Lertwattanarak, The University of Texas Health Science Center San Antonio; Nicolas Musi, The University of Texas Health Science Center San Antonio*

Objectives: To Examine the Effect of Aging and Exercise on Plasma Irisin and -aminoisobutyric acid (BAIBA) Levels in Humans

Abstract Body: Rodent studies suggest that skeletal muscle functions as an endocrine organ that releases substances that act on target tissues (e.g. adipose). One of these substances is irisin, a protein encoded by FNDC5 which expression is controlled by PGC1α. Another substance secreted by rodent muscle is BAIBA, a by-product of thymine catabolism. In vitro, irisin and BAIBA induce conversion of white to brown adipose tissue which is highly metabolically active. Thus, it has been hypothesized that exercise increases energy expenditure and improves glucose metabolism by contraction-induced release of irisin and BAIBA that promote “browning” of white fat. Here, vastus lateralis muscle biopsies were performed in 24 healthy young (age=26±3 y), lean (BMI=24.1±0.5 kg/m2), and 48 healthy older (age=73±7), lean (BMI=24.4±0.4) subjects, before and after 16 weeks of aerobic exercise. Baseline PGC1α (50%) and FNDC5 (24%) mRNA levels were lower in older subjects. Basal plasma irisin and BAIBA also were reduced in older subjects (both by ~12%). Exercise increased PGC1α (40%) and FNDC5 (30%) expression in older and younger (50% for both genes) subjects, accompanied by improvements in insulin sensitivity and Vo2max. Exercise also increased plasma irisin (44%) and BAIBA (23%) in older subjects. In younger subjects, exercise increased BAIBA (28%), whereas irisin did not change. Conclusions: 1) Human aging is associated with decreased muscle PGC1α and FNDC5 expression, and lower plasma irisin and BAIBA concentrations, changes that could be involved in the metabolic alterations of aging; 2) Exercise reverses these alterations, effects that may contribute to its beneficial metabolic effects.

302. Age-Associated Declines in Power and Contractile Velocity Increased Under Heavily Loaded Conditions, *Ted Graber, University of Minnesota Medical School Dept. of Physical Medicine and Rehabilitation; Jong-Hee Kim, University of Houston, Dept. of Health and Human Performance; Robert Grange, Virginia Tech University, Dept. of Human Nutrition, Foods, and Exercise; Linda McLoon, University of Minnesota Medical School, Dept. of Ophthalmology and Visual Neurosciences; LaDora Thompson, University of Minnesota Medical School, Dept. of Physical Medicine and Rehabilitation, Program in Physical Therapy*

Objectives: Those who view our poster will learn how age effects peak force, contractile velocity, and power production in the EDL and soleus muscles of the common aging model C57BL/6 mouse.; For the first time, we present data that shows that age has an increased effect on both contractile velocity and power production during concentric contraction against loads above 50% of peak force.; The observer will walk away from our poster with understanding that future research into using power and velocity training to improve functional ability may greatly benefit the elderly., rather than just strength training alone.

Abstract Body: Defining the fundamentals of skeletal muscle physiology in animal models of aging is required, pre-clinically, to assess treatment strategies designed to improve age-related conditions such as sarcopenia or frailty. Power production by skeletal muscle is critical for dynamic movement, but has not been fully investigated across the mouse lifespan. In this study, we determined the effect of age on power production, and its determinants, contractile velocity and force output, in male C57BL/6 mice. We hypothesized that both velocity and force would decline with age, therefore reducing power. We also predicted age would diminish power more during concentric contractions against loads above 50% of peak isometric force (P0). P0 and contractile velocities at loads from 10-90%P0 were determined in vitro in the soleus and EDL muscles of adult, old and elderly mice, representing 100, 75 and 50% survival, respectively. Power curves were then derived from the force-velocity relationships. We found that power, velocity, and force all declined in an age-associated manner. Furthermore, there was an increased age-effect on both velocity and power during heavily loaded contractions. Thus, age-associated movement challenges during more difficult tasks in the elderly may be due, in part, to an accelerated deterioration of power production and contractile velocity under heavy loads, not just from reduced force output. Training regimens to improve contractile velocity throughout the load range in the elderly may synergistically benefit power output beyond simple strength training alone.

303. mTOR Regulates PGC-1α Turnover and Activity Through GSK3β in Mouse Adipocytes, *Porsha Howell, University of Wisconsin- Madison Department of Nutritional Sciences; Karl Miller, University of Wisconsin- Madison; Tapas Nayak, University of Wisconsin- Madison; Stephen Martin, University of Wisconsin-Madison; Maggie Burhans, University of Wisconsin-Madison; Michael Polewski, University of Wisconsin-Madison; Rozalyn Anderson, University of Wisconsin-Madison*

Objectives: 1)After attending this session participants will be able to synthesize previous knowledge regarding regulation of GSK3β in the presence of oxidative stress and CR with new knowledge of mTOR.; 2)Participants will also be able to compare the effect of rapamycin an lithium on adipocyte lipid metabolism in differentiating adipocytes from mature adipocytes and in vivo adipose tissue.;

Abstract Body: Caloric restriction (CR) is a dietary regimen that extends lifespan. In white adipose tissue, CR positively regulates peroxisome proliferator-activated receptor gamma coactivator 1α (PGC-1α), a master regulator of mitochondrial metabolism, and negatively regulates glycogen synthase kinase 3β (GSK3β), which targets PGC-1α for proteasomal degradation. Lifespan is also extended by rapamycin, an inhibitor of the mechanistic target of rapamycin (mTOR). Here we show that under conditions of oxidative stress rapamycin treatment increased inhibitory phosphorylation of GSK3β and blocked GSK3β-mediated turnover of PGC-1α. The PGC-1α transcriptional program in response to oxidative stress was also blocked by rapamycin. In cultured adipocytes rapamycin treatment increased GSK3β inhibitory phosphorylation but now promoted PGC-1α nuclear localization within one hour of treatment and increased the mitochondrial transcriptional program and mitochondrial activity. In differentiating adipocytes rapamycin prevented lipid accumulation as cells transition to mature adipocytes. GSK3β inhibition using lithium chloride produced a similar response where cells failed to accumulate lipids following adipogenic stimulus. In mature adipocytes three days of rapamycin treatment did not affect lipid mobilization but GSK3β inhibition using lithium chloride caused a reduction in lipid stores. Similarly in rapamycin fed mice, adipocytes are not smaller and while GSK3β is inhibited there is no evidence of a difference in PGC-1α levels or activity. In lithium carbonate treated mice, adipocytes were reduced in size and adiposity was substantially reduced. These data show that GSK3β is downstream of mTOR signaling but that the impact of this axis on PGC-1α is specific to cell type and duration of inhibitory stimulus.

304. A Validated Mouse Frailty Index: Impact of Factors That Affect Lifespan, *Alice Kane, University of Sydney; Sarah N Hilmer, University of Sydney and Royal North Shore Hospital; Susan E Howlett, Dalhousie University; Rafael de Cabo, National Institute on Aging; Sarah J Mitchell, National Institute on Aging*

Objectives: We aimed to investigate the effect on the mouse frailty index, of factors known to influence lifespan and healthspan in mice: mouse strain (short lived DBA2/J mice versus long-lived C57BL/6 mice), calorie restriction and resveratrol treatment

Abstract Body: A clinical frailty index (FI) scale based on deficit accumulations has been validated in C57BL/6 mice (Whitehead et al., 2014). We aimed to investigate the effect on the mouse FI, of factors known to influence lifespan and healthspan in mice: mouse strain (short lived DBA2/J mice versus long-lived C57BL/6 mice), calorie restriction (CR) and resveratrol treatment. FI scores were measured on male aged (18 month) ad-lib fed and CR DBA2/J and C57BL/6 mice, as well as male aged (24 month) C57BL/6 mice ad lib or resveratrol-diet fed. Mean scores of 2 raters were used. There was a trend towards higher FI scores in the ad-lib DBA2/J mice compared to the C57BL/6 mice (FI=0.25±0.09 DBA2/J, 0.20±0.08 C57BL/6, p>0.05). CR reduced FI in C57BL/6 mice (FI=0.13±0.03 CR, 0.20±0.08 ad-lib, p=0.04) but not in DBA2/J mice. Aged mice with chronic resveratrol treatment had a lower FI than ad-lib fed mice (FI=0.18±0.01 resveratrol, 0.22±0.01 ad-lib, p=0.01). The 2 raters had excellent inter-rater reliability (ICC = 0.88, 95% CI [0.80, 0.92]). CR and resveratrol were shown to decrease FI in male C57BL/6 mice, compared to age matched controls. Furthermore the DBA2/J mice had a trend towards higher FI scores than the C57BL/6 mice, and had no change in FI with CR. This study further validates the mouse FI developed by Whitehead et al. (2014) in a different mouse colony with dietary and pharmaceutical interventions. It provides preclinical evidence to support testing the effects of these interventions on frailty index in humans.

305. Development of a Microfluidic Experimental System for the Study of Dietary Influences on C. elegans Life History Traits, *Michael Kiflezghi, Virginia Commonwealth University; Stephen Banse, University of Oregon; Nadine Timmermeyer, University of Oregon; Benjamin Blue, University of Oregon; Patrick Phillips, University of Oregon*

Objectives: Determine the proper flow rate for channels in a microfluidic device designed to measure life history traits of a population of nematodes.; Determine the proper channel width for a microfluidic device that allows for isolation and visualization of a single nematode.;

Abstract Body: The soil dwelling bacterivore Caenorhabditis elegans exhibits variance in life history traits, even after experimental standardization of genetics, environment, and diet. What is the basis of this variance? One possibility is that different food preferences and rates of consumption undo attempts to standardize diet, creating variable life history outcomes. Can a pattern be elucidated from the behavior of individuals to allow for meaningful life history predictions? Can reporters for dietary input detect behaviorally generated differences among individuals in the same food environment? The adoption of microfluidic technologies may provide the needed level of environmental and dietary control to answer these questions. Here we will present an experimental system based on three microfluidic devices to answer these questions. (1) The “Imaging

Chip" allows for trapping of individual worms for a lifetime. While trapped the worm is unable to leave food, unlike traditional experiments, and the experimenter has complete control of their diet as a bacterial suspension flowing through the device. (2) The "Arena Chip" allows the experimenter to create controlled, yet more complex, food environments in which a small population of worms are free to behave. Worms are monitored as they act on any preferences they may have by swimming into different fluid flows. (3) The "Sorter Chip" that enables high throughput visual phenotyping of animals expressing a previously published dietary sensor, Pacdh-1::gfp, to determine the relationship between behavior and dietary input. These devices form a microfluidic experimental system for the study of dietary influences on C. elegans life history traits.

306. PDGF/FGF Mediates Rejuvenation Effects of Mouse ESC Conditioned Media on Cellular Senescence, *Jae-Ryong Kim, Department of Biochemistry and Molecular Biiology, College of Medicine Yeungnam University; ,*

Objectives: To elucidate whether conditioned media from embryonic stem cells exert inhibitory activity on cellular senescence.; To elucidate what factors in conditioned media from embryonic stem cells play an important role in the rejuvenation of cellular senescence.

Abstract Body: Cellular senescence, an irreversible state of growth arrest, underlies organismal aging and age-related diseases. Recent evidence suggests that aging intervention based on inhibition of cellular senescence or rejuvenation of senescent cells might be a promising strategy for treatment of aging itself as well as age-related diseases. Embryonic stem cells (ESCs) and ESCs-conditioned medium (ESCs-CM) have been suggested to be desirable source in regenerative medicine. However, effects of ESCs-CM on cellular senescence were not determined yet. Here, we showed that treatment of senescent human dermal fibroblasts (HDFs) wih CM from mouse ESCs (mESCs) (mESCs-CM) decreases senescence phenotypes, which is confirmed by decreases in senescence-associated beta-galactosidase activity and the levels of p53 and p21 proteins, and an increase in cell proliferation. We further determined that platelet-derived growth factor-BB (PDGF-BB) is a key molecule for rejuvenating activity of mESC-CM through up-regulation of fibroblast growth factor-2 (FGF-2). Finally, we confirmed that mESCs-CM accelerates wound-healing process by reducing dermal p53 expression and increasing epithelial proliferation in vivo models. Taken together, our results suggest that mESCs-CM has rejuvenating capacity to revert senescent cells to young cell-like phenotypes and might emerge as a novel therapeutic strategy for age-related diseases.

307. Births Cohorts, Age, and Sex Are Strong Modulators of the Effects of Lipid Risk Alleles Identified in Genome-Wide Association Studies, *Alexander Kulminski, Duke University; Irina Culminskaya, Duke University; Konstantin Arbeev, Duke University; Liubov Arbeeva, Duke University; Svetlana Ukraintseva, Duke University; Eric Stallard, Duke University; Anatoli Yashin, Duke University*

Objectives: To provide evidences of complex role of genes in polygenic health traits which is often overlooked in genome-wide association studies; To discuss more appropriate strategies for addressing complex role of genes.;

Abstract Body: Insights into genetic origin of diseases could substantially impact strategies for improving human health. GWAS results are often positioned as discoveries of unconditional risk alleles of complex health traits. We re-analyzed the associations of SNPs discovered as correlates of total cholesterol (TC) in a large-scale GWAS meta-analysis. We focused on three generations of 9,167 participants of the Framingham Heart Study (FHS) which was a part of that meta-analysis. We show that the effects of all 10 available SNPs, without exception, were clustered in different FHS generations and/or birth cohorts in sex-specific or sex-unspecific manner. The sample size and procedure-therapeutic issues play at most minor role in this clustering. A striking result was clustering of significant associations with the strongest effects in the youngest 3rd Generation cohort. These results imply that an assumption of unconditional connections of SNPs with TC is generally implausible and that demographic perspective can seriously improve GWAS efficiency. The analyses of genetic effects in age-matched samples suggest predominant role of qualitatively different environmental and age-related mechanisms in the associations of different SNPs with TC. Analysis of literature supports systemic roles and differences in these roles for genes for SNPs from the age-related and environmental sets. The results suggest antagonistic effects of rs2479409 from PCSK9 gene that cautions strategies aimed to target this gene in the next generation lipid drugs. Our results suggest that standard GWAS strategies need to be advanced to appropriately address the problem of genetic susceptibility to complex traits that is imperative for clinical translation.

308. The light at the end of the tunnel: Long-lived naked mole-rat resistance to UV-induced skin tumorigenesis, *Kaitlyn Lewis, University of Texas Health Science Center at San Antonio; Thomas Slaga, University of Texas Health Science Center at San Antonio; Rochelle Buffenstein, University of Texas Health Science Center at San Antonio/Barshop Institute for Longevity and Aging Studies*

Objectives: To determine if the strictly subterranean, cancer resistant naked mole-rat is sensitive to UV radiation-induced skin tumorigenesis and to identify genomic response to this treatment.; To utilize the naturally long-lived naked mole-rat and identify a relationship between cancer resistance and prolonged healthspan and lifespan.;

Abstract Body: The long-lived naked mole-rat is resistant to spontaneous neoplasia, chemical-induced tumorigenesis, and to an array of carcinogenic and DNA-damaging compounds. We attributed its resistance to chemical-induced tumorigenesis to having evolved to lead a strictly subterranean lifestyle in soils riddled with heavy metals and other toxins. We therefore speculated that while resistant to toxins these underground dwelling rodents may be exquisitely sensitive to ultraviolet radiation induced skin carcinogenesis. In vitro data revealed that skin fibroblasts showed increased susceptibility to UV exposure. We therefore hypothesized that naked mole-rats would develop tumors at a faster or similar rate to that of hairless SKH1 mice. Surprisingly, we found that naked mole-rats were extremely resistant to UV-induced skin tumorigenesis. Even after 6 months of UV irradiation, no mole-rat developed tumors whereas all mice had tumors by 18 weeks. We attribute species differences in response to UV to pronounced differences in DNA repair and cell turnover. Current studies explore interspecific differences in molecular response to UV irradiation with our long term goal to identify potentially novel and translatable mechanisms that may play a role in skin cancer prevention and highlight mechanistic relationships between cancer resistance and longevity.

309. Quality of Life among Stroke Patients in the Russian Federation, *Victoria Adams, University of West Florida; Daniel Durkin, University of West Florida*

Objectives: After attending this session, participants will be able to discuss the effectiveness of treatment with stroke patients in the Russian Federation

Abstract Body: Research shows that quality of life for stroke patients who have difficulties with activities of daily living can be improved through treatment. Although there is a significant amount of literature on the effects of stroke on daily function and quality of life, most of the published research is based on Western populations. Very little is known about treatment outcomes in non-Western countries. Using secondary data from the World Health Organization's Study on Global Aging and Adult Health (SAGE) from the Russian Federation we examined the relation between difficulties with activities of daily living (ADL) and quality of life (QOL) in 239 stroke patients when controlling for sex, age, income, and whether or not they had treatment in the last 12 months. Regression analysis revealed that difficulties with ADLs significantly predicted subjective QOL; however, treatment was not significant. Participants with higher ADL difficulty scores reported lower QOL. Income and age were also significant in that higher income and higher age were associated with higher appraisals of quality of life. Results suggest that participants who reported greater difficulty with ADLs appraised their QOL as lower than those with less difficulty, regardless of whether or not they received treatment in the last 12 months. This suggests that treatment in the Russian Federation may not be effective in improving the QOL of stroke patients. Interestingly, participants who were older reported higher QOL. This matches research using socioemotional selectivity theory that suggests that older adults are more likely to focus on the positive.

310. Age, postoperative interlukin-6, and perfusion time predicted hospital length of stay among cardiac surgery patients, *Amy Ai, Florida State University*

Objectives: To educate health related gerontologists about an important function of an aging related biomarker in relation to a common procedure in late life

Abstract Body: Background: Interleukin-6(IL-6) is a multi-function, pro-inflammatory cytokine that is chronically elevated in heart diseases. Research suggested that IL-6 may play an important role in the development of systemic inflammatory response syndrome(SIRS) following cardiopulmonary bypass(CPB) used in major open-heart surgery. The present study capitalized on a previous report that used non-laboratory preoperative data of 235 patients undergoing open-heart surgery to predict their hospitalization(LOH) LOH following open-heart surgery. Methods: All patients underwent cardiac surgery (e.g., CABG, valve repair/replacement surgery), requiring CBP. Two weeks prior to their scheduled operation, trained research assistants blinded to cardiac indices and lab data recruited patients for a psychosocial study and conducted interviews. Key cardiac indices were obtained from a national database: the Society of Thoracic Surgeons' Adult Cardiac Database at the hospital. Blood samples were collected three days postoperatively for biomarker assays. Plasma was stored within 30 minutes of acquisition. Plasma IL-6 was measuredusing a sandwich enzyme immunoassay kit, Quantikine High-Sensitivity IL-6(R&D Systems, Minneapolis MN) with no modification of the manufacturer protocol. Results: Univariate analysis shows that significantly correlated with LOH were age, more medical comorbidities, perfusion time and postoperative IL-6. Results from the regression model predicting LOH[F(10,N=215)=8.042,p<.001,R2=.282], showed that, among known predictors in the previous report and other STS cardiac indices, only age, perfusion time and postoperative IL-6were significantly associated with LOH(p<.01).Conclusion: Advancingthe previous finding that linked postoperative IL-6 and perfusion time, this study associated IL-6 with LOH, which might mediate the impact of age and medical comorbidities shown in bivariate analyses.

311. Readiness for Interprofessional Learning in the Innovative Community-Based Richmond Health and Wellness Program (RHWP) for Community Dwelling Older Adults, *Sierra Alewine, Virginia Commonwealth University, School of Nursing; Antoinette Coe, Virginia Commonwealth University, School of Pharmacy; Pamela Parsons, Virginia Commonwealth University, School of Nursing; Elizabeth Pohoreskey, Virginia Commonwealth University, School of Nursing; Fay Parpart, Virginia Commonwealth University, School of Nursing; Kelechi C. Ogbonna, Virginia Commonwealth University, School of Nursing; Arzo Hamidi, Virginia Commonwealth University, School of Pharmacy*

Objectives: Examine students' attitudes towards interprofessional, team-based learning in a collaborative clinical practice setting

Abstract Body: The Richmond Health and Wellness Program (RHWP) is an innovative, interprofessional, student-led, care coordination and wellness clinic located in a Section-8 apartment building serving low-income health disparate older adults in Richmond, Virginia. Interprofessional student teams provide care coordination and chronic illness education during visits. At completion of the visit, students debrief with clinical faculty to discuss resident care plans. Student attitudes toward interprofessional learning were assessed prior to the experience with the 23-item Readiness for Interprofessional Learning Scale (RIPLS). Higher scores on the RIPLS indicate a more positive attitude towards interprofessional learning. Fifty-nine students completed the questionnaire for the Spring and Summer of 2014. The majority of students were under 30 years (70.7%), female (81.0%), and had at least some healthcare experience prior to starting their program (63.9%). Students disciplines included: nursing (BSN: n=18 (31.6%), NP: n=17 (29.8%)), pharmacy (n=6 (10.5%), medicine (n=7 (12.3%)), social work (n=4 (7.0%)), and other (n=5 (8.8%)) programs. The students had high mean values on the three RIPLS subscales indicating a readiness for interprofessional learning: teamwork and collaboration (M=4.4 (SD: 0.53); Cronbach's alpha=0.93), patient-centeredness (M=4.7 (SD: 0.62); Cronbach's alpha=0.94), and sense of professional identity (M=3.9 (SD: 0.72); Cronbach's alpha=0.80). There were no significant differences in the three subscales based on gender, age, prior healthcare experience, or program of study. Understanding students' readiness for interprofessional learning is important for faculty program development and evaluation. We will continue to evaluate student groups on these measures to ensure discipline specific congruency in their interprofessional learning attitudes.

312. Examining the Role of Confounding Factors in Meta-analysis of Observational Cohorts of Aging Populations: Artificially-Sweetened Beverages and Type 2 Diabetes as an Example, *Michelle Althuis, EpiContext; Michelle Althuis, EpiContext; Cara Frankenfeld, George Mason University, Department of Global and Community Health; Dominik Alexander, Epidstat Institute*

Objectives: 1.To examine the role of confounding factors in a meta-analysis of observational studies of a chronic disease of aging.; 2.To suggest a simple measure that quantifies the degree of measured confounding across studies included in the meta-analysis.; 3. To develop an approach to the evaluation and reporting of confounding factors in meta-analyses of observational studies that may be used by other investigators.

Abstract Body: Background: Interpretation of meta-analysis of aging cohorts that have decades of follow-up is complicated when exposure-disease relationships are weak/modest (i.e. relative risks < 1.4) and many potential confounding factors are present. An example of this challenge is nutritional epidemiology studies of chronic diseases, for which it is often unclear whether the association is attributable to a specific food item or collinear relationships with other diet and lifestyle factors. Methods: We examine this issue by evaluating the role of confounding factors in a meta-analysis of prospective studies of artificially-sweetened beverage (ASB) intake and type 2 diabetes (T2D). We present a structured approach, including a priori identification of confounders, assessment of control for confounding in the primary studies, and summary relative risk estimates (SRREs) for meta-analytic models with different levels of adjustment. Results: We synthesized data from 7 observational studies, noting considerable design heterogeneity overall, but particularly across statistical modeling approaches which included up to 17 co-variables. The pooled estimate for extreme categories of ASB intake across fully adjusted models (including body size, SRRE = 1.12, 95% CI 1.03 – 1.22; I2 =39%) relative to the age-adjusted models (SRRE = 1.79) resulted in a large (83%) attenuation in T2D risk. Conclusion: Examining the influence of confounding factors is critically important for interpreting meta-analyses of observational cohorts of diseases of aging. The observed weak ASB-T2D association, which decreased considerably with adjustment for known/measured co-variables, suggests the use of caution is appropriate when interpreting the summary risk estimate.

313. Getting Into the Mouth: The Effect of the EBMC-D Intervention on Refusals and Rejection of Mouth Care by LTC Residents with Dementia, *S. Danielle Baker, University of Alabama at Birmingham SON; Rita Jablonski-Jaudon, University of Alabama at Birmingham; Vicki Winstead, University of Birmingham; Corteza Jones-Townsend, University of Alabama at Birmingham*

Objectives: To compare the effect of an evidence-based mouth care program (EBMC) to one that combines evidence-based mouth care practices with dementia-centric communication strategies (EBMC-D) on refusals and rejection of mouth care by LTC residents with dementia

Abstract Body: Background: Persons with dementia in long-term care (LTC) often refuse and reject mouth care. We compared an evidence-based mouth care program (EBMC) to one that integrated dementia-centric communication strategies (EBMC-D) in 7 LTC facilities on mouth care refusals and rejection. Methods: LTC residents with dementia who exhibited care-rejection behaviors during mouth care were randomized to experimental or control groups. Both groups received twice daily mouth care for three weeks from the research team. Care-rejection behavior was quantified during each mouth care interaction using a modified Resistiveness to Care Scale. Data were analyzed to capture overall refusals and amount of completed mouth care. Results: Sixty-eight residents participated: 34 in both the experimental and control groups. Mean age was 81 years; 76% were female and 80% were white. All had moderate to severe dementia (mean Global Deterioration Score, 6.0). Both groups were similar on all variables except for two. The experimental group had resided in LTC longer (26 months versus 14.5 months, p<0.01) and was more resistant to care (5.3 versus 3.0, p<0.01). The EBMC-D intervention reduced overall mouth care refusals (13% experimental versus 21% control, p<0.01) and improved completion rates (71.1%

experimental, 67.6% control, not statistically significant). Conclusion: Mouth care can only be delivered if LTC residents with dementia accept it. EBMC-D reduced refusals and rejection of mouth care. Although the difference in completion rates between the two did not approach significance, the difference may have been affected by the use of an active control.

314. Facilitators and Barriers to Self-Management of Nursing Home Residents: Perspectives of Health Care Professionals in Korean Nursing Homes, *Hwal Lan Bang, College of Nursing, and The Research Institute of Nursing Science, Seoul National University; Hwal Lan Bang, The Research Institute of Nursing Science, Seoul National University; Ga Hye Kim, College of Nursing, Seoul National University; Ji Yeon Ha, College of Nursing, Seoul National University*

Objectives: To explore facilitators and barriers of self-management from the viewpoint of staffs taking care of nursing home residents with multiple chronic diseases in South Korea

Abstract Body: Purpose: To explore facilitators and barriers of self-management from the viewpoint of staffs taking care of nursing home residents with multiple chronic diseases in South Korea. Methods: : A qualitative content analysis using the focus group interview method was used. Total of 23 health care professionals (16 nurses and 7 social workers) from three urban nursing homes with more than 100 beds were interviewed. Results: 5 facilitators were identified: grouping of the residents, awareness of the resident, willingness of the resident, residing in the facility, and support from the staffs. 7 barriers were identified: deterioration of health status of the resident, dependency of the resident, hesitant to ask for help, discrepancy of expectancy between the staffs and the resident and their family, deficient staffing and time, lack of standardized guidelines, and defensive attitude of the staff due to the rigid policy. Conclusion: The findings from this study should help nurses to recognize the factors that influence self-management and provide direction for nurses and other health professionals involved in supporting self-management programs for nursing home residents. Keywords: self-management, self-care, aged, focus group, geriatric nursing *This study was supported by Basic Science Research Program through the National Research Foundation of Korea (NRF) funded by the Ministry of Education, Science and Technology.

315. Comparison Of The MNA-SF, NRS-2002 And MUST Adequacy To Assess Malnutrition In Hip Fracture Operated Elderly Patients, *Yichayaou Beloosesky, Department of Geriatrics, Rabin Medical Center, Petach Tikva, Sackler School of Medicine, Tel Aviv University, Israel; Avraham Weiss, Department of Geriatrics, Rabin Medical Center, Petach Tikva, Sackler School of Medicine, Tel Aviv University, Israel; Avital Hershkovitz, Beit Rivka, Geriatric Rehabilitation Hospital, Petach Tikva, Sackler School of Medicine, Tel Aviv University, Israel; Irena Otzrateni, Department of Geriatrics, Rabin Medical Center, Petach Tikva; Ronit Anbar, Nutrition unit , Rabin Medical Center, Petach Tikva, Sackler School of Medicine, Tel Aviv University, Israel; Moshe Salai, Nutrition unit , Rabin Medical Center, Petach Tikva, Sackler School of Medicine, Tel Aviv University, Israel; Tamar Koren-Hakim, Nutrition unit , Rabin Medical Center, Petach Tikva, Israel*

Objectives: To compare the adequacy of 3 nutritional screening tools,in hip fracture operated elderly patients.; To assess malnutrition and predict outcome in hip fracture operated elderly patients.

Abstract Body: Objectives: To compare the adequacy of 3 nutritional screening tools, to assess malnutrition and predict outcome in hip fracture operated elderly patients. Methods: Mini Nutrition Assessment Short Form (MNA-SF), Malnutrition Universal Screening Tool (MUST), Nutrition Risk Screening 2002 (NRS-2002) were prospectively determined. Length of stay (LOS), complications, 6 months readmissions, up-to 36 months mortality were recorded. Results: 215 patients (mean age 83.5±6.09 years) were included. According to the: MNA-SF; 95 patients were at risk of malnutrition, 25 were malnourished. MUST; 31 patients were at medium risk of malnutrition, 13 at high risk. NRS-2002; 70 patients were at medium risk of malnutrition, 11 at high risk. There was a significant relationship between the nutritional groups of the 3 scores ($p<0.001$). In all screening tools; BMI, weight loss and food intake prior to admission, were related to the patients' nutritional status ($p<0.001$). No differences in LOS & complications were found between the nutritional statuses of each screening tool. Only the MNA-SF could predict that well-nourished patients had less readmissions in a 6 months follow-up ($p=0.024$). During a 36 month follow-up, 79 patients died. Mortality was lower in the well-nourished patients of the MNA-SF vs. the malnourished ($p=0.001$) & at risk of malnutrition patients ($p=0.01$). Less significant association was found between the NRS-2002 patients' nutritional status and mortality ($p=0.048$). No such relationship was found using the MUST. Conclusions: All screening tools were adequate in assessing malnutrition parameters in hip fracture operated elderly patients. However, only the MNA-SF could also predict readmissions and mortality.

316. Changes In Health In Older Adults: Comparing The Health Retirement Study And The English Longitudinal Study, *Rebecca Bendayan, MRC Unit for Lifelong Health and Ageing University College London; Andrea Piccinin, Department of Psychology University of Victoria; Scott M. Hofer, Department of Psychology University of Victoria; Scott M. Hofer, Department of Psychology University of Victoria; Graciela Muniz, MRC Unit for Lifelong Health and Ageing; , MRC Unit for Lifelong Health and Ageing*

Objectives: The main aim of this study was to compare change in health over eight years in the Health Retirement Study (HRS) and the English Longitudinal Study of Ageing (ELSA). Comparing international studies of ageing through the same statistical analysis provides

Abstract Body: We compared change in health over 8 years in the Health Retirement Study (HRS) and the English Longitudinal Study of Ageing (ELSA). Nine measures of health were compared: self-reported health, activities of daily living, fine motor skills, large muscles index and difficulties with activities as getting up from a chair, walking across a room, managing money, walking a block and climbing one or several flights of stairs. All variables were standardized to a 100-point scale, using self-rated health as standard, and rates of change for each individual computed. Within each study, all the variables declined with age but at significantly different rates. Similar patterns were found in both studies: large muscles index (49.45 points in HRS and 42.25 points in ELSA); climbing several flights of stairs (33.42 points in HRS and 30.01 points in ELSA); and, getting up from a chair (31.90 points in HRS and 23.51 points in ELSA) declined the most whilst managing money (6.21 points in HRS and 2.59 points in ELSA) and walking across the room (6.73 points in HRS and 2.37 points in ELSA) declined the least. Across studies, significant differences in all variables were found, with HRS indices declining the fastest compared to ELSA, except for the activities of daily living and the fine motor skills index. Having difficulties with climbing several flights of stairs, getting up from a chair, sitting during 2 hours, kneeling or pushing/pulling an object may be the most sensitive indicators of age-related decline in older adults.

317. An Evaluation of a Geriatric Day Hospital and Outcomes at Four Months Post Discharge, *Anna Berall, Baycrest; Paul Katz, Baycrest; Jurgis Karuza, Baycrest; Terumi Izukawa, Baycrest; Olivia Meggetto, Baycrest; David Jo, Baycrest*
Objectives: To describe functional and psychosocial characteristics of patients attending a geriatric day hospital, which offers interprofessional risk management and rehabilitation for older adults living in the community, and to follow up a cohort of patients to de
Abstract Body: Purpose: To describe functional and psychosocial characteristics of patients attending a geriatric day hospital, which offers interprofessional risk management and rehabilitation for older adults living in the community, and to follow up a cohort of patients to determine their status four months post discharge. Methods: A retrospective chart review and four month post discharge telephone calls were conducted for 39 patients. Findings: Mean age was 82.5 (5.8), 74.4% were female, 44.7% were married, 42.1% were widowed and 13.2% were divorced. On admission, 12% of patients had moderate to severe cognitive impairment (MMSE < 20). 10.5% had severe depression, Geriatric Depression Scale (GDS) >11, and 57.9% had mild depression GDS 5-10. 62.1 % of patients had medium to high risk for falls with a Berg Balance Scale of ≤ 40. 90% of patients used a mobility aid with 74% using a walker. Clinical Frailty Scale (1-9) revealed 75% were mild to moderately frail and 14.3% were severely frail. Post discharge follow up calls indicated 24% of patients were hospitalized, a 14% decrease in reported falls, no significant difference in mobility aids, assistance with activities of daily living (ADL) and in living location, and only one death. Conclusion: This was an initial step in understanding the characteristics of the patient population and the processes of care. Even though patients had moderate to severe impairment and frailty, the geriatric day hospital appeared to have helped them successfully maintain their mobility, ADLs and remain in the community four months post discharge.

318. Health Benefits of Dog Walking for Older Adults, *Jessica Bibbo, University of Missouri; Angela Curl, University of Missouri; Rebecca Johnson, University of Missouri*
Objectives: Attendees will learn how dog walking is associated with physical health of older adults.; These findings will suggest to attendees that health interventions for older adults could be strengthened by including recommendations that encourage dog walking activities.;
Abstract Body: Pet ownership has been recognized as being instrumental in positively influencing one's health (e.g., petting a dog reduces blood pressure and cholesterol while increasing oxytocin and decrease cortisol; Friedmann et al., 1983; Odendaal & Meintjes, 2003). This study utilized recently released data from the 2012 wave of the Health and Retirement Study to explore the extent to which the physical activity and physical health of older adults is influenced by dog walking. Sample selection criteria included responding to the HRS in 2012 and being randomly selected for the Human-Animal Interaction Module (N=696). We tested the hypothesis that older adults who walk their dog would have better physical health and health behaviors than people who do not engage in dog walking. Five weighted regression models were conducted with dog walking as a key predictor of BMI status, number of ADL limitations, number of chronic conditions, frequency of moderate exercise, and frequency of vigorous exercise. All models controlled for age, gender, marital status, years of education, race, Hispanic ethnicity, and household income. We found that dog walking was associated with a half point lower body mass index (β = -.06), fewer ADL limitations (β = -.08), fewer chronic conditions (β= -0.10), and fewer doctor visits (β= -0.08). It was also associated with more frequent moderate exercise (β= 0.11) and vigorous exercise (β= 0.13). These findings suggest that health interventions for older adults could be strengthened by including recommendations that encourage dog walking activities.

319. Bridging the Gap Between Aging and Disability: A Scoping Review, *Kristen Bishop, Western University; Lynn Shaw, Pacific Coast University For Workplace Health Science; Sandra Hobson, Western University*
Objectives: To understand the scope of the theoretical and methodological approaches used in empirical research on the topic of Aging with Disability (AWD)
Abstract Body: Background: People aging with long-term disability are living longer than ever before, and presenting a number of new and unique challenges. 'Bridging the Gap' between aging and disability has drawn international attention, however successful partnerships have been hindered. In order to address these challenges this population presents, we must

first understand the state of the knowledge base and how the topic of aging with disability (AWD) is being approached in the literature. Purpose: The purpose of this scoping review was to understand the scope of the theoretical and methodological approaches used in empirical research on the topic of Aging with Disability. Methods: A scoping review was completed using Arksey & O'Malley's (2005) framework. Twenty-two articles met selection assessment criteria. Results: The AWD knowledge base is fragmented. Terminology is not consistently defined, methodologies are not always clearly articulated, authors are not grounding their work theoretically, and few articles make distinctions between AWD and aging 'into' disability (AID). On the other hand there is a trend toward pluralism within the knowledge base as a number of disciplines are interested in, and are collaborating on AWD work. Discussion/Conclusion: There is a need for increased interdisciplinary collaboration and a clearly defined framework to extend future pluralism in AWD. A central venue is needed to publish and access AWD literature. Future research should explore male experience of AWD and role of finances in AWD. There is a need to improve consistent use of terminology, clearly define populations, theoretically ground research and ensure coherence in methodologies.

320. The Natural Course of Later Life Disability in Older Persons., *Nienke Bleijenberg, University Medical Center Utrecht, department Julius Center for Health Sciences and Primary Care.; Peter Zuithoff, Julius Center for Health Sciences and Primary Care, department of Biostatistics, University Medical Center Utrecht,; Niek de Wit, . Julius Center for Health Sciences and Primary Care, department of General Practice; Marieke Schuurmans, Department of Rehabilitation, Nursing Science and Sports Medicine, University Medical Center Utrecht*

Objectives: After attending this session, participants will be able to: (1) discuss the course of ADL and IADL disability and the influence of specific characteristics on this disabling process;; and (2), have a better understanding of the prevalence per specific ADL/IADL disability and why this is important for the development of interventions aimed at preventing disability in older people.

Abstract Body: Maintaining independence as long as possible is an important goal for older people. However, each year 10% of non-disabled older persons develop disability, i.e. the need for assistance in activities of daily living (ADL) such as bathing and dressing. Moreover even a higher percentage develops disability in instrumental ADL (IADL). Until now, community-based interventions aimed at preventing disability in older people have shown conflicting results or modest effects. To enable the design of successful interventions an in-depth understanding of the course of disability is needed. The aim of this study is to examine the course of disability on (I)ADL in a community-based population (n=830) aged 60-95 years and examine the influence of personal characteristics and chronic conditions. Disability was measured with the modified Katz-15 index. Generalized linear mixed models were applied. The mean age was 74.6 (SD: 8.8), 54.6% were woman and the average number of chronic conditions was 1.91 (SD: 1.4). Disabilities with the highest prevalence over time were shopping, traveling, and household tasks (prevalence range between 25-47% for an older person aged 75 years). Disabilities with the lowest prevalence were using the telephone, managing finances, medication, and transfer (prevalence range between 2-6% for a 75 years old). The prevalence of bathing and preparing a meal showed a similar pattern over time. Females, older persons with a low education and more chronic conditions showed greater levels of dependence compared to their counterparts. The results inform and facilitate the design of future personalized interventions aimed at preventing disability.

321. Hearing Assessment and Personal Amplifier Use in a Multidisciplinary Geriatric Evaluation and Management (GEM) Clinic, *Becky Brott Powers, Veterans Affairs Pittsburgh Healthcare System Geriatric Research Education and Clinical Center; Marcia Homer, Veterans Affairs Pittsburgh Healthcare System Geriatric Research Education and Clinical Center; Michelle Rossi, Veterans Affairs Pittsburgh Healthcare System Geriatrics Research Education and Clinical Center*

Objectives: To report on the addition of audiology to a multidisciplinary Geriatric Evaluation and Management (GEM) Clinic. Quality improvement efforts focused on hearing testing for all patients and personal amplification use during clinic visits

Abstract Body: Background: Hearing loss affects approximately two-thirds of adults in their seventies with only a small percentage ever wearing hearing aids. Age related hearing loss is associated with several geriatric syndromes including functional decline, depression, dementia, and increased hospitalizations. Hearing loss is frequently unrecognized by healthcare providers and may lead to communication breakdowns in the healthcare setting. Clinic Development: The Geriatric Evaluation and Management (GEM) Clinic in the Pittsburgh VA is a consultative comprehensive geriatric assessment clinic previously consisting of eight disciplines including: geriatricians, geriatric psychiatrists, geropsychologists, pharmacists, social workers, physical therapists, occupational therapists, and speech therapists. To address patient needs, audiologists were recently added to the GEM team. Audiologists see all patients first to perform audiometric testing, to check existing hearing aids, and to fit patients for hearing aids if needed. If a previously unknown hearing loss is detected, the patient is loaned a personal amplifier to use while meeting with the other GEM Clinic consultants. These consultants were then asked what percentage of the conversation they thought the patient could hear. Findings: Of the first 14 patients to complete a full GEM evaluation with audiology, 10 had hearing loss. Four of those were new diagnoses, and of the remaining 6 only 2 wore their hearing aids. Not all patients wore personal amplifiers when suggested. This was found to be due to provider education issues and a Plan-Do-Study-Act model was initiated to remediate this. When personal amplifiers were worn, provider ratings of patient speech understanding rose from 80% to 96%.

322. Do Older Home Care Clients Need Help To Get Up After Falling?, *Elissa Burton, Curtin University and Silver Chain; Gill Lewin, Curtin University and Silver Chain*

Objectives: This study aimed to determine the proportion of home care clients who had fallen over 12 months and to identify whether they used an ambulance to help them up

Abstract Body: One in three older Australians have at least one fall each year and if they are receiving home care services they are likely to fall more frequently [1]. Many who fall are uninjured, but have difficulty in getting themselves up off the floor. In the United Kingdom they found 293,000 ambulance call-outs were made over a year by older people who needed assistance to get up from where they had fallen, at a cost of £75.5 million pounds. Yet in Australia little is known as to whether this is an issue or not. A sample of 11,080 clients from two health and community care organisations was invited to complete a survey. Survey data were summarised using descriptive statistics. Response rate was 32.5% with the majority of respondents being female (52.7%) and aged between 70-89 years (58.3%). Over 40% of respondents had had a fall during the previous year and of these, 30.1% had called an ambulance to just help them get up. As the minimum cost of an ambulance in Western Australia is $847, approximately $376,915 would have been spent on this group who required no medical assistance. A relatively high proportion of home care clients who fall cannot get up off the floor and are calling an ambulance for assistance. As the population ages the numbers of older people in this situation can be expected to increase. Further research is required to ascertain the size of this problem across Australia and to identify cost effective strategies to address it. References: 1.Smith J, Lewin G. Home care clients' participation in fall prevention activities. Australasian Journal of Ageing. 2008;27(1):38-42.

323. Prevalence and Risk Factors of Atrial Fibrillation in Chinese Elderly: Results from the Chinese Longitudinal Healthy Longevity Survey, *Choy-Lye Chei, Health Services and Systems Research, Duke-NUS Graduate Medical School Singapore, Singapore; Prassanna Raman, Health Services and Systems Research, Duke-NUS Graduate Medical School Singapore, Singapore; Zhao-Xue Yin, Division of Non-Communicable Disease Control and Community Health, Chinese Center for Disease Control and Prevention, Beijing, China; Xiao-Ming Shi, Division of Non-Communicable Disease Control and Community Health, Chinese Center for Disease Control and Prevention, Beijing, China; Yi Zeng, Center for Study of Healthy Aging and Development Studies, Peking University; David Matchar, Center for Study of Healthy Aging and Development Studies, Peking University*

Objectives: To recognize population-specific differences in AF prevalence; To understand the specific AF risk factors for an elderly Chinese population;

Abstract Body: Prevalence of atrial fibrillation (AF) is increasing as the world ages. AF is associated with higher risk of mortality and disease, including stroke, heart failure, and dementia. Prevalence of AF differs with each population studied, and research on non-Western populations and the oldest old is scarce. We used data from the 2012 wave in the Chinese Longitudinal Healthy Longevity Survey, a community-based study in eight longevity areas in China, to estimate AF prevalence in an elderly Chinese population (N=1418, mean age= 85.6 years) and to identify risk factors. We determined presence of AF in our participants using single-lead echocardiograms. The weighted prevalence and 95% confidence intervals of AF were estimated in subjects stratified according to age groups (65-74, 75-84, 85-94, 95 years and above) and gender. We used logistic regressions to determine the potential risk factors of AF. We found that the prevalence of AF was 3.5%; 2.4% of men and 4.5% of women had AF ($p>0.05$). The overall prevalence rate in our study was higher compared to prevalence in other Asian populations. This was the first study to report an association between AF and being underweight, in addition to being overweight/obese. We also found that advanced age (85-94 years), history of stroke or heart disease, low triglyceride levels, and no regular physical activity were associated with AF. In urban elderly, AF prevalence increased with age ($p<0.05$), and in rural elderly, women had higher AF prevalence ($p<0.05$). Further exploration of population-specific risk factors is needed to address the AF epidemic

324. Geographic Disparities of Dementia Risk in Older Women: Evidence from the WHI Memory Study, *Jiu-Chiuan Chen, 1Department of Preventive Medicine, University of Southern California, Keck School of Medicine; Xinhui Wang, 1Department of Preventive Medicine, University of Southern California, Keck School of Medicine,; Steven Cen, Department of Neurology, University of Southern California, Keck School of Medicine; Julia Robertson, 5Department of Biostatistical Sciences, Division of Public Health Sciences, Wake Forest University School of Medicine; Jack McArdle, Department of Psychology, University of Southern California; Mark Espeland, Department of Psychology University of Southern California*

Objectives: To describe the geographic differences in the risk for dementia in older women in the US; To determine the population and individual characteristics contributing to the observed geographic disparities;

Abstract Body: Geographic disparities of stroke in the US have been documented for decades, but examining geographic difference in dementia incidence has been difficult in multi-site populations with only few studies using identical design and measurements. We conducted a prospective (1996-2010), population-based study on 7479 community-dwelling, cognitively-intact older women (aged 65-80 years) from the Women's Health Initiative Memory Study (WHIMS) across 40+ centers in

24 states. Identical WHIMS protocols (based on central adjudication with detailed cognitive screening, neuropsychiatric evaluation, and clinical examinations) were used to ascertain dementia by the DSM-IV criteria. Baseline geographic indicators were determined according to US-census and NHLBI-defined Stroke-Belt regions. Cox models were constructed to examine the geographic differences in dementia and Alzheimer's disease (AD) incidences. Of 318 (157 AD) incident dementia, 52 (28 AD) were among Stroke-Belt residents (n=748). We found significant regional differences in dementia and AD risk (p=0.01). Comparing Stroke-Belt residents to non-Belt residents, the adjusted hazard ratios (HRs, 95% confidence intervals) were 1.75 (1.29-2.38) for dementia and 1.96 (1.29-2.97) for AD, adjusting for age, race/ethnicity, and socioeconomic status. Such disparities between Stroke-Belt and non-Belt regions remained for dementia (HR=1.49, 1.05-2.12) and AD (HR=1.57, 0.96-2.55), after further adjusting for lifestyles, depressive symptoms and Framingham stroke risk profile. This study provides the first epidemiologic evidence for geographic disparities in dementia risk of older women in the US. Late-life residence in Stroke-Belt region increased the subsequent risk for dementia including AD. Future studies need to examine other socio-environmental determinants of geographic disparities in dementia risk of older women.

325. Senior's Sweet Tooth: Age-Associated Preference for Carbohydrates in the Baltimore Longitudinal Study of Aging, *Chee Chia, National Institute on Aging; David Liu, National Institute on Aging; Toshiko Tanaka, National Institute on Aging; Eleanor Simonsick, National Institute on Aging; Josephine Egan, National Institute on Aging; Luigi Ferrucci, National Institute on Aging*

Objectives: To characterize the longitudinal association between carbohydrate consumption and age

Abstract Body: Taste bud number and sweet taste sensitivity have been found to decline with age. Whether such changes affect dietary preferences, such as carbohydrate consumption, during aging has not been studied although would be of great interest given the potential effects on metabolic disease risk. We hypothesized that the decline in sweet taste sensitivity with age may lead to a compensatory increase in carbohydrate consumption. Using repeated 7-day food diary data from 1454 participants (51% men) in the Baltimore Longitudinal Study of Aging with at least two visits starting from 1984, we examined %carbohydrate-intake (calories from carbohydrates divided by total calories). At analytic study baseline, participants had the following characteristics: age (men:63.4±15.1years;women:58.0±16.1years), waist circumference (men:93.7±10.4cm;women:81.3±11.4cm), number of visits (men:2.2±1.5;women:2.1±1.4), follow-up years (men:5.5±7.1years;women:5.3±6.9years), %carbohydrate-intake (men:48.4±9.0%;women:49.5±8.8%), total-intake (men:2112±510kcal;women:1734±485kcal). Sex-stratified mixed-effect models adjusted for waist circumference and date-of-visit evaluated the associations between age and %carbohydrate-intake over time. In men, there was a strong positive association between age and %carbohydrate-intake (Age:β=0.048,95%CI=0.009–0.087,P<0.05). In women, there was a significant quadratic association between age and %carbohydrate-intake with an inflection point (trough) at age 57 (Age^2:β=-0.326,95%CI=-0.526–-0.126,P<0.01; Age:β=0.003,95%CI=0.001–0.005;P<0.001). Findings of increased carbohydrate consumption with aging are consistent with the observed age-related decline in taste bud number and sweet taste sensitivity. Whether this age-related change in dietary habits is a compensatory response to reduced sweet sensitivity or reflects food marketing trends and/or ease of preparation in the face of declining capacities remains to be established. The quadratic relation of age with %carbohydrate-intake in women also warrants more study.

326. Bisphosphonate and Walking Aid Associated Upper Extremity Stress Fractures, *Grace Shu Hui Chiang, National University Hospital; Kelvin W.B Koh, St Lukes Hospital; Tsung Wei Chong, St Lukes Hospital; Boon Yeow Tan, St Lukes Hospital*

Objectives: To increase awareness among both physicians and patients about the possibility of upper extremity stress fractures occurring and the signs and symptoms associated with such fractures.; To highlight that the risk of upper extremity stress fractures is higher in patients who are on bisphosphonate therapy and use walking aids.

Abstract Body: Introduction: Upper extremity stress fractures are rare. However, the likelihood of such fractures occurring increases in patients on long-term bisphosphonate therapy and who use walking aids. Case Description: A 77 year old female, was started on alendronate for osteoporosis in 2004. 9 years after starting alendronate, she suffered an atraumatic fracture of the right ulna. The patient had noted pain of her right forearm for 3 months, however pain had worsened when she had transferred more weight to her right forearm whilst ambulating with a walking cane. X-ray of the right forearm showed a transverse fracture of the proximal shaft of the right ulna with increased sclerosis around the fracture. She was active premorbidly and ambulating with a walking cane for 6 years. She did not have premature menopause or history of steroid use. Physical examination revealed right forearm deformity with tenderness, neurovascularly intact. Laboratory work-up was normal. Bone scan showed no scintigraphic evidence of bone metastasis. In view of the atraumatic nature of the fracture, X-ray findings distinctive of atypical fractures and further investigations excluding other causes of atypical fractures, the diagnosis of atypical ulna shaft fracture secondary to long term alendronate use was made and alendronate was discontinued. Conclusion: This case illustrates the importance of having a high index of suspicion of upper extremity stress fractures occurring in patients who complain of chronic upper limb pain if they are on bisphosphonate therapy and are using walking aids. Early detection will facilitate appropriate management.

327. High-Dose Inactivated Influenza Vaccine is Associated with Cost Savings Compared to Standard-Dose Inactivated Influenza Vaccine in Seniors, *Ayman Chit, Sanofi Pasteur; Debbie L. Becker, OptumInsight; Carlos A. DiazGranados, Sanofi Pasteur; Michael Maschio, OptumInsight; Eddy Yau, inVentiv Health Clinical; Michael F. Drummond, inVentiv Health Clinical*

Objectives: High Dose (HD) influenza vaccine reduces health care resource utilization compared to Standard Dose (SD) influenza vaccines; Compared to SD vaccine, HD vaccine saved the health care system over $100/person immunized even after accounting for the cost of the vaccine

Abstract Body: Background: Adults ≥65 years of age account for most seasonal influenza-related hospitalizations and deaths. A recent head-to-head RCT (FIM12, NCT01427309) demonstrated that a high-dose influenza vaccine (HD) was 24.2% more efficacious than a standard-dose influenza vaccine (SD) in adults 65+ years. This economic sub-study estimates the total medical and societal costs in FIM12 participants. Methods: Health care resource utilization data collected in the FIM12 study included: medications, non-routine medical and emergency room visits, and hospitalizations. Utilized resources were summarized across vaccine arms and unit costs were applied, using standard US cost sources, to each resource item (including vaccines; HD $31.82; SD $12.04) to estimate the mean total direct medical and societal costs associated with each vaccine. Results: The average medical costs (including influenza vaccine cost) per-participant were $106 lower in the HD arm. In both arms, hospitalizations represented over 95% of the total cost and were less frequent in the HD arm (7.7% of HD participants reported ≥1 hospitalization versus 8.4% in SD arm) and average length of stay (LOS) across all participants was shorter in the HD arm (0.4859 days (HD) vs 0.5626 days (SD)). The average per-participant societal costs were $118 lower for HD. Conclusions: Despite the higher price of HD compared to SD, the total direct medical and societal costs were over $100 lower per vaccinee in those who received HD. This was driven by a reduction in the number of hospitalizations as well as in the LOS for those hospitalized.

328. Integrating Gerontological Nursing Evidence-Based Guidelines in Nursing Education, *Karen Clark, Our Lady of the Lake College; Stazel Guerin, Our Lady of the Lake College; Lisa Skemp, Our Lady of the Lake College; Fayron Epps, Our Lady of the Lake College; Bronwyn Doyle, Our Lady of the Lake College; , Our Lady of the Lake College*

Objectives: Describe the gerontological nursing EBP guideline classroom project; Discuss classroom strategies for infusing gerontological nursing science into the nursing curriculum.

Abstract Body: As gerontological nursing science expands to meet the needs of a growing population, nursing education must prepare students to understand and use evidence-based practice (EBP) in the care of older adults. Yet the majority of nurses have limited preparation in gerontological nursing EBP. Purpose This study evaluated a class project whereby pre-nursing students reviewed, researched and then presented the John A. Hartford Foundation Center of Geriatric Nursing Excellence Evidence-Based Practice guidelines to members of the college community. Methods An educational evaluation survey was conducted with 420 students and 41 faculty who participated in the EBP project. The seven-question survey assessed perceptions of the EBP project. Face to face interviews were conducted with eight faculty members who taught the course. Findings 343 students and 27 faculty reported an improved understanding about EBP (88%/93% respectively), increased knowledge about gerontological nursing (84%/100%), a positive influence on perceptions of older adults (83%/96%), and improved provision of care of older adults (73%/96%). Faculty stated “it enhances their practice and helps them understand why we do what we do” and “make the connection from research to practice”. Students stated they “have more respect” and it “sparked” their interest in gerontology. Faculty expressed students “stopped looking at them just as old people but as human beings with emotions and feelings”. Recommendations Engage more faculty and integrate EBP across the curriculum. Limitations Composite of all six classes and a variety of educators conducting the project. After attending this activity, participants will be able to: 1. Describe the gerontological nursing EBP guideline classroom project. 2. Discuss classroom strategies for infusing gerontological nursing science into the nursing curriculum.

329. A Comparison of Characteristics by Age of Hospitalized Adults with a Diagnosis of Malnutrition: United States, 2010, *Rose Ann DiMaria-Ghalili, Drexel University College of Nursing and Health Professions; Jamie Slaughter, Drexel University; Elizabeth Gonzalez, Drexel University; Purni Abeysekara, Drexel University; Helaine Resnick, American Society for Parenteral and Enteral Nutrition; Peggi Guenter, American Society for Parenteral and Enteral Nutrition*

Objectives: . To compare the differences in demographic characteristics, cost, and comorbidities between older and younger hospitalized adults with diagnosis of malnutrition from the 2010 Healthcare Cost and Utilization Project (HCUP)

Abstract Body: Purpose: To examine differences in demographic characteristics and comorbidities in a nationally representative sample of older (≥65 years) and younger (18-64 years) hospitalized patients with diagnosis of malnutrition (dxmal). Methods: Data are from the 2010 Healthcare Cost and Utilization Project (HCUP), which contain patient-level data with ICD-9CM diagnosis codes on hospital inpatient stays. Data were weighted to generate nationally representative estimates of US hospitalizations. Characteristics of older and younger adults with a dxmal during their hospital stay were identified and compared. Results: Among patients with a dxmal, those ≥ 65 years were 1.5 times more common than those <65 (727,858 vs 467, 378). Older dxmal patients were more likely to have chronic comorbidities than younger adults. However, among older dxmal patients, length of stay (11.6 vs 13.7 days, p<.001) and cost of care ($80,191 vs 106, 535, p<.001) were lower and more older dxmal patients died during their hospital stay (10.7% vs 6.6%, p<.001). Older dxmal patients were three-times more likely to be admitted to the hospital from a skilled nursing facility (6.4% vs 2.0%, p<.001), and twice as likely to be discharged to an intermediate or skilled care facility (49.2% vs 25.0%, p<.001). Conclusions: Older hospitalized dxmal patients appear to be more frail and have greater comorbidity than their younger counterparts. While their length of stay and cost of care is lower, their mortality is higher. It may be beneficial to carefully monitor nutritional status in hospitalized older adults with dxmal, especially those admitted from skilled nursing facilities.

330. Aging-in-Place: The Service Needs of Minority Seniors, *Suzanne Dupuis-Blanchard, Université de Moncton; Odette Gould, Mount Allison University; Danielle Thériault, Université de Moncton; Lita Villalon, Université de Moncton; Caroline Gibbons, Université de Moncton*
Objectives: Participants will be able to better understand the needs of minority seniors for aging-in-place.; Participants will be able to describe the challenges faced by minority seniors for aging-in-place.
Abstract Body: Aging-in-place is gradually making grounds as a long term care option in North America. In fact, in Canada, only 8% of older adults are institutionalized while the majority are living in the community. However, for aging-in-place to be successful, older adults need access to appropriate community supports and services. For minority French speaking older adults living in dominantly English speaking communities, access to services is problematic. The goals of this qualitative descriptive study were: 1) to better understand aging-in-place for minority French speaking older adults living in three English dominant communities in the province of New Brunswick (Canada); 2) identify the services required to support successful aging-in-place. Thirty-eight minority French speaking older adults over the age of 75 years, aging at home, and residing in three specific communities were interviewed. Semi-structured interviews were recorded and transcribed followed by content analysis to identify common themes related to study objectives. Results confirm the general lack of services for aging-in-place and the greater difficulty of obtaining services in a minority language. Participants explained that it takes too long to obtain services in French. Accepting services is also substantial since many participants related asking for services to accepting loss of independence. Also, contrary to popular belief, the most common services required are not healthcare but home maintenance related. This project provides a better understanding of the needs in services of minority speaking seniors living in dominant English speaking communities and confirms the need for continued research on this topic.

331. Recruiting African-Americans With Dementia And Their Family Caregivers: What Worked, *Fayron Epps PhD, RN, Our Lady of the Lake College/NHCGNE Claire M. Fagin Fellow 2013-15; Lisa Skemp PhD, RN, FGSA, Our Lady of the Lake College/University of Iowa; Janet Specht PhD, RN, FGSA, FAAN, University of Iowa*
Objectives: After attending this session, participants will be able to explain recruitment strategies used to access the African American families that are caring for loved ones with dementia.; After attending this session, participants will be able to discuss the benefits and barriers associated with recruiting African-American dementia families.;
Abstract Body: Challenges of accessing and recruiting African American (AA) research participants has been explained by a lack of trust developed because of historical ethical issues such as the Tuskegee Syphilis Study and Henrietta Lacks' "immortal" cells. Additionally, dementia is a dormant topic among the AA community. Consequently, advancing the understanding of and treatment for many conditions in the AA population are hampered because of these barriers. The purpose of this presentation is to describe recruitment approaches that were used while conducting a qualitative descriptive study on family involvement in health promotion activities for AA older adults with dementia. Recruitment strategies went beyond the current thinking related to having a minority recruiter and recruiting from faith-based organizations. These strategies included becoming familiar with the context of southern Louisiana through systematic engagement with the community and attaining buy-in from formal and informal contacts. Field notes and journals were kept and a tracking matrix emerged that facilitated management and assured accountability during recruitment efforts. Field notes were reviewed using inductive content analysis. Themes included "gaining trust", "community engagement", "networking", "follow-up", and "visibility". Most importantly, "purposeful activity" through attending social gatherings resulted in surprising success for recruitment. Barriers identified were the context of words and terminology linked to dementia and family dynamics associated with AA caregiving. Benefits included community awareness and development of community and family partnerships. To have successful AA participation in research, it's necessary to understand their culture, make research appealing, think "out the box" and show a beneficial gain.

332. Functional Disability and Ability in 75-year-olds: A Comparison of Two Swedish Cohorts Born 30 Years Apart., *Hanna Falk, Institute of Neuroscience and Physiology at Sahlgrenska Academy, University of Gothenburg; Ingmar Skoog, Institute of Neuroscience and Physiology, Sahlgrenska Academy at University óf Gothenburg*
Objectives: To compare the level of functional disability and involvement in leisure activities between two birth cohorts of Swedish 75-year-olds examined in 1976-77 and 2005-06
Abstract Body: Objective - To compare the level of functional disability and involvement in leisure activities between two birth cohorts of Swedish 75-year-olds examined in 1976-77 and 2005-06. Design - Cohort comparison. Setting and Participants - Representative data from the general population in Gothenburg, Sweden, examined at age 75 in 1976–77 (N= 744), and in 2005–06 (N= 731) with comprehensive somatic and psychiatric examinations. Measurements - Activities of daily living (ADL); Instrumental activities of daily living (IADL); a battery of self-report measures, including involvement in

leisure activities, satisfaction with home environment, social networks, and self-rated health. Results - Functional disability in ADL decreased between the cohorts (13.9% vs. 5.6%, p<.001). Functional disability in IADL also decreased between the cohorts (33.4% vs. 13.0%, p<.001). Combining ADL and IADL resulted in an overall decreased dependency, with the largest decrease seen in women (42.3% vs. 15.1%, p<.001). Involvement in leisure activities increased between the cohorts. For example, the proportion going on international and domestic holiday travels increased (44.6% vs. 72.8%, p<.001), and the proportion who independently drove their own car also increased (10.0% vs. 53.0%, p<.001). Conclusion - Later born cohorts of 75-year-olds are less dependent in activities of daily living and more engaged in leisure activities compared to earlier cohorts. Later born cohorts of 75-year-olds are thus better equipped to maintain a non-age related identity compared to earlier cohorts. Our findings might serve as a reason to adopt a more positive view to aging in a world with an increasing number of older people.

333. Prevalence and Predictors of Potentially Inappropriate Medications in Frail Elderly, *Joseph Finkelstein, Johns Hopkins University; Xuan Li, Johns Hopkins University*

Objectives: To identify prevalence of potentially inappropriate medications in frail elderly; To identify risk factors of potentially inappropriate medications in frail elderly; To compare prevalence and risk factors of potentially inappropriate medications in frail and non-frail elderly

Abstract Body: Frailty is associated with the decline of physiologic reserves in multiple systems and the inability to respond to stressful insults. Inappropriate medication prescription may results in significant adverse events which in frail elderly frequently lead to hospitalization. The objective of this project was to estimate prevalence of potentially inappropriate medications (PIM) in frail and non-frail elderly and identify PIM predictors. The National Health and Nutrition Evaluation Survey (NHANES) dataset (2003-2006) containing results from 20470 participants was used for the analysis. Frailty was identified using previously validated criteria reflecting physical, psychological and social domains of frailty. Physical activity was measured by an accelerometer, psychological and social domain variables were based on self-report. PIM prevalence in frail elderly was 44% both in males and females, 44% in Whites and 48% in Blacks. PIM prevalence in non-frail elderly was significantly lower in all subgroups (males: 36%; females 35%). PIM prevalence depended on underlying condition and number of comorbidities. Frail elderly with CHF had highest PIM prevalence (79.5%). Increase in comorbidities resulted in increase of PIM. PIM prevalence in frail elderly with one chronic condition was 37%; more than 5 conditions was associated with 82% PIM prevalence. After adjustment for covariates in logistic regression, following factors were identified as significant predictors of PIM in frail elderly: polypharmacy (OR=6.1; CI=3.1-11.8), health status compared to a previous year (OR=2.4; CI=1.3-4.6), and private insurance coverage (OR=0.5; CI=0.2-0.9). PIM is widespread in frail elderly. Risk factors for PIM may help in identification and prevention of PIM in elderly.

334. A Virtual Healthcare Neighborhood: Providing Support for Dementia Caregivers, *Christianne Fowler, Old Dominion University,*

Objectives: Review the impact dementia caregivers have on our healthcare community.; State the components of the Virtual Healthcare Neighborhood; Review the results of the VHN study

Abstract Body: INTRODUCTION One out of every nine people in the United States over 65 has dementia. In 2014, care for those with Alzheimer's disease is expected to cost the United States $214 billion. Many of these individuals are cared for by informal family caregivers. These caregivers provide approximately 17 billion hours of unpaid care each year averaging 20 hours a week. This care saves the healthcare system over $220 billion per year. The Virtual Healthcare Neighborhood (VHN) was developed as an interactive website to help meet some of the needs of dementia caregivers (CG) in hopes of helping them continue in this role. METHODOLOGY 28 individuals caring for a homebound person with dementia were recruited from Alzheimer's support groups. They were enrolled in either a control group, receiving usual support, or an intervention group participating in the 4 month VHN. The VHN provided education, access to interprofessional providers and virtual interactive support for the CG's. Both groups were also given a sleep actigraphy band to monitor their sleep quantity and quality. At the beginning and end of the study they were given several surveys (demographic, CG burden, ADL, self efficacy, insomnia severity, agitation). RESULTS There were 14 participants in each group. Results of the surveys, qualitative data and the sleep actigraphy information are currently being evaluated. Information will be presented describing the demographic characteristics and measures of any differences between groups. Implications and further research plans will also be presented.

335. Risk and Protective Factors Affecting Decline in Cognitive Functioning Among Newly Admitted Residents to Long-Term Care, *Shannon Freeman, School of Health Sciences, University of Northern British Columbia; Lina Spirgiene, Lithuanian Univesrity of Health Scienes; Melinda Martin-Khan, University of Queensland School of Medicine; John Hirdes, University of Waterloo*

Objectives: To examine modifiable risk factors driving decline in cognitive status among residents newly admitted to long-term care facilities.; To highlight that decline in cognition is not inevitable for persons upon entry to a long term care facility and that there are things that a facility can do to reduce the risk for decline in cognitive status (ex. minimize restraint use and engage all residents regardless of presence/absence of a diagnosis of dementia) in social activities and life in the facility.;

Abstract Body: Introduction: Declining cognitive function impacts on an individual's perception of their quality of life (QoL). We examined factors affecting that affect cognitive decline among residents newly admitted to a long-term care facility (LTCF) to identify factors amenable to intervention. Methods: Secondary data analysis used interRAI Minimum Data Set (MDS 2.0) data gathered at admission and first follow-up assessment. The study population included 111,052 residents (aged 82.9 ± 9.8 years; range 18 to 110 years) from LTCFs in Ontario, Canada. Regression analyses investigated the role of physical restraints, antipsychotic use, and indicators of engagement in social activities affecting cognition in LTCFs. Analyses were stratified based on presence/absence of diagnosis of dementia. Results: Nearly 15% of residents (n=17,444) exhibited decline in cognition at follow-up. Residents with one or more physical restraints (chair, trunk, and limb) were at increased risk for cognitive decline evidenced among residents with and without a diagnosis of dementia. Antipsychotic medication use did not emerge as a strong predictor of cognitive decline. Social engagement was protective against cognitive decline and more pronounced for residents without a diagnosis of dementia. Conclusion: Physical restraint use was closely linked with decline in cognition and should be avoided, or used only as a last resort. Engagement in social activities should begin for all residents as soon as possible upon entry to the LTCF even for persons with diagnosed dementia. Prioritization of social networks and increased involvement in LTCF activities may decrease risk for cognitive decline thereby improving or maintaining resident QoL.

336. Decision Support Through Focused Observations From the Electronic Health Record: The Informing of Non-Clinical Skilled Professionals Using HEADS-UP Technique, *James Friedman, University of Minnesota, School of Nursing*
Objectives: 1.The viewer will be able to discuss the components of the HEADS-UP review technique.; 2.The viewer will be able to discuss the proposed benefits of the HEADS-UP review technique.;
Abstract Body: The HEADS-UP template is a documentation review technique, applicable in both electronic and paper documentation, to develop an understanding of the current status of an individual. The purpose of the HEADS-UP technique is to direct a focused review of the Electronic Health Record (EHR) or paper health record of a given individual, in key areas, to develop a general understanding of the diagnoses and co-morbidities involved, overall wellness, and possible areas of concern for an individual. This practice informs the general understanding of illnesses with which an individual is living and to what degree that individual may be burdened by symptoms and disease. Additionally, the HEADS-UP technique fosters critical thinking in the non-clinical reviewer in terms of how various factors may influence an individual's life, identification of possible resource needs and highlighting shared decision making opportunities. The acronym, HEADS-UP, represents areas of review: number of Hospitalizations in the last 12 months, number of Emergency department visits in the last 12 months, Advance care planning, current Diagnoses, current and recent Symptoms, Unknowns or questions raised, and Pharmacology or medication regimen. The reviewer undertakes a concise, review of the documentation present in these areas of a patient's chart. The knowledge gleaned is then applied to the building of relationship, and to the process of identifying what matters most to patients and those close to them. The desired outcome is the empowerment of patients and those close to them, in collaboration with providers to actualize richly informed, patient directed plans of care.

337. Combined Ratchet and Twiddler´s Syndrome, *Manfred Gogol, Hospital Lindenbrunn Departemnt of Geriatrics*
Objectives: Know that Twiddler´s syndrome is a rae but typically complication of pacemaker therapy in the elderly.; Know reasons an early signs for the syndrome.; Know managemnet strategies.
Abstract Body: Twiddler´s syndrome is a rare but serious and potential life-threatening complication of pacemaker (PM) implantation. We report a case of an 80 year old man who came for inpatient geriatric rehabilitation after major abdominal surgery with a longterm complicated course on ICU. He received a single lead ICD three years ago and chest X ray (CXR) demonstrated a correct positioning of pacemaker (PM) and lead in April 2011. Three years later we revealed a Twiddler´s syndrome with a total of nine twists in different lead positions. CXR after PM implantation detected a Ratchet syndrome (white arrow) with 180° rotation of the PM by it´s short axis in April 2012 and 6 plus 1 twists in two lead positions in January 2014. On June 4 and June 16, 2014 CXR show a progression of lead twisting (7 twists) and an additional twisting position. A CXR in lying position revealed the possible mechanism with a 90° tournament and axillar shifting of the PM. The patient denied manipulation of the device. Device testing at his primary cardiologic department revealed a correct function of the device.

338. Evaluating Methods for Assessing Hydration of Older Adults in the Home, *Elena Gonzalez, Georgia Tech Research Institute; Hannah Glazebrook, Georgia Tech Research Institute; Linda Harley, Georgia Tech Research Institute; Adrienne Jones, Georgia Tech Research Institute; Brad Fain, Georgia Tech Research Institute; , Georgia Tech Research Institute*
Objectives: Learn about older adults' perspectives on best methods for assessing hydration in the home; Explore user testing results of a sensor straw prototype, that can monitor fluid consumption in real-time;
Abstract Body: Dehydration in older adults can be life-threatening. Unfortunately, many older adults do not realize they are dehydrated until a health complication occurs or they become hospitalized. In order for older adults to better monitor and manage their own hydration, assessments will need to shift from the clinical setting to the home. This pilot study aims to 1) evaluate which methods of assessing hydration in older adults are best suited for the home environment and 2) provide

consumer feedback on a sensor straw prototype that monitors fluid consumption in real-time. For five days, six older adult participants (Mage = 71; SD = 5.2, 4 male) completed various assessments and surveys in their homes regarding their hydration status and drinking behaviors. Each day, participants were asked to keep a food and beverage journal, record their morning weight, rate their level of thirst, wear an activity tracker, provide a morning urine sample, and drink all beverages using the sensor straw. Additionally, researchers conducted daily, in-home appointments to take blood pressure readings and run urinalysis tests. Preliminary findings suggest that in terms of hydration self-monitoring, older adults are more willing to adopt passive, less-involved methods, such as drinking out of a sensor straw, wearing an activity tracker, or weighing themselves. Participants expressed concerns about the amount of time and detail involved in keeping a food and beverage journal and the discomfort of regular urine testing. User testing feedback for the sensor straw will be incorporated in the continued development of the device.

339. Quantitative Ultrasound for Sarcopenia Screening: Interrater Reliability Using a Novel Method of Force Feedback, *Michael Harris-Love, Washington DC VA Medical Center; Catheeja Ismail, The George Washington University; Reza Monfaredi, Children's National Hospital; Paula Woletz, Washington DC VA Medical Center; Claudia Ranniger, The George Washington University; Marc Blackman, The George Washington University*
Objectives: Determine the interrater reliability of portable sonographic assessment using force feedback among examiners with varied experience levels.
Abstract Body: Background: Ultrasound has been proposed as inexpensive method to assess age related changes in muscle tissue composition and lean body mass without the use of ionizing radiation. However, the reliability of the method may be affected by examiner technique and experience. Augmented ultrasound feedback may aid measurement consistency among multiple examiners. Methods: We conducted a study involving 3 pairs of ultrasound examiners (experience: > 10 years, 1 year, and < 1 year) to determine if augmented sonography using force feedback could foster reliability among the examiner groups, and with automated image acquisition, using a graduated range of forces (1 N to 10 N). The scanned material was a custom calibration phantom designed as a skeletal muscle mimetic (i.e., anechoic gel, 15 kPa, speed of sound, 1540 m/s, attenuation, est. 0.1 dB/cm/MHz). The KUKA Light Weight Robot (±0.05 mm motion error) was used to apply uniform force levels on the muscle mimetic to obtain criterion reference automated ultrasound images. Results: The material thickness values obtained by the examiners resulted in an ICC 2, k of .88 ($p < .001$; CV = 1.5% to 2.9%, SEM = .02-.04 cm). No differences in material dimension measures were detected among the 6 examiners. Additionally, there was a high degree of association among the examiner-derived and the robot-arm aided material thickness values ($R2 = .86-.97$, $p < .001$). Conclusions: Sonography with augmented force feedback allows examiners with varied experience levels to exhibit high interrater reliability, and holds promise as an alternative sarcopenia screening method.

340. Activity Effort and Stress in Women Aging with Mobility Disability, *Tracie Harrison, The University of TX at Austin; Janiece Walker, The University of TX at Austin; Carol Dellville, The University of TX at Austin*
Objectives: The learner will identify the mechanisms behind accelerated aging for women with mobility limitations.; The learner will be able to identify successful tips for the recruitment and retention of hard to reach populations with disabilities.;
Abstract Body: The cumulative impact of activity effort while living with a disability is theorized to increase stress and inflammatory responses resulting in accelerated aging. It was our purpose to test the feasibility of in-home data collection for this bio-social study of aging with disability. To this end, we recruited 28 Non-Hispanic White and Mexican American women, age 55 to 76, with severe mobility limitations to complete in home data collection. Women were recruited with fliers and word of mouth in two months' time; after which, multiple women were placed on a wait-list for future studies. The final sample of women completed biological measures of accelerated aging (telomere length), inflammation (C-reactive protein), and stress response (cortisol) using reliable laboratory procedures. They also completed surveys of depression, pain, activity effort, co-morbidity, and functional limitations. All scales were reliable and valid measures. Of note, results of the pilot data indicated that perceived activity effort was associated with serum stress [cortisol levels ($r=-0.54$, $p<0.05$)], but not with inflammatory markers [C-reactive protein levels ($r=-.11$, $p=0.65$)]. Results of telomere analyses are pending. The pilot data provides preliminary support for the continued study of this phenomenon. Procedures for data collection and analysis with women with severe mobility limitations living within the community were supported.

341. How are robotic Rollators evaluated by the User Perspective: A Systematic Review, *Klaus Hauer, Bethanien-hospital/Geriatric Centre at the University of Heidelberg; Christian Werner, Bethanien Hospital/ Geriatric centre at the University of Heidelberg; Milad Geravand, TU Muenchen; Phoebe Koepp, Bethanien-Hospital/Geriatric Centre at the University of Heidelberg; Angelika Peer, TU Muenchen*
Objectives: The purpose of this systematic review was to summarize assessment strategies and results of evaluation studies of robotic rollators with focus on the user perspective
Abstract Body: Background: Robotic rollators enhance basic functions of established devices by technically advanced physical, cognitive or sensorial support to increase autonomy in persons with severe impairment. In the evaluation of such robotic rollators both the technical as well as the user perspective is important to ensure safety, usability and effectiveness and to approve adequate application. Methods: A systematic review was conducted following Cochrane review methodology

in large data bases representative for the research field. Articles were selected according to the following inclusion criteria: Evaluation studies of robotic rollators documenting human robot interaction and subjective user perception, no case reports, published in English language. Results: Based on the heterogeneous study methodology and study results, a meta-analysis was not feasible in identified articles (n=23). Major methodological shortcomings related to user definition, study design, lack of appropriateness, standardization and validation of assessment instruments and insufficient sample size without statistical analysis of results. Robotic devices were described as usable and effective in most studies, however without giving statistical evidence. In those studies in which robotic devices were compared to standard devices, most, but not all, technically advanced devices showed superior performance. Long-term use in habitual environment was not evaluated. Discussion: Recommendations for future evaluation studies include clear definition of target user group and adequate, user-focused assessment strategy with internationally well-established tests to allow comparison of results and include documentation of long-term use. Assessment strategies may focus on specific functionalities of devices allowing an individually tailored assessment of innovative features to document added value.

342. Cognitive Status effects Therapy in geriatric Rehab, *Klaus Hauer, Bethanien-Hospital /Geriatric Centre at the University of Heidelberg; Ilona Dutzi, Bethanien-Hospital/Geriatric Centre at the University of Heidelberg; Michael Schwenk, University of Arizona College of Medicine*

Objectives: The purpose of this study was to analyze the effect of cognitive status on quality and quantity of therapy during ward based geriatric rehabilitation

Abstract Body: Background: Patients with cognitive impairment show less favorite rehab outcome compared to cognitively intact persons. Impairment-specific limitations, selective priority setting by therapists, or other causes have been discussed as potential influencing factors. However, up to date only very limited data on objectively documented therapy in a clinical routine setting have been published for geriatric rehabilitation. Methods: Study design: Prospective, observational study. Participants: Geriatric patients (mean age: 83.1 yrs.) consecutively recruited at ward-based geriatric rehabilitation (n=426). Assessment: Qualitative and quantitative documentation by electronic data documentation chart (ORBIS) during 3-week rehabilitation. Data analysis according to sub-groups defined by cognitive screening (Mini Mental State Examination; MMSE: cognitively intact (30-27), mild to moderate impairment (26-17); advanced impairment (<17 scores). Results: Patients with advanced cognitive impairment receive significantly less therapy (therapeutic units, total) (p=0.001), as well as significantly less personal as well as group-based therapy (p=0.04-0.002) compared to cognitively intact patients. Results seem to be impairment-related, as patients with moderate impairment showed an intermediate position with only singular significant differences between other patient groups (e.g. frequency of personal therapy; p=0.01). Analysis of covariance (ANCOVA) identified age and functional status (Barthel –Index) as significant covariates apart from cognitive status. Discussion: The study results document a significant effect of cognitive status on frequency as well as quality of therapy during geriatric rehabilitation. Effects are partly associated with age and functional status as significant covariates for group differences.

343. Dual-task Walking in Older Adults with Type 2 Diabetes without Diagnosed Diabetic Peripheral Neuropathy or Retinopathy: A Pilot Study, *Patricia Hewston, Queen's University; Nandini Deshpande, Queen's University*

Objectives: To discuss how divided attention may affect the ability to employ proactive strategies (ie. head-trunk coupling) while walking in older adults with type 2 diabetes; To emphasize that subtle differences in postural control may occur in older adults with type 2 diabetes before the onset of overt complications (i.e., diabetic peripheral neuropathy or retinopathy); To highlight the need for systematic monitoring and early intervention to help reduce the incidence of falls in older adults with type 2 diabetes before the onset of overt complications

Abstract Body: Diabetes-related declines in executive function may further heighten balance impairments, in addition to sensorimotor deficits, in older adults with type 2 diabetes (OAT2D); specifically, during mobility tasks requiring divided attention. Our study examined dual-task walking performance in OAT2D without diagnosed diabetic peripheral neuropathy (DPN) or retinopathy (DR). Twelve OAT2D without DPN or DR (OAT2D, age:70.50±5.12) and 12 healthy controls (OAHC, age:72.00±5.53) were recruited. A motion capture system tracked body segment position while participants walked a 6-meter path at their self-selected comfortable or fastest possible pace. The dual-task involved serial subtraction by 3's (SS3). Outcome measures included: walking speed, peak-to-peak displacement of the head and trunk in the mediolateral direction, and head-trunk correlation. The Trail Making Test (TMT) measured executive function. In both groups, walking speed significantly reduced with SS3; more at the fastest than self-selected pace ($p<0.001$). Head movement increased with SS3, regardless of pace or group ($p<0.05$). Trunk movement increased with SS3 at the self-selected pace ($p<0.05$) but not at the fastest pace ($p>0.05$). Higher overall head-trunk correlations were observed in OAT2D than OAHC ($p<0.001$). Head-trunk correlations reduced with SS3 in both groups ($p<0.001$). No significant differences in TMT were found ($p>0.05$). Higher head-trunk coupling in OAT2D reflects a need for segmental co-contraction strategy to simplify postural control (i.e., reduced degrees of freedom) without sacrificing their overall mobility. However, the ability to employ this strategy was affected by divided attention in the dual-task. Overall, subtle differences in postural control may occur before the onset of diabetes-related complications in OAT2D.

344. Cross-sectional and longitudinal associations between anaemia and frailty in older Australian men: The Concord Health and Ageing in Men Project, *Vasant Hirani, Centre for Education and Research on Ageing, Concord Hospital, University of Sydney, NSW, Australia. School of Public Health, University of Sydney, NSW, Australia.; Vasi Naganathan, University of sydney; Fiona Blyth, University of Sydney; David Le Couteur, Centre for Education and Research on Ageing, Concord Hospital, University of Sydney, Sydney, NSW, Australia.; Robert Cumming, University of Sydney*

Objectives: Participants will learn about the evidence relating to the causal association between low haemoglobin levels and development of frailty

Abstract Body: Introduction: Anaemia and frailty are both common in older people, and associated with adverse health outcomes. The objectives of this study were to examine cross-sectional and longitudinal associations between anaemia and frailty in older Australian men. Methods: 1666 men aged 70 years and older from the Concord Health and Ageing in Men Project (CHAMP) were assessed at baseline (2005-2007), 1314 men came for the 2-year follow-up (2007-2009), and 917 men returned for the five year follow-up (2012-2013). The main outcome measurement was frailty, assessed using the Cardiovascular Health Study method. Anaemia was defined as a hemoglobin levels <13.0 g/dl. Model covariates included age, income, measures of health, estimated glomerular function (eGFR), inflammatory markers (white cell count and albumin) and use of non-steroidal anti-inflammatory drugs. Results: At baseline prevalence of anaemia was 14.6% and prevalence of frailty was 9.1%. There were significant cross-sectional associations between anaemia and frailty in both unadjusted (OR 5.03 (95%CI 3.50,7.25, p<0.0001)) and fully adjusted analysis (OR 2.90 (95%CI 1.87,4.51, p<0.0001)).Generalized estimating equations time-lag models were used to examine the longitudinal associations between repeated measurements of haemoglobin and frailty. There were significant associations between measurements of anaemia status taken 2 years prior to the measurement of frailty in unadjusted (OR 2.51 (95%CI 1.58,4.00, p<0.0001) and in fully adjusted analysis (OR 1.80, 95%CI 1.14,2.85, p=0.01). Conclusion: Anaemia was associated with frailty, suggesting a causal relationship. The risks and benefits of interventions including nutritional therapy to correct anemia among frail older adults is an area that needs further investigation.

345. A Snoezelen® Room vs 'Standard Care' for Managing Wandering, Aggression and Restlessness among Residents with Dementia: An Observational Study., *Michael Bauer, La Trobe University; Jo-Anne Rayner, La Trobe University; Judy Tang, La Trobe University*

Objectives: To report on the effectiveness of using Snoezelen compared to usual care for the management of dementia related behaviours in residential aged care

Abstract Body: Background: The use of Snoezelen® rooms has become increasingly popular in residential aged care facilities in Australia for allaying the behavioural symptoms of dementia, despite no evidence of clinical efficacy. Aims: To compare the use of a Snoezelen® room and usual care practices in the management of the dementia related behaviours of wandering, aggression and restlessness in residential aged care facilities in Victoria, Australia. Methods: An observational study was undertaken in different aged care facilities over a four week period. Sixteen residents had their behaviour and their responses to Snoezelen® or usual care practices observed and recorded over three time periods. Data was analysed using repeated measures of ANOVA with adjustments for differences between subjects and intervention times. Results: A significant reduction in reported behavioural symptoms was found immediately post-intervention for both groups, however no significant differences were found at other post intervention time points. No significant differences were found between residents receiving Snoezelen® and usual care for the management of the dementia related behaviours of interest.Conclusion: The study findings suggest that the use of Snoezelen® as it is delivered currently in Victoria, Australia for allaying the dementia related behaviours of wandering, aggression and restlessness has no advantages over the use of usual care.

346. Understanding the Loss of a Spouse Two years Post-Loss, *Suzanne Beans, University of Akron; Ruth Walker, University of Akron; Toni Bisconti, University of Akron; Sara Powers, University of Akron; Cindy Bergeman, University of Notre Dame*

Objectives: To understand how older adult women are faring two years post-loss after conjugal bereavement.; To examine how depression, life satisfaction, control, and coping styles change over time.

Abstract Body: Losing a spouse is considered one of the most stressful transitions in older adulthood. This traumatic, yet normative, life event can pose a threat to a widow's well-being. During the first year of widowhood, researchers have found increased rates of physical and psychological morbidities, as well as trajectories of resilience (Bonanno et al., 2004); however, little is known about the specific anniversary effects. Therefore, the current study aimed to understand the effect of death anniversaries on a sample of bereaved women. Participants included 57 Caucasian widows from the Midwest region, who ranged in age from 57 to 83 (M=71.30; SD=6.25). Depression, Life Satisfaction, Perceived Control, Emotion-Focused and Problem-Focused Coping were examined at 4 month intervals starting 2-3 weeks post-loss and ending at 24 months. Results indicated a significant difference in Depression from 1 month to 24 months, with women scoring higher on Depression 1 month post-loss. Similarly, Life Satisfaction showed the same pattern with 1 month data showing lower Life Satisfaction than 2 years post-loss. Interestingly, Control showed an inverse relationship with lower Control being reported at 2 years post-loss than previous time points, whereas Problem-Focused Coping was reported to be higher at the two-year post-loss mark than in the initial months. Consistent with previous research by Bisconti et al. (2006), there might be a time sensitivity to the benefits of Emotion-Focused vs. Problem-Focused Coping strategies, with strategies focusing on our emotions being more salient at the beginning of the grieving process and more instrumental strategies being more helpful later.

347. More Older Iowans Share their Medical Preferences with Attorneys than with Physicians, *Mercedes Bern-Klug, The University of Iowa, School of Social Work; Tobokane Manthai, The University of Iowa School of Social Work*
Objectives: Compare and contrast Iowa's version of the POLST paradigm, IPOST (Iowa Physician Orders for Scope of Treatment) with other states.; Describe the extent to which older Iowans have communicated advance care wishes, and to whom.
Abstract Body: In July, 327 adults age 50+ who were part of the statewide STAR research volunteer registry completed an on-line survey about advance care planning including the extent to which they were familiar with IPOST (Iowa's version of the POLST paradigm—Physician Orders for Scope of Treatment, enacted into state law as of July 2012). Sample: two-thirds women, two-thirds with a 4 year college degree or more, 98% who reported their race as white. 88% indicated they had never heard of IPOST. 70% had a living will and 70% had appointed a proxy decision-maker through a DPOA-HC. Close to 60% reported they had been asked to be someone else's health care decision maker, although 23% were not sure if they were officially appointed. Thirty percent of the sample indicated they were "very concerned" about getting the type of medical care they prefer if they become terminally ill. Almost all (98.5%) indicated they would be interested in having a 30 minute discussion with their physician about medical care options, in the event they received a serious life-threatening diagnosis. When asked if they had had a conversation in the past 5 years with anyone about their preferences should they get in a serious accident and not be able to communicate, a higher percentage had spoken with a lawyer (33%) about their medical preferences than a physician (20%); 94% of the sample indicated it was important to have the discussion. More consumer education about advance care planning and IPOST is called for.

348. Non-driving Older Adults in Appalachian Ohio: An Exploratory Look into Transportation Resources, *Sarah Boehle, Department of Sociology and Gerontology Miami University*
Objectives: After attending this session participants will be able to identify strengths, barriers and challenges in transportation resources available to this Appalachian population.; After attending this session participants will be able to identify opportunities for policy and program developments to enhance transportation resources in Appalachian Ohio communities.
Abstract Body: Appalachian residents are described in the literature as having disadvantages in education, higher rates of illiteracy than national averages, poor housing, a lack of public transportation, and poor social service resources. Rural disadvantages of higher poverty rates, higher rates of chronic illness and disability, lower incomes, and less access to medical care and transportation services are also common. Several counties in Appalachian Ohio are projected to have an older population of around 30% by 2030, yet we know little about how transportation resources enhance or impair their ability to age in place. This study examines how non-driving older adults living alone in Appalachian Ohio utilize transportation resources to access medical care, groceries, employment, and maintain social relationships. Face to face interviews were conducted with 19 informants during the summer of 2014 to explore transportation resources. Utilizing ALTAS.ti and a content analysis process of inductive and deductive coding, richly detailed stories emerged about their experiences. The findings suggest that many trips for medical care meet essential needs; distant trips for specialized care are problematic, especially for those dependent on oxygen; return trips may entail waits of several hours; ER's are over utilized when transport is unavailable; and care is sometimes delayed and/or stopped due to transportation challenges. Additional findings suggest that home care workers provide transportation beyond authorized work boundaries; and concerns exist regarding the skills and training of transportation providers. The findings bring voice to the informants, and allow them to share their visions for improving services.

349. The Gender Gap in Nation-State social insurance Retirement Benefits: Sweden; Germany; Belgium, France and Italy, *Sally Bould, Gerontology Institute, University of Mass, Boston; ,*
Objectives: What social policies and practices come closest to providing equal financial security for women as compared to men in state provided retirement schemes. Does Sweden provide the model most favorable for women?; What is the impact of motherhood (the number of children from 0 to 3 or more) on women's state provided retirement income? Retirement income includes income from social insurance retirement schemes as well as old age public pensions; it excludes disability pensions and private pensions.
Abstract Body: New results from the European survey, SHARE, provide an initial understanding of the gender gap in social insurance retirement income provided by the state– the European system of public pension benefits. These data are the first to systematically document this critical gender gap under different systems of generous public pension provision. Pensions from the private sector in these countries are limited as the vast majority of older adults depend primarily on a universal public retirement or old-age pension, including survivor's pensions. The SHARE data allow for the calculation of the total amount of these public pensions in a sample of 17,000. Each national system is evaluated separately and cross-national comparisons are made. Within each country, different marital statuses and living arrangements are studied separately.

While a significant gender gap between married men and women exists in each country, this gap is not so critical in terms of total household income. It is among the widowed where the gender gap becomes more critical because of the reduction of household income and the loss of economies of scale. The widow/widower gender gap is consistently the greatest in each of the countries studied for all unmarried/un-partnered individuals. Women are best protected by survivor benefits in Belgium. In contrast, for Sweden, widowed women's median pension is 14,793 euros in comparisons to widower's median pension of 18,315. There is a significant motherhood penalty in all countries except Italy. This regression result for women controls for age, education, marital status and the decade last worked.

350. Predictors of Physical Activity and Sedentary Behaviors Among Older African American Women: NHANES 2003-2006

Pamela Bowen, The University of Alabama at Birmingham School of Nursing; Olivia Affuso, UAB Department of Epidemiology School of Public Health; Denise Houston, Wake Forest School of Medicine:Department of Internal Medicine

Objectives: Identify correlates that influence sedentary behaviors, light physical activity, and moderate-to-vigorous physical activity among older African American women.; Describe the amount of time this population spends performing sedentary behaviors, light physical activity and moderate-to-vigorous physical activity.

Abstract Body: Although physical activity is vital for the promotion of successful aging, many older African American women have a high prevalence of physical inactivity, which has been associated with mobility and functional impairments. The purpose of this study was to examine the correlates of physical activity and sedentary behaviors in older African American women. Data for African American women, aged 60 and older, from the National Health and Nutrition Examination Survey (NHANES) surveys 2003-2006 were used for this analysis. Objectively measured physical activity and sedentary behavior were assessed using accelerometry and physical function by self-report. Multivariable linear regression was used to examine the correlates of physical activity and sedentary behavior. The mean age of the sample was 68.5 years (± 7.1), 35.4% were married, 60.9% had at least a high school education, and 53.4% were obese. Mean time spent performing moderate-to-vigorous physical activity (MVPA) was 5.7 minutes/day (metabolic equivalent [METs] > 3.0), light activity was 3.6 hours/day (1.1-2.9 METs), and 7.5 hours/day were spent being sedentary (1.0 MET). Significant predictors ($p<0.05$) included: education, weight status, amount of computer usage, and difficulty stooping, crouching, and kneeling for sedentary behaviors; TV/video viewing and difficulty walking up 10 steps for light behaviors; and education for MVPA. Physical inactivity continues to be a public health issue. Our findings suggest that older African American women need to be empowered to move from sedentary behaviors to a light and/or MVPA level. Further exploration is needed to develop appropriate interventions that will motivate this population to move more.

351. Immigrants As They Age: Asian Elders and Functional Disability

Keith Chan, University at Albany SUNY; Thanh Tran, Boston College

Objectives: After attending this session, participants will be able to explain the conceptualization of disability in regards to biological limitations in relation to cultural, social and physical environmental factors.; After attending this session, participants will be able identify ethnic differences in the perception of functional disability for major groups of foreign-born Asian elders.; After attending this session, participants will be able to demonstrate culturally competent insights that can be applied to improve service delivery and shape policies to enhance healthy aging for foreign-born Asian elders.

Abstract Body: Purpose: Recent advances in the conceptualization of disability have emphasized the importance of cultural, social and physical environmental factors. Despite well-known projections of growth, only a few studies have examined how disability is understood for Asian elders. Most are immigrants and came from distinct ethnic groups, which have influenced how they have interacted with their environment and managed their chronic conditions as they aged into disability. Design and Methods: This study examined trends in how functional disability was perceived by Asian immigrant elders using large-scale, population data from the 2009, 2010, 2011, and 2012 American Community Survey. Reliability and Confirmatory Factor Analyses were conducted with five major groups of foreign-born Asian American elders (Chinese, Filipino, Vietnamese, Korean, and Japanese), to examine two major dimensions in functional disability, 1) Sensory Disability and 2) Activities of Daily Living. Results: Analyses indicated that functional disability was reasonably captured by the items for all five groups of foreign-born Asian elders from the ACS. However, foreign-born Korean elders appeared to be the most homogeneous in their perception of functional disability. Additionally, the factor loadings for the sensory perception item, Difficulty Hearing, varied the most for Chinese elders ($\lambda = 0.71$) compared to the other ethnic groups (λ ranged from 0.57 to 0.59). Implications: The perception of disability varied for ethnic groups of Asian elders, most likely due to differences from the pathways and motivations for immigration. Policies and practice must take into account these differences in order to promote healthy aging for this growing population.

352. Trust and Volunteerism in Hong Kong Adults: A Cultural Perspective, *Alice Ming Lin Chong, City University of Hong Kong; Susu Liu, City University of Hong Kong*

Objectives: To examine the differential effect of generalized trust and particularized trust on Chinese adults' volunteering motives and behaviors.; To explore ways to promote voluntarism among older Chinese;

Abstract Body: Introduction: Chinese people are usually found to reduce their voluntary involvement with age, which is contrary to the global trend. The present study aims to explore reasons behind this puzzling phenomenon by examining the effect of two main types of social trust, namely generalized trust and particularized trust, on volunteering. Method: The respondents were Hong Kong Chinese adults aged between 40 and 79 (N=715). They were interviewed by trained interviewers using a self-constructed questionnaire in a randomized household survey. Results: Age was found to be positively related to particularized trust, but negatively correlated with participation in voluntary work. Significant differences were found between the middle-aged (40-59 years old) and older adults (60 and over) in terms of volunteer hours in past month, volunteer motivations and particularized trust. Hierarchical regression analysis showed that generalized trust marginally and positively predicted voluntary work, while particularized trust indicated negative effect. Conclusion: This study is one of the very few to examine the effect of particularized and generalized trust on volunteerism. The findings suggest that Chinese people hold a higher level of trust towards individuals (particularized trust) than society (generalized trust), and this trend increases with age; thus leading to a decrease in volunteering hours with increase in age. People endorsing particularized trust might stick to personal and family values, and were less inclined to participate in voluntary work. Strengthened efforts should therefore be taken to raise generalized trust and appropriate measures are suggested to promote volunteerism in late life.

353. Poverty in old age: Evidence from Hong Kong, *Kee-Lee Chou, The Hong Kong Institute of Education*

Objectives: To differentiate the different concepts of poverty mesaured by income, expenditure and asset

Abstract Body: Identify the poor in aged population is particularly particular because a number of them may have insufficient income but enjoy adequate consumption due to their assets at hand. This study investigates poverty among older adults by using income and consumption in the defining poverty. We use a data set with a representative sample of 4,306 older adults aged 60 years old and older. Using the official poverty line (i.e. half of the median of household income), 36.4% of older adults are below the threshold using income whereas 31.1% are below the threshold using the consumption flows. However, the poverty rate is cut to 25.3% when both income and consumption are used to define poverty. Results indicate that older adults who are consumption poor but income non-poor are more likely to still engage in employment and receive wages, but they will be retired very soon. Therefore, they attempt to save more when they are still working. On the other hand, among those who were income poor but consumption non-poor consume much more than their income but a much higher percentage of them were homeowner and had higher asset (beside self-occupied properties). Lastly, our results indicated that older adults who were both income and consumption poor were the poorest because they were mostly likely depended on family support and welfare for their living and the level of asset they possessed was very low. Understanding the nature of this double poverty population is crucial in evaluating the anti-poverty measures in the aged population.

354. To What Extent Can Hospitals Control Readmissions? Predictors of 30-day Hospital Readmission Among At-Risk Older Adults, *Alexis Coulourides Kogan, University of Southern California; Adria Navarro, Azusa Pacific University; Eileen Koons, Huntington Memorial Hospital; Susan Enguidanos, University of Southern California*

Objectives: After attending this session, attendees will have a greater understanding of the policy and practice implications for 30-day hospital readmissions among older adults.; After attending this session, attendees will understand the patient-level factors and consequences associated with 30-day hospital readmissions and receipt of a social work intervention.;

Abstract Body: Older adults transitioning from hospital-to-home are at high risk for adverse outcomes and rehospitalizations. Under the Affordable Care Act, hospitals are penalized for high 30-day readmission rates, and have thus undertaken efforts to reduce readmissions among their older patients by improving transitional care. This poster reports findings from the Social Work Intervention Focused on Transitions (SWIFT) study, a randomized controlled trial testing the impact of a brief social work transition intervention on hospital readmissions. The study enrolled 181 patients; most were married (45%), Caucasian (61%), male (51%), and, on average, 78.8 years old (sd=8.3). Results reveal that predictors of 30-day readmission included Caucasian race (p=.036) and having a cancer diagnosis (p=0.017). As compared to racial minorities, odds of readmission were 4.7 times higher for Caucasians and 6 times higher among participants diagnosed with cancer. Additionally, those assigned to the intervention arm that refused the social work intervention were more likely to be readmitted. Randomization to the SWIFT intervention was not significantly associated with lower 30-day readmissions. These results suggest that certain patient groups, such as those diagnosed with cancer, may need ongoing support, and that a brief social work intervention may not be sufficient in reducing short-term readmissions among at-risk older adults. Current policies have charged hospitals with the task of reducing 30-day readmission rates and these results along with new, emerging research may indicate that patient-level factors may contribute to readmissions. More research is needed to confirm these findings and better understand patient characteristics associated with 30-day rehospitalization.

355. Developing a Multi-Dimensional Measure of Successful Older Persons' Transitions in Care (OPTICS), *Greta Cummings, University of Alberta; Sarah Cooper, university of Alberta; Colin Reid, University of British Columbia; Carole Estabrooks, University of Alberta; Brian Rowe, University of Alberta*

Objectives: To discuss the development of the measure of the success of transitions across multiple settings (nursing homes via emergency medical services to emergency department and back)

Abstract Body: Purpose: To develop a measure of successful transitions of frail seniors who reside in nursing homes to emergency departments and back via emergency medical services. Methods: Multi-method, multi-perspective procedures were used to develop quality indicators of care for frail nursing home residents during transitions. Data were gathered from qualitative interviews with residents, family/friend caregivers, and healthcare providers from all transition settings, real-time tracking of 628 transitions and a growing body of research and policy literature on quality care and transitions. The six domains (safety, resident-focused, timeliness, effective, efficient, equity) in the Institute of Medicine (IOM) Quality Framework were used to categorize and analyze data from all sources. Analysis: Steps included a) development of an OPTIC (Older Persons’ Transitions in Care) definition of successful transitions; b) development of standards of care for each IOM domain across the entire transition; c) operationalization of the standard into quality indicators in each setting of the transition; d) identification of normative/comparative data from the literature; e) analysis of OPTIC data from 628 full transitions in two Canadian provinces; and f) development of an interactive dashboard of quality indicators of success for use by healthcare decision-makers to monitor quality of transitions in their jurisdictions. Conclusion: The complexity of measuring multi-setting transitions for frail seniors with multiple co-morbidities and cognitive issues is enormous. However a multi-perspective matrix of quality indicators can be developed and displayed as an interactive dashboard to provide important information to improve transitions of frail seniors in nursing homes who require acute care services.

356. Fall Incidence and Social Support in Older Mexican Americans: A Longitudinal Study of Development and Predictive Factors, *Leah Dierking, University of Texas Medical Branch, Galveston, Texas; Kristen Peek, University of Texas Medical Branch, Galveston, Tx.*

Objectives: The results and analysis provide a glimpse into the nuances found in specific ethnicities regarding fear of falling and fall incidence as it relates to health outcomes and social support.; The study also provides a starting point for the development and implementation of interventions specifically aimed specifically among fall incidence education and recovery among a minority population and within their community;

Abstract Body: Social and physical isolation has been shown to be a debilitating factor for adults in regards fall incidence. Few studies regarding fall incidence have focused on minority populations regarding prediction and prevention. The purpose of this study is to expound on prior research and to examine longitudinally the incidence and predictive factors of any falls as compared to multiple fall incidence over a 7 year period. The data for this study was taken from the Hispanic EPESE, a population based study of 3050 non institutionalized Mexican-Americans residing in five Southwestern states: Arizona, Texas, California, New Mexico and Colorado (86% response rate). Of the 1682 respondents at baseline, 32.88 % of them reported varying incidents of falls in the last 12 months. Subjects that have a high CES-D score, self-reported fear of falling, high chronic conditions, and high IADL limitations were more likely to report baseline fall incident during the last year. Stratifying between presence of any and 3 or more falls during a 12 month period across time revealed that having the number of family interactions became significant for those with 3 or more falls in a 12 month period. This study supports the hypothesis that fall incidence is a common concern for not only the general population as prior studies have shown, but also for the specific Mexican-American older community in the Southwestern United States. Social activity among sub culture specific clusters needs to be explored further in regards to a range of physical, psychological and functional complications

357. Publicly Assisted Senior Housing: The Structure of Residents’ Social Convoys, *Jessica Drum, Wichita State University; Dr. Louis Medvene, Wichita State University*

Objectives: To understand the differences in the social convoys of publicly assisted senior housing residents as compared to nursing home and assisted living residents, specifically in relation to friends and fellow residents.; To understand the implications of social programming and a service coordinator at publicly assisted senior housing locations.;

Abstract Body: The largest percentage of adults over 65-year-of-age (95%) live outside of nursing homes. These arrangements are likely to continue given limited public resources. Of most concern are low-income older adults, two million of whom live in publicly assisted housing (Stone, 2013). We know little about these older adults. This exploratory study focused on the social networks of 31 residents of a 66-unit subsidized senior housing building. Residents were interviewed about their social convoys (Antonucci et al, 2010), isolation (Lubben, 1988), and loneliness (Russell, 1996), and a cluster analysis was carried out. On average, residents were 78 years-of-age, 90% were female, and almost 90% were Caucasian. Friends constituted 47% of residents’ networks, 42% were family/relatives, and 11% were professional staff. Residents’ length of stay was positively correlated with the number of fellow residents in their social convoy ($r = .39$, $p < .03$). Using frequency of contact as criteria variables, a cluster analysis yielded two large clusters – religious/community organizations (n=14), and family/friends (n=12) – and two small clusters – restricted (n=4), and an outlier (n=2). A series of ANOVA’s indicated that residents embedded in the family/friend cluster were significantly less isolated than other residents (p < .03), and less lonely than residents embedded in the restricted cluster (p <.01).   The number of friends/residents in participants' social convoys is larger than has been reported in studies of nursing homes and assisted living. This site had a service coordinator and extensive social programming, suggesting that publicly assisted senior housing sites are well-suited for social interventions.

358. An Interdisciplinary Framework To Support An Age-friendly Workplace In The NHS, *Isaiah Durosaiye, University of Central Lancashire, Preston, United Kingdom*

Objectives: The factors that inhibit the work ability of older nurses within the NHS will be presented. For example, the physical, cognitive, sensory or emotional demands of the jobs will be explored.; The extent to which the design features of the workplace support or hinder the work ability of older nurses will be discussed.; Finally, the main features of an age-friendly workplace from the perspective of older nurses and how the developed framework supports the health and well being of older nurses will be highlighted.

Abstract Body: Introduction The nursing profession is a key part of the healthcare services in the United Kingdom (UK); hence ensuring their work environment is accommodating to advances in age is crucial to the continued delivery of high standard healthcare services. However, ill-designed jobs are forcing an increasing number of nurses to exit the profession through early retirement.   Aims This PhD research project seeks to develop a design framework that will support the creation of a fit between older nurses and their job demands within the National Health Service (NHS), in the UK. This poster presentation will summarize the initial findings of the recently completed MPhil stage, as the project advances to the PhD stage.   Methodology After an in-depth literature review, semi-structured interviews were conducted with 10 participants within the NHS. Participants are from various backgrounds, including occupational health, facilities management, human resource management and practicing older nurses. Participants were invited to describe their understanding of an age-friendly workplace and if their particular workplace was age-friendly or not.   Results The initial findings revealed that older workers: 1) Depend much more on their physical and sociocultural environments compared to their younger peers; 2) Compensate for decline in their work ability through work experience and familiarity with their physical and sociocultural environments;   3) Are concerned about their health and risk of work-related injuries; 4) Value adaptable workplaces and flexible job designs and work patterns; and 5) Are generally apprehensive of coping with their post-retirement lifestyle.

359. FITS Into Practice: Reducing The Use Of Antipsychotics For People With Dementia In Care Homes, *Simon Evans, University of Worcester, UK; Dawn Brooker, University of Worcester; Isabelle Latham, University of Worcester; Nicola Jacobson, University of Worcester*

Objectives: To describe the structure and key elements of a training approach that has proven successful in reducing the use of antipsychotics by people with dementia living in care homes.; To highlight the main outcomes that a person-centred training approach can deliver for people with dementia living in care homes.; To explore the main barriers to successful implementation of an innovative training programme that aims to improve quality of life for people with dementia living in care homes.

Abstract Body: The Focussed Intervention Training for Staff (FITS) intervention demonstrated an effective way of significantly reducing inappropriate antipsychotic use in UK care homes. The Association for Dementia Studies at the University of Worcester worked with the Alzheimer's Society to draw up an intervention that would remain true to the FITS programme but that could be delivered across a large number of care homes. This is the FITS into Practice Programme. Over a 2-year period two "Dementia Practice Development Coaches" delivered an intensive nine month education and supervision programme to care home staff designated as "Dementia Care Coaches" (DCCs) to enable care-homes to safely reduce antipsychotic medication and to put in place best evidence based practice interventions to improve well-being and reduce BPSD in residents with dementia.   Quantitative and qualitative data were gathered from the viewpoint of multiple stake-holders including the impact on anti-psychotic prescribing. In addition nine care homes case studies were undertaken to deepen understanding of the processes involved in practice.   106 care homes were recruited and 67 successfully completed the programme. Participants reported significantly improved confidence and knowledge and felt able to provide a positive role model to other staff. There was a statistically significant reduction in anti-psychotic prescribing following the intervention. Feedback and case studies also demonstrated very positive changes in practice in terms of improving resident well-being, staff team attitudes, quality of the care environment, good feedback from families and enhanced reputation with CQC and local commissioners.

360. Implementation of screening tools of patients at risk of hospital readmissions in Spain: impact on the management of chronic patients, *Jordi Garcés Ferrer, Prince of Asturias Distinguished Visiting Professor. Georgetown University.; Francisco Ródenas Rigla, Polibienestar Research Institute; Estrella Durá Ferrandis, Polibienestar Research Institute - University of Valencia; Ascensión Doñate-Martínez, Polibienestar Research Institute - University of Valencia; Irene Monsonís-Payá, Polibienestar Research Institute - University of Valencia*

Objectives: The main objective of the study presented is to assess the use of tools to detect patients at risk of hospital readmission developed in the United States in the Spanish Healthcare System, and their inclusion in specific programmes to manage patients with chronic conditions from the public administration.

Abstract Body: Most of the healthcare systems in European countries are experiencing a burden in the care and management of elderly patients with chronic conditions. Polibienestar Research Institute from the University of Valencia (Spain) – lead by Dr. Jordi Garcés, Prince of Asturias Distinguised Visiting Professor at Georgetown University – focus its research on the sustainability, ICTs and social innovation in long-term care systems with the aim of improving the quality of care provided to vulnerable elders and their quality of life. Authors implemented two screening tools to detect patients at risk of hospital readmission in the Valencian Region (Spain): The Community Assessment Risk Screen (CARS) and the Probability of Repeat Admissions Tool (Pra); both originally developed in the United States. The main results indicated that both predict with high efficacy the proportion of patients not to be readmitted (91% for CARS and 92% for Pra). Besides, Pra was less sensitive (54%) and more specific (81%) than CARS (with both values of 64%). Results obtained show that both CARS and Pra do not identify efficiently elderly population at risk of hospital admissions. So, currently, authors are working in the development of an own tool validated in a Spanish sample and based on our specific cultural, health and social features. The applicability of this kind of screening tools in the Spanish Healthcare System is demonstrated through the implementation of a version of CARS – revised and improved by clinicians' criteria – to identify high-risk patients to be introduced in a programme to manage chronic diseases.

361. Home Care for Older Clients with Mental and Behavioral Health Diagnoses: Workforce implications, *Hayley Gleason, University of Massachusetts Boston; Caitlin Coyle, Yale University*

Objectives: After attending this presentation, participants will be able to discuss the demand for home care services by older adults with mental and behavioral health problems and the implications of these conditions for the direct care workforce.; After attending this presentation, participants will be able to explain the skills and knowledge needed for home care aides to provide high quality care to older clients with mental and behavioral health diagnoses.

Abstract Body: Home care aides are critical to providing the care needed by the growing number of older adults who choose to remain in their home as they age. Despite home care aides' importance to the overall safety and quality of life for clients, these workers often do not have the necessary skills to provide care to increasingly complex and frail individuals. One challenging area of concern is providing care to adults with complicated behavioral health diagnoses. These elders and disabled adults represent a growing percentage of those receiving care in the home and require highly trained caregivers who can manage not only the personal care responsibilities, but also the consumer's difficult behaviors. To better understand the training needs of aides providing care to clients with mental and behavior health problems, a state-wide exploratory study was conducted in Massachusetts. Focus groups and interviews with ninety aides, supervisors, and key informants were used to explore this important area. The results from this qualitative analysis will be shared, including the principal behavioral and communication challenges experienced by aides and supervisors working with these clients and the implications of these challenges for both the aide's and client's well-being. Additionally, the availability of training to aides will be discussed, as well as, the mechanisms in place for including the aide in the communication and support of the client across the care continuum. Participants will learn the researcher's recommendations for the development of a training curriculum and the implications for future research and policy in other states.

362. Neighborhoods. Does place matter for volunteering in later life?, *Ernest Gonzales, Boston University, School of Social Work; Huei-Wern Shen, University of Missouri-St. Louis, School of Social Work; Yi Wang, Washington University in St. Louis, Brown School of Social Work; Julie Norstrand, Boston College, School of Social Work*

Objectives: Participants will learn of the intersection of productive aging and Age Friendly Cities initiative by the World Health Organization.; Participants will learn of the need for further conceptualization and measurement in order to make a direct link between formal volunteering in later life and neighborhood characteristics.

Abstract Body: OBJECTIVES. Research has established a strong link between individual factors and formal volunteering in later life, yet the concept of Age Friendly Cities by WHO signals the importance of the social and built environment. We ask: What are the economic and social determinants, as well as neighborhood characteristics, that may leverage older adults into volunteer roles? Does place matter? METHODS. We surveyed 289 residents aged 58-106 in the greater St. Louis, Missouri region in 2014. Neighborhood data were drawn from public records (e.g. online FBI records). Bivariate and logistic regression examined relationships between individual factors (sex, race, mental health, physical health, formal education, income, total assets, marital status) and neighborhood factors, e.g. safety (violent crime, property crime), economic status (percentage of unemployed, house values, number of households receiving food stamps), walkability, and stability (percentage of people living in same house for 5 years). RESULTS. Bivariate analyses revealed formal volunteering was associated with race, mental health, physical health, income, total assets, and marital status; none of the neighborhood factors were significantly related to formal volunteering. Regression results revealed mental health and total assets are significantly related. Although walkability was trending toward significance, none of the neighborhood characteristics were significantly related to volunteering. DISCUSSION. While transforming our cities and neighborhoods to become age friendly has much appeal, preliminary research suggests the link between formal volunteering and age friendly neighborhoods has yet to be established. Further conceptualization, measurement, as well as examining objective and subjective perceptions of neighborhoods are required.

363. Aging with a Physical Disability in Medicaid Managed Care, *Tamar Heller, University of Illinois at Chicago; Randall Owen, University of Illinois at Chicago; Hailee Gibbons, University of Illinois at Chicago; Dale Mitchell, University of Illinois at Chicago*

Objectives: Increased understanding of the consumer experiences of people aging with physical disabilities in Managed Care.; Understand impact of Managed Care on use of emergency room and hospital among people aging with physical disabilities.

Abstract Body: This study examines healthcare experiences and outcomes for older and younger adults with and without physical disabilities in Medicaid receiving managed care (MC) versus fee for services (FFS) over two years. The study uses survey data from 652 individuals in MC and 659 in FFS two years after the start of MC. 55% of survey respondents were 50 and older. The survey includes measures of health care appraisal and unmet needs. Regression analyses with these outcomes included demographic variables and enrollment in MC versus FFS. Health care appraisal was not related to enrollment or age, although the interaction of MC and being older was significant ($p<.05$). Among people with physical disabilities, older adults were more positive about MC versus FFS whereas younger people were less happy with MC versus FFS ($p<.05$). Regardless of age or receiving MC, people with physical disabilities had more unmet needs ($p<.01$) than people without physical disabilities. It is important to consider the experiences of people aging with physical disabilities in MC because this group has numerous unmet needs that need to be addressed to support them aging well. Identifying unmet needs is the first step in improving the MC system.

364. Development and Evaluation of a Novel Dignity-Conserving End-of-Life Care (EoL) Model for Nursing Homes in the Hong Kong Chinese Context, *Andy Hau Yan Ho, Sau Po Centre on Ageing, The University of Hong Kong.; Annie Dai, Sau Po Centre on Ageing, The University of Hong Kong.; Vivian Lou, Sau Po Centre on Ageing, The University of Hong Kong*

Objectives: To understand the programme structures and implementation mechanisms of a novel Dignity-Conserving End-of-Life Care (EoL) Model for Nursing Homes in Hong Kong; To identify ways in which a novel Dignity-Conserving EoL Care model serves to enhance Chinese older nursing home residents' dignity and quality of life at the end-of-life; To appreciate the imperative integration between end-of-life care and long-term-care through appropriate care coordination and management, family-centered care as well as physical-psycho-socio-spiritual Support

Abstract Body: Background: The provision of end-of-life (EoL) care in long-term-care settings remains largely underdeveloped in Hong Kong, China and other Asian regions, and older nursing home residents often fail to obtain good care as they approach death. Objective: This research systematically describes the development and implementation mechanisms of a novel Dignity-Conserving EoL Care model that has been successfully adopted by three nursing homes in Hong Kong, and presents preliminary evidence of its effectiveness on improving the quality of life (QoL) of terminally-ill residents. Methods: Nine terminally-ill nursing home residents (Mean-age=92years, SD=7.54, Range=82–102years) completed the McGill Quality of Life Questionnaire and the Nursing Facilities Quality of Life Questionnaire at baseline and 6-months post EoL programme enrollment. Wilcoxon signed rank test was used to detect significance changes in each QoL domains across time. Results: Although significant deterioration was recorded for Physical QOL (pre=1.83, post=1.31; $z=2.19$, $p<0.05$), significant improvement was observed for Social QoL (pre=2.16, post=2.60; $z=2.26$, $p<0.05$). Moreover, a clear trend towards significant improvements was identified for the QoL domains of Individuality (pre=2.33, post=2.63; $z=1.78$, $p=0.075$) and Relationships (pre=2.11, post=2.40; $z=1.88$, $p<0.061$). Conclusion: A holistic and compassionate caring environment, together with the core principles of family-centered care, inter-agency and interdisciplinary teamwork, as well as cultural-specific psycho-socio-spiritual support, are all essential elements for optimizing quality of life and promoting death with dignity for older nursing home residents facing morality. This study provides a useful framework to facilitate the future development of end-of-life care in long-term-care settings in the Chinese context.

Poster Numbers 365-374 are NIA Travel Awardees for CNS Junior Investigators

365. The Relationship between Inflammatory Burden, Mobility and Cognition is Influenced by White Matter Characteristics in Older Adults: Secondary Analysis of the Health, Aging and Body Composition (Health ABC) Study, *Neelesh Nadkarni, University of Pittsburgh School of Medicine / UPMC Division of Geriatric Medicine and Gerontology Department of Medicine; Robert Boudreau, University of Pittsburgh/Graduate School of Public Health;*

Caterina Rosano, University of Pittsburgh / Department of Epidemiology – School of Public Health; Oscar Lopez, University of Pittsburgh / Department of Neurology, School of Medicine and Alzheimer's Disease Research Center; Howard Aizenstein, University of Pittsburgh / Department of Psychiatry; Stephen Kritchevsky, University of Pittsburgh / Department of Psychiatry; Kristine Yaffe, University of California at San Francisco / Department of Psychiatry; Anne Newman, University of Pittsburgh / Department of Epidemiology – School of Public Health

Objectives: To study the cross-sectional and longitudinal associations between inflammation (interleukin (IL)-6), gait speed and processing speed in older adults.; To explore the underlying central nervous system mechanisms that could play an important role in the association between increased inflammation and decline in cognition and mobility.

Abstract Body: Objectives: To examine the relationships between inflammation, processing speed and gait speed and assess whether white matter (WM) characteristics mediate these relationships. Methods: In 314 adults (age: 83 years, 42% black) enrolled in the Health ABC study, cross-sectional (at year-10) and longitudinal (up to year-10) relationships between processing speed (digit symbol substitution test; DSST), gait speed and systemic inflammation (serum interleukin (IL)-6) were assessed. Rate of change of IL-6, DSST and gait speed were estimated by determining their respective slopes. Cerebral WM characteristics were assessed on neuroimaging (year-10) by quantifying small-vessel disease (white matter hyperintensities; WMH) and myelin integrity (total fractional anisotropy (FA) of normal appearing WM; WM-FA). Separate multivariable linear regression models quantified the association between IL-6, DSST and gait speed adjusted for relevant covariates. Tests of mediation with WMH and WM-FA were also conducted. Results: Cross-sectionally, in this sample of older adults (Modified Mini-mental Status score = 95 and gait speed = 0.9 m/sec), higher IL-6 levels were related to lower DSST (beta: -0.239, p=0.002) and slower gait (beta:-0.249, p=0.001). Higher IL-6 levels were also associated with higher WMH and lower WM-FA (beta: 0.156 and -0.174, p= 0.044 and 0.03 respectively). The mediation analyses found that with WMH and WM-FA in the model, the associations between IL-6, DSST and gait speed were no longer significant. Longitudinally, association between slopes of IL-6, DSST and gait speed were not statistically significant. Conclusion: The adverse effects of inflammation on mobility and cognition in older adults appears to be influenced by WM integrity.

366. Motor Imagery Ability In Persons With Parkinson's Disease: Does Physical And Cognitive Status Matter?,

Kristin Lowry, Des Moines University

Objectives: To examine associations between motor imagery ability, cognition, and physical function in persons with Parkinson's disease

Abstract Body: Background: Motor imagery (MI), imagining an action without physical execution, facilitates motor skill learning in persons in good health and post stroke, with emerging evidence that MI may benefit persons with PD. An important determinant of the clinical value of MI in PD is to understand characteristics associated with MI ability. Methods: Eight individuals with PD participated (mean age, 65 yrs ± 6). Assessments performed: Imagery ability, Kinesthetic and Visual Imagery Questionnaire (KVIQ, 0-170), Movement Imagery Questionnaire - Revised Second version (MIQ-RS, 0-98), higher scores indicate better imagery ability; Cognition, MoCA, (0-30); Global physical status, Hoehn & Yahr (HY) scale (0 – 5, 5 = bed ridden). Spearman's rho was used to determine associations between imagery ability, cognition, and physical status. Results: Participants had mild to moderate disease (mean HY, 2.5). Mean (SD) scores of assessments: KVIQ, 123 (25), MIQ-RS, 69 (19), MoCA, 25 (3.7). The KVIQ and MIQ-RS were related to the MoCA, r = 0.837, p = 0.010, and r = 0.732, p = 0.039, respectively. Neither the KVIQ nor the MIQ-RS were related to the HY scale, r = -0.013, p = 0.976, and r = -0.273, p = 0.514, respectively. Conclusion: The data suggest that MI ability is associated with cognitive, but not global physical ability. Specifically, better cognition is associated with better ability to imagine movement. Both cognition, (MoCA), and MI ability rely on frontal lobe function. Intact frontal lobe function, more so than actual physical ability, may be important for the effective use of MI.

367. Continuous monitoring of turning mobility is related to fall risk and cognitive function,

Martina Mancini, OHSU, Department of Neurology; Patricia Carlson-Kuhta, OHSU, Department of Neurology; Mahmoud El-Gohary, APDM, Inc; James McNames, APDM, Inc; Jeffrey Kaye, OHSU, Department of Neurology; Fay Horak, OHSU, Department of Neurology

Objectives: Continuous measures of mobility are more sensitive than overall quantity of mobility in predicting individual with fall risk and diminished cognitive resources

Abstract Body: Difficulty turning, or changing direction of walking, is a major contributor to mobility disability, falls and reduced quality of life in older people and people with movement disorders. The objective of this study was to determine the feasibility of continuous monitoring of turning during spontaneous, daily activity and its association with falls and cognitive function. Thirty-five elderly participants (85+8years) wore 3 Opal sensors on the belt and on each foot throughout 7 consecutive days in their homes. Neuropsychiatric assessment included cognitive domain z-scores: Executive function, Working memory, Attention/Processing speed, Memory, and Visuospatial function. Turning, gait bouts and activity rate were measured. Based on the history of falls, participants were grouped in non-fallers (N=16), fallers (N=12), and recurrent fallers (N=7). Quality of turning (mean turn duration, peak speed of turning, and number of steps to complete a turn) was significantly compromised in recurrent-fallers compared to non-fallers (p<0.05). In contrast, activity rate, gait bouts, and mean number of turns/h were similar across the 3 groups. Visuospatial and memory functions were associated with turning mobility (r=0.4, p<0.03) while attention-processing speed functions were associated to gait (r=0.52, p=0.006). Mobility was related to different aspects of cognition, consistent with shared neural resources for cognitive and dynamic balance functions. These findings suggest a less variable, cautious turning strategy in elderly subjects with a positive history of falls. We believe that characterizing functional turning during daily activities will address a critical barrier to clinical practice and clinical trials: objective measures of mobility in real life environments.

368. Improvements in Gait and Balance following Cognitive Training are Moderated by Age: Differential Impact for Old-Old and Young-Old Adults, *Renae Smith-Ray, University of Illinois at Chicago*
Objectives: To understand how cognition impacts gait and balance.; To begin to consider whether younger old adults (age 65-79) have a greater capacity for improvement in gait following cognitive training compared to their old-old counterparts.
Abstract Body: Older adult falls are a leading public health problem. Research supports a link between cognition and falls, yet cognitive interventions are notably absent from the repertoire of fall prevention programs. Our team performed two pilot RCTs to examine the impact of cognitive training on balance and gait among older adults. The purpose of this presentation is to share results of a combined analysis from these two pilot trials. Ninety-six participants were recruited into the two studies. Both were RCTs that tested the hypothesis that a 10-week cognitive training intervention improves mobility. Distinct cohorts of older adults were recruited from (1) independent living communities (N=51) and (2) senior centers (N=45). Primary outcomes collected at baseline and 10-weeks included gait speed, distracted gait speed, and balance as measured by Timed Up and Go (TUG). The average participant's age was 77.2, with 62% categorized as young-old (age 65-79) and 38% old-old (age 80+). Old-old intervention participants performed significantly better than controls on TUG (F(2,26)=7.68; p=0.003) post-intervention while there was no significant difference between young-old groups. Conversely, young-old intervention participants significantly improved in gait speed (F(2,45)=3.94; p=0.03) compared to controls while old-old intervention participants did not significantly differ. Moreover, mean post-intervention improvements for all outcomes were more pronounced in young-old participants compared to old-old participants. These results shed light on the trajectory of balance and gait in late life, indicating that young-old adults may be more responsive to a cognitive training intervention than old-old adults. Additional studies are warranted to confirm these findings.

369. The Effect of Experience Corps on Lifestyle Physical Activity, *Vijay Varma, Johns Hopkins University; Greg Harris, Johns Hopkins University; Michelle Carlson, Johns Hopkins University*
Objectives: Examine whether participants randomized to the Baltimore Experience Corps program, compared to controls, increased objectively measured daily walking activity post-exposure.
Abstract Body: Physical inactivity is associated with a number of adverse health outcomes. Increasing daily physical activity can help prevent chronic illness and decline, however only 20% of older adults meet the aerobic and muscle strengthening components of U.S. physical activity guidelines. Additionally, older adults, particularly of low socioeconomic status (SES), have difficulty adhering to exercise programs due to a high prevalence of chronic medical conditions and functional impairments as well as restrictive environmental and neighborhood characteristics. Experience Corps (EC), a community-based model of health promotion, was designed to attract a diverse population of older adults who may not engage in typical health promotion interventions. EC places older adults as volunteers within the public school system to simultaneously increase the physical, social, and cognitive activity of older adults, while improving the academic outcomes of children. Within the NIA-funded Baltimore Experience Corps Trial (BECT), we explored the effectiveness of the two-year EC intervention, to increase physical activity in a non-demented, older, mostly sedentary cohort. Using longitudinal, linear mixed effects models we found that following two years of exposure, older women, but not men, randomized to the EC intervention showed higher levels of step activity. Intervention and control groups had similar baseline physical activity; after two years, the intervention group completed, on average, 2000 more steps/day and 4 more 10-minute bouts of activity/day than control participants. Our findings suggest that engagement in a community-based senior service program, like EC, may lead to sustained increases in daily physical activity among community-dwelling, mostly sedentary, older adults.

370. Small Vessel Disease of the Brain and Peripheral/Sensory Impairments Have Similar Contributions to Poor Mobility, *Andrea Rosso, University of Pittsburgh; Stephanie Studenski, National Institute of Aging; William Longstreth, University of Washington; Caterina Rosano, University of Pittsburgh*
Objectives: Understand the importance of different body systems to mobility performance
Abstract Body: Mobility limitations with aging are common and debilitating. The traditional focus of research and clinical practice has been peripheral systems or overt neurological diseases. The importance of subtler neurologic impairments, particularly small vessel disease (SVD), has increasingly been recognized but is rarely considered concurrently with peripheral/sensory impairments. We used the Cardiovascular Health Study (n=2734, age≥65 years) to characterize the association of SVD with mobility in the presence or absence of peripheral/sensory impairments. Obesity (body mass index>30), peripheral vascular (ankle-arm index<0.9), joint pain (self-report), lung function (sex-specific lowest quartile forced vital capacity), poor vision (self-report), and muscle strength (grip strength<16kg for women or <26kg for men) were examined in separate general linear models adjusted for age, gender, and race; each model had a 4-level variable: no SVD or peripheral/sensory impairment, only peripheral/sensory impairment, only SVD, both SVD and peripheral/sensory

impairment. For all systems, gait speed was approximately equal for those with only peripheral/sensory impairment and those with only SVD (p range=0.06-0.3). For example, mean gait speed was 0.96m/s (95% confidence interval: 0.94, 0.97) for those with no joint pain or SVD, 0.90m/s (0.89, 0.92) for those with joint pain only, 0.92m/s (0.90, 0.94) for those with SVD only, and 0.86m/s (0.84, 0.88) for those with both. Results were similar for other peripheral/sensory impairments or with self-reported mobility disability. SVD, peripheral, and sensory systems should be considered together to estimate severity of mobility disability and in intervention development.

371. Association Between Perceptual Effort During Mobility and Executive Function in Older Adults., *Duane Corbett, University of Florida; David Gundermann, University of Florida; Michael Marsiske, University of Florida; Benji Kluger, University of Colorado Denver; Immanuel Samuel, University of Florida; Todd Manini, University of Florida*
Objectives: To investigate the relationship between perceptual effort during mobility and executive function in older adults
Abstract Body: Purpose: To investigate the relationship between perceptual effort during mobility and executive function in older adults. Methods: 30 men and women (71.7±5.2 yrs) with normal cognition (MMSE score = 28.39±1.55) rated perceptual effort during a standardized walking test (400m walk test). Rating of perceived exertion (RPE) was captured using the Borg Categorical Ratio scale (1 = nothing at all, 10 = extremely strong) that was provided during each lap over 10 laps. The maximal RPE was used for data analyses. Executive function was assessed using the 2-back test— a complex test of working memory and attention control. The 2-back task required participants to decide whether each stimulus in a sequence matched the one that appeared 2 items ago. The test was conducted for 20 minutes. Results: Overall, the RPE value during the walk test was low (CR-10 = 1.72±1.99). Individuals who reported low exertion while walking (0.0±0.0) recorded faster preferred walk speeds (1.13±0.14 vs. 1.03±0.14 m/s, p=0.05) and were similar age (p=0.31) compared to high RPE (3.43±1.39) individuals. Individuals reporting low RPE levels had a significantly higher number of correct responses (proportion: 0.77±0.15 vs. 0.57±0.21, p=0.01), however, there was no difference in reaction time of correct responses (p = 0.82). Interestingly, there was no association between working memory performance and walking speed. Conclusion: Older adults who report higher perceptual effort during mobility tasks perform worse on a test of working memory and attention control. These results suggest that perceptual effort during mobility in older adults is linked to executive functioning.

372. Effectiveness Of Exergaming For Improving Balance In People With Mild Cognitive Impairment: A Randomized Controlled Trial, *Michael Schwenk, University of Arizona, Interdisciplinary Consortium on Advanced Motion Performance (iCAMP), Department of Surgery; Marwan Sabbagh, Banner Sun Health Research Institute; Ivy Lin, University of Arizona, Interdisciplinary Consortium on Advanced Motion Performance (iCAMP), Department of Surgery; Pharah Morgan, University of Arizona, Interdisciplinary Consortium on Advanced Motion Performance (iCAMP), Department of Surgery; Gurtej Grewal, University of Arizona, Interdisciplinary Consortium on Advanced Motion Performance (iCAMP), Department of Surgery; Jane Mohler, University of Arizona, Interdisciplinary Consortium on Advanced Motion Performance (iCAMP), Department of Surgery; Bijan Najafi, University of Arizona, Interdisciplinary Consortium on Advanced Motion Performance (iCAMP), Department of Surgery*
Objectives: The purpose of this study was to evaluate an innovative Exergaming approach, specifically designed for rehabilitation of balance deficits in people with mild cognitive impairment
Abstract Body: Background: Besides cognitive deficits, people with mild cognitive impairment (MCI) experience a decline in motor performance, including postural balance. This study aimed to evaluate an Exergaming program designed for improving balance in people with MCI. Methods: Memory clinic MCI patients (mean 78.2±8.7 years) were randomized to the intervention group (IG, n=12) or control group (CG, n=10). The IG underwent 4 weeks (twice a week) of Exergaming, including weight shifting and virtual obstacle crossing. Real time visual/audio lower-extremity feedback was provided using validated wearable sensors. The CG received no intervention. Outcome measures included changes in center of mass (CoM) sway, ankle and hip joint sway measured during eyes open (EO) and closed (EC) balance testing (feet together) at baseline and post-intervention. Gait (speed, variability), fear of falling, and user experience were also measured using validated assessment tools. Results: Post-intervention sway of CoM, hip, and ankle were significantly reduced in IG compared to CG during EO balance testing (p= .015-.047). Effect sizes were moderately-large (eta squared= .213-.302). Previous fallers showed greatest improvement in balance. Fear of falling was significantly reduced in IG, compared to CG (p= .015). Change in EC balance (p= .178-.333) and gait (p= . 222-833) were non-significant. Users expressed a positive training experience including fun, safety, and helpfulness of sensor-feedback. Discussion: This study shows that a tailored Exergaming approach can improve balance in people with clinically validated MCI. Study findings may help to inform interventions combining virtual reality environments and wearable sensors for rehabilitation of MCI-specific motor deficits.

373. Derivation of a High-Quality Summary Factor of Physical Functioning Scaled to NIH PROMIS Norms, *Nicole Armstrong, Center on Aging and Health Johns Hopkins Bloomberg School of Public Health; Jeanine Parisi, Johns Hopkins Bloomberg School of Public Health; Laura Gitlin, Johns Hopkins School of Nursing; Michelle Carlson, Johns Hopkins Bloomberg School of Public Health; George Rebok, Johns Hopkins Bloomberg School of Public Health; Alden Gross, Johns Hopkins Bloomberg School of Public Health*

Objectives: To derive and validate a summary factor of physical functioning across studies with different but overlapping sets of activities of daily living (ADLs) and independent activities of daily living (IADLs).; To describe the prestatistical harmonization procedures involved in developing the harmonized measures.;

Abstract Body: Background. Because of low prevalence of disability and small samples, individual datasets capture part of the range of mobility impairment in older adults. To better measure physical functioning, we pooled physical functioning data from eight intervention trials onto a common metric and externally scaled it to nationally representative norms. Methods. To derive a summary factor for physical functioning, we used physical-functioning items in the PROMIS item bank (versions 1.0 and 1.2) and the following intervention trials: Baltimore Experience Corps, Advancing Better Living for Elders, Advancing Caregiver Training, Alzheimer's Quality of Life, Beat the Blues, Care of Persons with Dementia in their Environments, Resources for Enhancing Alzheimer's Caregiver Health, and Tailored Activity Program. We used Rasch-type item response models to derive a common factor. For items in common with PROMIS, PROMIS item thresholds were used to externally scale the factor to national norms. We used Monte Carlo simulations to test for bias and precision, and to verify the factor was on the same scale across datasets. Results. The sample included N=2,555 persons aged 42-105 years. We identified 179 items representing physical-functioning across eight studies, of which 39 overlapped with PROMIS. Simulations revealed no systematic evidence of bias in physical functioning factors but some evidence of imprecision especially in the less impaired range. Conclusions. Item-level harmonization approaches may facilitate direct comparison of physical functioning measures across existing and future studies using a common, population-based metric. These scores may facilitate future investigations regarding links between disability and the CNS through integrative analysis.

374. Exergaming In Diabetics With Peripheral Neuropathy: A Randomized Controlled Trial, *Gurtej Singh Grewal, Department of Surgery, University of Arizona; Michael Schwenk, Department of Surgery, University of Arizona; Jacqueline Lee-Eng, Department of Surgery, University of Arizona; Talal Talal, Hamad Medical Corporation; David Armstrong, Department of Surgery, University of Arizona; Bijan Najafi, Department of Surgery, University of Arizona*

Objectives: To evaluate effectiveness of a personalized sensor-based exercise that provides real time joint movement feedback during exercise on postural balance in diabetes

Abstract Body: Background: Sensory and motor skill deficits from diabetes lead to impaired postural balance, and higher fall-risk. Conventional exercise training is not always be appropriate for diabetes patients with lost joint perception and reduced joint mobility. We investigated effectiveness of a sensor-based balance training on postural balance in older diabetic. Methods: Thirty-nine older adults with diabetic peripheral neuropathy (Age:63.7±8.2years) were randomized to intervention (IG,n=19) or control (CG,n=20) group. IG received virtual-reality based exercise training (twice a week/4 weeks) focused on weight shifting and crossing virtual obstacles using body-worn sensors to provide joint visual feedback during exercise on a monitor screen. Outcome measures included changes in body sway, ankle and hip joint sway measured during eyes open and closed balance test and activities of daily living at baseline and post-intervention. Results: With no significant group differences at baseline four week sensor based Exergaming significantly reduced CoM sway (59.8%, p=0.009), ankle sway (62.2%, p=0.008), and hip joint sway (72.4%, p=0.017) in the IG during eyes open balance test. During eyes closed measurements, only ankle sway reduced significantly for IG group (62.41%, p=0.037). Activities of daily living did not change significantly but the number of steps walked demonstrated a trend of increase (+27.68% p=0.064) in IG following training. No significant improvements were observed in the control group. Conclusion: Significant improvement in postural balance from personalized Exergaming was observed that may be translated to activities of daily living. Sensor-derived visual feedback may compensate for lost ankle joint perception for accurate exercise performance.

307. Ethnic Differences in Health Outcomes Among Older Latinos Living in the United States, *Catherine Perez, University of Southern California*
Objectives: After attending the session, participants will be able to describe ethnic variation in chronic disease among older Latinos in the Health and Retirement Study.; After attending the session, participants will be able to identify that non-Mexican Latinos have higher levels of chronic conditions compared to Mexicans.; After attending the session, participants will be able to determine that the assumption of homogeneity of health outcomes across Latino subgroups is not tenable.
Abstract Body: Latinos are often lumped together in one group in respect to analyses on health outcomes and there are important health disparities within this subgroup that have often been overlooked. Research has focused, most predominantly, on the Latino health advantage, that has masked ethnic variability in assessing health outcomes. Using data from the 2010 Health and Retirement Study (HRS) and RAND HRS, this study uses multigroup modeling and logistic regression to assess chronic conditions among older Mexican (N=826) and non-Mexican Latinos (N=602) controlling for age, gender, education, body mass index (BMI), self-rated health, and current smoking status. Results reveal that the number of chronic conditions and types of chronic conditions are clearly different among Latino ethnic groups. Mexicans report on average, 1.19 chronic conditions, whereas non-Mexican Latinos report 1.49 chronic conditions. Compared to Mexicans, non-Mexican Latinos are 12% more likely to have high blood pressure, 42% more likely to have cancer, 29% more likely to have lung disease, 36% more likely to have heart problems, 3% more likely to have a stroke, 49% more likely to have psychiatric problems, and 43% more likely to have arthritic problems. However, Mexicans were twice as likely as non-Mexican Latinos to have diabetes. Therefore, findings support the hypothesis that the assumption of homogeneity of health outcomes across Latino subgroups is not tenable. Supplementary analyses also revealed that compared to Whites, non-Mexican Latinos had poorer health outcomes but Mexicans displayed a health advantage.

308. Evaluating the Lifestyle Intervention for Veterans Program, *Y. Tony Yang, George Mason University*
Objectives: Retrospectively assess cardiometabolic and quality of life parameters of 500 veterans who completed the program and compare them to a matched control group.
Abstract Body: This research aims to evaluate the effectiveness of personalized lifestyle intervention on treating overweight and obesity in a cohort of veterans. Study participants are 500 overweight and obese veterans who are enrolled in the lifestyle intervention program at the Washington D.C. VA Medical Center. Propensity score matching is used to create a control group which is compared with participants. After calculating propensity scores, members of the control and treated groups who have the closest propensity scores are matched up. Then, these pairs are used to estimate the average treatment effect with a difference-in-difference model. Health outcomes chosen as a success measure include (1) BMI, (2) Systolic blood pressure, (3) Diastolic blood pressure (4) Pain, (5) Pulse, (6) HbA1c, and (7) Glucose. The results show as compared with the matched control group, the participants have 0.66 reduction in BMI. At the average height of 68.67 inches for study participants, that would represent a loss of 4.47 lbs over the course of the program. Personalized exercise program and dietary interventions are effective in three of seven measures. Many veterans suffer from chronic health conditions associated with overweight and obesity. A relatively new development in veterans' care, this program could serve as a model for future applications in veteran affairs hospitals across the country. GSA participants will learn about the extent to which this lifestyle program can influence health outcomes in veterans. In addition, the paper will highlight next steps for future research.

309. Examining Dementia Simulations through a Disability Studies Lens, *Hailee Gibbons, University of Illinois, Chicago*
Objectives: Increased understanding of how a Disability Studies lens contributes to our knowledge about dementia simulations
Abstract Body: Dementia simulations are increasingly used as interactive, educational tools for dementia caregivers and the general public. Advocates claim that these simulations increase awareness, teach caregivers about the behaviors and needs of patients and loved ones with dementia, and promote empathy rather than sympathy. While studies of dementia simulations have found positive outcomes (Bellville, 2002), these simulations have not been examined through a Disability Studies lens. By using a Disability Studies lens, scholars can critically interrogate how dementia and other disabilities are viewed and treated as a social construct. Using a case study methodology, this study examines two dementia simulations – an online simulation called “FaceDementia” and an in-person simulation called “The Virtual Dementia Tour.” These simulations were studied and analyzed. The analysis revealed that these simulations might reinforce negative beliefs and stereotypes about dementia due to their temporal nature, focus on individual outcomes, inclusion of other types of disability, and lack of first-person narratives by people with dementia. Furthermore, these simulations do not highlight how the environment, attitudes of others, and social context play a role in disability people with dementia. Therefore, although dementia simulations intend to be positive, a Disability Studies lens reveals that these simulations actually present a narrow, predominantly negative view of dementia. Thus, dementia simulations may not be the best way to raise awareness, and we may want to refocus our efforts on other, more empowering ways to educate others about dementia and the experiences of those aging with dementia and other disabilities.

310. Examining Older Adult Quality of Life: Participation Patterns in High-Value Activities, *Elizabeth Marfeo, Boston University School of Public Health Department of Health Policy & Management Health & Disability Research Institute; Elizabeth Simpson, Boston University School of Public Health; Alan Jette, Boston University School of Public Health, Health & Disability Research Institute*

Objectives: The objectives of this research were to: (1) identify patterns of participation in high-value activities among community dwelling older adults, and (2) explore health and contextual factors associated with limitations in participation in those favorite activities.

Abstract Body: Background: Identifying key factors that relate to participation in high-value activities may help to promote increased quality of life among older adults. Research Objectives: The objectives of this research were to: (1) identify patterns of participation in high-value activities among community dwelling older adults, and (2) explore health and contextual factors associated with limitations in participation in those favorite activities. Study Design & Population: Secondary data analysis of the 2011 Round 1 National Health and Aging Trends Study (NHATS), a national sample drawn to be representative of Medicare beneficiaries ages 65 and older. Results: The majority of the sample of 7197 older adults was between ages 65-84 (80.8%). Physical activities (48%) emerged as the predominant favorite activity, followed by Mental/Cognitive (29%), Social (12%), Instrumental (ADL/IADL) (9%), then Sedentary (2%). Both health (pain, hospitalizations, self-rated health) and contextual factors (activity type, race/ethnicity, social isolation, physical and mental function) were significantly associated with limitations in participation in high-value activities. Conclusion: Distinct patterns emerged in older adult’s participation in favorite activities based on health and contextual factors. Additional studies are needed to gain a deeper understanding of the underlying mechanisms of how health and contextual factors act as facilitators or barriers to participation in valued activities among older adults over time.

311. Experiences with Technology by Older Adults in the Deaf Community, *Wendy Rogers, Georgia Institute of Technology; Jenny Singleton, Georgia Institute of Technology; Tracy Mitzner, Georgia Institute of Technology; Evelyn Chang, Georgia Institute of Technology*

Objectives: Provide insights into the technology experiences of older individuals in the Deaf community.; Identify the challenges and frustrations for these individuals when using a broad range of everyday technologies.; Determine how these findings may be used to improve design and training for technologies and enable full participation in society (and thereby increase quality of life).

Abstract Body: An understudied sector of the older adult population is the Deaf Community, whose members communicate using American Sign Language (ASL). These individuals may experience unique or additional challenges as they age, especially when using technology. This poster summarizes recently collected data on the use of technology by this understudied cultural and disability group. We surveyed 31 attendees at the Summer 2014 meeting of the National Association of the Deaf. Participants were 60-82 years of age (M = 69.81; SD 7.5). Participants were Deaf since birth or early childhood, and use ASL as their primary language. The 52-item survey asked participants to evaluate their usage of technologies in the domains of Communication, Social Networking, Computers, Everyday Technology, Health, Recreation, Transportation, and Assistive Technology. For technologies used at least once in the past year, participants also indicated their perceived difficulty with using that technology. Deaf older adult participants endorsed “Somewhat Difficult or Difficult” ratings for items from all categories of technology, including those in Assistive Technology, which we presume are designed to support activities of daily living. We include a analysis of the most common reported difficulties with and attitudes toward technology. Our results have implications for technology design, instructional support for technology use, and ultimately improving technology interactions for seniors, especially this understudied sector who are Deaf and rely primarily on ASL. Reducing existing barriers to technology use will improve participation in society and access to information that can support activities of daily living for Deaf older adults.

312. Factors Associated with Healthy Aging among Adults of Low SES: Similarities and Differences with those of Higher SES, *Sara McLaughlin, Miami University*

Objectives: To gain an understanding of factors associated with the maintenance of good health in the face of socioeconomic disadvantage

Abstract Body: Individuals of lower socioeconomic status (SES) are less likely to experience healthy aging than those of higher SES. Nevertheless, some socioeconomically-disadvantaged adults manage to maintain good health into older adulthood. Little is known about the factors associated with healthy aging among lower SES adults and the extent to which those factors may be shared with those of higher SES. Using 2010 Health and Retirement Study data, I examined correlates of healthy aging across educational strata among 9,545 adults age 65 and over (56% female, 16% non-white, 19% with less than a high school diploma). After stratifying by education (≥ high school diploma vs. < high school diploma), multiple logistic regression was used to examine the association between healthy aging (freedom from disability, functional limitations and cognitive impairment) and demographic, psychosocial, and health characteristics. Approximately 25% of those with less than a high school diploma experienced healthy aging compared to 40% of those with higher education. Among those with less than a high school diploma, age, wealth, physical activity, BMI, depression, and chronic disease were significantly associated with healthy aging. These factors were also associated with healthy aging in those with higher education. Additional correlates in those of higher SES included gender, neighborhood safety, productive engagement, alcohol use, and smoking history. Similarities and differences in factors associated with healthy aging were evident across educational strata. Future research should be directed at understanding observed differences and the acquisition of modifiable health-promoting characteristics in the low SES context.

313. Factors Related to the Accuracy of Caregiver Knowledge about Patient Medications among Informal Caregivers of Community Dwelling Patients with Memory Loss, *Jennifer Seaman, University of Pittsburgh, School of Nursing; Jennifer Linger, University of Pittsburgh, School of Nursing; Lisa Tamres, University of Pittsburgh, School of Nursing; Susan Sereika, University of Pittsburgh, School of Nursing; Martin Houze, University of Pittsburgh, School of Nursing; Robert Kaufman, University of Pittsburgh, School of Nursing; Judith Erlen, University of Pittsburgh, School of Nursing;* ,
Objectives: To identify 3 significant factors that healthcare professionals need to consider when teaching informal caregivers of patients with memory loss about medication management
Abstract Body: Preventing or lessening adverse outcomes related to medications challenges informal caregivers of patients with memory loss. Caregiver knowledge about the indications for patient medications may enhance medication management. However, research describing critical factors associated with medication management is limited. We examined the relationships among caregiver demographic characteristics, cognitive function, mood, self-efficacy, problem solving, medication taking deficiencies, health literacy, and the accuracy of caregiver knowledge about prescribed FDA-approved patient medications. Baseline data from the parent RCT targeting problem solving related to medication management were used. Data analysis included descriptive statistics and correlations. Of 91 caregivers, 64 (70%) were female and 77 (85%) were white. On average caregivers were 66.97±12.17 years of age and had 14.91±3.31 years of formal education. Mean health literacy scores were moderately high 4.02±1.81 (0-6.0). Percent medication indication accuracy scores were 85.2±22.77. Health literacy was negatively associated with age (r=-.421, p=.000) and caregiver cognition (r=-.545, p=.000) and positively associated with number of formal years of education (r=.361, p=.000). Medication taking deficiencies was inversely related to health literacy (r=.21, p=.05). Percent accuracy was not associated with years of education (r=.05, p=.64), but was associated with health literacy (r=.25, p=.02). Caregivers with higher health literacy were younger, had more formal education, were less likely to have questionable or impaired cognition, and had higher overall indication accuracy scores for FDA-approved medications. Limitations included the small sample, missing data, and limited diversity. The findings support the need to assess health literacy of informal caregivers and their understanding of instructions regarding patient medications.

314. Filial obligation, adult attachment, and preparedness among prospective caregivers, *Daniel Paulson, University of Central Florida; Rachel Bassett, University of Central Florida*
Objectives: After viewing the proposed research, gerontologists will be able to describe the relationship between adult attachment variables, filial obligation, and caregiver preparedness among prospective caregivers. After viewing the proposed research, gerontologists will be familiar with Mechanical Turk, an emerging technology useful for data collection in the social sciences.
Abstract Body: Background: Sorenson et al (2002) found that secure attachment style predicts caregiver preparedness. Characteristics of closely-attached adult relationships suggests that filial obligation may mediate that relationship. The goal of this study was to test that hypothesis. Methods: The sample, collected using Mechanical Turk, included 165 women between the ages of 45 and 65 years, who were not providing care to an aging parent. Participants were reimbursed $.75 for completing an online survey including the Revised Adult Attachment Scale (Collins, 1996), CES-D, the Short Preparation for Caregiving Scale (Sorenson, 2002), the Obligation Scale (Seelbach, 1977), and four items establishing response validity, among other variables. Results: The mean participant age was 52.2 years (SD = 5.5). The sample was predominantly White/Caucasian 82.6% White/Caucasian, and 7.3% Black/African American. With respect to education, 14.5% completed high school or GED, 32.7% completed some college, 36.4% completed a Bachelor’s degree, 15.7% completed graduate degrees. The three attachment dimensions (close, dependent, and anxious) and filial obligation were all significantly inner-correlated. Stepwise multiple regression analyses found that filial obligation fully mediates the relationship between close attachment and caregiver preparedness, even after controlling for age, education, income, depression, birth order. Conclusions: The primary finding is that filial obligation mediates the relationship between close attachment style and caregiver preparedness among prospective caregivers. This finding suggests that, with respect to caregiver preparedness, perceptions of filial obligation may develop in relation to attachment style.

315. From Past to Future: Temporal Self-continuity Across the Life Span, *Joshua Rutt, Cornell University; Corinna Löckenhoff, Cornell University*
Objectives: Attendees will be able to understand age effects that were found across the various measures of temporal self-continuity.; Attendees will be able to understand how our findings contribute to the literature on self-construal and well-being over the life span.

Abstract Body: Although perceived continuity with one's future self was shown to have implications for well-being and decision making in younger adults, age differences in this phenomenon remain poorly understood. The present study is the first to simultaneously examine past and future self-continuity across multiple time intervals using both explicit and implicit measures and controlling for a range of theoretically implicated covariates in an adult life span sample (N=43, aged 18-92, M=50.3, SD=21.9, 60% female). Perceived similarity to one's self across 6 past and 6 future time points (1 month to 10 years) was assessed with an explicit self-report measure and an implicit me/not me trait rating task. In multilevel analyses, age was significantly associated with greater implicit and explicit self-continuity, especially for more distant intervals. Reaction times for implicit me/not me ratings showed no age differences for past ratings; but for future ratings, older as compared to younger adults responded more slowly to increasingly distant time frames. This points toward age differences in the underlying mechanisms of self-continuity. A multilevel model examining the role of covariates including personality, cognition, future horizons, and subjective health found that better subjective physical health was selectively associated with greater explicit self-continuity in older adults but not in younger age groups. This converges with prior research suggesting age-related shifts in the role of physical well-being in self-construal (e.g., Frazier & Hooker, 2006). Taken together, our findings suggest that chronological age is associated with greater self-continuity although specific mechanisms and correlates may vary by age.

316. Hanging On to Those Who Are Still Here: The Meanings African American Caregivers Ascribe to Dementia-Related Changes in Care-Recipients, *Allison Lindauer, Layton Aging and Alzheimer's Disease Center Oregon Health & Science University; Theresa Harvath, Betty Irene Moore School of Nursing, University of California, Davis; Patricia (Pat) Berrry, Hartford Center for Gerontological Nursing Excellence at OHSU, Oregon Health and Science University, School of Nursing; Peggy Wros, School of Nursing, Oregon Health & Science University*

Objectives: 1.Discuss the unique perspectives these African American caregivers have on dementia-related changes. 2.Consider how historical oppression shaped the meaning these caregivers gave to dementia-related changes. 3.Explore how clinicians can use these findings to broach the subject of end-of-life care.

Abstract Body: Background. Our knowledge of the meaning African Americans (AA) caregivers give to dementia-related changes in family members is limited. While many White caregivers perceive dementia-related changes as losses (and thus grieve long before care-recipient death), little is known about the meanings AAs ascribe to dementia-related changes. Purpose/Method. This interpretive phenomenological study explored the meaning AA caregivers gave to dementia-related changes in their care-recipients. Data were gathered through two in-depth interviews with 11 AA caregivers in the Pacific Northwest (22 interviews). Four caregivers participated in an optional observation session. Results. Two themes emerged from our hermeneutic analysis. First, the dementia-related changes meant that the caregivers had to "hang on" to the care-recipients for as long as possible. Second, caregivers recognized that their venerated care-recipients were "still here" and worthy of love and compassion. The history of oppression of AAs in the US influenced caregivers' perceptions of their care-recipients. Discussion/Implications. Our findings suggest that AA caregivers tend to focus on the aspects of the care-recipients' personalities that remain. These findings vary from the current literature that suggests that White caregivers tend to grieve for dementia-related losses. In contrast, the caregivers in our study focused not on what was lost, but what was not lost. Clinicians can use these finding to initiate conversations about sensitive subjects such as placement and end-of-life care. Educators can integrate the findings into cross-cultural curricula and diversity training. Finally, this study lays the foundation for future research that measures pre- and post-death grief in AA caregivers.

317. How Do Employers and Employees Deal With an Increasing Pension Age: Qualitative Evidence From the Dutch Metalworking Industry, *Jaap Oude Mulders, Netherlands Interdisciplinary Demographic Institute; Kène Henkens, Netherlands Interdisciplinary Demographic Institute; Joop Schippers, Utrecht University*

Objectives: After attending this activity, participants will be able to understand employers' evaluations of the up- and downsides of an aging workforce.; After attending this activity, participants will be able to understand the tension that exists in organizations between retaining older workers and hiring younger workers.; After attending this activity, participants will be able to understand how older workers view working into old age in a country with comparatively high state and occupational pensions.

Abstract Body: Governments in Western countries are trying to increase the retirement age of their population. Recently, the Dutch government has increased the state pension age from 65 to 67, which is slowly leading to later retirement. In this study, we examine the considerations regarding longer employment (both up to and after state pension age) of employers and employees in five mid- to large-sized organizations in the Dutch metalworking industry, a sector characterized by long organizational tenure, low job mobility, and relatively many older workers. We conducted qualitative interviews with both employers (e.g., CEOs, HR managers) and older workers. The interviews were transcribed and coded using qualitative software, then analyzed to detect common themes and conflicting viewpoints. The results suggest that organizations in the Dutch industry sector are first and foremost concerned with rejuvenating their workforce and thus put little emphasis on retaining older workers. Most employers signal a conflict between retaining older workers' valuable knowledge and experience and simultaneously trying to hire younger workers and educate them in order to guarantee their organizations' long-term success. The employers try to resolve this conflict by hiring younger workers and matching them to older workers, in an attempt to transfer experience and tacit skills. However, this process is regularly frustrated by economic difficulties, which leads to older workers feeling undervalued and disappointed. Employers stress the need for more individualized gradual retirement plans and the possibility of demotion, in order to more efficiently manage an aging workforce and to facilitate employment after state pension age.

318. Identifying Medication Management Challenges during Older Adults' Transitions from Hospital to Skilled Home Care: A Human Factors Approach, *Nicole Werner, Johns Hopkins University School of Medicine; Mahiyar Nasarwanji, Johns Hopkins University Armstrong Institute for Patient Safety and Quality; Ayse Gurses, Johns Hopkins University Schools of Medicine, Public Health and Engineering; Bruce Leff, Johns Hopkins University Schools of Medicine, Public Health and Nursing; Alicia Arbaje, Johns Hopkins University School of Medicine;*

Objectives: We used a Human Factors Engineering (HFE) approach to (1) identify barriers to successful medication management (MM) during hospital to skilled home healthcare (SHHC) transitions from the perspective of SHHC providers, patients, and their caregivers; and (2) categorize process failures associated with suboptimal MM.

Abstract Body: Objectives: We used a Human Factors Engineering (HFE) approach to (1) identify barriers to successful medication management (MM) during hospital to skilled home healthcare (SHHC) transitions from the perspective of SHHC providers, patients, and their caregivers; and (2) categorize process failures associated with suboptimal MM. Introduction: Older adults requiring SHHC after hospital discharge are at risk for suboptimal care transitions. MM challenges are cited as a significant contributing factor to suboptimal hospital/SHHC transitions. Methods: Qualitative ethnographic methods were used to observe and interview 22 older adults and their caregivers, and their associated SHHC provider (SHHCP) (N=15). Participants came from 9 medical and surgical units, a skilled nursing facility, and one SHHC agency. Data collection took place at multi-disciplinary rounds, the bedside, home visits, and during SHHCP office work. The HFE-based Systems Engineering Initiative for Patient Safety (SEIPS) model guided data collection and grounded theory analysis. Results: Grounded theory analysis resulted in a categorization of barriers to MM as follows: 1) complicated multi-source information management systems; 2) breakdowns in communication across healthcare settings; 4) challenges associated with identifying/communicating with primary care providers; 5) ambiguity in SHHCP and caregiver roles in MM; 6) unsupported MM strategies of SHHCP and patients/caregivers; and 7) SHHCP and caregivers delivering care with incomplete information. Conclusions: MM challenges are potential risks to older adults' safety during hospital/SHHC transitions. Understanding MM challenges using an HFE approach can guide the development of interventions to identify processes and system-level challenges that put patients at risk for suboptimal MM during transitions.

319. Implementing Two Community-Based Fall Prevention Programs to Reach a Diversity of Older Adults, *Erin Parker, Centers for Disease Control and Prevention; Matthew Smith, University of Georgia; Luohua Jiang, Texas A&M Health Science Center School of Public Health; Judy Stevens, Centers for Disease Control and Prevention; Luohua Jiang, Texas A&M Health Science Center; Ashley Wilson, Texas A&M Health Science Center; Marcia Ory, Texas A&M Health Science Center*

Objectives: Identify two differences among participants reached by two evidence-based fall prevention programs—Tai Chi Moving for Better Balance and Stepping On.; Identify two similarities among participants reached by the two evidence-based fall prevention programs.; List at least one benefit of community-based fall prevention programs.

Abstract Body: Background Falls are a pervasive threat to older adults' health and independence. To address this issue, the US Centers for Disease Control and Prevention (CDC) funded state health departments in Colorado, New York, and Oregon to implement clinical and evidence-based community fall prevention programs. We compare baseline and post-intervention characteristics of older adults who participated in two community-based programs—Stepping On (SO) and Tai Chi Moving for Better Balance (TCMBB)—that teach older adults behaviors to reduce their fall risk. Methods Information was collected from 336 SO and 421 TCMBB participants, attending 32 and 36 program offerings respectively. At the first and last sessions of the program, participants completed a self-administered survey including demographics and self-reported health status and were administered a standardized functional assessment test, Timed Up and Go (TUG). Results TCMBB participants were younger than SO participants (75.3 years vs. 78.7 years) and more likely to report being in excellent or very good health at baseline (50.7% vs. 34.1%). Participants in both programs showed significant functional improvements, but TCMBB participants had better (faster) TUG test scores at enrollment (11.2 vs. 13.4 seconds) and completion (9.9 vs. 11.4 seconds), while SO participants showed greater improvement. Clinical provider referrals to both programs were low (8.5% for TCMBB and 6.7% for SO). Conclusion Community-based programs can change the behavior of older adults and reduce fall-related risk. TCMBB and SO attracted participants with different age and health statuses, highlighting the importance of offering multiple fall prevention programs that appeal to diverse audiences.

320. Improvements from Cognitive Training in Older Adults At Risk for Dementia, *Alison Perez, University of Texas at Dallas; Justin Eroh, University of Texas at Dallas; Raksha Mudar, University of Illinois Urbana-Champaign; Audette Rackley, University of Texas at Dallas; Sandra Chapman, The Center for BrainHealth at the University of Texas at Dallas; , The Center for BrainHealth at the University of Texas at Dallas*

Objectives: To address the potential of cognitive training to enhance cognitive function in adults with early (eMCI) and late Mild Cognitive Impairment (lMCI).; To determine whether diagnosis of eMCI and lMCI are predictive the whether participants will respond to a cognitive training program;

Abstract Body: Objectives: Recent studies in normally aging adults have shown extensive benefits of cognitive training programs. Relatively few studies have examined whether training may provide the opportunity to prevent further cognitive decline in older adults at risk of developing dementia. This study is the first to address the potential of cognitive training to enhance cognitive function in adults with early (eMCI) and late Mild Cognitive Impairment (lMCI). Methods: A sample of 34 adults (50-80 years old) participated in a cognitive training program specifically designed to enhance reasoning and abstraction abilities. Participants completed 8 hours of cognitive training and cognitive testing before and after training. Individuals who improved in abstraction abilities were classified as responders and all others as non-responders. Results: 52.9% of our participants were responders to training. Diagnosis classification (eMCI/lMCI) significantly predicted whether participants were classified as responders (t(33)=3.149, p=.041). All participants significantly improved from pre- to post-training in untrained measures of immediate (t(33)=3.33, p=.002) and delayed memory (t(33)=4.97, p<.001), reasoning (t(33)= 2.43, p=.021) and fluency (t(30)=2.09, p=.044). Discussion: SMART training significantly improved both trained and untrained cognitive abilities in adults at risk for dementia. The SMART training was most effective in the eMCI group suggesting that cognitive training programs such as SMART are most effective in the earliest stages of declining cognition. Although SMART training shows benefit to all groups, just as pharmacological interventions are more useful in the earliest stages of disease, this cognitive training may have the most potential benefits in the earliest stages of cognitive decline.

321. Income Level, Cytomegalovirus and CD4 and CD8 T Cell Repertoire Among Adults Living in Detroit, *Amanda Simanek, Joseph J. Zilber School of Public Health, University of Wisconsin-Milwaukee; Lydia Feinstein, Department of Epidemiology, Gillings School of Global Public Health, University of North Carolina at Chapel Hill; Caroline Cheng, Department of Epidemiology, University of Michigan-School of Public Health; Jennifer Dowd, CUNY School of Public Health, Hunter College, City University of New York; Allison Aiello, Department of Epidemiology, Gillings School of Global Public Health, University of North Carolina at Chapel Hill*

Objectives: To examine the association between income level and CD4/CD8 T cell ratio, effector/naïve (E/N; CCR7-CD45RA+CD27-CD28-/CCR7+CD45RA+CD27+CD28) ratio among CD4 cells and E/N ratio among CD8 cells in a community-based sample of Detroit residents.; To examine whether elevated CMV Immunoglobulin G antibody levels mediate the association between income level and alterations to the T cell compartment.

Abstract Body: Socioeconomic disparities in mortality in the U.S. persist and are ever widening. Researchers have hypothesized that increased levels of psychosocial stress may contribute to immune alterations linked to mortality in elderly cohorts. We examined for the first time the association between income level and alterations to the T cell compartment which may serve as markers of immune aging including CD4/CD8 T cell ratio and effector/naïve (E/N; CCR7-CD45RA+CD27-CD28-/CCR7+CD45RA+CD27+CD28+) ratio among CD4 and CD8 cells. We also examined whether elevated cytomegalovirus (CMV) immunoglobulin G (IgG) antibodies mediated these associations. Data were from a subset (N=79) of individuals in the Detroit Neighborhood Health Study, a population-based longitudinal study of 1,547 adults aged 18 or older living in Detroit with data on annual income level (low: < \$35,000 versus high ≥\$35,000), CMV IgG antibody level and each ratio outcome. We used multiple linear regression to estimate the geometric mean risk ratio comparing the geometric mean of each ratio outcome among those with low versus high income level. Low income level was statistically significantly associated with higher E/N ratio among CD4 T cells (RR: 7.16, 95% confidence interval (CI): 1.62, 31.68) and CD8 T cells (RR: 3.49, 95% CI: 1.50, 8.14) after adjusting for age, gender, race, smoking status and medication use. The association between income level and CD4 E/N ratio was attenuated and no longer statistically significant (RR: 2.59, 95% CI: 0.69, 9.72) after additional adjustment for CMV IgG antibody level. Impaired immune control of CMV may partially explain socioeconomic gradients in immune aging.

322. Independent and Combined Effects of Cognitive and Physical Activity on Incident Mild Cognitive Impairment, *Tiffany Hughes, Youngstown State University; James Becker, University of Pittsburgh; Ching-Wen Lee, University of Pittsburgh; Chang Chung-Chou, University of Pittsburgh; Mary Ganguli, University of Pittsburgh*

Objectives: To enhance the understanding of the independent and combined influences of late-life cognitive activity (CA) and physical activity (PA) on risk of incident mild cognitive impairment (MCI)

Abstract Body: There is growing interest in combined cognitive activity (CA) and physical activity (PA) intervention strategies to delay or prevent cognitive impairment in late life. However, there is sparse support from observational research that a combination of these activities has greater and/or broader benefits to risk of cognitive impairment than either alone. This study examined the independent and combined effects of CA and PA on risk for incident mild cognitive impairment (MCI). Participants were 864 cognitively normal (Clinical Dementia Rating (CDR) =0) members of a population-based prospective cohort study of MCI. We used interval censored survival modelling to examine risk of incident MCI (CDR=0.5) as a function of high vs. low CA and/or any vs. no engagement in at least moderate intensity PA. During three annual follow-up waves, 72 participants developed MCI. Compared to low CA and no PA, the greatest reduction in risk for MCI was observed in those with a combination of high CA and engagement in any PA (HR = 0.20, 95% CI = 0.07-0.52).

Engagement in any PA, even with low CA, also reduced risk (HR = 0.52, 95% CI 0.29-0.93), but high CA in the absence of any PA did not reduce risk (HR = 0.94, 95% CI 0.45-1.95) of MCI. These findings suggest that a combination of CA and PA may be the most efficacious intervention strategy to reduce risk for cognitive impairment, with the contribution to risk reduction being greater for PA relative to CA.

323. Indicators of Resilience and Healthcare Outcomes: Findings from the 2010 Health and Retirement Survey, *Cherie Simpson, University of Texas, at Austin School of Nursing; Amara Ezeamama, Department of Epidemiology and Biostatistics, University of Georgia; Jennifer Elkins, University of Georgia, School of Social Work; Toni Miles, University of Georgia, Institute of Gerontology*

Objectives: At the completion of the session participants will be able to describe the association between health efficacy and health care outcomes defined as health care utilization and self reported health improvement.; At the completion of the session participants will be able to describe the association between cumulative lifetime adversity and health care outcomes defined as health care utilization and self reported health improvement.

Abstract Body: Objective: To test the hypothesis that higher levels of resilience in aging adults protect from adverse health outcomes using a sample of 12,943 adults 50 to 70 years old enrolled in the 2010 Health and Retirement Survey (HRS). Methods: Multivariate logistic regression models were used to estimate odds ratios (OR) and 95% confidence intervals (CI) for indicators of resilience as predictors of healthcare utilization and improvements in self-rated health (SRH) over two years. Two indicators of resilience were defined: health efficacy (control over health) and cumulative life-time adversity (total number of adverse life events). Healthcare utilization included hospitalization and frequency of physician visits in the past two years. Findings: Risk of hospitalization declined by 9% (OR = 0.91, 95% CI: 0.89, 0.94), risk of ≥ 20 physician visits declined by 14% (OR = 0.86, 95% CI: 0.83, 0.89) and the likelihood of SRH improvement increased by 11% (OR = 1.11, 95% CI: 1.05, 1.18) per unit increase in health efficacy. Conversely, per unit increase in cumulative lifetime adversity, the risk of hospitalization rose significantly by 7%, (OR = 1.07, 95% CI: 1.05, 1.11) and ≥ 20 physician visits rose marginally by 3% (OR = 1.03, 95% CI: 1.00, 1.06), but no association with SRH. Conclusion: In this sample of adults near or in retirement, health efficacy was associated with lower healthcare utilization and improvement in SRH while greater life adversity increased the risk of healthcare utilization. Building resilience is a promising framework for reduction of healthcare utilization.

324. Intergenerational Paradox: Invest Less but Expect More, *Agus Surachman, Purdue University Calumet; Hartoyo Hartoyo, Bogor Agricultural University; Anne Edwards, Purdue University Calumet*

Objectives: To add to the knowledge of intergenerational transmission of poverty in Indonesia; To compare poor and non-poor families in Indonesia concerning intergenerational support

Abstract Body: Objective. This work tried to expand the analysis of intergenerational transmission of poverty by connecting the intergenerational relationship with the issue of aging in the term of family support, especially financial support from children. Method. Data were gathered from the study of Intergenerational Transmission of Poverty in Different Agro Ecological Area in Indonesia. Information from 102 married women with children (age range=21-40 years old, M=31.86, SD=5.19; poor=53%, non-poor=47%) were analyzed regarding their investment behavior toward their children's human capital and their expectation of financial support from children in their old age. Comparisons were made based on the SES of participants (poor vs. non-poor). Results. Poor participants had fewer years of education, were married earlier, had more children, and the majority were not working. They also invested less in their children's human capital (t=6.76, p<.001) but were six times more likely to expect financial support from their children when they became old (p<.01). Discussion. The body of research about intergenerational transmission of poverty in Indonesia indicates that children who were born and raised in poor families tend to be poor as adults, as the consequence of low investment in human capital. The result of this analysis support and expand those findings; that there is possible cyclic disadvantage effect of poverty for both parents and children, as poor parents are more likely to ask for financial support as older adults. The bigger pressures will reside on the shoulder of poor sandwich generations. Key Words: aging, financial support, intergenerational relationship, poverty

325. Job Profiles in Midlife Predict Daily Functioning Disability Severity in Later Life, *Clas-Hakan Nygard, University of Tamperee; Prakash K.C., University of Tampere; Subas Neupane, University of Tampere; Paivi Leino-Arjas, University of Tampere; Monika von Bonsdorff, University of Jyväskylä; mikaela von Bonsdorff, University of Jyväskylä; Taina Rantanen, University of Jyvaskyla*

Objectives: Physical work demands in midlife are associated with disability severities in daily living activities in old age.; Promotion of midlife work demands may be essential for less disabilities in old age;

Abstract Body: Objectives To analyze if physical work demands in midlife are associated with disabilities in daily living activities in old age. Methods The design was a prospective follow-up study of Finnish municipal employees aged 44-58 years at baseline (n=6257). The largest occupational groups were analyzed in 1981 and 1993 with a job description method. Thirteen different job profiles emerged from the results of cluster analysis at baseline. Disabilities in activities in daily living (ADL) data was collected in 2009 for 5 different activities using a questionnaire survey distributed among the survivors (n=3101). Generalized linear models with binary logistic regression assumption was used to calculate adjusted risk ratios (RR) and their 95% confidence intervals (CI). The administrative work was the reference group for both gender. Results

There were no larger changes in the work from base-line until retirement. Among women, kitchen supervision (adjusted RR 3.89, CI95% 1.90-7.96), home care workers (2.60, 1.48-4.54) and auxiliary work (2.11, 1.21-3.67) and among men technical supervision (2.50, 1.19-5.22) and auxiliary work (2.35, 1.09-5.05) had risk for ADL disability in old age in comparison with administrative work. More specifically, a high amount of static (1.22, 1.07-1.47), dynamic (1.63, 1.33-2.01) and repetitive muscular work (1.36, 1.13-1.64) associated with disability in old age, while sitting at work was protective (0.63, 0.52-0.77) in comparison with low amount. Conclusion Job profiles among employees in midlife were predictive of disability severity in activities in daily living in old age.

326. Looking to the Future: Time Perspective Mediates Age Effects on Goals, *Amy Knepple Carney, West Virginia University; Julie Hicks Patrick, West Virginia University; Nipat Pichayayothin, West Virginia University*

Objectives: To test whether and in what ways time perspective effects the number of goals adults have; Examine whether Present or Future Time influence the age whether time perspective mediates or moderates the age --> Goals (# recent, # current) relation; This is important because it suggests ways to help middle-aged and older adults meet their personal goals

Abstract Body: Future time perspective is linked with the number, and type, of goals adults hold for themselves (Ebner et al., 2006; Lang & Carstensen, 2002; Tabachnick et al., 2008). Whether a positive future orientation differentially predicts goal-related outcomes relative to current positive perceptions or whether time orientation relates differently to recent versus current goals has not been extensively studied. We examined these questions using data provided by 68 adults representing emerging adulthood (M age ~ 20) and midlife (M age ~ 40). Mean age differences emerged for the goals of being more social, being happier, and appreciating beauty. Neither Positive Future nor Positive Present Time orientations moderated the association between age and goals. However, significant mediation effects emerged for Positive Future, b = -.70, t(64) = 3.03 p <.05, for number of current goals. No significant mediation effects were detected for Positive Present on current goals. There is a need to examine the intricate relationship of time perspective and its effects on goal orientation. We need to understand if people have a better future outlook they are willing to make and participate in more goals.

327. Married Individuals' Satisfaction with Saving for Retirement, *Helen Gutierrez, Oklahoma State University; Helen Gutierrez, Oklahoma State University; Douglas Hershey, Oklahoma State University*

Objectives: The objective of this investigation was to examine how individuals’ marital satisfaction level influences the quality of their shared goals and financial planning activities

Abstract Body: Previous studies have explored individuals’ communication satisfaction with their spouse (Canary, Brossmann, & Weger, 1995; Canary, Cupach, & Serpe 2001; Givertz, Segrin, & Hanzal, 2009). However, few studies have examined individuals’ marital communication patterns as they relate to financial preparation for retirement. This, despite the fact that approximately half of the adults in the United States who financially plan and save for retirement are in a committed relationship—either as a married spouse or cohabitant. The present study examined couples’ involvement in financial planning activities as it relates to retirement. Participants were 59 married individuals (52 percent female), who ranged in age from 25-57 years. A hierarchically-structured path model was tested, in which individuals’ financial planning involvement level was regressed on retirement goal clarity, shared goals and values with their spouse, satisfaction with spousal communication about retirement, and general marital satisfaction. The model was successful in accounting for 51 percent of the variance in couples’ involvement in planning activities. This study suggests that individuals who are satisfied with both their marriage and the quality of their marital communication tend to be highly involved in retirement-linked financial planning activities. Valuable insights were revealed pertaining to the way in which spousal communication dynamics influence both the quality and nature of couples’ retirement planning practices. These findings have implications for retirement counselors and intervention specialists who work with couples in an effort to establish clear goals and adaptive saving behaviors for the post-employment period.

328. Meaning-Centered Men's Groups for Men Facing Retirement: A Preventive Intervention to Reduce Risk for Suicide, *Marnin Heisel, 1. The University of Western Ontario 2. Lawson Health Research Institute 3. University of Rochester Center for the Study and Prevention of Suicide; Gordon Flett, York University; Paul Links, The University of Western Ontario; Ross Norman, The University of Western Ontario; Sisira Sarma, The University of Western Ontario; Sharon Moore, The University of Western Ontario; Norm O'Rourke, Simon Fraser University*

Objectives: Participants will gain familiarity with an innovative new intervention designed to enhance psychological resiliency and well-being, and decrease risk for the onset of depression, hopelessness, and suicide ideation among older men facing retirement.; Participants will learn about mental health challenges faced by older men facing retirement.; Participants will learn about meaning-centered approaches to enhancing mental health and well-being among older adults.

Abstract Body: Older men have the highest rates of suicide in North America and worldwide, accounting for over 80% of the nearly 9,400 North Americans over 60 who die by suicide every year. Few intervention studies have investigated suicide risk reduction among older adults to date, and nearly none has demonstrated significant reduction of suicide risk among older men. The present study describes a novel meaning-centered group intervention designed to enhance Meaning in Life (MIL) and prevent the onset of depression and suicide risk among men facing retirement. We aim to recruit 100 community-residing men, 60 years and older, who plan to retire within the coming year or who have retired within the past year, into a 12-session course of meaning-centered group sessions designed to focus on transitions associated with retirement in the context of discussions about the meaning of work, retirement, leisure, relationships, and generativity. Eligible participants will be at potential risk for the onset of depression, hopelessness, and suicide ideation by virtue of facing retirement, a challenging life transition, and by endorsing extremely low levels of Meaning in Life (MIL), a key psychological resiliency factor shown to decrease risk for the onset of suicide ideation. The design, methods, and preliminary findings of this recently-initiated 3-year, multi-centre study will be presented, along with preliminary findings from our study eligibility assessments and from early in our intervention. Discussion will include focus on approaches we are implementing to recruit at-risk older men, group experiences, and initial findings investigating potential change in presence and severity of symptoms of depression, hopelessness, and suicide ideation and in MIL, perceived social support, and other psychological well-being variables.

329. Measuring Driving-related Attitudes Among Older Adults: Psychometric assessment of the Decisional Balance Scale across time and gender, *Paweena Sukhawathanakul, University of Victoria; Holly Tuokko, Centre on Aging; Laura Walzak, Centre on Aging; Alexandra Jouk, Centre on Aging; Anita Myers, School of Public Health & Health Systems; Shawn Marshall, School of Public Health & Health Systems; Gary Naglie, Toronto Rehabilitation Institute*

Objectives: The objective of this study was to determine the reliability of the Decisional Balance Scale in assessing driving-related attitudes among older adults over time

Abstract Body: Aging and age-related diseases may put older adults at increased risk of crashes and other unsafe driving behaviors. Considerable evidence has demonstrated that some older adults voluntarily regulate their driving (e.g., restrict driving in risky situations or stop driving altogether) and psychological processes like attitudes and beliefs play important roles in driving self-regulation among older adults. The Transtheoretical Model of Behavior Change (Prochaska & Velicer, 1997) has been used to understand the decisional balance process in which older adults weigh the pros and cons of driving (Tuokko et al., 2006). Based on this model, the Decisional Balance Scale (DBS) was developed to assess driving attitudes related to positive and negative beliefs concerning intrinsic (i.e., self; beliefs concerning one's driving) and extrinsic (i.e., other; beliefs concerning one's driving in relation to others) motivations for driving. This study examined the psychometric properties of the DBS ratings across 3 time points in a sample of 928 older drivers (Mage = 76.21) who participated in the Canadian Driving Research Initiative for Vehicular Safety in the Elderly (CanDRIVE). Results from confirmatory factor analyses revealed that a two-factor model (positive and negative attitudes) for both self and other driving beliefs provided a good fit to the data at each time point. Results also indicate measurement invariance across time and gender. Recommendations for continued use of the DBP in future research on driving behaviours with older adults are discussed.

330. Mediating Effects of Health Literacy and Linguistic Ability on the Relationship between Young Adult Cognition and Later-Life Pulmonary Function, *Terrie Vasilopoulos, University of Florida*

Objectives: After attending this session, participants will be able to better understand how health literacy and linguistic ability affect the relationship between cognition in young adulthood and pulmonary function in later life

Abstract Body: Several previous studies have established the relationship between cognition in adolescence and young adulthood with pulmonary function in later life. However, the mechanism that underlies this relationship is unclear. The present study examined the potential mediating effects of health literacy on this relationship. Furthermore, because of previously reported links between health literacy and reading comprehension, the influence of linguistic ability on this relationship was also evaluated. This study included 616 individuals from the Wisconsin Longitudinal Study (those with complete data for all included variables); the average age was 71.3±0.9. Young adult cognitive ability was indexed by Henmon-Nelson test recorded in high school. Health literacy was measured by the New Vital Sign Health Literacy Assessment. Pulmonary function was the maximum peak expiratory flow (PEFmax) after three measurements. Linguistic ability was a composite score including tests of comprehension, recognition, and identification. All analyses were adjusted for sex, smoking, pulmonary disease diagnosis, height and education. Young adult cognition was significantly associated with PEFmax ($\beta=0.039$, $p<0.001$). After including health literacy as a mediator, this association was reduced ($\beta = 0.013$, $p = 0.534$). The indirect effect of cognition via health literacy was statistically significant (effect=0.026, 95%CI:0.011–0.042). However, the inclusion of the composite linguistic ability measure into the model attenuated this mediation effect (effect=0.008, 95%CI:-0.061–0.076). Thus, our findings suggest that, while health literacy may mediate the relationship between young adult cognition and later-life pulmonary function, this effect is at least partly explained by an individual's overall linguistic skills.

331. Mental health service use among lesbian, gay, and bisexual older adults, *Ian Stanley, Center for Innovative Care in Aging, Johns Hopkins University; Jeffrey Duong, University of California Davis School of Medicine*

Objectives: Describe and compare mental health service use between lesbian, gay, and bisexual (LGB) and heterosexual older adults.; Determine factors that may account for the relationship between sexual orientation and mental health service use among older adults

Abstract Body: Objectives: We assessed associations between sexual orientation and mental health service use among older adults and determined the mediating role of non-specific psychological distress, excessive alcohol use, and self-perceived general health. Methods: Data from the New York City Community Health Survey were analyzed. The analytic sample comprised 5,138 adults ages 50 and over. Logistic regression modeling was used to examine associations between sexual orientation (lesbian, gay, bisexual [LGB] vs. heterosexual) and past-year mental health service use (counseling or medication), adjusting for socio-demographic and clinical characteristics. Mediation was tested using bootstrapping. Results: Among LGB older adults, 23.9% reported receiving counseling and 23.4% reported taking psychiatric medication in the past year. LGB respondents were significantly more likely than heterosexuals to have received counseling (AOR=2.16, 95% CI=1.49, 3.13) and psychiatric medication (AOR=1.97, 95% CI=1.36, 2.86). Psychological distress, excessive alcohol use, and self-perceived general health did not mediate the association between sexual orientation and mental health service use. Conclusions: LGB older adults were more likely than heterosexuals to utilize mental health services, and this association was not explained by indicators of physical, mental, or behavioral health.

332. Sex, Health and Lifespan: Untangling the Response to Calorie Restriction in Mice, *Sarah Mitchell, National Institute on Aging*

Objectives: Understand the underlying effects of calorie restriction in mice; Determine the differential response to calorie restriction in different strains and genders.

Abstract Body: Calorie restriction (CR) is the only laboratory intervention that consistently delays the onset of aging and age-related diseases. Recent evidence suggests that CR may not be universal and that the response to may dependent on more than just a reduction of calories without malnutrition. Here we performed longitudinal assessments of healthspan and assessed lifespan on male and female DBA/2J (D2) and C57BL/6J (B6) mice. One of the hallmarks of CR-mediated lifespan extension is preservation of insulin sensitivity. Here, serum insulin and glucose levels were proportionally reduced with increasing dose of CR in D2 mice, whereas 20% CR was the most effective in lowering these two parameters in B6 mice. D2 mice exhibited lifespan extension when maintained on 20% and 40% CR; however, 40% CR was detrimental to female B6 mice. 20% CR extended lifespan in both male and female B6 mice. Principal component analysis of livers of 22-month old mice showed clear separation between experimental groups based on strain, sex and diet. Interestingly, no clear separation was observed between 20 and 40% CR in females of either strain despite large difference in their lifespan, indicating that a discrete subset of genes could be implicated in CR-mediated lifespan extension instead of having a global, multidimensional alteration in gene expression profile. Our data highlight the importance to systematically examine the contributions of sex and strain of the mouse vis-à-vis CR actions to further our understanding of normal aging.

333. Accessing JAX Nathan Shock Center Data in the Mouse Phenome Database for Genetic Analysis of Murine Lifespan and Healthspan, *Luanne Peters, The Jackson Laboratory; Molly Bogue, The Jackson Laboratory; Gary Churchill, The Jackson Laboratory; Elissa Chesler, The Jackson Laboratory*

Objectives: To demonstrate how to access multiple large datasets on lifespan and healthspan in > 30 inbred mouse strains using the Mouse Phenome Database (MPD).; To demonstrate MPD tools available to analyze the multiple datasets.;

Abstract Body: The Jackson Laboratory Nathan Shock Center (JSC) of Excellence in the Basic Biology of Aging has performed broad characterization of aging in genetically diverse laboratory mice. JSC has extensively characterized over 30 commonly used inbred strains of mice for lifespan and healthspan-related phenotypes, greatly increasing the genetic diversity of the mouse models available for aging research. This is the most comprehensive well-controlled lifespan study in mammals to date. The study includes both longitudinal and cross-sectional assessments. Longitudinal data include lifespan and a host of non-invasive multi-system physiological measures. The cross-sectional study includes invasive assessments, pathology, and the collection of tissues to evaluate apoptosis and chromosome stability. Data generated from these efforts have been placed in a rich and interactive software environment, the Mouse Phenome Database (MPD; phenome.jax.org), which serves as the authoritative source for JSC data and protocols. The data may be freely accessed and analyzed by researchers interested in finding mouse models for specific aging processes, age-related health and disease states, and for genetic analysis of aging variation and trait covariation. Data from ongoing and future studies of aging and healtspan using Diversity Outbred (DO) mice, knock-out mice and other populations are being added as projects are completed. We expect that by making these data public that there will be 1) accelerated genetic analyses of aging processes, 2) discovery of genetic loci regulating lifespan, 3) identification of compelling correlations between lifespan and susceptibility for age-related disorders, and 4) discovery of concordant genomic loci influencing lifespan and aging phenotypes between mouse and humans. NIH AG038070, DA028420

334. Mouse and primate lifespan is correlated with changes in immunoproteasome expression, produced through variable levels of interferon-γ receptor 2, *Andrew Pickering, University of Michigan; Richard Miller, University of Michigan*

Objectives: Using the comparative biology to identity novel pathways involved in regulation of lifespan and the aging process.; The role of different forms of proteasome in aging.; The role of MHC class I presentation and interferon-y sensitivity in aging and lifespan.

Abstract Body: Comparative biology provides powerful tools for identifying novel genes and pathways that control the rate of aging. Fibroblasts from longer lived species are more resistant to both oxidative stress and protein damage than fibroblasts from shorter lived species of the same clade. We demonstrate that amongst primates species longevity is correlated with an elevation in immunoproteasome expression. The enhancement in immunoproteasome appears to play an important role in increasing MHC class I antigen presentation in cells from longer lived primates. In addition we establish that the increase in immunoproteasome is correlated with, and perhaps caused by, increased sensitivity to interferon-γ signalling, which in turn is correlated with an increases in expression of the interferon-γ receptor protein IFNGR2. We observe similar increases in immunoproteasome and IFNGR2 in the livers of long lived mouse models. This work identifies a novel pro-longevity pathway amongst primate species and laboratory mice.

335. Cardiovascular Risk Profile Associated With Frailty: Cross-sectional Results From A Population-based Study of Older British Men, *Sheena Ramsay, University College London; Deborah Ariyanagam, University College London; Peter Whincup, St George's University of London; Steve Iliffe, University College London; A.O. Papacosta, University College London; S.G. Wannamethee, University College London*

Objectives: To gain further understanding of the range of cardiovascular risk factors associated with frailty.; To understand the importance of the management of cardiovascular risk in frail and pre-frail older people.

Abstract Body: Background: Frailty in older age is associated with cardiovascular disease (CVD) risk. However, the extent to which frailty is associated with the CVD risk profile has been little studied. Our aim was to examine the associations of a range of cardiovascular risk factors with frailty and to assess whether these are independent of established CVD. Methods: Data come from a socially representative sample of 1622 men from 24 British towns aged 71-92 between 2010-2012. Frailty assessment was based on weight loss, grip strength, exhaustion, slowness and low physical activity. Results: Among 1622 men, 19% were frail and 54% were pre-frail. Compared to non-frail men, those with frailty had a higher odds of obesity (odds ratio (OR) 2.03, 95%CI 1.38-2.99)), high waist circumference (OR 2.30, 95%CI 1.67-3.17), low HDL-cholesterol (OR 2.28, 95% CI 1.47, 3.54) and high blood pressure (OR 1.79, 95% CI 1.27, 2.54). Frail individuals had a worse cardiovascular risk profile with increased risk of high heart rate, poor lung function (FEV1), raised white cell count (WCC), poor renal function (high creatinine, low estimated glomerular filtration rate), low alanine transaminase (ALT), and low serum sodium. Some risk factors (HDL-cholesterol, blood pressure, WCC, FEV1, renal function) were also associated with being pre-frail. These associations remained when prevalent CVD cases were excluded. Conclusion: Frailty (as well as pre-frailty) was associated with a range of cardiovascular risk factors in older people, independent of established CVD. Assessing and reducing adverse cardiovascular risk is an important component of management of frail older individuals.

336. High Levels Of The Small Chaperone HSP25 In Naked Mole-Rats May Be A Determinant Of Rodent Longevity, *Karl Rodriguez, University of Texas Health Science Center San Antonio; Joe Valentine, University of Texas Health Science Center San Antonio; D. Alexander Kramer, University of Texas Health Science Center San Antonio; Johnathan Gelfond, University of Texas Health Science Center San Antonio; Rochelle Buffenstein, University of Texas Health Science Center San Antonio*

Objectives: The long lived naked mole-rat globally has a more robust molecular chaperone network than the short-lived mouse; HSP25 correlates with rodent maximum lifespan potential; Protein homeostasis is a key determinant of longevity

Abstract Body: Proteostasis is an integral component of healthy aging. Protein quality declines during aging, resulting in accrual of damaged or self-aggregating cytotoxic proteins, linked to several age-associated diseases (e.g, Alzheimer’s Disease, Parkinson’s Disease) and pathology (e.g.,sarcopenia). The naked mole-rat [NMRs] lives ~5 times longer than expected based on body size and maintain good health for most of their long lives. Like other long-lived animal models, both in vivo and in vitro studies reveal that NMRs are resistant to a broad spectrum of environmental stressors. These findings suggest that NMRs possess efficient mechanisms to maintain protein quality. Here we examine key molecular chaperones [HSPs] and the heat-shock factor 1 [HSF1] transcription factor in a number of different tissues comparing protein expression between mice and NMRs. HSP70 was higher in NMR for most tissues compared to mice. For HSF1 (total and phosphorylated forms), HSP110, HSP90, and HSP70 co-chaperones, such as HSP40, protein levels showed tissue-specific trends where there was no difference, higher levels in one or the other species. HSP25 both showed higher levels of protein in NMRs compared to mice in all the tissues examined. Hence we then measured HSP25 protein content in seven rodents with ages ranging from four to 32 years in both liver and muscle, where HSP25 showed the greatest species differences between mole-rats and mice. This comparison resulted in a significant correlation with longevity suggesting that HSP25 may play a key role in age-related maintenance of protein homeostasis in long-lived animals.

337. Scientific Basis Of Two Febrile Intervention Studies With Young And Aging Cancer Patients, *Barbara Holtzclaw, University of Oklahoma Health Sciences Center/ College of Nursing/ Associate Dean for Research*

Objectives: Describe the mechanisms underlying febrile shivering. Describe the metabolic and cardiorespiratory effects of shivering on patients with compromised cardiovascular systems. Explain the scientific basis for insulative wraps as shivering prevention.

Abstract Body: Fever is a ubiquitous systemic host response causing shaking chills, but many clinicians minimally understand its mechanisms. Research findings that report a "blunted" febrile response in older adults is increasingly accepted as a maxim, so caregivers may fail to intervene when febrile shivering appears with older patients. Shivering plays a role in both the cause and effect of fever. Elevation of the hypothalamic set point range widens temperature gradients between skin/core. Shivering is a host response that effectively raises core temperature to overcome the deviation. Fever is not limited to infections, yet treatment rarely goes beyond antipyretic and anti-infective drugs or cooling measures that are distressful and counterproductive. Published intervention studies are few and situation-specific. Two studies of a non-pharmacological intervention to control amphotericin B (AmB) induced febrile shivering in immunosuppressed adult patients with cancer [n = 40, 25-65 yrs. and n = 20, 26-71 yrs.], demonstrate older as well as young patients experience febrile shivering and benefit from treatment. Method: To modify heat loss from the skin to prevent shivering, three layers of terry cloth toweling were wrapped around extremities prior to administration of pyrogenic antifungal drug AmB. Measurements and Findings: Comparisons of duration and intensity of shivering, amount of meperidine for shivering suppression, and cardiorespiratory indicators of metabolic effort between treatment and control groups, found wrapped patients with lower shivering incidence, duration, and severity, heart rates and blood pressure (calculated to rate-pressure product). Translational interpretation of this work offers renewed research paths for emerging science in fever management of older adults.

338. Signs of Water-Loss Dehydration in Older Adults: a Diagnostic Accuracy Systematic Review, *Lee Hooper, Norwich Medical School, University of East Anglia; Phyllis Gaspar, Colleges of Medicine and Nursing, University of Toledo; Janet Mentes, University of California Los Angeles; Marcel Olde Rikkert, Department of Geriatrics, Radboud University; James Powers, Medicine, Vanderbilt University School of Medicine; David Thomas, Medicine, Vanderbilt University School of Medicine*

Objectives: Participants will be able to state several tests that should not be used to diagnose water-loss dehydration in elders; Participants will know and name promising tests for diagnosing water-loss dehydration, but that still need additional research.

Abstract Body: Introduction Water-loss dehydration is common in elders and associated with increased risk of disability, mortality, respiratory infections, urinary tract infections, unplanned hospital admissions, constipation, pressure sores, falls and impaired cognition. We need to accurately diagnose water-loss dehydration to help protect older people. Objective We aimed to assess the diagnostic accuracy of possible clinical and physical signs, symptoms and indications of water-loss dehydration in elders against serum osmolality or weight change (reference standards). Methods Structured searches were run in seven databases. Assessment of inclusion, data extraction and assessment of validity were duplicated. Where data sets included index tests and a reference standard, but were not analysed for diagnostic accuracy, reviewers analysed the data. Diagnostic accuracy of each indicator was assessed against the best reference standard, and data presented in sensitivity and specificity forest plots. Pre-set minimum sensitivity was 60%, specificity 75%. Secondary analyses created receiver operating characteristic (ROC) curves for continuous tests. Results We included 24 studies (67 tests). No index tests were reproducibly usefully diagnostic of water-loss dehydration in older people, but promising tests included expressing fatigue, missing drinks between meals, BIA resistance at 50kHz, axillary moisture, drinks intake and urine osmolality. There was sufficient evidence to suggest that some tests should not be used to indicate dehydration: dry mouth, feeling thirsty, heart rate, urine color and urine volume. Conclusions There is limited evidence of the diagnostic utility of any individual sign to indicate water-loss dehydration in elders. Individual signs should not be used in this population to indicate dehydration.

339. Standard Laboratory Tests to Identify Older Adults at Increased Risk of Death, *Susan Howlett, Dalhousie University, Department of Pharmacology; Michael Rockwood, Dalhousie University; Arnold Mitnitski, Dalhousie University; Kenneth Rockwood, Dalhousie University*

Objectives: After attending this activity, participants will be able to discuss how a frailty index score can be obtained from routinely collected laboratory tests. After attending this activity, participants will understand how frailty index scores can predict mortality in older adults. After attending this activity, participants will understand how data obtained from routine blood tests could be combined with clinical assessments of frailty to produce a frailty index score that is highly predictive of mortality.

Abstract Body: Methods to identify frail people often require time-consuming interactions with health care providers. We evaluated whether standard laboratory tests, on their own, or added to a clinical frailty index (FI), could identify older adults at increased risk of death. Community-dwelling and institutionalized participants in the Canadian Study of Health and Aging who also volunteered for blood collection (n=1,013) were followed for up to 6 years. A standard FI (FI-CSHA) was constructed from clinical evaluation data and a second, novel FI was constructed from laboratory data plus blood pressure measurements (FI-LAB). A combined FI included all items from each index. Predictive validity was tested using Cox proportional hazards analysis and discriminative ability by area under Receiver Operating Characteristic (ROC) curves. Of 1,013 participants, 51.3% had died by 6 years. The mean baseline value of the FI-LAB was 0.27 (SD 0.11; range 0.05-0.63), the FI-CSHA was 0.25 (0.11; 0.02-0.72), and combined FI was 0.26 (0.09; 0.06-0.59). In an age- and sex-adjusted model, with each increment in the FI-LAB, the hazard ratios increased by 2.8% (95% CI 1.02-1.04). Hazard ratios for the FI-CSHA and combined FI were 1.02 (1.01-1.03) and 1.04 (1.03-1.05), respectively. The FI-LAB and FI-CSHA remained independently associated with death in the face of the other. The areas under the ROC curves were 0.72 for FI-LAB, 0.73 for FI-CSHA, and 0.74 for the combined FI. An FI based on routine laboratory data can identify older adults at increased risk of death. Additional evaluation of this approach in clinical settings is warranted.

340. A Open-label, No-treatment-controlled, Parallel, Pilot Phase II Study to Evaluate the Efficacy and Safety/Tolerability Profiles of G-CSF in Subjects with Mild to Moderate Alzheimer's Disease., *Wen-Chuin Hsu, Chang Gung Dementia Center Chang Gung Memorial Hospital, Taoyuan Chang Gung University*
Objectives: Granulocyte-colony stimulating factor (G-CSF) is a safe drug of older patients with Alzheimer disease (AD).; G-CSF might slow the cognitive decline in mild to moderate AD.
Abstract Body: BACKGROUND: Granulocyte-colony stimulating factor (G-CSF) is a growth factor linked with the blood cell proliferation and differentiation. Previous studies showed injection of G-CSF could help hematopoietic stem cell (HSCs) release from bone marrow to the peripheral blood and then migrate to repair damaged areas, e.g. heart tissue and ischemia brain tissue. G-CSF migrated stem cells to the brains and rescue the memory impairment in the animal model with Alzheimer disease (AD). DESIGN: A randomized open-label trial, Phase 2; parallel design using no-treatment group as control. The subjects with AD aged between 50 and 85 years with MMSE 10~26 and CDR 1 (mild) or 2 (moderate) were randomized. RESULTS: There was no significant difference in changes of ADAS-Cog from the baseline between G-CSF (n=10) and No-Treatment (n=11) groups with mild to moderate AD. The decline in ADAS-Cog and Instrumental ADL might be slower in Treatment group than in the No-Treatment. Enlargement of the spleen by >30% in 3 subjects (37.5%) of G-CSF group in a total of 16 G-CSF courses. There was none of splenic rupture. G-CSF is a safe drug of older patients with AD. It might slow the cognitive and ADL decline in mild to moderate AD. This study encourages further trials with larger size and longer duration to evaluate the efficacy of G-CSF on AD.

341. Gaining Insight into the Impact of Body Fat on Cognitive Function among Older Adults, *Chun Liang Hsu, Aging, Mobility, and Cognitive Neuroscience Lab - University of British Columbia; John Best, Aging, Mobility, and Cognitive Neuroscience Lab - University of British Columbia; Elizabeth Dao, Aging, Mobility, and Cognitive Neuroscience Lab - University of British Columbia; Jennifer Davis, Center for Clinical Epidemiology and Evaluation - University of British Columbia; Ken Madden, Geriatric Medicine - University of British Columbia; Teresa Liu-Ambrose, Geriatric Medicine - University of British Columbia*
Objectives: After attending this session, participants will be able to discuss our current understanding in the relationship between body fat and cognitive function
Abstract Body: Obesity and dementia are both increasing in prevalence worldwide. While obesity are associated with key vascular risk factors (e.g., hypertension, diabetes) for dementia, the relationship between body fat and cognitive function in older adults remain equivocal. In fact, there is evidence body fat may be neural-protective for older adults. Neuroimaging studies of otherwise healthy adults demonstrate that increased body mass index (BMI) is associated with global and regional brain atrophy, as well as altered functional connectivity. However, few studies to date have investigated neural mechanisms of obesity-induced cognitive changes in older adults. In a 12-month prospective study, we aimed to examine: 1) the impact of BMI on functional brain connectivity; and 2) the role of functional brain connectivity in the association between BMI and cognitive function. Methods: A 12-month prospective fMRI study with 66 seniors aged 70 to 80 years; 24 normal weight (with BMI≤18.50), 26 overweight (with BMI between 18.5 and 29.99), and 15 obese (with BMI ≥ 30.00). Participants performed a finger tapping task during fMRI scanning. Clinical measures of executive functions were assessed at baseline and 12 months. Results & Conclusion: Obese individuals showed decreased connectivity in the default mode network (DMN; p<0.006), which was significantly correlated with Digit Span Test performance at 12 months (p<0.02) and BMI (p<0.001). Contrary to studies that report high BMI negatively impact cognitive function, we found increases in BMI indirectly lead to reduced DMN connectivity, which, in turn, lead to improved performance on Digit Span Test. This suggests DMN connectivity mediates and suppresses the effect of BMI on cognitive function, and may be involved in compensatory processes in older adults.

342. Comparative Study of Two Drug Administration Processes in the Preparation of the Eye for Cataract Surgery, *JinPing Hu, Peking University Third Hospital*
Objectives: To compare the effect of two drug administration processes on decreasing the rate of conjunctival cac bacterial infection among senile patients in the preparation of the eye for cataract surgery
Abstract Body: Methods: Participants who made surgery appointments were recruited by convenient sampling in an eye center of Beijing, China. History control group was borrowed (control group: 146 cases; experimental group: 107 cases). Patients in the control group were given the eye medication by traditional process that patients only got the drug-related education from their doctors. Patients in the experimental group were given the medication by the new drug administration process, which was cooperatively conducted by physicians and nurses and emphasized each sub-process of drug administration at drug preparation, personalization, application, and follow-up. Results: Conjuntival sac bacteria culture was conducted at two time points for both groups (the day of surgery appointment vs. 3rd day after surgery appointment which was the morning of surgery). Rates of germiculture positive for both groups at the day of surgery appointment were not significant (control group=35.6%, experimental group=36.4%; p>0.05), while the rates were significantly different at the 3rd day after surgery appointment (control group=13.0%, experimental group=2.8%; $\chi 2=6.48$, p=0.01). Conclusions: Compared with the traditional process, the new process of administering the eye medication for senile patients in the preparation of the

eye for cataract surgery is more effective on decreasing the rate of conjunctival sac bacterial infection. The better cooperation between physicians and nurses on the drug administration process are considerable.

343. Balance Impairments and a History of Falls Influencing Quality of Life in Community-Dwelling Older Cancer Survivors, *Min Hui Huang, Physical Therapy Department, the University of Michigan-Flint; Tracy Shilling, Physical Therapy Department, the University of Michigan-Flint.; Kara Miller, Health Quest Physical Therapy; Kristin Smith, Life In Balance Physical Therapy; Kayle Fredrickson, Mary Free Bed Rehabilitation Hospital*
Objectives: To analyze the impact of balance impairments (measured by the short version of Activity-specific Balance Scale (ABC-6) and the Balance Evaluation Systems Test (BESTest)) and a history of falls (the status of being a faller vs. non-faller; a faller was a person who reported having one or more falls in the past 12 months prior to enrolling in the study) on health-related QoL (measured by the SF-36v2 Physical Component Summary (PCS) and Mental Component Summary (MCS)) in community-dwelling older cancer survivors.
Abstract Body: Introduction: Cancer and its treatments cause adversely outcomes in postural control systems, leading to impaired balance and increased risks of falls. Long-term declines in health-related quality of life (QoL) after the cancer diagnosis have been documented. This study examined the impact of balance and falls on QoL in older cancer survivors. Subjects: Forty-one cancer survivors (age=67.9±8.8) living in the community volunteered. Inclusion criteria were age 55 years and over, a history of cancer not involving the nervous, musculoskeletal, or integumentary systems, completion of primary cancer treatment at least 3 months, and no history of neurologic conditions. Methods: Multiple linear regression was performed with the scores of Physical Summary Component (PCS) or Mental Summary Component (MCS) of SF-36v2 separately as the dependent variable. The scores of the short version of Activity-specific Balance Confidence scale (ABC-6), Balance Evaluation Systems Test (BESTest), and the history of falls in the past 12 months were the independent variables. Age was a covariate. Significance level was $p<0.05$. Results: BESTest ($p<0.01$), history of falls ($p<0.001$), and age ($p<0.05$) were significant predictors of PCS. Only age significantly predicted the MCS scores ($p<0.01$). For PCS and MCS, the adjusted R2 values were 0.53 and 0.11, respectively, suggesting that the models adequately explain a small portion of PCS but not MCS. Discussion: Balance impairment and a history of falls are strong predictors of QoL, particularly in the physical domain. Clinicians should identify older cancer survivors with balance problems, inquire about falls, and initiate interventions to optimize QoL.

344. Long-Term Consequences of an Intensive Care Unit Stay in Critically Older Patients, *Marie-Madlen Jeitziner, Department of Intensive Care Medicine, University Hospital (Inselspital) Bern; Maastricht University CAPHRI; Sandra Zwakhalen, Maastricht University, CAPHRI; Reto Bürgin, University of Geneva; Virpi Hantikainen, University of Applied Sciences St. Gallen; Jan Hamers, Maastricht University, CAPHRI*
Objectives: Identify how an ICU stay influences an older person's experiences later in life.
Abstract Body: Worldwide, an increasing number of critically ill older patients are treated at the intensive care unit (ICU). Critically ill older patients are at risk for negative outcomes due to the combination of acute critical illness, co-morbidities, age-related vulnerability and the ICU environment. However, relatively little is known about long-term outcomes. Therefore, a prospective longitudinal study was conducted in older critically ill patients admitted to the ICU. Data on pain, anxiety, agitation, health-related quality of life (HRQoL) and the use of the resources were collected during ICU admission and 1 week, 6 and 12 months after discharge. A comparison group matched by age and gender was included. This study included 145 older patients (ICU group) and 146 participants (comparison group). Findings show that although critically ill older patients experience slightly more pain and anxiety 1 week after discharge, they did not report increased levels of pain, anxiety and agitation during the year following an ICU stay. Factors associated with pain in the ICU group during follow-up included: pain before ICU admission, pain during the ICU stay, surgical procedures, and higher doses of sedatives. HRQoL was lower in older ICU patients than in the age-matched group before and after ICU admission but remained stable over one year. More resources were used by older patients after ICU discharge, however most were able to live at home with no or minimal assistance after one year. Based on these findings we conclude that long term consequences of critically ill older patients treated in an ICU are minimal.

345. A Fall Prevention Guideline for Older Adults Living in Long-term Care Facilities, *Dukyoo Jung, Ewha Womans University, Seoul, Korea; Sujin Shin, Soonchunhyang University; Hyejin Kim, Ewha Womans University*
Objectives: This study aimed to develop a guideline covering risk factors and interventions for falls in order to prevent them from occuring in long-term care facilities
Abstract Body: Background: Falls are among the most frequent critical health problems for older adults over 65 years of age and often result in consequential injuries. Aims: This study aimed to develop a guideline covering risk factors and interventions for falls in order to prevent them from occurring in long-term care facilities. Methods: This study was grounded in the methodological approach of the Scottish Intercollegiate Guideline Network (SIGN) for establishing evidence-based guidelines: (1) establishment of the target population and scope of the guideline; (2) systematic literature review and critical analysis; (3) determination of the recommendation grade; (4) development of a draft nursing intervention guideline and algorithm; (5) expert evaluation of the draft nursing intervention guideline; and (6) confirmation of the final intervention

guideline and completion of the algorithm. Results: This algorithm consists of three assessment stages and three intervention stages. At the first assessment stage, if the subject is found to have a previous fall, then he/she should participate in the comprehensive intervention. The second stage provides drug management as well as strengthening and gait and balance training along with general fall prevention. At the same time, the subjects were assessed regarding further risk factors. If they had one of the remaining risk factors, they moved to the comprehensive intervention. Conclusion: This guideline can be used by nurses to screen for patients who are at a high risk of falling to provide patient interventions to help prevent falls.

346. Walkability, Walking Behavior, and Health of Seniors Living in Tokyo, *Keiko Katagiri, Graduate School of Human Development and Environment, Kobe University*

Objectives: To explore what aspect of walkability is important for the seniors.; To explore how walkability relates to walking behavior of the elderly; To examine walking behavior relates to improve the elderly's health

Abstract Body: Three Asian cities, Tokyo, Hong Kong, and Singapore, share the social issue of how to promote health behavior among seniors. We aimed to study the environmental conditions of walkability and its effect on seniors' walking behavior and health (given that the promotion of everyday walking habits is the most efficient way to promote health). In this study, we report the descriptive results of walkability, walking behavior, and health of the elderly who use senior centers in two areas of Tokyo, Nerima (located in the suburbs) and Meguro (located near the heart of Tokyo). Participants consisted of 315 seniors. Participants provided assessments of their neighborhoods' walkability, their walking behaviors, and their health status through face-to-face interviews in 2013. Walkability was assessed by three sub-concepts, safety, convenience, and comfortableness, as well as an overall score out of a hundred. Walking behavior was measured by how many days in the last week they walked for more than ten minutes. Convenience, overall walkability, and walking behavior of Meguro scored higher than those of Nerima. Safety and comfortableness significantly correlated with overall walkability scores. Only convenience correlated with walking behavior. Walkability, walking behavior, area, gender, and age were regressed on depression, revealing associations between overall walkability and walking behavior with lower depression. These preliminary results suggest that the walkability of an area promotes walking behavior, and that more walking contributes to lower levels of depression. Further examination of these variables is necessary to unravel the relevance of the relationships between walkability, walking behavior, and health.

347. Rehabilitation Outcomes in Aging Patients with Bilateral Lower Extremity Peripheral Neuropathies- A Pilot Study, *Tim Kauffman, Kauffman Physical Therapy*

Objectives: The reader will learn the effectiveness of physical therapy intervention for patients with bilateral lower extremity peripheral neuropathy.; The reader will learn a variety of assessment tools that are appropriate when evaluating patients with bilateral lower extremity peripheral neuropathy.; The reader will be able to discuss the importance of co-morbidities when evaluating and treating patients with bilateral lower extremity peripheral neuropathies

Abstract Body: Rehabilitation outcomes of aging persons with peripheral neuropathy (PN) are varied due to idiosyncratic aging changes and co-morbidities. This single case design study was completed in an outpatient physical therapy office to determine individual outcomes and optimal assessments. Charts from 15 persons, 5 females, with primary or secondary diagnosis of lower extremity PN, were reviewed. Mean age was 77.6 years, range 68 to 90 years. All complained of numbness and gait abnormality; most complained of pain. Co-morbidities ranged between 4-10 for each. The evaluating therapist chose functional assessment tools based on co-morbidities and thus were not identical for all subjects. Each subject was his/her own control. Seven subjects were excluded because of medical changes and cessation of intervention before reevaluation. Among the individualized assessments were dynamometric muscle strength, the Gait Abnormality Rating Scale, gait velocity, computerized balance testing, Dynamic Gait Index, sit to stand and ABC Scale. Seven patients improved in at least 2 of the measurement tools. The 8th subject had made good progress initially but her condition worsened and she was referred to her neurologist. Six of seven subjects who made the best gains in functional tests were treated only 10-13 visits. Physical therapists and assistants with a team approach provided all care. Conclusion: All patients were pleased to be exercising. 88% improved well on 2 or more functional assessments. There may be no gold standard in assessment tools for persons with PN. A grading scale for persons with PN may be helpful for future researchers.

348. Cancer Survivorship Research in Medicare Advantage Enrollees: the Surveillance, Epidemiology and End Results –Medicare Health Outcomes Survey (SEER-MHOS) Linked Dataset, *Erin Kent, National Cancer Institution; Rochelle Malinoff, Health Services Advisory Group; James Burroughts, Health Services Advisory Group; Gigi Yuan, Information Management Services; Marie Topor, Information Management Services; Heather Rozjabek, Information Management Services; Anita Ambs, National Cancer Institute*

Objectives: 1.Describe health-related quality of life and socio-demographic and clinical characteristics of older adults diagnosed with breast, prostate, colorectal, and lung cancer and individuals with no history of cancer.; 2.Examine highlighted patient-reported outcomes of SEER-MHOS participants, including body mass index, number of recent unhealthy days, problems with balance and falls, and fall risk management.

Abstract Body: The Surveillance, Epidemiology, and End Results (SEER) -Medicare Health Outcomes Survey (MHOS) linkage provides cancer registry data and health-related quality of life of Medicare managed-care beneficiaries with and without cancer. We provide descriptive data on socio-demographic and clinical characteristics of participants with a history of breast, prostate, colorectal, or lung cancer, and those without cancer. We highlight items in MHOS 2.0, including self-reported body mass index (BMI), number of unhealthy days in the past month, past-year history of balance problems/falls, and fall risk management. 258,108 individuals without a history of cancer, 1,311 males with prostate cancer, 982 females with breast cancer, 689 individuals with colorectal cancer, and 458 individuals with lung cancer were included in the analysis. A higher proportion of obesity (BMI>30 kg/m2) was observed among breast cancer patients (26.9%) than females without cancer (25.7%). The number of days individuals reported their health status kept them from performing usual activities also varied across groups; 36.9% of lung cancer patients and 21.0% colorectal cancer patients reported 14-30 days vs. 13.5% of individuals without cancer. Approximately 42.4% post-dx cancer patients and 39.4% of individuals without cancer reported problems with balance/falls. Of those that reported problems with falls/balance, 35.2% with and 34.5% without cancer reported no healthcare provider discussions/suggestions regarding fall risk management. Comparisons of reports from older individuals with/without cancer reveal challenges in providing care to aging cancer patients. Monitoring patient-reported data on health outcomes, behaviors, and care experiences can provide useful information population-level surveillance and quality improvement.

349. Frailty Assessment and Long-Term Mortality After Cardiac Surgery: A Systematic Review, *Caroline Kim, Beth Israel Deaconess Medical Center, Harvard Medical School; Sebastian Placide, Beth Israel Deaconess Medical Center; Edward Marcantonio, Beth Israel Deaconess Medical Center, Harvard Medical School; Jeffrey Popma, Beth Israel Deaconess Medical Center, Harvard Medical School; Dae Hyun Kim, Beth Israel Deaconess Medical Center, Harvard Medical School*

Objectives: To learn that the presence of preoperative frailty is a strong predictor of long-term mortality after cardiac surgery, independent of comorbid conditions

Abstract Body: Background: Current preoperative risk scores for cardiac surgery estimate short-term mortality and major complications but perform poorly in predicting long-term mortality. Frailty has been associated with long-term mortality in older patients undergoing cardiac surgery. However, a wide variation in frailty measurements may limit uptake of such measurements in clinical practice. Methods: We conducted a systematic search of Medline and EMBASE, from inception to 4/2014, to identify prospective studies that evaluated preoperative measurements of frailty in relation to long-term mortality (≥6 months) in populations (mean age ≥60 years) undergoing coronary artery bypass graft or valve surgery. Results: Of the 12 measures of frailty evaluated, 11 were associated with mortality beyond 6 months (relative risk [RR] range: 1.2-3.5 comparing the most frail versus the least frail groups), after adjusting for demographic characteristics and comorbidities. The frailty measurement frequently involved mobility (Timed Up-and-Go test, 6-minute walk test, gait speed; RR: 1.7-6.7 in 9 studies), self-reported functional status (activities of daily living, mobility disability; 1.5-3.6 in 7 studies), nutritional status (Mini Nutritional Assessment, serum albumin, weight loss; 3.4-6.7 in 5 studies), muscle strength (grip strength, chair rise; 1.6 in 3 studies), and cognition (Mini-Mental State Examination; 3.0 in 3 studies). Conclusion: The presence of preoperative frailty is a strong predictor of long-term mortality after cardiac surgery, independent of comorbid conditions. Although the choice of measurements will depend on resources available, a mobility assessment is a simple, standardized, most widely studied test of frailty. The comparative performance of each frailty measurement remains to be established.

350. Non-Cardiovascular Mortality Risk Influences the Mortality Benefit of Statins: Meta-Regression, *Caroline Kim, Division of Gerontology, Department of Medicine Beth Israel Deaconess Medical Center, Harvard Medical School; Dae Hyun Kim, Division of Gerontology, Department of Medicine Beth Israel Deaconess Medical Center, Harvard Medical School*

Objectives: To learn that the mortality benefit of statins depend on both cardiovascular and non-cardiovascular mortality of the population

Abstract Body: The current guideline recommends statin treatment mainly based on the risk of cardiovascular (CV) events, without considering the risk of non-CV mortality. To identify a population that is more likely to derive a mortality benefit from statins, we conducted a meta-analysis and meta-regression of randomized placebo-controlled trials of statins to examine whether the relative risk (RR) reduction in mortality differed by CV and non-CV mortality risks of the population. The effect of statins on total mortality was examined using: 1)random-effects meta-analysis according to the median 5-year CV and non-CV mortality risks of the study population; and 2)meta-regression to model the RR reduction associated with increase in the CV-to-non-CV mortality ratio of the population. In 18 studies including 60,145 statin-treated patients and 60,173 placebo-treated patients with and without CV disease (mean age: 55-75 years), the mortality benefit of statins diminished as the non-CV mortality risk of the population increased. In populations with low CV mortality, the pooled RR (95% confidence interval [CI]) was 0.82 (0.74,0.91) for low non-CV mortality and 0.90 (0.71,1.14) for high non-CV mortality. In populations with high CV mortality, the corresponding pooled RRs (95% CI) were 0.79 (0.72,0.87) and 0.94 (0.86,1.02). Meta-regression analysis showed that every unit increase in the CV-to-non-CV mortality ratio was associated with additional 9% reduction in RR of total mortality (0.91 [0.86-0.96]). The risks of CV and non-CV mortality may be used together to identify patients who are less likely to derive mortality benefit from statins. Our findings should further tested using individual-level data.

351. The relationship between executive function and attention screening of mild cognitive impairment (MCI), *Taiki Komatsu, Tokyo University of Technology*

Objectives: the establishment of methodology for Reaction time(RT) measurement; it is possibility of screening of mild cognitive impairment;

Abstract Body: 【Purpose】 It is said that the probability of 16% per year progress to dementia, to progress to Alzheimer's dementia, especially with 8.5% MCI. The aim of this study was examined MCI and the association with executive function. 【Method】 The subjects that average age was 82.7 ± 6.9 years 15 people nursing home residents (4 male, 11 female patients). The measurement used Flanker task test as executive function test. Object is displayed simultaneously (Flanker) that type of stimulus to be presented was two (incongruent condition) arrow facing the direction opposite to the target (congruent condition). And, was performed at 4 second intervals round in random order total 120 enforcement of 60 enforcement both stimulation challenge, were calculated error rate and median reaction time. Performs a partial correlation analysis confirmed the relationship between various parameters and was divided into two groups at the cut-off value of 23 by Montreal Cognitive Assessment (MoCA). 【Result】 Total RT of Flanker task and MoCA score ($r = -0.600$, $p <0.05$), congruent RT ($r = -0.525$, $p <0.05$), congruent error ($r = -0.569$, $p <0.05$), and was a significant correlation ($r = -0.523$, $p <0.05$) in incongruent error. In addition, in the Flanker task test was a significant difference in only incongruent error ($p <0.05$). 【Conclusion】 The Flanker task test and reliable that it can be processed by the PC on conveniently be carried out relatively therefor also can be useful as a screening method for MCI.

352. An Assessment of a Pet Therapy Program for Community Dwelling Older Adults, *Cheryl Krause-Parello, University of Colorado Denver; John Kolassa, Rutgers University*

Objectives: To appraise a community based pet therapy program for older adults.; To explore the effect of a pet therapy on blood pressure and heart rate measurements in older adults.;

Abstract Body: Older adults living in the community are at risk for social isolation. Pet therapy programs have been cited in the literature to promote sociability. The aim of this research was to appraise a pet therapy program for older adults living in the community. A crossover design was used to establish a relationship among blood pressure and heart rate before and after pet therapy. A convenience sample ($N = 28$) included both male ($n = 12$) and females ($n = 16$) whose age ranged from 60-102 (M = 82.9: SD 9.62). Participants completed a demographic, stress, pet attitude, and coping measures. The findings supported that systolic BP dropped in stress ($p = 0.0220$) and self-health rating increased ($p =.0210$). Moreover, HR dropped as health rating increased ($p =0.0431$). The result of this study supported pet therapy is of particular use for older adults who identified their health as poor.

353. Prevalence of Prediabetes and Undiagnosed Diabetes Among Older Adults in Mexico., *Amit Kumar, Department of Rehabilitation Sciences/ Departments of Preventive Medicine and Community Health UTMB/ University of Texas Medical Branch at Galveston; Rebeca Wong, Sealy Centre on Aging/Departments of Preventive Medicine and Community Health/ University of Texas Medical Branch at Galveston; Kenneth Ottenbacher, Department of Rehabilitation Sciences / Sealy Centre on Aging/University of Texas Medical Branch at Galveston; Alai Tan, Departments of Preventive Medicine and Community Health / Sealy Centre on Aging/University of Texas Medical Branch at Galveston; Soham Al Snih, Department of Rehabilitation Sciences / Sealy Centre on Aging / University of Texas Medical Branch at Galveston;*

Objectives: Examine the prevalence of prediabetes and undiagnosed diabetes among older adults in Mexico.; Identify the factors associated with prediabetes and undiagnosed diabetes.; Describe the prevalence of pre-diabetes and undiagnosed diabetes by gender, BMI categories, rural, and urban population.

Abstract Body: Objective: People with prediabetes have a high risk of progressing to diabetes. In developing countries like Mexico, without universal health insurance, high rates of undetected diabetes may exist. This study aims to estimate the prevalence of prediabetes and undiagnosed diabetes among older Mexican adults. Method: A secondary analysis was conducted using a cross-sectional sub-sample (n= 1827) of the third wave of the Mexican Health and Aging Study collected in 2012. The outcome variable was the number of prediabetes and undiagnosed diabetes cases. Hemoglobin A1C (HbA1c) criterion was used to define the prediabetes and undiagnosed diabetes cases. HbA1c between 5.7 to 6.4% was classified as prediabetes and individuals with HbA1c ≥ 6.5 %, no diabetes as per self-report, and not currently on diabetic treatment were classified as undiagnosed diabetes. Covariates included demographic characteristics, BMI, central obesity, smoking, hypertension, and stroke. Logistic regressions were computed to examine the factors associated with prediabetes and undiagnosed diabetes after adjusting for covariates. Result: Prevalence of prediabetes and undiagnosed diabetes was 43.7% and 18.1%, respectively. Females had significantly higher rates of prediabetes (57%) and undiagnosed diabetes (60%). After adjusting for covariates, central obesity was associated with an increased risk of prediabetes (OR=1.02, 95% CI=1.00 -1.03). Central obesity (OR=1.02, 95% CI=1.01-1.03) and hypertension (OR=1.32, 95% CI=1.07-1.63) were significantly associated with undiagnosed diabetes. Conclusion: This study found a high prevalence of prediabetes and undiagnosed diabetes among older adults in Mexico, especially females. Findings suggest resources are needed to prevent, identify, and treat persons with pre- and current diabetes.

354. Do Genetic Factors have a Role in the Association between Oral Health and Diabetes Mellitus?, *Yuko Kurushima, Osaka University Graduate School of Dentistry Department of Prosthodontics, Gerodontology and Oral Rehabilitation; Kazunori Ikebe, Osaka University Graduate School of Dentistry, Department of Prosthodontics, Gerodontology and Oral Rehabilitation; Kenichi Matsuda, Osaka University Graduate School of Dentistry, Department of Prosthodontics, Gerodontology and Oral Rehabilitation; Soshiro Ogata, Osaka University Graduate School of Medicine, Center for Twin Research; Shinya Murakami, Osaka University Graduate School of Dentistry, Department of Periodontology; Yoshinobu Maeda, Osaka University Graduate School of Dentistry, Department of Periodontology*

Objectives: To evaluate genetic contribution between oral health and diabetes mellitus using middle-aged Japanese twins

Abstract Body: OBJECTIVE There is a strong relationship between oral health and diabetes mellitus (DM). Periodontal inflammation has been reported to be the common etiology. Environmental factors and genetic factors have important roles in this association, but studies focusing on genetic confounding between them are lacking. We evaluated the genetic contribution between oral health and DM using middle-aged Japanese twins. METHODS Japanese twins aged ≧50 years were the study cohort. Number of teeth, masticatory function, and periodontal status were used as indicators of oral health. We diagnosed individuals with hemoglobin-A1c levels ≧6.5% (National Glycohemoglobin Standardization Program) as having DM. As the first step of statistical analyses, the association of each of three oral health-related measurements with DM was calculated using generalized estimating equations (GEEs). At a second step, we examined the association only for monozygotic discordant twins using co-twin control analyses. By comparing the results of these two analyses we evaluated the genetic contribution between oral health and DM. RESULTS The number of twins was 242 (monozygotic, 218; dizygotic, 24). The mean age was 65.9±10.7 years. The prevalence of DM in this cohort was 11.6%. GEE analyses revealed that only the number of teeth was significantly related to DM (odds ratio, 0.71; 95% confidence interval, 0.57–0.89). Co-twin analyses revealed no significant association between the number of teeth and DM (odds ratio, 0.98; 95% confidence interval, 0.90–1.06). CONCLUSION Genetic factors contribute to the association between oral health and DM as confounders.

355. Ethnic Differences in Perception of Health Applications for Multiple Medications in Older Adults., *Jung-Ah Lee, University of California Irvine; Annie Nguyen, University of California Irvine; Alison Moore, UCLA; Lorraine Evangelista, University of California Irvine; Alpesh Amin, University of California Irvine;*

Objectives: To identify ethnic differences in perception regarding use of health applications to improve medication self-management.; To identify what factors are important to improving older adult care related to medication management.;

Abstract Body: Background: Poly pharmacy is a major problem in older adult care. Older adults may forget to take important medications such as oral anticoagulants. Strategies to help older adults better manage their medications need to be studied. Objective: to identify the ethnic differences in perception of the use of mobile health applications (apps) to improve medication self-management in older adults with chronic diseases. Methods: We conducted group or individual interviews with English and Spanish speaking older adults taking oral anticoagulants and other medications to understand their perception and attitudes towards using health applications to manage their medications. Results: We had 11 English speaking (ES) and 9 Spanish speaking (SS) participants. We interviewed them separately by language. More ES participants expressed favorable views towards the use of health apps via tablets or smartphones but none of the SS participants showed they were willing to use health apps citing lack of technological knowledge or financial burden of purchasing data service on mobile devices. However, participants expressed that medication reminder apps may be helpful in managing multiple medications. Both groups showed interest in learning how to use health technology devices but expressed the need for family support to use such devices properly to manage their medication. Conclusions: There are some ethnic differences in attitudes toward the use of health apps in older patients with multiple medications. Family support for older adults in using health devices will be a key factor to improving older adult care regarding multiple medication management.

356. Videogame-based physical activity in older adults with schizophrenia to improve mobility, *Heather Leutwyler, UCSF School of Nursing; Erin Hubbard, UCSF School of Nursing*

Objectives: Describe the impact of a videogame-based physical activity program on frequency of vigorous phsyical activity in older adults with schizophrenia

Abstract Body: Objectives: Adults with schizophrenia are a growing segment of the older adult population. Evidence suggests that they have poor mobility and low levels of physical activity contribute to their poor mobility. The purpose of this report is to describe the impact of a videogame-based physical activity program using the Kinect for Xbox 360 game system (Microsoft, Redmond, WA) on frequency of vigorous physical activity in older adults with schizophrenia. Materials and Methods: In our descriptive longitudinal study, once a week for 6 weeks, participants played an active videogame for 30-minutes. Physical activity was measured by self-report with the Yale Physical Activity Survey at enrollment and at the end of the 6-week program. Vigorous physical activity was defined as any activity that lasted at least 10 minutes and caused large increases in breathing, heart rate, or leg fatigue, or caused the person to perspire. Change in vigorous physical activity was analyzed with a non-parametric bootstrap with bias corrected and accelerated match-paired t-test. Results: At a 95%

confidence level and alpha equal to .05, we detected a significant increase in frequency of vigorous physical activity from enrollment to the end of the program for an average increase of 0.9 points. Conclusions: Our results suggest that a videogame-based physical activity program may be one way to increase the frequency of vigorous activity in older adults with schizophrenia. More frequent vigorous physical activity may improve mobility. Future studies should evaluate the frequency vigorous activity with objective measures, such as wearable monitors.

357. Home Health Care (HHC) Nurse Interactions with Homebound Geriatric Patients with Depression and Disability., *Dianne LIebel, University of Rochester School of Nursing; Bethel Powers, University of Rochester; Emily Hauenstein, University of Rochester*
Objectives: Understand how home health care participants and after attending this poster session participants will be able to understand how nurses interact during depression treatment and care management of geriatric HHC patient with existing depression; After attending this session participants will be able to.discuss the impact of therapeutic communication on home health care participants depression and disability self-care management ; After attending this poster session participants will be able to identify components of mental health promoting therapeutic work that can be integrated into formal training programs
Abstract Body: Purpose: Comparatively little is known about how depression is identified or which therapeutic strategies most effectively treat older HHC patients with depressive symptoms and concomitant disability. Thus, there is a pressing need to evaluate and characterize DCM in HHC, after CMS broadened depression requirements for depression assessment on the OASIS-C. Design & Methods: Qualitative exploratory descriptive design, conducted in 2 parts to explore the provision of optimum nurse care management for geriatric HHC patients. The first part, involved interviews regarding HHC nurse perceptions of depression and disability care management. The second part, the focus of this analysis, describes HHC nurses' use of care management and therapeutic strategies. Observation of nurse-patient interactions involved home visits to HHC patients, age 60> who had depression and disability. Analysis was informed by an adapted Chronic Care Model and Peplau's Interpersonal Relationship Theory. Results: Observation visit findings demonstrated that nurses drew on existing clinical knowledge and interpersonal skills, to build relationships and foster trust. However, despite nurses abilities to make these connections, there were multiple missed opportunities to engage in therapeutic nurse behavior. We recommend that training curricula be developed for HHC nurses including: agenda setting; sustaining continuity across visits, staying engaged despite barriers, recognizing nurse fears translating into avoidant disconnections. Conclusions: There is emerging evidence that HHC agencies need to design and test interventions that include formal training of nurses to effectively use therapeutic communication as part of their care delivery repertoire, HHC is well positioned to adapt these practices into its current infrastructure.

358. Arab Elders: Diverse Community Perspectives on Adult Day Programming, *Faith Hopp, Wayne State University School of Social Work; Jennifer Mendez, Wayne State University School of Medicine; Amne Darwish Talab, ACCESS; Kristine Ajrouch, Eastern Michigan University Department of Sociology*
Objectives: By attending this session, participants will gain insight into the views of a multicultural group of older adults, caregivers, and community leaders concerning the challenges of accessing services and support in an urban area.; By attending this session, participants will learn about perceived challenges and opportunities for development of adult day programming as perceived by prospective participants.; By attending this session, participants will learn about strategies and challenges in conducting qualitative research (focus groups and interviews) in an urban multicultural community.
Abstract Body: Purpose: This study was designed to obtain information about the perceptions of older adults, caregivers, and community leaders concerning their interest in the development of adult day care (ADC) programming in a multicultural community in Dearborn, Michigan. Method: Focus groups (between two and eight participants) were conducted in English for older adults (two groups) caregivers (one group) and one group that included both older adults and caregivers. One of the older adults groups was conducted in Arabic. Eight interviews were conducted with religious leaders and administrators of aging services organizations. The resulting qualitative data was analyzed using an inductive approach to identify emerging themes. Results: Themes identified included those related to transportation, socialization, access to care among the multicultural community in metropolitan Detroit, the desire of seniors to feel productive and display cultural talents, and the need for adult day centers celebrating varied cultural practices and languages. Conclusion: Older adults in the Detroit area, many of whom are of Arab descent, face many challenges in accessing supportive health and long-term care services. They are excited about possibilities to support their community by developing an adult day center that celebrates diverse multicultural programming while providing needed social and medical support.

359. Attitudes on Aging, Education, and Influences on Occupational Therapy Gerontology Practice, *Beverly Horowitz, York College-CUNY Occupational Therapy Department*
Objectives: Participants will be able to: 1. Discuss relationships among student and therapists attitudes about older adults, professional education, and willingness to work with older adults, with potential implications for other health professions.; Participants will be able to: Explain differences between verbalized ageist, negative attitudes about older adults documented in focus groups and quantitative Refined-Aging Semantic Differential scores indicating positive attitudes.; Participants will

be able to: Describe how students' pragmatism can influence their "willingness to work" with older adults, with potential implications for other health professions.

Abstract Body: By 2030 it is anticipated that over 70 million Americans will be 65 years or older (Federal Interagency Forum on Aging-Related Statistics, 2012). Population aging is anticipated to increase health care demands, including demands for rehabilitation and occupational therapy (OT) services (National Academy of Sciences, 2001; Maiden, et al., 2010; The Institute of Medicine Report, 2008) highlighting need for more OT gerontology practitioners. This mixed method NYS study using surveys and focus groups examined relationships among OT gerontology education, attitudes about older adults, OT and student interest in working with older adults, and student and therapists identification of gerontology practice settings. Instruments included Willingness to Work with Older Adult Scales, Gerontology Education and Experience Scales, the Refined-Aging Semantic Differential (Polizzi, 2003), and the Facts on Aging Quiz (FAQ1) (Palmore, 1998). Research Results: Significant relationships were found between OT gerontology education and "willingness to work" for therapists (n = 85) (rho= .351, p = .000) and students (n = 115) (rho =.342, p <.001); a weak significant correlation was noted between positive attitudes and therapists' "willingness to work" (rho=-.18, p = .049). Mean FAQI scores were 66% for therapists, 61% for students, similar to past studies. Focus group data found mixed attitudes about older adults, but 44% expressed "willingness" to work with older adults dependent on clinical experiences and opportunities. Findings have implications for OT education and gerontology practice with potential relevance for allied health education across disciplines.

360. Connecting Partners in the Dementia Care Triad to Knowledge and Community Resources, *Jennifer Inker, Virginia Commonwealth University, Department of Gerontology; Christine Jensen, Riverside Center for Excellence in Aging and Lifelong Health*

Objectives: 1)To identify the agencies and organizations that have appealed for a better approach to addressing the gaps in dementia care.; 2)To confirm the identified gaps in dementia care from the family/patient perspective and that of primary care physicians.; 3)To propose recommendations to strengthen the dementia triad.

Abstract Body: Connecting healthcare professionals, caregivers and people with dementia (the dementia triad) to knowledge and resources that support them to manage this devastating disease on a day-to-day basis is a growing and urgent priority. There remains a clearly identified discrepancy between what families and persons with dementia report they need and what physicians, particularly in primary care, report that they can provide. This project identified the needs of family caregivers and health care providers caring for persons with dementia. Participants included 128 caregivers, who completed a survey, and 27 health care providers, who participated in a focus group and completed a survey. Caregivers reported their primary source of information about the disease was the doctor; however, the majority also reported they were primarily informed of medications and not about needed resources. Health care providers identified limited time with patients and families, and lack of awareness of community services, as their main challenges. Recommendations include strengthening the partnership between physicians, patients, and caregivers (the dementia care triad) through additional support and training for physicians and caregivers; increasing awareness of the Alzheimer's Association; greater access to programs that support both professional staff and family caregivers (e.g., "Caring For You, Caring For Me"); and utilization of technology for families and professionals to track the needs of persons with dementia.

361. Examining Racial-Ethnic and Gender Differences in the Income-Health Gradient: Evidence From the Health and Retirement Study, *Jin Kim, Northeastern Illinois University*

Objectives: After attending this session, participants will be able to describe and explain racial-ethnic differences in the income-health gradient among older adults.; After attending this session, participants will be able to describe and explain gender differences in the income-health gradient among older adults.; After attending this session, participants will be able to describe and explain the relative importance of various income sources that impact health among older adults.

Abstract Body: The positive association between socioeconomic status and health is well-established in the policy literature. Prior research attempting to disentangle the causal pathways often rely on childhood studies since they are less susceptible to accusations of reserve causation (i.e., family income is used to purchase better health for children.) Few studies, however, rely on evidence from the older adult population to examine how lifetime earnings may impact health in later life. As such, this study extends the literature by investigating the established relationship between income and health under the presumption that lifetime earnings influence the "purchase" of better health in older adulthood, and goes further to examine racial-ethnic and gender differences in the so-called income-health gradient. The research uses data from the 1996 to 2010 Waves of the Rand Health and Retirement Study (HRS) to estimate a discrete-time hazard model of health status among older adults. The study tracks individuals ages 58 to 63 into retirement and varying health trajectories to investigate the nexus between income and health across different racial-ethnic and gender groups. The model reveals that while pension/annuity income is especially important in protecting against the risk of poor health among Hispanic, Black, and female older adults, a 1.0% increase in the replacement rate for Social Security income actually increases the odds of poor health by 1.6%. While the study validates the theory that income (from private sources) is used to purchase better health, the findings suggest a disconnect between income support policy and better health among older adults.

362. Impact of Older Adults' Internet Use on the Cost of Informal Caregiving, *Jeehoon Kim, Idaho State University; Hee Soo Joo, University at Albany*

Objectives: To assess the impact of older adults' Internet use on the formal and informal care hours and costs of informal caregiving; To discuss the implications of our findings with policy practitioners and gerontology researchers;

Abstract Body: Introduction: Internet use by older adults influences caregiving needs and their ability to maintain independence. However, little attention has been paid to whether their Internet use affects the economic burden of caregiving. The current study examines how older adults' Internet use impacts formal and informal care hours and costs. Methods: Using data drawn from the 2011 National Health and Aging Trend Study, this research uses a nationally representative sample of Medicare beneficiaries aged 65 and above with disabilities (N=2,315). Care is measured by total number of hours that older adults received in the past month, separated by formal and informal care. The Internet use is measured by older adults' online activity excluding email. We employ survey weighted generalized linear models with gamma distribution to estimate this model. We use a replacement approach to estimate informal caregiving costs. Results: About 30% of older adults went online for shopping, banking or dealing with health matters. After adjusting covariates, older adults' Internet use reduced informal care hours by 15% (19.4 hours per month, p=0.01) and formal care hours by 2% (18 minutes per month, p=0.04). A monthly estimated cost reduction of informal caregiving was $2,307 per person by applying 2011 median wage of home health aide workers. Discussion: Older adults' Internet use substantially reduced time invested in informal and formal care as well as cost of informal caregiving. This implies that the online activity can be a useful tool for maintaining independence in later life, and reducing the economic burden of caregiving.

363. Profiles of Clients in Medicaid 1915 (C) Home and Community-Based Waivers: Urban and Rural differences, *Min Hee Kim, School of Social Work & Department of Sociology, University of Michigan; Philippa Clarke, Institute for Social Research, University of Michigan*

Objectives: By attending this meeting, I expect to discuss how resource environments contribute to differences in Medicaid Waiver's client profiles and service utilization across urban-rural areas with policy makers, practitioners, and researchers

Abstract Body: Background: Medicaid 1915(C) home and community based waiver programs have received attention for their role in supporting vulnerable older adults aging in place. While research has focused on inter-state differences in program delivery, little attention has been paid to within-state differences in client profiles and service utilization. Methods: Using chi-squared and t-tests, we compared demographic, health status, living arrangements, and service utilization characteristics of 18,942 clients enrolled in the Medicaid Waiver program in the state of Michigan(1998-2000) by urban and rural residence (MSA vs. Non-MSA). Findings: According to the Census, the rural population in Michigan is much older and has a higher crude death rate than urban residents. Yet, clients served by the Waiver program in urban areas were generally older and exhibited more functional health and cognition problems than those in rural areas ($p<.05$). Yet, the prevalence of chronic illness, including lung disease or cancer, was much higher for rural clients ($p<.001$). In terms of service utilization, urban clients stayed longer in the program on average, and were more likely to receive home health aides and skilled nursing services than rural clients ($p<.01$). However, rural clients received more home makers, meal, and volunteer services. Discussion: Differences in the demographic, health and service utilization characteristics across the two populations were significant, suggesting differences in resource environments (e.g. organizational factors) that might contribute to such differences. In conditions of state funding restrictions, policy makers, researchers, and field practitioners should be cognizant of equity across urban-rural regions when designing and implementing services.

364. Understanding Well-being in Older Adults: Findings from the National Health and Aging Trends Study and Implications for Future Research, *Kyeongmo Kim, University of Maryland; Amanda Lehning, University of Maryland*

Objectives: Participants will be able to evaluate the validity and reliability of well-being measures in the National Health and Aging Trends Study.; Participants will be able to understand how the measure of well-being can be incorporated into future research on older adults.

Abstract Body: Well-being has been conceptualized as two dimensional constructs: 1) maximizing positive affect and minimizing negative affect (i.e., the hedonic dimension), and 2) achieving a sense of personal growth and meaning in life (i.e., the eudaimonic dimension). To date, existing measures of well-being may not adequately capture both of these dimensions for older adults, and limited literature has explored whether the two constructs can be integrated into one factor to measure well-being in this population. This study examined the factor structure of the 11 well-being items from the National Health and Aging Trends Study (NHATS), a nationally-representative panel study of Medicare recipients. Using data from the 2011 wave, we randomly split the community-dwelling sample into two subsamples for an exploratory factor analysis (EFA) (n=3,302) and a confirmatory factor analysis (CFA) (n=3,297). A weighted EFA resulted in both a single factor and a two-factor structure to measure well-being. However, weighted CFA results indicated the single factor structure is preferred ($\chi^2(44) = 530.811$; $p < .001$; CFI = .937; TLI = .921). Internal reliability of the single factor structure was acceptable at .74, and was significantly and negatively associated with symptoms of depression and anxiety ($r = -.47$; $p<.01$). Findings highlight that researchers and practitioners should be aware that assessing both constructs of well-being is crucial to understanding well-being in later life. Implications for future research using the NHATS, as well as research using other data sources and focusing on other vulnerable populations, will be discussed.

365. Using Independence at Home [IAH] Criteria to Target VA Home Based Primary Care, *Bruce Kinosian, Philadelphia VA Medical Center Geriatric and Extended Care Data Analysis Center; Orna Intrator, Canandaigua VAMC; Rajesh Makineni, Providence VAMC; Thomas Edes, Department of Veterans Affairs*
Objectives: 1) Determine the size of the enrolled veteran population that meets IAH criteria (IAH-Q); 2) Determine the clinical course of those who are IAH-Q;; 3) Determine access to HBPC services of the IAH-Q veteran population
Abstract Body: Background: The Independence at Home demonstration tests a shared savings, inter-professional team model to deliver primary care in the home within Medicare. We applied IAH qualifying criteria (IAH-Q) to the enrolled veteran population to determine the unmet need for home-centered primary care. All 139 VA medical centers operate HBPC programs. Methods: We assembled complete Medicare, Medicaid, and VA utilization and cost files for all enrolled veterans from 2008-2010. We implemented IAH-Q as follows: 1) hospitalization and post acute care in prior year (composite claims files); 2) 2 or more ADLs (use of JEN frailty index>7); and 3) 2 or more chronic conditions (using the Chronic Condition Warehouse conditions). Diagnoses from 2008 were used to identify IAH-Q for FY 2009, who were then followed through the year using the Residential History File. Results: IAH-Q enrolled veterans are frail, with a 31% mortality in the qualifying year (2008). Among 96,129 IAH-Q enrolled veterans at the start of F2009, 64,713 survive, of whom 11% are institutionalized, while among the subset of 55,221 VA users, 38,522 survive, with 11% institutionalized and 9% (range 2-16% by VISN [VA region]) receiving HBPC. Among enrolled veterans, 59% of terminal VA users received hospice services, compared to 32% of non-users . Medicare and Medicaid covered 49% of total annual costs [$41-$72,000 by VISN] for IAH-Q VA users. Conclusion: IAH criteria identify a frail, high cost population with high mortality. Despite a extensive coverage, a substantial share of the IAH-Q veterans are not reached by home based primary care.

366. Buffering or Juggling? Mediation Effects of Working on Caregivers' Depression, *Yeonjung Lee, University of Calgary; William Gallo, City University of New York*
Objectives: After attending this session, participants will be able to…identify the mediating effects of working on caregivers' depression.; After attending this session, participants will be able to…discuss the role enhancement and role strain perspectives in the relationship between caregiving and working.;
Abstract Body: Previous literature on the relationship between informal caregiving and caregiver well-being has indicated adverse effects across multiple health domains. Little attention has focused on the pathways through which caregiving affects health. Our research analyzes the mediating function of employment in this relationship. There exist theoretical arguments to support employment's position as both positive and negative mediator. The role enhancement perspective purports that employment buffers the stress of caregiving demands by providing a respite and links to psychosocial coping resources, which suggests that employed caregivers would report better health than those not working. Alternatively, the role strain perspective posits that work exacerbates stress by creating a caregiver identity with two significant roles, which would lead to lower well-being among employed caregivers. Using the 2006 wave of Health and Retirement Study, this study applies structural equation modeling (SEM) to test the mediating effect of working on the relationship between informal parental caregiving and depressive symptoms among older US adults. Our results suggest that although parental care has a negative effect on working, labor force participation among caregivers decreases levels of depression. The total effect of caregiving on depression is significant (B= 0.39), as is the direct effect (B= 0.31), although the strength of the association between caregiving and depression is weaker, suggesting that employment partially mediates the caregiving-depression association. The findings support the role enhancement perspective, and thus support policies to maintain employment.

367. Predictors of Variation in the Depression Trajectories of Korean Middle and Older Adults during the Transition into Chronic Patients: A Growth Mixture Modeling, *Eunjee Lee, Yonsei University; Heyjung Jun, Yonsei University*
Objectives: After attending this session, participants will be able to understand the variation in the depression trajectories during the transition to chronic patient of middle and older adults over time.; After attending this session, participants will be able to discuss the risk factors of variation in trajectories of depressive symptoms.
Abstract Body: This study was conducted to identify different trajectories of depressive symptoms during the transition to patients with chronic diseases and to test the association of several predictors with these variations. Four waves of Korean Longitudinal Study of Ageing (KLoSA) were used for analyses, and demographic and clinical characteristics and social and family relationships were included as predictors on the basis of previous studies. Using growth mixture modeling (GMM) and multi-nominal logistic regression with Mplus 5.21, 433 Korean middle and older adults (aged 45 and over) who experienced the transition between 1st and 2nd waves, which means that individuals were healthy at Time 1 and had one or more chronic diseases at Time 2 to 4, were examined. GMM results indicate that three distinct depression trajectory classes were specified: decreasing (17.2%), stable (61%), and increasing then decreasing (21.8%) depressive symptoms over time. In multi-nominal logistic regression, lower level of cognitive function, higher perceived limitation of activities, lower frequency of social contact and lower quality of family relationship distinguished the increasing then decreasing class from other trajectories; higher level of cognitive functioning and higher quality of family relationship differentiated the decreasing trajectory from stable class. These findings allow for improved identification of chronic patients at risk for depression

trajectories and for development of interventions. It is highly recommended to develop the Interventions tailored to individuals who experienced transition into chronic patients and also have factors related to riskier depression patterns.

368. Factors Associated with Volunteer Participation among Racially and Ethnically Diverse Older Adults, *Seungah Lee, University of Massachusetts Boston; Kimberly Johnson, Indiana University*

Objectives: Gain knowledge about the prevalence of volunteering among racially/ethnically diverse older adults.; Acquire an understanding of factors associated with volunteerism among Asian, Black, and Hispanic older adults and the similarities and differences in comparison to White non-Hispanic adults.

Abstract Body: Volunteer participation is related to human and social capital. However, much of the empirical evidence is based on homogeneous samples. This study seeks to investigate factors associated with volunteerism in a diverse population. Using data from the 2011-2012 California Health Interview Survey, we investigate volunteer participation and correlates with volunteering among White, Asian, Black, and Hispanic adults 50 and older (n = 27,300). Results from logistic regression indicate the odds of volunteering are lower for Asians (OR = .46, p < .01) and Hispanics (OR = .48, p < .01) compared with Whites. Additional analysis shows interesting differences and similarities between the racial/ethnic groups. Across all groups the odds of volunteering are significantly higher for those with more than a high school education. Having good self-rated health is related to volunteering for all groups except Asians. The odds of volunteering are higher for nonsmokers and exercisers, but only among Whites. Compared to moderate alcohol consumption, nondrinking is related to lower volunteer participation only for Hispanics and Whites. While the odds of volunteering are higher for married Whites and for Whites who report being in a safe neighborhood, neither social factor is related to volunteering among Hispanics, Blacks, or Asians. Having children in the household is associated with volunteering among Whites and Blacks, but not among Hispanics and Asians. The findings suggest different social/cultural factors are associated with volunteerism among ethnically and racially diverse adults. Additional research is needed to determine ways communities can increase inclusive volunteer opportunities for minority elders.

369. A First Assessment of the ACA: Changes in Health Insurance Coverage and Affordability among Adults Age 50-64, *Zoya Gubernskaya, University at Albany, SUNY; Judith Treas, University of California, Irvine*

Objectives: To evaluate 2011-13 changes in health insurance coverage for adults age 50-64.; To gauge 2011-13 changes in affordability of health insurance for adults age 50-64.; To assess 2011-13 differences in coverage and affordability by nativity among adults age 50-64.

Abstract Body: The major goal of the 2010 Affordable Care Act (ACA) was to make health insurance affordable. We take advantage of the new data from the 2011-2013 National Health Interview Survey to look at changes in health insurance coverage and affordability for adults age 50-64. The risk of being uninsured higher during the pre-retirement years as some adults in this age group begin experiencing health decline and/or switch to part-time employment, but they are still ineligible for Medicare. We calculate weighted percentages and construct logistic regression models, paying special attention to differences by nativity. Although higher among the foreign-born (26% vs. 12%), the percent of uninsured adults age 50-64 remained stable over the 3 years. However, public health insurance usage increased slightly, primarily among the native-born (from 7.9% to 9.6%). Fewer adults age 50-64 evaluated their health insurance as “worse” compared to the previous year in 2013 than in 2011 (19.7% vs. 16.2%). Native-born were more likely to attempt to purchase insurance directly than the foreign-born (9.6% vs. 8.5%). Slightly over a half of those who tried to purchase insurance directly did, and this percent increased among the foreign-born (from 47% in 2011 to 52% in 2013). While it is more difficult to find affordable than appropriate insurance,the percent finding it “very difficult” decreased for both measures.Still, among those who tried but did not purchase health insurance the main reason was the cost(74%) followed by preexisting conditions(13%) and being turned down (11.2%).

370. What's Age Got To Do With It?: Subjective Experiences of Multiple Sclerosis, *Kyle Carr, Boston College; Renee Beard, College of the Holy Cross*

Objectives: Inform practice about the implications of MS on aging experiences; Inform policy about the implications of MS on aging experiences and aging in place; Apply social gerontology to the study of MS

Abstract Body: Multiple Sclerosis (MS) is a chronic illness impacting millions of people worldwide at a time of life that many would consider their prime years and severely impacts their aging experiences. Yet, compared to many chronic illnesses, MS continues to be overlooked by leading health organizations like the World Health Organization and Centers for Disease Control, which results in limited funding, research, media attention and, thus, public awareness. Semi-structured, in-person interviews with 17 individuals diagnosed with MS were conducted. Grounded theory techniques were utilized to collect, code, and analyze textual data. Among these unique illness narratives, a number of common themes were discovered. Core findings included the importance of early diagnosis, the role of the internet and social media on MSers ability to be proactive in the fight against MS, and the strategies used to overcome the symptoms and stigma associated with MS. The social construction of MS in the media and medical arenas as well as core sociological variables such as age and gender also shaped illness experiences in meaningful ways. It is important to understand the experiences of people with MS in order to support them in their aging experiences and to foster aging in place. This information can be used to improve both the biomedical approach to MS and the social policies aimed to support those with the condition.

308. Methodological Considerations in Conducting Cross-Cultural Qualitative Research: Reflections from Previous Studies in Three Asian Countries, *Hannah Stohry, Indiana University School of Social Work, Indianapolis, IN; Karel Kalaw, Department of Sociology and Gerontology, Miami University, Oxford, OH.; Jaylene (Jiayin) Liang, Centre for Research and Expertise in Social Gerontology (CREGÉS), Concordia University, Montreal, Canada*

Objectives: 1. Possession of a culturally sensitive lens, a heightening cultural awareness, and thus, understanding certain social phenomena.; 2. A call for a global understanding of social realities across societies.; 3. Preparing emerging young qualitative scholars and researchers.

Abstract Body: Although globalization has been a buzzword since the 1990s and its prevalence is growing across disciplines, the awareness of bringing cross-cultural perspectives to the field of social gerontology is still minimal. As young scholars, the three of us have adopted phenomenology (10 informants in 2009), grounded-theory approach (20 informants in 2011), case study (5 informants in 2011), and indigenous methodology (26 informants in 2013) in exploration of the lives of older Chinese, Korean and Filipinos in the past few years. The purposes of this collaborative presentation are: to reflect on our qualitative research experiences in cross-cultural settings, to disseminate the lessons learned, to identify some similarities and differences, and to empower and communicate with other scholars who share common research interests. We demonstrate and explain how such studies inform the field and fill the literature gap, empower marginalized groups, challenge dominant paradigms and models and thus contribute to theory construction, and substantiate/complement quantitative research. For example, in terms of good old age, we find that these older Asians' experiences cannot be understood and explained by the Western concepts such as "active aging" and "independence." Meanwhile, we discuss challenges such as the appropriateness of available methodological approaches to be applied in culturally-sensitive research; the potential problem of translation cost throughout the process; and the use of indigenous knowledge and concepts to understand relevant social phenomena as experienced by older adults. Thus, these endeavors contribute to cross-cultural gerontological research and communication and promote culturally-fit research protocols.

309. Negative Social Interactions and Perceived Stress Levels in Older Persons Aging with HIV/AIDS, *Moka Yoo, Nell Hodgson Woodruff School of Nursing, Emory University; Marcia Holstad, Nell Hodgson Woodruff School of Nursing; Drenna Waldrop-Valverde, Nell Hodgson Woodruff School of Nursing*

Objectives: To examine psychosocial contributors to perceived stress levels (PSL) in older persons aging with HIV/AIDS (age >50)

Abstract Body: Background: Various HIV-associated challenges may trigger stress responses in persons living with HIV/AIDS, which may negatively impact health outcomes. Older persons aging with HIV/AIDS (OPAH) may face similar challenges that may be escalated with aging. In order to examine contributors to perceived stress levels (PSL) in OPAH, this cross-sectional study assessed the relationships of psychosocial challenges such as negative social interactions (NSI), stigma, and living situation (i.e., living alone) to PSL in OPAH. Method: OPAH (n=213) who completed baseline visit in an ongoing larger study that examines the effects of health literacy on medication adherence in Atlanta, GA were analyzed. Dependent variable, PSL, was measured by the Perceived Stress Scale (PSS-10). NSI (assessed by Negative Social Interactions Scale), perceived HIV/AIDS-stigma (assessed by Internalized HIV/AIDS-Stigma Scale), race, and living alone were independent variables. Gender, sexual orientation, and age were included as covariates. Results: Sixty-three percent of OPAH were African Americans. 22% of OPAH showed high PSL (PSS-10>20) and 5% showed high NSI. All participants reported high levels of stigma. 54% reported living alone. Using multiple regression, NSI was significantly associated with PSL, adjusting for independent variables and covariates [$R2=0.22;F[1, 211]=59.49,p<0.0001$]. Other variables were not statistically significant. Conclusion: These findings suggest that even with high stigma, OPAH may not experience negative social relationships, which in turn may be associated with reduced stress levels. Future studies should investigate other risk and protective factors related to negative social interactions and characterize those who may possess high levels of stress.

310. Neuroticism and Response Time Inconsistency in Adulthood, *Elizabeth Munoz, Department of Human Development and Family Studies, The Pennsylvania State University; Robert S. Stawski, College of Public Health and Human Sciences, School of Social and Behavioral Health Sciences, Oregon State University; Stuart W. S. MacDonald, Department of Psychology and Center on Aging, University of Victoria; Joshua M. Smyth, Departments of Biobehavioral Health and Medicine, The Pennsylvania State University; Martin J. Sliwinski, Department of Human Development and Family Studies and Center for Healthy Aging, The Pennsylvania State University*

Objectives: After attending this session, participants will be introduced to a novel measurement of cognitive health; After attending this session, participants will be able to understand the connection between personality trait neuroticism and cognitive health as evidenced by response time inconsistency.

Abstract Body: Response time (RT) inconsistency is increasingly becoming recognized as an indicator of transient lapses of attention, cognitive health status and central nervous system integrity, as well as a potential early indicator of normal and pathological cognitive aging (Hultsch et al., 2008; MacDonald et al., 2006). Little research, however, has examined personality and psychosocial predictors of RT inconsistency. Neuroticism has emerged as an important predictor of aging-related cognitive decline, increased risk of mild cognitive impairment and Alzheimer's disease (Duchek, 2007; Wilson et al., 2005), and greater RT inconsistency among young adults (Robinson et al., 2006). The current study extended previous research by examining the relationship of neuroticism to RT inconsistency in adulthood and old age and, further, we tested negative affect (NA) and intrusive thoughts (IT) as potential mediators of this link. A sample of 317 adults (Mage= 49.44, SD=17.23, range: 19-83; 36% Black) completed self-reported measures of trait neuroticism, NA and IT, in addition to computerized RT-based processing speed tasks. Results from multiple regression analyses revealed that trait neuroticism predicted greater RT inconsistency (defined as greater trial-to-trial variability in RT) independent of average task performance, age, education, gender, race, and ethnicity (βs range: 0.001 to 0.074, ps<.05). NA partially mediated the neuroticism-RT inconsistency link (ps<.05), but IT did not. These results suggest that elevated neuroticism is a risk factor for increased RT inconsistency and negative affects plays an important role in explaining this association.

311. Nursing Student Learning in a Free Standing Course: Project Results, *Regina Phillips, Towson Univeristy; Elizabeth Crusse, Towson University; Michelle M. Kirwan, Towson University*

Objectives: As a result of this poster, attendees will be able to differentiate pre- and post test data about knowledge on an adapted version of the Facts on Aging Quiz; Attendees will be able to identify items on the Facts on Aging Quiz that were most often 'missed';

Abstract Body: Across the United States, nursing educators are being called on to better prepare nursing graduates to care for the growing numbers of older adults in the population. Gerontological nursing educators agree that pre-licensure nursing programs have an ongoing need for an increased quantity and quality of content about older adults. In addition, a variety of strategies have been identified in the literature to present this content, such as across several courses in the curriculum versus a focused, free-standing gerontological course. Yet few studies exist documenting the effectiveness of these strategies. In this baccalaureate nursing program, a free standing, senior level, nursing course was developed and implemented as part of a curricular change. In addition to student evaluations about their impressions of the course, an adapted version of Palmore's Facts on Aging quiz was used to measure knowledge about older adults at the beginning and the end of the class. Findings from this project will be presented and the next phase of this project identified.

312. Odor Recognition Memory and Alzheimer's Disease: The Role of Neurofibrillary Tangles in the Enthorinal Cortex, *Patricia Cintora, San Diego State University; Terrence Ellis, San Diego State University; Claire Murphy, Ph.D., San Diego State University & University of California, San Diego*

Objectives: To investigate the potential relationship between odor recognition memory and tangles in the enthorinal cortex of alzheimer's disease

Abstract Body: Research has demonstrated that the ability to remember odors deteriorates at a very early stage of Alzheimer's disease (AD). Supporting research has found that primary regions that process olfactory information become affected in the earliest stages of the disease. A critical region is the enthorinal cortex, one of the first areas to exhibit AD pathology, specifically, neurofibrillarly tangles (NFTs). It is speculated that NFTs in this region may hinder olfactory processing and encoding in the hippocampus. The current study examined whether there is a correlation with odor memory performance and number of neurofibrillary tangles in the enthorinal cortex of pathologically confirmed AD patients (n = 48). Odor memory performance was assessed via an odor recognition memory task subdivided into two components: odor familiarity and recollection. After ratings for stimuli familiarity were obtained, participants proceeded to a recollection task and attempted to identify previously presented and novel stimuli. This latter component tested participant's ability to recognize previously encountered odors from the familiarity phase. Preliminary results revealed a significant correlation between entorhinal neurofibrillary tangles and false recognition of odors. Although preliminary, the data provides support for the hypothesis that impaired olfactory processing may reflect neurodegeneration in the brain. Further research in this area is warranted as olfactory measures may potentially provide for low cost, non-invasive procedures for aiding in the diagnosis and understanding of AD. Supported by NIH grant RO1 #AG004085 and PO1 #IAG005131. We gratefully acknowledge Dr. Lawrence Hansen and the members and patients of the UCSD Alzheimer's Disease Research Center.

313. Older Adults' Perceptions of Memory Change Does Not Necessarily Signify Memory Loss, *Christopher Hertzog, Georgia Institute of Technology; Ann Pearman, Georgia Institute of Technology; Gizem Hülür, Humboldt University; Denis Gerstorf, Humboldt University; Rahel Eynan, Lawson Health Research Institute*

Objectives: Understand the possible geneses of subjective perceptions of memory change in the oldest old.; Learn the variables that do and do not predict subjective memory decline over time.;

Abstract Body: Older adult's perceptions of change in their memory performance has several possible origins, including accurate monitoring of changing memory ability, an age-related belief system about how much one's memory should change over time, and emotion-driven self-appraisals that covary with concurrent emotional states. A longitudinal study of the oldest-old, the Berlin Aging Study (BASE), provided data on predictors of subjective memory change in adults 70 and older. Given a focus on monitoring change in memory, we evaluated results for persons who had available data on memory for Times 1 and 3 through 3 (N = 182) and predicted T3 subjective memory change from other variables, including depressive symptoms, neuroticism, the PGC Morale Scale subscales, concurrent memory complaints, and subjective age. A structural regression model with subjective memory change at T3 as the outcome variable showed that perceived memory change was reliably correlated with several variables, including concurrent (T3) neuroticism, PGC Morale Scale subscale of Non-Agitation, current memory complaints, and subjective age. It was not predicted by concurrent levels of memory ability or prior change in memory ability (T3-T1), controlling on other predictors. The results support the view that subjective memory change does not reflect accurate memory monitoring but is instead more highly aligned with how the older adult's mood and emotional well-being at the time of testing, along with beliefs about one's own aging process. Researchers and clinicians who rely on subjective reports of memory change may be misled by older adults concerns and fears about impending memory loss.

314. Older Mothers Use of Technology to Maintain Contact with Adult Children, *Sangbo Nam, Iowa State University; Sangbo Nam, Iowa State University; Megan Gilligan, Iowa State University; Karl Pillemer, Cornell University; J. Jill Suitor, Purdue University*
Objectives: After attending this session participants will learn more about rates of older mothers' technology use to maintain contact with their adult children.; After attending this session participants will gain an understanding of predictors of older mothers' technology and also understand which factors may inhibit older mothers' technology use.;
Abstract Body: In the 1960's Litwak challenged Parson's assumption of the isolated nuclear family by introducing the concept of the "modified extended family" (Litwak, 1960; Parsons, 1943.) In particular, Litwak proposed that older parents would be able to overcome increased rates of geographic mobility by maintaining contact with adult offspring through technological improvements. In this research, we use data from the Within-Family Differences Study II (2008) to examine older mothers' (ages 73-85) use of modern technologies- including email, text message and instant message- to maintain contact with their adult children. Findings revealed a moderate amount of technology use among these older mothers. Approximately 30% of the 407 mothers used technology to maintain contact with at least one adult child. We also examined mother-level and adult-child level predictors of contact through the use of technology. Multilevel models revealed that mothers with higher levels of education and White mothers were more likely to use technology to maintain contact with their adult children. In contrast, mothers in poor health were less likely to use technology. Mothers were more likely to use technology to maintain contact with adult children who also had higher levels of education and lived at a greater distance. These findings indicate that although older mothers are utilizing technology to maintain contact with their adult children- this contact may be limited to a select group of individuals. Future research should consider the affordability and accessibility of technologies to older adults.

315. Perceived Age-Related Changes Mediate Resource Effects on Aging Satisfaction, *Daniela S. Jopp, University of Lausanne, Institute of Psychology; Yuyu Fan, Fordham University; Ying Liu, Fordham University; Marina Schmitt, Heidelberg University*
Objectives: To better understand what contributes to middle-aged and older individuals' satisfaction with their aging; To examine whether the roles of personal resources and age-related changes for aging satisfaction differ depending on age.;
Abstract Body: Individuals' satisfaction with their own aging is an important construct which was found to be related to health conditions and even mortality. As a consequence, it seems important to learn what contributes to aging satisfaction, however, the mechanisms involved are less clear to date. The present study investigated to what extent personal resources influence the experience of aging satisfaction, and to what extent their effect is mediated by perceptions of age-related resource changes. SEM analyses were conducted using a sample of 980 middle-aged and older individuals from the German ILSE Study. Personal resources included various indicators of health, cognition, and demographic characteristics, age-associated changes were assessed with the Nuremberg Self-Rating List and aging satisfaction was measured with the PGCMS Aging Satisfaction subscale. Findings supported the expected relationships, in that higher resources went along with lower perceived age-related change and higher aging satisfaction, and less age-related changes were associated with higher aging satisfaction. In addition, age-differential effects were found indicating that middle-aged individuals the direct effect of resources on aging satisfaction was much stronger than in the older adults, whereas the direct effect of age-related changes on aging satisfaction was stronger for the older adults. In sum, findings suggest an important role of resources as well as age-associated changes for the experience of aging satisfaction and that their importance may vary with age.

316. Personality Change Preceding Diagnosis of Dementia in the Oldest-Old., *Tomiko Yoneda, University of Victoria; Andrea Piccinin, University of Victoria; Boo Johansson, University of Gothenburg*
Objectives: To assess personality change prior to dementia diagnosis using self-report measures from longitudinal data. Understanding the connection between trajectories of change in personality and cognition is valuable for early identification of dementia
Abstract Body: Introduction: Although personality traits are mainly consistent through adulthood, considerable changes in personality can indicate underlying neurological disease (Lautenschlager & Forstl, 2007). Previous research using informant reports has shown that approximately half of people who develop dementia show substantial personality changes prior to diagnosis (Balsis et al, 2005). Objective: To assess personality change prior to dementia diagnosis using self-report

measures from longitudinal data. Understanding the connection between trajectories of change in personality and cognition is valuable for early identification of dementia.   Methods: The study used data from the Swedish OCTO-Twin Study, a longitudinal panel of 702 twins aged 80 and older. Among these, 408 individuals completed the Eysenck Personality Inventory at up to four occasions during a 6-year period. Analysis was restricted to 127 individuals who were cognitively healthy at the first measurement occasion and received a diagnosis of dementia during follow-up occasions. Latent growth curve analyses were run to examine the trajectory of personality change preceding dementia diagnosis.   Results: Controlling for age, sex and education, growth curve analyses revealed a linear increase in neuroticism and stability in extraversion. Individuals who converted to dementia showed a significant increase in neuroticism preceding diagnosis of dementia. Additionally, a significant relationship was identified between years of education and neuroticism: individuals with more education increased less in neuroticism preceding dementia diagnosis.   Conclusions: Personality change, specifically an increase in neuroticism, may be an early indicator of dementia. Higher levels of education may be protective against increase in neuroticism for individuals who develop dementia.

317. Pilot Testing of a Safe Sex Education Website for Divorced Older Women, *Lu Xing, Environment and Health Group; Xin Lu, Environment and Health Group; Paul Goulet, Massachusetts Department of Public Health; Hongtu Chen, Environment and Health Group; Sue Levkoff, Environment and Health Group; Patricia Weitzman, Environment and Health Group*

Objectives: The aim of this study is to develop and evaluate the usability and impact of a safe sex education website for culturally-diverse, divorced older women

Abstract Body: Background: HIV infections are increasing among older women, especially minority women, yet few interventions have been developed for this group. Concomitant with this phenomenon is a rise of gray divorce rates. Divorce is an independent risk factor for unsafe sex practices. With ten million older women divorced or separated and more women online, this is the first effort to develop and test a web-based safe sex intervention for divorced older women. Objective: The aim of this study is to develop and evaluate the usability and impact of a safe sex education website for culturally-diverse, divorced older women.   Methods: A pre-post testing approach was used, followed by brief focus groups. Twenty-seven women, age 50 and older, completed pre-tests, viewed the site for approximately 45 minutes, and completed post-tests. Approximately half viewed the website with text plus short videos of older women discussing safe sex experiences and half viewed the website with text only. Participants also discussed site impact and usability in focus groups. Primary hypothesis: Older women would demonstrate increased HIV knowledge and safe sex self-efficacy after viewing the site.   Results: Group 1 (n=18) viewed the website with only text. Group 2 (n=19) viewed the website with text and videos. In Group 1, the difference between pre-post-test HIV knowledge scores was not significant. Safe-sex self-efficacy scores were significantly improved (t = -1.75, P=.05). In Group 2, post-test HIV knowledge scores were significantly improved (t=-1.76, P=.05), while safe sex self-efficacy scores were marginally significant (t=-1.57, P=.07). Qualitative findings indicated videos were well-received, and more videos were desirable.   Conclusions: A web-based intervention can be effective in delivering safe sex education to culturally-diverse divorced older women. Videos adds interest and may increase educational effect.

318. Positive Aspects of Caregiving for an Aged Parent, *Kimberly Morton, BA, West Virginia University; Tara Rose, PhD, Alzheimer Disease Research Center, University of Southern California; Margaret Gatz, PhD, Professor, Department of Psychology, University of Southern California*

Objectives: After visiting the Positive Aspects of Caregiving for an Aged Parent poster presentation individuals will be able to discuss positive themes that the caregiver participants reported while they were caring for an aged parent

Abstract Body: Background: The purpose of the study was to examine positive aspects of caring for an aged parent. While there is research on caregiver burden for the middle generation, very little has been written about the positive aspects of caregiving and, what has been written, is more often about caregiver populations outside of the U.S., or in the clinical literature in the context of finding positive aspects to help relieve caregiver burden and stress. Method: Using the University of Southern California (USC) Longitudinal Study of Generations (LSOG), the current study analyzed interviews conducted at two time points with caregivers to older adults with a variety of physical and cognitive conditions, along with depression (CES-D) and caregiver burden (ZBI) scores. Qualitative data analysis was completed using Strauss and Corbin’s (1984; 1990) method of identify themes. Results: The study found several themes that described positive aspects of caregiving for an aged parent: (1) spending time together (2) care-recipient and caregiver closeness (3) familial closeness (4) caregiver and spousal closeness, and (5) care-recipient independence and improvement. Reporting positive aspects of caregiving was not associated with scoring either lower or higher on ZBI or CES-D. Implications: Integrating measures and questions about the positive aspects into studies of caregiving for an older parent is important for obtaining a more complete picture of the caregiving experience. Clinicians may consider focusing on the positive themes found in this study in an effort to balance the caregiver’s perspective.

319. Positive Versus Negative Priming of Older Adults’ Generative Value: Do Negative Messages Impair Memory?, *Elizabeth Hagood, Davis School of Gerontology, University of Southern California; Diana Wang, Davis School of Gerontology, University of Southern California; Mollie Grossman, Davis School of Gerontology, University of Southern*

California; Kezia Rusli, Division of Occupational Science and Occupational Therapy, University of Southern California; Ramy Rashad, Dornsife College of Letters, Arts and Sciences; University of Southern California; Shivanti Kariyawasam, Dornsife College of Letters, Arts and Sciences; University of Southern California; Tara Gruenewald, Davis School of Gerontology, University of Southern California

Objectives: After this presentation, attendees will understand that the experimental manipulation of older adults' perceptions of their generative social value is both feasible and effective.; After this presentation, attendees will understand that experimental exposure to negative messages regarding older adults' generative value appears to impair memory relative to exposure to positive messages regarding the same.

Abstract Body: Exposure to aging stereotypes has been shown to powerfully influence cognitive performance among older adults. The goal of the current investigation was to test whether such effects extend to stereotypes regarding older individuals' generative (contributory) social value in a substudy of the Recording Everyday Activities, Cognition, and Health (REACH) Study. Prior to the launch of the study, mock news articles were composed which contained portrayals of older individuals as either an asset (positive prime) or a burden (negative prime) to society. The effect of exposure to either the positive or negative prime was examined in a sample of 51 older adults (M = 68 years; R = 55-85 years), who were randomly assigned to read one of the two articles. Those exposed to the negative prime showed significantly poorer memory performance as assessed with a verbal recall task in comparison with those exposed to the positive prime (d = 0.63). After controlling for both baseline memory performance and for the sociodemographic covariates of age, sex, race, and education, the mean number of correctly recalled words in the positive priming group was 16.3, while those in the negative priming group recalled 13.0 words (B = 3.3; p = 0.005). These results indicate that negative messages regarding older adults' generative social value may impair memory relative to positive ones. The findings also point to the potential consequences of long-term exposure to such negative ideas and may indicate a need to promote more positive societal conceptualizations of older adults' generative worth.

320. Psychosocial and Economic Resources of African-American Centenarians: Findings from the Georgia Centenarian Study

Meneka Johnson, Iowa State University; Peter Martin, Iowa State University; Carolyn Cutrona, Iowa State University; Daniel Russell, Iowa State University; Megan Gilligan, Iowa State University; Thomas Schofield, Iowa State University; Leonard Poon, University of Georgia

Objectives: After attending this session participants will be able to identify the psychosocial and economic resources that contribute to optimal aging in African American centenarians.; After attending this session participants will be able to identify how age, gender, and cohort affect psychosocial and economic resources in African American centenarians.;

Abstract Body: This purpose of this study was to examine three types of resources (i.e., individual, financial, and social) in a sample of older African Americans in their 60s, 80s, and 100s to assess the level of resources they have available and choose to utilize. Using data from the Georgia Centenarian Study, a cross-sectional population-based interdisciplinary study of the oldest-old, participants included 127 African American older adults who were interviewed about their psychosocial and economic resources. Older African Americans reported high frequencies of varied resource types. Centenarians were significantly more likely than octogenarians and females were more likely than males to report the use of individual resources in the form of active coping. Centenarians also had have lower social resources than octogenarians. Age group and education were predictors of financial resources. Further gender, age or cohort differences were not present. Active coping resources and financial resources were associated with each other indicating potential for a bi-directional relationship. Despite their lifetime of disadvantages, African-American older adults are high on psychosocial and economic resources. However, the oldest old show significantly fewer resources that may have negative effects on their quality of life. These findings can be used to more readily identify older African American individuals who may be more susceptible to reduced levels of psychosocial resources without the need for clinical assessments. Program interventions can specifically target individuals to aid them in developing skills and/or resources that will assist them with the social, financial, and psychological transitions that older African-American may face.

321. Purpose and Cognitive Functioning from Middle to Older Adulthood

Nathan Lewis, Carleton University; Nicholas Turiano, West Virginia University; Brennan Payne, University of Illinois; Patrick Hill, Carleton University

Objectives: The first objective was to build upon existing research linking purpose in life to a diminished risk for cognitive issues, by examining its association with aspects of cognitive functioning.; The second objective was to test whether these relationships remained consistent across age groups.

Abstract Body: With Alzheimer's Disease (AD) and other dementias projected to increase in upcoming years, it is imperative that groups at-risk for such cognitive decline be identified. One emerging health indicator is an individual's sense of purpose in life. Purpose in life has been shown to predict susceptibility to Alzheimer's and related cognitive disorders, but its effects on cognitive functioning more broadly have yet to be examined. This study sought to examine the impact of purpose on memory and executive functioning aspects of cognition. Participants (n = 3605, Mage = 56.3 years, SD = 12.29, Range = 32 to 84 years) were selected from the Midlife in the United States (MIDUS) longitudinal study. Purpose in life was associated with higher scores for memory (r = .17) and executive functioning (r = .24). Bootstrapping analyses were used to test purpose by age interactions, to investigate whether these relationships differed across adulthood. No significant age

moderation was found for purpose and memory (t = 1.77, p = .08), or for purpose and executive functioning (t = 0.48, p = .63). These findings add to the growing body of research linking purpose to cognitive health later in life by demonstrating the linkages between purpose and different aspects of cognitive functioning, a relationship that does not appear to differ substantially by age group. Future studies should attempt to explain why purpose is associated with greater cognitive functioning, and explore the potential for purpose interventions to promote healthy cognitive aging.

322. Remains of the Day: Stress Residue and Daily Co-Occurrence of Affect in Older Adults, *Jennifer Ramsey, North Carolina State University; Shevaun Neupert, North Carolina State University; Daniel K. Mroczek, Weinberg College of Arts & Sciences and Feinberg School of Medicine Northwestern University; Avron Spiro, III, VA Boston Healthcare System and Boston University School of Public Health*

Objectives: This study examines the effects of stress residue and daily co-occurrence of affect on stress reactivity in older adults. A lag model was employed to examine these effects two days subsequent to the original stressor reported

Abstract Body: Increased emotional complexity, operationalized as daily co-occurrence of affect, is related to reduced stress in older adults. Older age is associated with a greater likelihood of co-occurrence. Additionally, stress residue from one day to the next may differentially impact an individual's ability to respond adaptively to lingering stress in the absence of the original stressor. This study examined the relationship between daily co-occurrence of affect, stress residue, and negative affect in 333 participants (60-89 years) responding to a daily diary study of the VA Normative Aging Study. Co-occurrence was calculated as each participant's intraindividual correlation between positive and negative affect over the 8 days. Stress residue is "lingering" stress that remains on days subsequent to the original stressor. Stress and stress residue were entered as level 1 predictors and within-person negative affect as the outcome variable. Age and co-occurrence were level 2 variables. Lagged multi-level models revealed a main effect of stress on negative affect two days from the original stressor. We found a level 1 x level 2 (stress residue x co-occurrence) interaction only the day prior to the original stressor. Findings suggest that stress does remain up to two days after the original stressor was reported and that this stress residue has a prolonged impact on negative affect. Additionally, daily co-occurrence of affect may be an important buffering factor for older adults as the effect on negative affect is present prior to the occurrence of a stressor.

323. Residential Mobility is Associated with Worse Social and Health Outcomes in Midlife Adults, *Nicole Usher, Suffolk University; Cynthia Davis, Judge Baker Children's Center/Harvard Medical School; Sean McCormick, Suffolk University/Judge Baker Children's Center; Sarah Trifiletti, Judge Baker Children's Center; Ayelet Barkai, Cambridge Health Alliance/Harvard Medical School; Christos Mantzoros, Cambridge Health Alliance/Harvard Medical School; Judith Crowell, Stony Brook University/Judge Baker Children's Center*

Objectives: Examine adult residential mobility in relation to social and health functioning during midlife

Abstract Body: Research shows many child and adult outcomes related to childhood residential mobility (e.g., behavioral and emotional problems, poor midlife health). There is less known about adult residential mobility and its associations with adult physical/mental health. This study examines adult residential mobility in relation to social and health functioning during midlife. Eighty racially diverse midlife adults (35-55 years) of diverse SES completed two visits separated by 2 years. Twenty participants changed addresses during this time. Census data were used to calculate a neighborhood disadvantage index (i.e., percentages of families below poverty line, receiving public assistance, unemployed, and female-headed households). Neighborhood status was assessed via perceived relative standing in one's community on a 10-point status ladder. The Social Adjustment Scale assessed participants' overall social adjustment (domains: work, marital, social, economic, extended family, parental). The Block Food Frequency Questionnaire assessed participants' dietary quality. Body Mass Index (BMI) was obtained. We found no significant difference between neighborhood disadvantage scores between Visit 1 and Visit 2, suggesting participants did not move to better or worse neighborhoods. Residentially mobile participants had greater neighborhood disadvantage at both times points, reported lower perceived neighborhood status, and scored worse on social adjustment. They had higher BMIs and worse dietary quality. We found no differences between dietary quality at Visits 1 and 2, suggesting that residentially mobile participants have consistently poorer diets compared to those with stable addresses. Conclusions: Health indicators, such as poor diet and high BMI, represent another domain in which residentially mobile adults are vulnerable during midlife.

324. Resilience and Cardiovascular Disease Risk by Race/Ethnicity, *Ronica Rooks, University of Colorado Denver; Cassandra Ford, The University of Alabama; Kate Coleman-Minahan, University of Colorado Denver; Patrick Krueger, University of Colorado Denver*

Objectives: To understand the relationship between resilience and CVD risk by race/ethnicity among middle-aged and older adults.; To understand the Reserve Capacity Model as a conceptual framework applied to racial and ethnic, middle-aged and older adults.

Abstract Body: Objective: We used the Reserve Capacity Model as a framework for examining the relationship between resilience (i.e., the ability to overcome adversity), race/ethnicity, and cardiovascular disease (CVD) risk, with health behaviors, socioeconomic status, and physical health mediators. We hypothesized that (a) resilience will be inversely related to CVD risk factors, and (b) the inverse relationship between resilience and CVD risk will be stronger among Mexican-

Americans and non-Hispanic Blacks than non-Hispanic Whites. Methods: We tested our hypotheses with multivariate negative binomial and logistic regression models among adults aged 40-85 in the 2005-8 waves of the nationally-representative National Health and Nutrition Examination Survey (n=6,063). Resilience is measured as a series of physiological, social, and psychological variables. We measured CVD risk using clinically-measured triglycerides, total cholesterol, and hypertension. We tested for interactions between resilience and race/ethnicity related to CVD risk. Results: We found inverse relationships between resilience and triglycerides and hypertension in the base models, but in final models with all mediators no significant relationships existed. When resilience interacted with race/ethnicity in the relationship with CVD risk, resilience was more protective for Whites than for Blacks or Mexican-Americans. Conclusions: We contributed to the literature by using clinically-measured CVD risk factors in a diverse, nationally-representative sample of adults aged 40+, to better understand the relationship between resilience and CVD risk by race/ethnicity. We also broadened the dimensions of resilience adding to existing scale measures in the literature.

325. Role Captivity and Stress Over 12-months in New vs. Ongoing Caregivers to Hip Fracture Patients, *Cristan Smith, University of Maryland Baltimore County; Rasheeda Johnson, University of Maryland Baltimore; Erik Barr, University of Maryland Baltimore; Lynn Lewis, University of Maryland Baltimore; Alan Rathbun, University of Maryland Baltimore; Lisa Fredman, University of Maryland Baltimore; Denise Orwig, University of Maryland Baltimore*

Objectives: To compare new and ongoing hip fracture caregivers, as well as their feelings of role captivity, on the impact of Perceived Stress Scale (PSS) scores over 12-months post-fracture

Abstract Body: Hip fracture is an acute event, requiring some people to assume the role of caregiver unexpectedly. These new caregivers may differ from those who had been providing care prior to the event (ongoing caregivers) on perceived stress and reactions to caregiving. This study compared new and ongoing caregivers on their feelings of role captivity and the impact on Perceived Stress Scale (PSS) scores over 12-months post-fracture. Hip fracture patients and their caregivers (n=145 dyads) were assessed at the time of fracture (baseline) and 12 months later. One-third of the caregivers (n=45) were new caregivers at baseline. New caregivers were significantly (p<0.01) more likely to be the patient's spouse (94% vs. 39%), male (67% vs. 41%) and older (mean age 76 vs. 71). At baseline, ongoing caregivers reported significantly more role captivity (3.11 vs. 1.53, p<0.01), but not higher PSS (20.4 vs. 17.8 p=0.12). Longitudinal mixed effects models showed that PSS decreased at a similar rate for new and ongoing caregivers over time; after adjusting for baseline sociodemographic factors, comorbidities, depression, and caregiver status at follow-up, baseline caregiver status was not significant. When analyzed according to sample-based tertiles of role captivity at baseline, change in PSS between baseline and follow-up was -0.65, +0.08 and -3.12, respectively; these associations were significantly different between the second and third tertiles (p=0.02), but not between the first and third tertiles (p=0.12). In summary, feelings of role captivity may be more important than prior caregiving experience in associations with PSS over time in hip fracture caregivers.

326. Safe Mobility for Older Adults in Acute Care Settings: Simulation Training for Interprofessional Providers, *Angela Rothrock, University of Alabama at Birmingham; Donna Bearden, University of Alabama at Birmingham; Emily Simmons, University of Alabama at Birmingham; Patricia Sawyer, University of Alabama at Birmingham; Cynthia Brown, University of Alabama at Birmingham; Kellie Flood, University of Alabama at Birmingham*

Objectives: Describe an evidence-based practice program focused on simulation training for safe mobility of older patients in an acute care setting; Describe the process of coordinating unit staff and resources to deliver an educational program during clinical service.

Abstract Body: Simulation has long been used in formal healthcare career training programs. However, simulation is not routinely utilized for continuing education in clinical practice. The UAB Geriatric Education Center implemented a two-part "Safe Mobility" evidence-based practice program in the acute care setting. Part one included a 30-minute didactic orientation, delivered during the clinical unit monthly staff meeting. Part two included mandatory participation in a half-hour simulation session, repeated 17 times over three days. The simulation focused on the interaction of an older patient and his daughter (both actors) who were resistant to staff efforts to get the patient out of bed. A team of clinical observers rated staff performance on a battery of environmental hazards and clinical behaviors related to safe mobility. Part one participants (N=42) had a mean age of 42 with 35% between the ages of 20-29; all were female with 45% African American and 52% Caucasian. The predominant discipline was nursing (75%); others were medicine and social work. The 36 participants who completed the simulation had similar demographics. Ninety percent of part two participants (N=28) reported that the simulation increased their confidence, that they strongly agreed they would be able to apply the principles learned, and that the experience was valuable. The majority of participants rated the program as good (16.7%), very good (22.2%), or excellent (61.1%). The presentation will include details regarding the process of case development and implementation, the simulation sessions, and the process of observation, debriefing, and evaluation.

327. Satisfaction with Aging and Overnight Hospitalization in the US Population over Age 50, *Jennifer Sun, Medical Scientist Training Program, University of Michigan Medical School, Ann Arbor, MI; Department of Psychology, University of Michigan, Ann Arbor, MI; Eric Kim, Department of Psychology, University of Michigan, Ann Arbor, MI; Jacqui Smith,*

Department of Psychology, University of Michigan, Ann Arbor, MI; Institute for Social Research, University of Michigan, Ann Arbor, MI

Objectives: To determine the association between aging satisfaction and overnight hospitalizations among the US population over age 50; To propose aging satisfaction as a modifiable construct amenable to intervention; To describe the potential role of physicians and health care providers in increasing aging satisfaction

Abstract Body: Older adults account over half of hospital stays, but little is known about the impact of psychosocial factors on hospitalization rate among this rapidly growing segment of the population. The present study uses data from the Health and Retirement Study, a nationally representative panel study of community-dwelling adults over the age of 50 in the United States, to determine the association between aging satisfaction and the number overnight hospitalizations from 2008-2012. Over the four-year follow-up, 43.93% of the 4,735 respondents in our sample were hospitalized overnight at least once. The number of hospitalizations ranged from 0 to 76, with an average of 1.10 over four years. In the fully adjusted model (sociodemographics + baseline health + health behaviors), one standard deviation increase in aging satisfaction was associated with 11% fewer overnight hospitalizations over follow-up (RR = 0.89, 95% confidence interval [CI] = 0.83–0.95, p = .001). The association remained after adjusting for the number of previous hospitalizations over the previous four years. After dividing respondents into quartiles based on level of aging satisfaction, the results of our analyses suggested a dose-response relationship in the core model (compared to low, low-moderate: RR = 0.67, 95% confidence interval [CI] = 0.57–0.79, p <.001; moderate-high: RR = 0.64, 95% confidence interval [CI] = 0.52–0.80, p <.001; high: RR = 0.45, 95% confidence interval [CI] = 0.37–0.55, p <.001). Aging satisfaction is a modifiable construct that could be targeted to decrease the rate of hospitalizations among older adults.

328. Satisfaction with Aging and Use of Preventive Health Services, *Eric Kim, University of Michigan; Armani Hawes, University of Michigan; Hannah Giasson, University of Michigan; Jacqui Smith, University of Michigan*

Objectives: Attendees will learn about how satisfaction with aging is longitudinally associated with use of flu shots, cholesterol tests, mammogram/x-ray, pap smears, and prostate exams

Abstract Body: Objective: The Brookings Institution estimates that in 2007, only 4% of the $1.7 trillion spent on national health expenditures was for prevention. Less than 30% of adults aged 50-64 and less than 50% of adults over age 65 are up-to-date with core preventive services. A central challenge is to identify factors that may increase the likelihood of using preventive health care services. This need is particularly critical in the current climate, given that increased access to preventive care has become available with the Affordable Care Act. We hypothesized that aging satisfaction would be associated with increased preventive health service use four years later. Method: We conducted multiple logistic regression analyses on a sample of 6,177 people from the Health and Retirement Study, a nationally representative study of U.S. adults aged 50+ (M age = 70.6; women n = 3648; men n = 2528). Results: In adjusted models aging satisfaction was not associated with obtaining flu shots. However, each standard deviation increase in aging satisfaction was associated with higher odds of obtaining cholesterol tests (OR = 1.10, 95% CI = 1.00–1.20)). Further, women with higher aging satisfaction were more likely to obtain a mammogram/x-ray (OR = 1.17, 95% CI = 1.06–1.29)) or pap smear (OR = 1.10, 95% CI = 1.00–1.21)). Among men, the odds of obtaining a prostate exam increased with higher aging satisfaction (OR = 1.20 95% CI = 1.09–1.34)). Conclusion: Aging satisfaction is potentially relevant and important for preventive service use after age 50.

329. Seriousness of older suicide in South Korea: How society responds, *Bum Jung Kim, University of Hawaii at Manoa*

Objectives: To examine factors that influence suicide among older adults in South Korea at micro, mezzo, and macro levels; To inform policymakers, community leaders, and scholars about the importance of understanding suicide risk factors and developing preventive strategies to minimize the older suicide rate.

Abstract Body: Suicide is a significant problem in South Korea, which has the highest suicide rate among OECD countries. A poignant statistic, the suicide rate among older adults (65+) in South Korea is not only higher than all other age groups within South Korea, but also globally. What's more, suicide in South Korean older adults is rapidly increasing, and has consequently resulted in substantial damage to society such as family bankruptcy, increase in social expenditure, and a mistakenly negative image of the nation. Previous studies examined individual risks and relevant personal factors of older adult suicide in South Korea, but few studies have conducted comprehensive examination of risk factors at both micro and macro levels of older adult suicide, nor preventive strategies at individual, community, and national levels. This study has two aims: (1) To examine factors that influence suicide among older adults in South Korea at micro, mezzo, and macro levels, and (2) To inform policymakers, community leaders, and scholars about the importance of understanding suicide risk factors and developing preventive strategies to minimize the older suicide rate. The study will first, provide background information about the importance of studying older adult suicide in South Korea and define suicide and theories of suicide. Second, the study will examine the risks of suicide at the personal and societal levels, including key factors related to older adult suicide. Finally, current policies will be investigated—5 year suicide prevention plan, facilities, and infrastructures–and implications of suicide prevention for older adults in South Korea will be provided.

330. Sleep Disruption due to Caregiving in Women Veterans is Associated with Worse Mental Health Condition and Impaired Daily life, *Yeonsu Song, Geriatric Research, Education, and Clinical Center, VA Greater Los Angeles Healthcare*

System; Joseph Dzierzewski, VA Greater Los Angeles Healthcare System, Geriatric Research, Education, and Clinical Center, CA; Constance H. Fung, VA Greater Los Angeles Healthcare System, Geriatric Research, Education, and Clinical Center, CA; Juan C. Rodriguez, VA Greater Los Angeles Healthcare System, Geriatric Research, Education, and Clinical Center; Stella Jouldjian, VA Greater Los Angeles Healthcare System, Geriatric Research, Education, and Clinical Center, CA; Cathy A. Alessi, VA Greater Los Angeles Healthcare System, Geriatric Research, Education, and Clinical Center, CA; Jennifer L. Martin, VA Greater Los Angeles Healthcare System, Geriatric Research, Education, and Clinical Center, CA

Objectives: To learn relationships between sleep disruption due to caregiving and mental health in women veteran caregivers.; To learn relationships between sleep disruption due to caregiving and daytime impairment.; To learn if there is age difference in sleep disruption by different types of caregiving.

Abstract Body: Despite significant negative effect of poor sleep in caregivers on their health and well-being, information on the relationship between poor sleep and health in women veteran caregivers is lacking. This cross-sectional, secondary data analysis from a large nation-wide postal survey of insomnia among women veterans examined whether poor sleep due to different types of caregiving was associated with mental health and daytime impairments. Mental health was measured using the Patient Health Questionnaire (PHQ)-4 and daytime functioning was measured with 11 questions addressing the insomnia-related impairments listed in the International Classification of Sleep Disorders-2. Among a total of 1,525 women veterans (mean age 52±15), 63 had trouble sleeping due to caring for adults (group1); 97 had trouble sleeping due to caring infants/children (group2); 1,365 had no trouble sleeping due to caregiving or were noncaregivers (group3). Caregivers in group 1 were significantly older than those in group 2 (age 54 vs. 36). In both age- and multivariate-adjusted models (i.e., age, race, marital status, employment status, comorbidity, physical activity, and subjective health status), caregivers in group1 had higher score of PHQ-4 ($p<0.05$) than those in group 2 (4.97 vs. 3.56) and group 3 (4.07). Caregivers in group 1 also had more daytime impairments (e.g., fatigue, sleepiness; $p<0.05$) than those in group 2 (8.23 vs. 6.83) and group 3 (7.34). Women veterans with sleep disruption due to caring for adults may have high risk for negative health outcomes. Further studies of older women veteran caregivers are needed to explore predictors of their poor sleep.

331. Sleep-Related Behavior Associated with Cognitive Functioning and Risk of Dementia, *Kathleen Bokenberger, Karolinska Institutet; Peter Ström, Karolinska Institutet; Anna K. Dahl, Institute of Gerontology, School of Health Sciences, Jönköping University; Anna L.V. Johansson, Karolinska Institutet; Nancy L. Pedersen, Karolinska Institutet; Torbjörn Åkerstedt, Karolinska Institutet*

Objectives: Understand the extent to which sleep-related behavior is associated with initial cognitive functioning in older adults.; Identify sleep-related factors associated with dementia risk.; Gain knowledge on the concept of deviating sleep patterns among the geriatric population.

Abstract Body: Background: There is a lack of research on sleep behavior prior to dementia onset while accounting for baseline cognitive status. Aim: To examine the cognitive effects of sleep behavior from a cross-sectional and longitudinal perspective. Methods: A prospective cohort study with up to 11,247 persons from the population-based Swedish Twin Registry who were at least 65 years of age and had self-reported sleep and cognitive functioning information from a telephone screening interview were followed up for a median of 11.3 years for incident dementia. Dementia ascertainment was obtained from the Swedish National Patient Register and Cause of Death Register. Ordinal logistic regression was performed for cross-sectional analyses and Poisson regression for longitudinal analyses. Results: Long sleep duration relative to moderate sleep length was associated with baseline cognitive status (OR=1.15, 95% CI=1.04-1.26) and incident dementia (RR=1.39, 95% CI=1.13-1.71), even after adjustments were made for age, follow-up time, sex and education. Compared to those who experienced premature awakening to a moderate extent, persons who responded that they “never” experienced premature awakening had an 11% greater odds of baseline cognitive dysfunction (95% CI=1.03-1.21) and 33% higher risk of dementia (95% CI=1.12-1.58). The absence versus moderate experience of repeated awakenings was related to a 23% higher dementia risk (95% CI=1.04-1.45). Conclusion: Long sleep duration and deviations in sleep patterns among older individuals is related to poorer baseline cognitive status and increased dementia risk. Characterizing sleep behavior prior to the presentation of symptoms associated with dementia may aid clinicians in identifying early stage dementia.

332. The Assessment of Pain Amongst Older Adults with Cognitive Impairment; Experiences of Healthcare Professionals, *N. Allcock, Glasgow Caledonian University; R. Docking, University of Greenwich; I. Gnass, Institute of Nursing Science and Practice; P. Schofield, University of Greenwich; E. Sirsch, University of Witten/Herdecke; C. Stewart, University of Witten/Herdecke; S. Zwakhalen, Maastricht University*

Objectives: The overall objective of this study is gain insight into experiences of health care professionals about the assessment of pain amongst older adults with cognitive impairment.; This study aims to identify care providers’ experiences of assessing pain in cognitively impaired older adults cognitively impaired older adults.; This study aims to identify challenges care workers face in the assessment of pain impaired older adults cognitively impaired older adults.

Abstract Body: Worldwide, an increasing number of pain assessment tools are available to assess pain in cognitively impaired non-verbal older adults. In daily clinical practise these tools are rarely used. A convenience sample of care workers was approached through nursing, geriatric care and professional organizations to complete an online SurveyMonkey questionnaire. This web based questionnaire was available in English, German and Dutch. Alongside socio-demographic data the survey contained open ended and multiple-choice questions about opinions on the usefulness and usability of existing tools to identify attitudes towards assessment tools and potential barriers to their implementation from a nursing perspective. The sample (n=810) consisted of 206 healthcare professionals working in hospital care (HC), 127 working in institutional long term care (ILTC) and 38 in primary care. Study findings showed that many health care professionals (41.8%; n=302) not use any standards/guidelines or local policies in their institutions. Only 34.1% (n=201) of the respondents used an observational pain assessment tool in their current practice. Although different pain scales were applied across countries, there was universal agreement about the ease of using the tools. However, applicability in daily practise is limited. Respondents reported that there is a need to know the patient and many professionals reported the difficulty of interpreting pain scores correctly. The results of this study will be used to inform the development of a pain assessment toolkit and improve the clinical utility for use amongst cognitively impaired (e.g. dementia) older adults, a European COST collaboration. Findings of this study will be used. Acknowledgement. The authors would like to acknowledge the contribution of the COST Action-td1005

333. Blood Metabolomic Markers Associated with Cognitive Performance During Aging: the Baltimore Longitudinal Study of Aging, *Brittany Simpson, Clinical and Translational Neuroscience Unit, National Institute on Aging, National Institute of Health; Kim Min, Kings College London; Seth Lirette, Center of Biostatistics and Bioinformatics, University of Mississippi Medical Center; B Gwen Windham, Department of Medicine, University of Mississippi Medical Center; Luigi Ferrucci, Clinical and Translational Neuroscience Unit, National Institute on Aging, National Institute of Health; Michael Griswold, Clinical and Translational Neuroscience Unit, National Institute on Aging, National Institute of Health; Cristina Legido-Quigley, Kings College London; Madhav Thambisetty, Clinical and Translational Neuroscience Unit, National Institute on Aging, National Institute of Health*

Objectives: To examine associations of plasma concentrations of PC 16:0/20:5, PC 16:0/22:6, and PC 18:0/22:6 with cognitive performance in non-demented older individuals.; To investigate whether plasma concentrations of these PCs predict future cognitive impairment.

Abstract Body: Purpose: We tested associations of plasma concentrations of [PC16:0/20:5; PC16:0/22:6; PC18:0/22:6] with cognitive performance in non-demented older individuals in the Baltimore Longitudinal Study of Aging neuroimaging substudy (BLSA-NI). Methods: Plasma PC concentrations[PC16:0/20:5; PC16:0/22:6; PC18:0/22:6] and cognitive performance [California Verbal Learning Test (CVLT), Trails A&B, and the Mini-Mental State Exam (MMSE)] were measured in BLSA-NI participants who were non-demented at baseline (n=126, age 49-89 yrs, follow-up over 7.7 years). Associations of PCs with cognitive decline were examined using mixed-effects linear regression. PC associations with conversion to AD/mild cognitive impairment (n=37) were examined using logistic regression. Models were adjusted for baseline age, sex, education, and APOE genotype. Results: Higher baseline PC concentrations were associated with better baseline memory (β with 95% confidence interval subscripts: CVLT total recall: PC16:0/20:5: 0.623.686.74 p=0.019, PC16:0/22:6: 0.843.125.39 p=0.007, and PC18:0/22:6: 0.632.845.06 p=0.012; CVLT Short Delay Recall: PC1620: 0.201.071.95 p=0.016, PC1622: 0.200.851.50 p=0.011, and PC1822: 0.180.811.44 p=0.012; CVLT Long Delay Recall: PC16:0/20:5: 0.261.111.96 p=0.010, PC16:0/22:6: 0.090.721.35 p=0.026 and PC18:0/22:6: 0.030.641.26 p=0.041). No associations were observed with Trails A&B or MMSE. There were no significant associations between PC concentrations and subsequent conversion to AD/MCI. Implications: Lower plasma concentrations of the candidate AD biomarkers, PC16:0/20:5, PC16:0/22:6 and PC18:0/22:6 are associated with poorer memory performance in non-demented older individuals. Altered levels of these metabolites may be an early feature of perturbed brain function during aging.

334. Aging with MCMV maintains TCR repertoire diversity in late life, *Megan Smithey, University of Arizona, College of Medicine; Vanessa Venturi, University of New South Wales; Miles Davenport, University of New South Wales; Janko Nikolich-Zugich, University of Arizona*

Objectives: Describe how lifelong persistent viral infections might impact the immune repertoire over a life time

Abstract Body: The human immune system is constantly challenged with acute, chronic and/or persistent pathogens. Cytomegalovirus (CMV) is ubiquitous, with seroprevalence between 45-100% worldwide. Lifelong interactions between CMV and the immune system lead to memory inflation of CMV-specific T cells, occupying up to 50% of the CD8 pool in aged humans. It has been proposed that memory T cell inflation comes at a price, with expanded CMV-specific cells impacting the maintenance of other T cells, exacerbating the age-related loss of T cell diversity. We previously showed further loss of antigen-specific precursors in aged mice that had experienced lifelong infection with murine CMV (MCMV), resulting in reduced effector function and bacterial clearance following Listeria challenge. Detailed analysis of the anti-Listeria TCRβ CDR3 repertoire of adult and old mice, and lifelong MCMV+ old mice found that CD8 effector T cells generated in old MCMV+ mice were populated by low copy number clonotypes expressing non-canonical TCR genes relative to adult and old MCMV- animals. These clonotypes showed loss of a conserved amino acid motif within their CDR3, and increased recognition of altered peptide ligands. Thus, lifelong MCMV infection appeared to increase the diversity of the CD8 T cell response to a new infection in late life, by recruitment of low avidity clonotypes with cross-reactive antigen recognition capacity. These results have profound implications for our understanding of naïve T cell maintenance over a lifespan, and suggest that our evolution with CMV may include surprising benefits to adaptive immunity in late life.

335. Increased Coagulation and Suppressed Generation of Activated Protein C in Aged Mice during Intra-Abdominal Sepsis, *Marlene Starr, University of Kentucky; Hitoshi Takahashi, University of Kentucky; Daiki Okamura, University of Kentucky; Amy Mrazek, University of Texas Medical Branch; B Mark Evers, University of Kentucky; Charles Esmon, University of Kentucky; Hiroshi Saito, University of Kentucky*

Objectives: After attending this activity, participants will be able to understand how an impaired anti-coagulant system in the aged may contribute to excessive coagulation and death during sepsis

Abstract Body: Sepsis is a life-threatening clinical condition which is particularly serious among the elderly who experience considerably higher mortality rates compared to younger patients. Using a sterile endotoxemia model, we previously reported age-dependent mortality in conjunction with enhanced coagulation and insufficient levels of anti-coagulant factor activated protein C (aPC). The purpose of the present study was to further investigate the mechanisms for age-dependent coagulation and aPC insufficiency during experimental sepsis. Intra-abdominal sepsis was induced by cecal ligation and puncture (CLP) using 21 or 16 gauge (G) needles (double-puncture) on young (4-6 months old) and aged (20-25 months old) male C57BL/6 mice. Compared to young, aged mice showed significantly increased mortality (92% vs 28%), systemic inflammation, and coagulation in the lung and kidney after 21G CLP. Young mice with more severe CLP (16G) showed a mortality rate and inflammation equivalent to aged mice with 21G CLP; however, enhanced coagulation and kidney dysfunction were significant only in the aged. In young mice, increased levels of aPC after CLP was coupled with reduced levels of PC suggesting the conversion of PC to aPC; however, PC and aPC levels remained unchanged in aged mice, indicating a lack of PC to aPC conversion. Activation of fibrinolysis, determined by plasma D-dimer levels, was similar regardless of age or CLP severity and plasminogen activator inhibitor-1 (PAI-1), an inhibitor of fibrinolysis, showed severity-dependent induction independent of age. These results suggest that enhanced coagulation in aged mice during sepsis is due to dysfunction of the PC activation mechanism.

336. Transcriptomic Profiles of Aging in Purified Human Immune Cells, *Jackson Taylor, Wake Forest Baptist Health; Lindsay Reynolds, Wake Forest Baptist Health; Jingzhong Ding, Wake Forest Baptist Health; Kurt Lohman, Wake Forest Baptist Health; Stephen Kritchevsky, Wake Forest Baptist Health; Ina Hoeschele, Wake Forest Baptist Health; David Herrington, Wake Forest Baptist Health; Yongmei Liu, Wake Forest Baptist Health*

Objectives: Understand the common patterns of age-associated transcriptional changes in human monocytes and T cells.; Understand monocyte-specific age-associated transcriptional changes in humans.

Abstract Body: Transcriptomic studies hold tremendous potential towards understanding the human aging process, yet previous work has been limited by small samples sizes and mixed cell types. In this study, transcriptomic profiles and methylomic profiles of CD14+ monocytes from 1,264 individuals (aged 55–94 years), and transcriptomic profiles of CD4+ T cells from a subset (423) of the population, were utilized to identify shared and cell-specific gene expression profiles associated with age, and to explore DNA methylation as a regulator of age-related gene expression. Association analysis in 423 monocyte and T cell samples identified 415 genes and 219 genes differentially expressed with age in monocytes and T cells, respectively (FDR<0.01), with 33 genes significant in both cell types. Protein synthesis machinery gene expression declined with age in both cell types, particularly mitochondrial ribosome genes. Increasing the monocyte sample size to 1,264, we observed a decline in autophagy, protein synthesis, and oxidative phosphorylation genes with age. Age-related differences in cis-methylation did not mediate the relationship between age and expression for the majority of genes in these age-related pathways. Overall, mitochondrial ribosome gene expression tended to decline with age in both monocytes and T cells; however, the monocyte transcriptome also included a decline in expression of genes involved in other key biological processes, oxidative phosphorylation and autophagy. These results reflect the complexity of biological aging and underscore the importance of functional genomic studies using purified cells.

337. Endothelial Health in Brain and Circulating Vascular Cell Adhesion Molecule-1: Association with Cerebral Blood Flow Dysregulation, Cerebral White Matter Damage, Mobility Impairment, and Injurious Falls in Older Adults, *Achille Tchalla, Beth Israel Deaconess Medical Center, Boston, Massachusetts,; Lewis Lipsitz, Beth Israel Deaconess Medical Center; Gregory Wellenius, Brown University; Farzaneh Sorond, Stroke Division, Brigham and Women's Hospital; Thomas Travison, Beth Israel Deaconess Medical Center; Thierry Dantoine, Beth Israel Deaconess Medical Center*

Objectives: sVCAM-1 high levels may be a marker of cerebral blood flow dysregulation due to endothelial damage from hypertension.; sVCAM-1 high levels may also signal the presence of cerebral microvascular disease and its clinical consequences, including slow gait speed and falls.

Abstract Body: BACKGROUND: Soluble vascular Cell adhesion molecule-1 (sVCAM-1) is elevated in hypertension, atherosclerosis, renal and cardiovascular disease, and is a presumed marker of endothelial dysfunction. Its relationships to abnormal cerebral endothelial function and the physiologic and clinical consequences of cerebral microvascular disease are unknown. METHODS: We studied the cross-sectional relationships between plasma sVCAM-1 levels and cerebrovascular variables, and its longitudinal relationship with falls in 680 community-dwelling participants in the MOBILIZE Boston Study who were aged 65 and older. Falls were recorded prospectively for one year on daily calendars. sVCAM-1 was measured by

ELISA assay and beat-to-beat blood flow velocity (BFV) in the middle cerebral artery during rest and in response to changes in end-tidal CO2 was measured by transcranial Doppler ultrasound. RESULTS:The mean sVCAM-1 concentration (±SD) was 1048.45 ± 26.03 ng/mL in normotensives, 1129.16 ± 20.21 ng/mL in controlled hypertensives and 1184.00 ± 32.82 ng/mL in uncontrolled hypertensives (p = 0.0080). sVCAM-1 was associated with resting BFV (P = 0.017) and BFV response to CO2 (vasomotor range, p = 0.0075). In a subset of subjects, sVCAM-1 was positively correlated with cerebral white matter hyperintensity volume (r = 0.47 (p=0.0176). Elevated sVCAM-1 levels were also associated with gait speed < 0.8 m/sec (OR = 3.01, 95 %CI (1.56 – 5.83), p = 0.0011), and odds of injurious falls (OR = 2.36, 95 %CI (1.35 – 4.15), p = 0.0028). CONCLUSIONS: Elevated plasma sVCAM-1 levels may be a marker of cerebral blood flow dysregulation due to endothelial damage from hypertension. It may also signal the presence of cerebral microvascular disease and its clinical consequences, including slow gait speed and falls.

338. Cognitive Assessment and Off-label Use of Antipsychotics: Challenges in Identifying At-Risk Nursing Home Residents, *Ryan Mace, Mansbach Health Tools, LLC *(Will be attending Suffolk University's Clinical Psychology PhD program this fall); Kristen Clark, Mansbach Health Tools, LLC; William Mansbach, Mansbach Health Tools, LLC; Isabella Firth, The Beacon Institute; Jacqueline Breeden, The Beacon Institute; , The Beacon Institute*

Objectives: To quantify the prevalence of off-label antipsychotic medication use for the behavioral and psychological symptoms of dementia in nursing home residents.; To determine whether moderately or severely demented nursing home residents are more or less likely to be prescribed antipsychotic medications than those with mild dementia.; To investigate the agreement between cognitive diagnoses posted on physician order sheets, based on various assessment methods, with cognitive levels identified by a validated objective brief cognitive test.

Abstract Body: The use of antipsychotic medications for behavioral disturbances in older adults with dementia is associated with increased lethality. Yet, off-label use of these drugs is frequent in US nursing home residents. To minimize health risks, methods for identifying residents with dementia should be improved. Nursing home residents (N = 231) prescribed antipsychotic medication from 17 Maryland skilled nursing facilities participated in this prospective study. Cognitive levels were reported by an objective screening tool (Brief Cognitive Assessment Tool; BCAT) and variable assessment methods (VAM) taken from physician order sheet diagnoses. Participants with dementia, and who did not have either schizophrenia or bipolar disorder, were identified as receiving off-label antipsychotics. The average BCAT score for this sample was 19.77 (SD = 14.27), which is within the range for moderate to severe dementia. Sixty percent were prescribed antipsychotic medication for off-label purposes based on VAM, and 66.8% based on BCAT scores. Of these participants, 80.1% had moderate-severe dementia and 19.9% had mild dementia based on BCAT scores. The identification of dementia differed significantly based on whether the VAM and BCAT method was used (p < .001). The two methods of assessment disagreed on 20.9% (n = 44) of the cognitive levels identified; moreover, the BCAT disagreed on 49.3% (n = 34) of the non-dementia identifications made by VAM. Off-label use of antipsychotics remains high, especially for severely demented residents. Because demented residents who are prescribed antipsychotics are at increased lethality risk, it is important to use objective cognitive assessment to accurately identify them.

339. Engaging Clinical Health Providers to Recruit Participants into a Chronic Disease Self-Management Program: Lessons Learned and Recommendations, *Christina Marsack, Wayne State University; Truemenda Green, 3National Association of County and City Health Officials; Idethia Harvey, University of Connecticut*

Objectives: To inform individuals of the Chronic Disease Self-Management Program and its outcomes.; To identify the results and lessons learned regarding the recruitment process for the Chronic Disease Self-Management Program.; To provide a model for the implementation of the Chronic Disease Self-Management Program.

Abstract Body: The National Association of County and City Health Officials (NACCHO) piloted the Stanford Chronic Disease Self-Management Program (CDSMP) (Lorig, et al., 1999) among 12 local health departments in the United States. NACCHO provided capacity-building assistance to support the logistics and resources used to plan, deliver, and sustain the six-week CDSMP, which was taught in a community setting. One of the five programmatic aims was to implement a clinical linkage component that involved recruiting and engaging clinical providers in the community to refer patients with a chronic illness to the local CDSMP. Data were obtained from key participant interviews and programmatic review. A process evaluation was conducted to assess NACCHO's ability to serve as a support system for LHD-delivered CDSMP and to assess LHDs' ability to implement the requirements of hosting the CDSMP. The evaluation demonstrated that NACCHO effectively supported the CDSMP for implementation by local health departments. The evaluation also identified components that may increase: 1) recruitment of clinical providers, 2) collaboration with local health departments, 3) promotion of and referrals to CDSMP, and 4) engagement with patients. Clinicians play an important role in increasing the effectiveness and success of the CDSMP in community settings.

340. Predictors of Benzodiazepine Use in Rural and Urban Older Adults, *Meghan Mattos, University of Pittsburgh School of Nursing; Steven Albert, University of Pittsburgh, Graduate School of Public Health; Susan Sereika, University of Pittsburgh School of Nursing and Graduate School of Public Health*

Objectives: Describe benzodiazepine use and distress in older, rural- and urban-dwelling adults.; Create discussion about predictors of benzodiazepine use and higher rates of benzodiazepine use in older, rural-dwelling adults compared to their urban counterparts.
Abstract Body: Benzodiazepine use in older adults is strongly discouraged, yet they are regularly prescribed benzodiazepines for treatment of insomnia and anxiety. Although there are high rates of illicit use in rural America, less is known about prescription use in older adults based on residence. This study examines predictors of prescribed benzodiazepine use in a sample of older Pennsylvanians. The sample consisted of older adults (N=419) enrolled in Pennsylvania's Healthy Steps for Older Adults program between 2010-2011 and participated in Pennsylvania's Pharmaceutical Assistance Contract for the Elderly. Predictors included sociodemographic variables and benzodiazepine use. Benzodiazepine use was confirmed by prescription pick-up; distress was measured by EuroQol-5D subscore for anxiety/depression, dichotomized as no distress/distress. Univariate and multivariate binary logistic regression and stratified contingency table analyses were performed. The sample was 79.0±6.3 years old, mostly female(88.5%), White(92.1%), high-school educated(58%), and of urban residence(85.9%). Rural adults had significantly higher benzodiazepine use(28.3%) versus urban adults(12.8%)(X2=9.691,p=.005). Older adults using benzodiazepines reported "no distress"(25.6%) significantly more than those not taking benzodiazepines(10.6%)(X2=15.501,p<.001). Regression analyses supported the association between rural residence and use(univariate OR=2.70,95%CI=[1.42,5.12];multivariate OR=2.99,95%CI=[1.46,5.82];ps<.05). Benzodiazepine use was associated with no distress (univariate OR=0.35,95%CI=[0.20,0.60];multivariate OR=0.33,95%CI=[0.19,0.58];ps<.05). Similar to illicit benzodiazepine use, older, rural adults had significantly higher prescribed benzodiazepine use compared to their urban counterparts. Older adults that reported taking benzodiazepines and no distress may indicate they are receiving the medication's therapeutic effects. Findings suggest that other factors may be relevant for benzodiazepine use in rural areas, such as prescribing differences based on less access to mental health services or specialists.

341. Wheelchair Art Quilts Increase Resident-to-Resident Socialization Among Older Adults with Dementia, *Ann Mayo, University of San Diego; Margaret Loomis, ArtsEtc; Janet Bernhard, ArtsEtc; Lynda Ozgur, ArtsEtc; Mary Ellen Dellefield, La Jolla Veterans Hospital; Jane Georges, La Jolla Veterans Hospital*
Objectives: Participants will be able to describe how an innovative art intervention research study improved resident-to-resident socialization among older adults with dementia.
Abstract Body: Background One third of all older adults with dementia spend their last years of life in skilled nursing facilities (SNFs). Advanced cognitive impairment and diminished senses leave the impression to many that these residents are no longer persons, contributing to their social isolation. Interventions to increase socialization are desperately needed. Methods This participatory action study tested the feasibility of using wheelchair art quilts (colorful, tactile, person-oriented quilts fitted over wheelchair backs made by volunteer textile artists) to increase socialization at the unit level (SNF secured unit housing 30 older adults with dementia). Forty-five minute group observations were conducted five times (one pre, four post) over 80 days using four trained observers placed in different locations on the unit. Socialization data was collected using an adapted version of the CARES Observational Tool, a checklist of socialization items (i. e., eye contact, use of name), as well as, observational notes. Measured at the group level, socialization behaviors were analyzed using descriptive statistics and observational notes were analyzed using thematic analysis. Results All 30 residents allowed quilts to be placed on their wheelchairs. There was a 58% increase in resident-to-resident socialization group mean scores. Thematic analyses revealed that residents complimented each other regarding their quilts and regarded the quilts as their personal property by the last observation period. Conclusions Wheelchair art quilts increased resident-to-resident socialization. While this feasibility study was an effective first step, more research needs to be conducted in additional SNFs to further test the effectiveness of the intervention.

342. LTPAC Nursing Assistants Connecting Resident Care and Technology: User Evaluation of Touch Screen Point-Of-Care, *Rebecc Meehan, Kent State University; ,*
Objectives: a.To document the end user's (nursing assistants) experience of a wall-mounted touch screen point of care (POC) system in a LTPAC setting.; a.To document the end user's (nursing assistants) experience of a wall-mounted touch screen point of care (POC) system in a LTPAC setting. b.To identify areas for improvement in the POC or processes around using the POC to optimize quality of care.
Abstract Body: The adoption rate of health information technology (HIT) among LTPAC facilities has been gradual, due in large part to lack of eligibility for federal financial incentives through the Health Information Technology for Economic and Clinical Health (HITECH) Act. Moreover, as revenue for LTPAC services decreases, facilities need to find ways to efficiently and accurately capture documentation of services to maximize their reimbursements. It is essential for LTPAC staff to have easy to use, efficient and effective technologies to support their role in providing quality care. This pilot study uses a qualitative method to examine the end user's (nursing assistants) experience of a newly implemented (within 6 months) wall mounted, touch screen point-of-care system in a LTPAC facility in the mid-western United States. Nursing assistants (n=26) reported satisfaction with the system, ease of use, and a more effective data capture experience than compared to using a paper chart. Frustrations included not being able to access the system if a computer 'froze' resulting in

potential data inaccuracies because of the lag time between care given and documentation of that care. Recommendations for improvements included more efficient screen parameters for data entry; ease of correcting errors; ergonomic concerns for reaching the screen and entering data. Additional recommendations included new filters for third shift (overnight) employees, to save data entry time based on the commonly used data fields at a time when residents were typically asleep. Implications regarding data privacy of screens (currently placed along common hallways) and quality of care are discussed.

344. ApoE-ε4 Genotype and Gait Cadence in Older Adults, *Kamiah Moss, University of Texas at Arlington; Olanrewaju Adumatioge, University of Texas at Arlington; Wyn Taylor, University of Texas at Arlington; Vale Shannon, Center for Healthy Living and Longevity; John Biggan, University of Texas at Arlington; Christopher Ray, University of Texas at Arlington*

Objectives: Discuss the relationship of ApoE-ε4 Genotype and gait cadence in older adults; Discuss ApoE-ε4 Genotype implications as a predictor of gait related disorders and as a potential diagnostic.

Abstract Body: Abnormal gait is prevalent in older adults, especially when the aging process may include diseases that affect their cognitive and physical abilities. Previous studies have taken the ApoE genotypes (especially ε4, which is linked to a higher risk of Alzheimer's) and evaluated gait speed decline in the elderly. Due to a lack of understanding between the relationships of genetic and gait components (temporal and spatial characteristics) in aging, cadence was taken as a factor of gait and assessed with the ε4 genotype. Cadence was chosen for its rhythmic element in assessing gait. We hypothesized that slower cadence patterns would be associated with one of three ApoE genotypes, particularly ε4. 49 older adults were tested for the alleles using buccal swabs and had their gait diagnostics evaluated using the GAITRite mat. TaqMan assays were designed for the ApoE polymorphisms and processed by quantitative PCR. An initial ANOVA determined all cadence scores to be statistically significant ($p<0.05$) among all subjects. The 2-way ANOVA showed lower cadence scores for elderly males than females for both carriers and non-carriers of ε4. A regression analysis was also performed that showed the variation of each genotype due to cadence values (0.02% for non-ε4 carriers 26.1% for ε4 carriers). Results suggested that elderly males were at a greater risk of abnormal or odd gait than the females. In addition, lower cadence scores due to the Apoe-ε4 genotype were a possible predictor of cognitive decline.

345. Functional Mobility as a Fall Risk Predictor in Active Nursing Home Residents, *Heidi Moyer, Angelo State University; S. Kyle Severe, Angelo State University; Jeff Gale, Angelo State University; Heather Braden, PT, MPT, GCS, PhD, Angelo State University*

Objectives: By the end of this presentation, the audience will be able to identify functional mobility measures that can accurately identify fall risk in the appropriate patients.; By the end of this presentation, the audience will be able to select a functional mobility outcome measure out of a list that is most appropriate for their patient.; By the end of this presentation, the audience will be able to identify the importance of fall risk assessment in relation to functional mobility outcome measures in elderly patients.

Abstract Body: Purpose: To assess factors related to fall risk in highly functioning, long term nursing home residents. Subjects: 18 nursing home residents, 60+ years old, who are able to ambulate 15 feet modified independent/independently, without past medical history of stroke or hospital discharge 6 weeks prior to testing. Methods: A single visit to the place of resident of the subject took place over the course of an hour. 8 outcome measures were recorded at this time: Mini-Mental Status Examination, Gait Speed, lower extremity manual muscle testing screen, ankle plantar flexion/Dorsiflexion range of motion, hand grip strength, Timed up and Go, Timed-5 Chair Sit-to-Stands, and assistive device assessment. Anthropomorphic data was gathered from the facility charts. These data included: age, height, BMI, gender, marital status, ethnicity, number of oral medicals, types of active diagnoses, and fall history. Data Analysis: SPSS version 21 was used to obtain Pearson's correlations and significance levels. Results: Significant correlations with falls include: Modified sit to stand time (.585), TUG time (.475), gait speed (.457), right dorsiflexion ROM(-.436) , and right dorsiflexion strength (-.504). Conclusions: Standard functional mobility tests including the tug, and gait speed tests were verified in their connection to fall risk. A modified sit to stand was also found to be connected to fall risk as well as dorsiflexion strength and range of motion, but only in the right ankle. Systolic blood pressure was also a surprising connection that will need to be looked at in more detail.

346. Web-based Teaching Strategies to Minimize Wrong Attribution of Medication Side-Effects, *Debra Newell, Soulutions Consulting; John Carlson, Baylor/Scott & White*

Objectives: Participants will identify medication side effects mimicking disease symptoms; Participants will demonstrate critical thinking skill in diagnostic assessment;

Abstract Body: As interdisciplinary students learn about the process of triage, problem solving, and diagnosis when approaching patient cases, medication use can add to the complexity of seemingly straight-forward symptoms. Drug side effects are often mistaken for symptoms of disease and several "wrong" paths are explored before identifying and correcting the offending issue. Given that the Geriatric population is subject to drug-disease interactions, often use multiple medications, and can be more susceptible to the adverse consequences of drugs, it is critical that students learn to recognize and keep a medication side effect in the front of the choice set. Our teaching approach is to use web-based case learning strategies to walk students through a critical thinking process to establish the skill necessary to appropriately diagnose and treat geriatric patients taking medications. The web-based modality is used to ensure uniformity in the way the material is taught, to track progress and provide formative feedback, and develop a summative scoring indicative of the students level of learning.

347. Neuroimagiang Substrate Of Gait Dysfunction In Mild Cognitive Impairment. Results From The Gait And Brain Study, *Robert Nikolov, email: robert.nikolov@sjhc.london.on.ca, Gait and Brian Lab, Parkwood Institute and University of Western Ontario; Simona Nikolova, Roberts Research Institute; Robert Bartha, Robarts Research Institute; Manuel Montero-Odasso, Gait and Brain Lab, Parkwood Institute and Lawson Healt Research Institute*

Objectives: To demonstrate the neuroanatomical substrate of distinct "motor signature" in mild cognitive impairment (MCI) using MRI; To examine how gait may differ by cognitive subtyping between amnestic(a-MCI) and non-amnestic MCI (na-MCI) and the associated brain areas;

Abstract Body: Introduction We aim to demonstrate the neuroanatomical substrate of distinct "motor signature" in mild cognitive impairment (MCI) and how they differ by cognitive subtyping between amnestic (a-MCI) from non-amnestic MCI (na-MCI). Through examining which brain regions are correlated, potential mechanisms behind cognitive sub-classification and disease progression are presented. We postulate that brain volume, in addition to gait performance and other biometric markers can assist in the identification of the substrate of gait dysfunction of MCI. Methods Our study consisted of 31 MCI participants (18 a-MCI). Motor function was evaluated by assessing quantitative gait performance using an electronic walkway. The effect of cognition on gait performance was evaluated using the dual-task paradigm: walking while talking. T1-weighted anatomical images of the brain were acquired using 3.0 Tesla MRI. Results A-MCI yielded significant correlation with gait variability and verbal memory performance to white matter motor networks and grey matter (cingulum, thalamus, frontal, temporal, precuneus). Na-MCI presented correlation to age (temporal, frontal, precuneus, and putamen) and blood pressure in cerebellum. When grouped together, age correlations were dominant in hippocampus, amygdala, cerebellum, and cingulum. Conclusions a-MCI patients have a stronger correlation of gait disturbances to motor-sensory regions of the brain. Gait variability is a subtle measurement that has correlations to brain volume in the a-MCI group. This higher risk group may have underlying motor degeneration in addition to cognitive impairment. Na-MCI presented correlation with high blood pressure.

348. Technology to Support Family Caregiving: Acceptance and Willingness to Pay, *Marci Nilsen, University of Pittsburgh, School of Nursing; Yun Jiang, University of Pittsburgh, School of Nursing; Annette DeVito Dabbs, University of Pittsburgh, School of Nursing; Judith Tabolt Matthews, University of Pittsburgh, University Center for Social and Urban Research; Karen Courtney, University of Victoria, School of Health Information Science; Scott Beach, University of Victoria, School of Health Information Science; Richard Schulz, University of Pittsburgh, University Center for Social and Urban Research*

Objectives: 1.After attending this session, participants will be able to identify caregiver characteristics that influence their likelihood of using mobile devices to monitor and manage their care recipient's health.; After attending this session participants will be able to identify caregiver characteristics that influence their willingness to pay for mobile devices to monitor and manage their care recipient's health.

Abstract Body: Recent data from a national web-based survey of 512 family caregivers were used to examine caregiver characteristics that influenced their likelihood of use and willingness to pay for personal and community-based technologies including mobile devices, health kiosks, and wearable camera systems. This poster focuses on caregivers' acceptance and willingness to pay for mobile devices to track care recipients' health parameters and provide decision support for health management. Caregivers were adults (18-64 years) caring for parents (79%), spouses (10%), or other relatives (11%) with a variety of health conditions. Ordinal logistic regression showed higher acceptance rates for mobile devices among caregivers with the following characteristics: African American ($p<.001$), Hispanic ($p=.004$), dealing with conditions other than Alzheimer's disease ($p<.001$), have positive technology attitudes ($p<.001$), searching the internet for caregiving information ("sometimes" $p=.046$; "often" $p=.009$), currently utilizing commercially available caregiving technologies ($p=.003$). Linear regression showed significant associations between willingness to pay higher amounts out-of-pocket for mobile devices and the following caregiver characteristics: income ($p=.038$), currently utilizing commercially available caregiving technologies ($p<.001$), searching the internet for caregiving information ("sometimes" $p=.008$; "often" $p=.037$). Thirty-five percent of caregivers were not willing to pay anything out of pocket, whereas 65% of caregivers were willing to pay a median of $25 per month. Patterns of results for health kiosks and wearable camera systems were similar. Although acceptance of these technologies is relatively high, particularly among current technology users, willingness to pay may be a formidable obstacle to adoption unless third-party payers cover costs.

349. Incidence of Geriatric Syndromes and Frailty in Community-dwelling Older Men, *Naomi Noguchi, Centre for Education and Research on Ageing, Sydney Medical School, University of Sydney; Robert Cumming, School of Public Health, University of Sydney; Fiona Blyth, Centre for Education and Research on Ageing, Sydney Medical School, University of Sydney; David Le Couteur, Centre for Education and Research on Ageing, Sydney Medical School, University*

of Sydney; Vasi Naganathan, Centre for Education and Research on Ageing, Sydney Medical School, University of Sydney; , Centre for Education and Research on Ageing, Sydney Medical School, University of Sydney

Objectives: To determine the incidence of Geriatric Syndromes of poor mobility, falls, incontinence, and cognitive decline in a representative sample of community-dwelling older men.; To determine the incidence of frailty in a representative sample of community-dwelling older men.

Abstract Body: Background: Geriatric Syndromes of poor mobility, falls, incontinence, cognitive decline, and frailty are common health conditions among older people. Less is known about the frequency of these conditions in men than in women. Moreover, there has been no study in men or women to date in which the incidence of all these conditions has been examined in one population. Methods: The Concord Health and Ageing in Men Project (CHAMP) involves a representative sample of 1705 community-dwelling men aged 70 and over in a defined geographic region in Sydney, Australia. Geriatric Syndromes and frailty were assessed by questionnaire and clinical examination at baseline and at 5-year follow up. Results: Among 1705 participants at baseline, 382 died, 369 declined follow up, and 954 were followed up over 5 years. Among men aged 70 to 74 years who were free of each condition at baseline, 5-year incidence of poor mobility, falls, incontinence, cognitive decline, and frailty were 3%, 5%, 7%, 10%, and 3% respectively. Among men aged 85 to 89 years, the corresponding incidence were 18%, 23%, 13%, 30%, and 47%. Conclusions: The incidence of Geriatric Syndromes and frailty are not high in men in their 70s, but increases substantially after the age of 85 years. The health status and need for health services of the 'older old' are different to those of the 'younger old'. This needs to be considered when planning health services.

350. Visual Environmental Cues and Wayfinding Performance Within a Virtual Senior Residence, *Jennifer Ohman, Grand Valley State University; Rebecca Davis, Grand Valley State University*

Objectives: The learner will identify the effect of salient cues on older adults' ability to find their way.; The learner will compare performance between men and women in cued and uncued environments.

Abstract Body: Wayfinding, or the ability to navigate to a specific location, can be impacted by aging. The fear of getting lost can impact the size of one's world and cause it to become smaller. The purpose of this study was to determine if salient visual cues affected wayfinding performance over time in a sample of cognitively intact older adults. Forty community dwelling adults aged 62 to 86 were asked to use a joystick to navigate through a large scale virtual simulation of a senior living center (VSL). The VSL contained 2 cue conditions: one without cues and one with salient cues (CC1 and CC2). The participants were given 5 trials for 2 consecutive days to find a target within each cue condition. Wayfinding performance was measured by latency (time) to find their way. Repeated measures ANOVA showed that the participants' ability to find their way improved with salient cues as evidenced by a significant effect of cue condition (F=20.855, df=1, p < 0.001). Wayfinding ability was better as the trials progressed (F=145.511, df= 3.687, p < 0.001), and participants' latency improved between the days (F=94.423, df=1, p <0.001). A significant effect of trial by gender was also found (F=2.987, df=4, p= 0.021), showing that males have a steeper learning curve regardless of cue condition. This study shows the importance of salient cues in helping older adults find their way.

351. Association between Inattention, Impulsivity and Physical Function in Older Adults with Type 2 Diabetes, *Erin Olson, Harvard Medical School; Edward McAuley, University of Illinois at Urbana-Champaign*

Objectives: Critically examine how physical functioning is related to a complex infrastructure of executive functioning, especially in older adulthood.; Be able to define and conceptualize sub-sections of executive functioning, which may influence other aspects of health status in older adulthood.; Cue critical thinking regarding possible interdisciplinary therapies targeting cognitive function, physical function and their relationship in older age.

Abstract Body: Growing evidence indicates a dynamic a relationship between cognitive function and physical performance in mid- and late-life, especially as functional limitations, disability, and comorbidity increase. This study examined the relationship between executive function performance and physical function in older adults with metabolic disease. Older adults (n = 125, Mage = 62.1 ± 6.4) with type 2 diabetes (n = 107) and/or metabolic syndrome completed assessments of physical function, physical activity, fitness, and executive function. The flanker paradigm was used to measure inhibitory control. Using a principal component analysis of flanker variables, a two-component solution emerged— "inattention" and "impulsivity"—which explained 76.6% of the variance. Demographics, physical activity, fitness, glycosylated hemoglobin and cognitive factors of inattention and impulsivity were entered into a heirarchical linear regression to explain variance in physical function tests related to balance [F(8,118) = 2.288, p < .05] and agility [F(6,118) = 7.108, p < .01]. Only inattention (β = - .208, p < .05) was a significant contributor to total balance scores. Income (β = -.309, p < .01) and physical activity (β = -.239, p < .01) were significant determinants of agility in the final model. These data suggest that inhibitory control may be an indicator of balance and agility in older adults with type 2 diabetes.

352. Bright Light Exposure for Individuals with Dementia: Effect on Depression and Agitation, *Lisa Onega, Radford University; Thomas Pierce, Radford University; Lora Epperly, Commonwealth Care of Roanoke, Inc.*

Objectives: Identify the effect of bright light exposure on depression in older adults with dementia.; Identify the effect of bright light exposure on agitation in older adults with dementia.

Abstract Body: Many older adults with dementia living in long-term care facilities experience depression and agitation, which cause angst and personal suffering. Prior to this research, evidence was inconclusive but indicated that bright light exposure may reduce depression and agitation in long-term care residents with dementia. The purpose of this study was to determine if the degree of improvement in depression and agitation scores over the course of eight weeks was significantly greater in persons with dementia receiving bright light exposure than in persons with dementia receiving placebo light exposure. Forty-seven individuals participated in the study, with 23 in the bright light group and 24 in the low level light group. Results revealed that 30 minutes of bright light exposure twice every weekday for eight weeks was associated with significant improvement in levels of depression and agitation in comparison to changes observed in a low intensity light exposure control condition. Participants randomly assigned to the bright light condition showed statistically significant improvement in eight of nine measures of depression and four of four measures of agitation. This effect was large in magnitude and would clearly be noticeable in everyday life. For participants in the control group, significant improvement was observed for only one of the nine measures of depression and for none of the four measures of agitation. These findings support the use of bright light therapy for older adults with dementia to decrease depression and agitation and thereby improve their quality of life.

353. Study of Cardiac Autonomic Nervous System in Older Adults with Different Frailty Status, *Saman Parvaneh, 1 interdisciplinary Consortium for Advanced Motion Performance (iCAMP), Department of Surgery, University of Arizona, USA 2 Arizona Center on Aging, University of Arizona, USA; Bijan Najafi, 1 interdisciplinary Consortium for Advanced Motion Performance (iCAMP), Department of Surgery, University of Arizona, USA; Jane Mohler, 1 interdisciplinary Consortium for Advanced Motion Performance (iCAMP), Department of Surgery, University of Arizona, USA*
Objectives: The objective of this research was to assess the cardiac autonomic nervous system in older adults across frailty categories
Abstract Body: Background: Clinical frailty leads to a progressive homeostatic dysregulation in physiological systems, including cardiac autonomic nervous system (CANS). Reduction of heart rate variability (HRV) and sympathovagal balance (SVB) reflect this multisystem homeostenosis. Our objective was to develop HRV and SVB algorithms based on acquired ECG data using a body-worn sensor, across Fried frailty categories in older adults. Methods: A four hour uni-channel ECG was recorded using an FDA-approved wearable-sensor in 49 elders aged 65 and above. After ECG data inspection, 16 individuals were excluded due to 20%/+ ectopic beats. Remaining subjects were classified as non-frail (n=16) and pre-frail/frail (n=17) using Fried's criteria. A custom algorithm extracted QRS complexes from the ECG and calculated frequency domain measures of HRV. Percentage of spectral density in low frequency (pLF: 0.04-0.15Hz) and high-frequency (pHF: 0.15-0.4Hz), as well as their ratio (LF:HF) were calculated. Results: pLF was significantly lower (p=0.01) in frail subjects (3.65±2.35), compared to non-frail subjects (6.86±4.15). pHF showed a decreasing trend (p=0.16) from non-frail (2.35±2.07) to frail (1.57±0.85). LF:HF (as an indicator of SBV) also demonstrated a trend of reduction (p=0.07) from non-frail (3.68±1.87) to frail (2.63±1.39) Discussion: Reduction in pLF of pre-frail/frail compared to non-frail, indicates a reduction in global HRV, in line with aging studies. pHF and LF:HF values suggest that frailty impairs the parasympathetic CANS, and the sympathetic/parasympathetic CANS balance (SVB). ECG based frailty assessment have high potential in geriatrics; however, further studies are warranted to validate findings in a larger sample.

354. Impact of Physical Activity Behavior on Residential Care/Assisted Living Residents' Physical Function, *Lorraine Phillips, University of Missouri; Gregory Petroski, University of Missouri*
Objectives: After attending this session participants will be able to discuss the impact of physical activity on physical function and disability in residential care/assisted living residents.; After attending this session participants will be able to identify factors amenable to intervention that affect physical activity in residential care/assisted living residents.;
Abstract Body: This study examined the influence of intra- and extra-individual factors related to physical activity (PA) on disablement in residential care/assisted living (RC/AL) residents. Data from 224 adults aged 65-100 across 34 RC/AL communities were used to test whether PA and antecedents to PA exerted direct or indirect effects on physical function and disability in activities of daily living (ADLs), controlling for demographic and health-related variables. Participants completed questionnaires and physical performance tests, and wore the Fitbit Motion Tracker® to capture daily PA. The fit of a series of models to the data was analyzed using 2-level path models with residents nested within facilities. Factor analysis methods were used to create composite variables for PA antecedents (attitudes towards aging, exercise self-efficacy, and exercise expectancies) and physical function (upper and lower body performance). The fit of the initial theoretical model was poor: $\chi 2(25, N=224) = 246.4, p<.001$; comparative fit index (CFI) = 0.28. Eliminating demographic and health-related variables generated a better-fitting model: $\chi 2(3, N=224) = 7.1, p=.07$; CFI = 0.93. In the final model, more positive PA antecedents were associated with greater PA (standardized path coefficient = 0.29), which in turn was associated with better physical function (standardized path coefficient = 0.46). The association between physical function and ADL performance was moderate (standardized path coefficient = 0.20). Unexpectedly, a greater number of facility PA programs predicted poorer ADL performance (standardized path coefficient = -0.12). Interventions should target PA antecedents and PA behavior to improve physical function and disability in RC/AL residents.

355. Occupational Cognitive Requirements and Late-life Cognitive Aging, *Lindsay Pool, Department of Epidemiology, School of Public Health, University of Michigan; Jennifer Weuve, Rush Institute for Healthy Aging, Department of Internal Medicine, Rush University Medical Center; Robert Wilson, Rush Alzheimer's Disease Center, Department of Neurological Sciences and Department of Behavioral Sciences, Rush University Medical Center; Ute Bültmann, Division of Community and Occupational Medicine, Department of Health Sciences, University Medical Center Groningen, University of Groningen; Denis Evans, Rush Institute for Healthy Aging, Department of Internal Medicine, Rush University Medical Center; Carlos Mendes de Leon, Rush Institute for Healthy Aging, Department of Internal Medicine, Rush University Medical Center*

Objectives: Determine whether adulthood cognitive activity contributes to late-life cognitive aging by estimating the association between the cognitive requirements for main lifetime occupation and a longitudinal global measure of cognitive function for participants

Abstract Body: Background: Early-life and late-life cognitively stimulating activity are associated with late-life cognition. However, the degree to which cognitive activity throughout adulthood affects late-life cognitive aging remains mostly unknown. In this analysis, we focus on occupational cognitive requirements as marker of adulthood cognitive activity. Methods: Occupational cognitive requirements were measured using main lifetime occupation information for 7,637 participants aged > 65 years of the Chicago Health and Aging Project (CHAP). This information was linked with standardized data on worker attributes and job characteristics from the Occupational Information Network (O*NET). Ratings of cognitive processes required in 10 work-related tasks were used to create a summary measure of occupational cognitive requirements (range 0-7). Linear mixed models were used to estimate the association between the occupational cognitive requirements score and a global measure of cognitive function (z-score). Results: Type of lifetime occupation was well-distributed across five categories: managerial (21%), administrative support (27%), service (15%), labor (26%), and homemaker (11%). The average occupational cognitive requirements score was 2.2 (SD 0.9). In adjusted analyses, the occupational cognitive requirements score showed a curvilinear association with late-life cognition at baseline, including a strong linear association (β=0.22; p<0.0001) and a weaker negative quadratic association (β=-0.04; p<0.0001). Higher occupational cognitive requirements score was associated with slower decline in global cognitive function over time (β=0.004; p=0.004). Conclusion: Findings suggest that occupational cognitive requirements are associated with better cognition and a slower rate of cognitive decline in older age. Therefore, adulthood cognitive activity may contribute to cognitive reserve in late life.

356. Longitudinal Associations between Perceived Stress and Caregiver Cognitive and Functional Outcomes, *Alan Rathbun, University of Maryland School of Medicine; Erik Barr, University of Maryland School of Medicine; Cristan Smith, University of Maryland School of Medicine; Rasheeda Johnson, University of Maryland School of Medicine; Lynn Lewis, University of Maryland School of Medicine; Lisa Fredman, University of Maryland School of Medicine; Denise Orwig, Univeristy of Maryland School of Medicine*

Objectives: This study aimed to examine longitudinal associations between perceived stress and prospective changes in cognitive and physical functioning among older caregivers to patients hospitalized for hip fracture

Abstract Body: The Stress Process Model (SPM) suggests that caregivers experience greater psychological strain, and consequently, poorer health outcomes. However, some studies have found better outcomes among caregivers compared to non-caregivers. Participants (n=125) with 12- and/or 24-month follow-up visits were identified from a cohort of informal caregivers to patients hospitalized for hip fracture (N=145 dyads). The longitudinal associations between the Perceived Stress Scale (PSS; baseline mean = 19.8) and the following outcomes was assessed: Instrumental Activities of Daily Living (IADLs), gait speed, memory (i.e., Hopkins Verbal Learning test; HVLT), and executive functioning (i.e., Digit Speed Substitution task; DSST). These measures were converted to z scores to permit between-outcome measurement comparisons and account for potential confounding by time. Linear mixed-effects models estimated the longitudinal associations between time-varying PSS and each outcome, adjusting for caregiver and care-recipient characteristics. The analytic sample included older (mean age=72.1; SD=9.3) female (51%) and male (49%) spousal caregivers (52%). Increases in perceived stress were associated with better performance in memory and executive functioning. Adjusted beta coefficients were 0.13 [0.01 – 0.26] and 0.08 [-0.04 – 0.20] for HLVT and DSST, respectively. Conversely, stress was associated with non-statistically significant increases in IADL limitations: 0.03 [-0.07 – 0.14]; but not slower mean gait speed: -0.01 [-0.11 – 0.11]. Among older caregivers, greater stress equated to better memory; yet, was not significantly or consistently associated with executive and physical functioning. These findings imply that perceived stress does not have a uniformly negative impact on hip fracture caregivers' health, as would be suggested by the SPM.

357. An Objective Method for Fall Risk Assessment in Hospitalized Older Adults Using Wearable Technology, *Javad Razjouyan, Postdoctoral Research Fellow Interdisciplinary Consortium for Advanced Motion Performance (iCAMP) Southern Arizona Limb Salvage Alliance (SALSA) Associate Member Arizona Center on Aging (ACoA) University of Arizona, College of Medicine; Cindy Rishel, University of Arizona College of Nursing & the University of Arizona Medical Center, USA; Saman Parvaneh, interdisciplinaryConsortium on Advanced Motion Performance (iCAMP), Department of Surgery, University of Arizona, USA & Arizona Center on Aging, University of Arizona, USA.; Jane Mohler,* *interdisciplinaryConsortium on Advanced Motion Performance (iCAMP), Department of Surgery, University of Arizona, USA & Arizona Center on Aging, University of Arizona, USA.; Bijan Najafi, interdisciplinaryConsortium on Advanced Motion Performance (iCAMP), Department of Surgery, University of Arizona, USA & Arizona Center on Aging, University of Arizona, USA*

Objectives: To explore the practicality of using an innovative wearable sensor to monitor activity behavior of hospitalized patients; To explore the association between sleep quality or activity behavior during night time, with risk of falling; to identify sensitive activity related parameters for falls and risk of readmission in hospitalized patients.

Abstract Body: More than 500,000 falls happen each year in U.S. hospitals, resulting in 150,000 injuries. We assumed risk of falling was associated with patient activity patterns and quality of sleeping. To validate this hypothesis, patients from a hematology/oncology unit at UAMC, where a high rate of falls was reported, were requested to wear an innovative BioPatch sensor during their entire hospital stay. The sensor includes a 3D accelerometer and was attached to subject's chest. An algorithm was designed to evaluate activity behavior during night time (11pm till 7am) and identified surrogate parameters for quality of sleeping, including duration and frequency of lying postures (supine, prone, and left/right sides). In addition, the longest posture (LP), longest singular bout in lying position without interruption, was estimated. Twenty-eight patients (mean age: 59.8±2.84 years) were recruited and classified as low risk (n=16) or high risk of falling (n=12) based on Hendrich II criteria. The high risk group had remained less in the lying posture (21%, p=0.051) and had shorter LP (35%, p=0.057), when compared to fallers. The proposed technology was perceived as easy to use, acceptable, and highly comfortable by both patients and nursing staff. The results demonstrated practicality of using a wearable technology to evaluate patient's activity behavior while hospitalized to assess fall risk. In addition, results revealed an association between risk of falling and night time activity behavior in hospitalized patients.

358. Things That Matter to Residents in Nursing Homes and the Nursing Care Implications, *Nila Reimer, Indiana University School of Nursing*

Objectives: After attending this poster presentation, participants will be able to describe the complementary nature of residents' positive and negative experiences revealing what was most important to them while living in nursing homes.; After attending this poster presentation, participants will describe a Person-centered Care Framework for guiding care of residents in nursing homes.; After attending this presentation, participants will be able to describe new ideas that expand on current person-centered care strategies.

Abstract Body: Integration of person-centered care has improved quality of care in nursing homes. However, care that includes things that matter from residents' perspectives needs investigation.The purpose of this qualitative study was to describe things that residents state matter to them while living in nursing homes. The findings revealed residents' positive and negative experiences that provide ideas for expanding on current person-centered care strategies used in nursing homes.

359. Frailty Syndrome: Implications for Practice, *Sheria Robinson, Wayne State University; Susan Bushinski, Wayne State University*

Objectives: Describe frailty syndrome.; Review benchmarks for diagnosis.; List four evidence-based guidelines for treatment.

Abstract Body: Background: Frailty is chronic, progressive, syndrome characterized by dysregulation of multiple body systems and a low-grade inflammatory state. Patients with a frailty diagnosis are more likely to have adverse outcomes such as increased hospitalizations, falls, decreased functional status, institutionalization, and death. Purpose: To describe the Syndrome of Frailty, provide benchmarks for diagnosis, and to summarize best evidence-based guidelines for treatment. Methods: Forty articles were selected from a review of literature using key words (frailty, frailty syndrome, failure to thrive). CINAHL and PUBMED data bases were explored without date restrictions to capture historical development of nomenclature. Articles were selected based on criteria of contributions to best-evidence based guidelines, standards of care, and relevance to advanced practice nursing. Results: Treatment is best focused on the "prefail" or early frail phase, or even before a diagnosis is made. All older adults should be considered at risk and offered preventative care based on treatment goals of increased physical activity, increased strength, increased exercise tolerance, and increased nutrition. There is no cure for the syndrome once the benchmarks for the diagnosis of Frailty Syndrome have been met. Treatment goals for the acute care phase should include end of life discussions and planning with the patient and family.

360. The Health and Functional Characteristics of Older Adult Primary Care Patients with Lumbar Spinal Stenosis, *Catherine Schmidt, Massachusetts General Hospital Institute of Health Professions; Pradeep Suri, VA Puget Sound Health Care System; Dennis Anderson, Beth Israel Deaconess Medical Center, Department of Orthopedics; Dan Kiely, Spaulding Rehabilitation Hospital; Rachel Ward, Health and Disability Research Institute, Boston University School of Public Health; Laura Kurlinski, Health and Disability Research Institute, Boston University School of Public Health; Jonathan Bean, Associate Professor, Department of Physical Medicine and Rehabilitation, Harvard Medical School*

Objectives: To identify the severity of health and functional characteristics among older adult primary care patients at risk for mobility decline with LSS

Abstract Body: Background: LSS is a leading cause of mobility limitation and disability experienced by older adults. NC is a characteristic self-reported pattern of symptoms that leads to impaired walking and contributes to mobility decline for individuals with LSS. Methods: This is a secondary data analysis of a longitudinal, prospective cohort study of older primary care patients at risk for mobility decline. Fifty participants received a lumbar spine computed tomography scan (CT) and underwent a comprehensive assessment of neuromuscular impairments and patient-reported and performance-based mobility tests. Based on the presence(+) or absence(-) of NC and CT LSS findings participants were separated into four groups (NC+/CT+, NC+/CT-, NC-/CT+, NC-/CT-). Participants with NC+/CT+ were viewed as having LSS. Results: NC was present within 20% (n=10) of participants, of which 50%(n=5) met criteria for having LSS. Self-reported pain, comorbidities and patient-reported function varied significantly across the 4 groups. On average participants within the group NC+/CT+ experienced greater pain, based on the Brief Pain Inventory, 3.8(2.0), greater comorbidities, 6.1(1.1), and lower function, 30.4(5.6), based on the Late-Life Function and Disability Instrument. The magnitude of difference for mean values in 400-meter walk, habitual gait speed and Short Physical Performance Battery for the group NC+/CT+ exceeded established clinically meaningful differences when compared across groups. Conclusion: Participants with LSS had greater comorbidities, pain and worse physical function than older primary care patients without LSS. Additional studies are needed to identify the modifiable impairments that underlie mobility status among older adults with LSS.

361. Factors Predicting Civic Engagement Among Older Adult Nursing Home Residents, *Skye N. Leedahl, University of Rhode Island; Alicia M. Sellon, University of Kansas*

Objectives: Discuss different types of civic engagement opportunities available to nursing home residents.; Describe factors that predict different types of civic engagement for nursing home residents.; Discuss strategies for increasing civic engagement among nursing home residents.

Abstract Body: Civic engagement has been shown to positively influence individuals’ physical functioning and psychological well-being. In nursing home settings, it is unknown what predicts civic engagement for residents. This paper describes characteristics and examines factors that predict civic engagement (i.e., group membership, participation in resident council meetings, volunteering within facilities, and voting behavior) among older adult residents. Methods: This study included a random sample of older adult nursing home residents (M age = 83.07) with moderate/high cognitive ability (N = 140) in Kansas. Residents answered questions from standardized surveys during in-person interviews. Binary logistic regression analyses were conducted to identify significant and non-significant demographic, health, and social predictors associated with four different measures of civic engagement. Results: The most common civic engagement activity reported was membership in social/community groups (67.9%). Nearly one-third of residents (27.1%) reported volunteering within the facility (e.g., helping in dining room, sitting with residents who were sick). Results showed that depression (OR, 1.07, p<.05) and social support (OR, 1.03, p<.05) predict resident council participation and group membership. Age (OR, 0.93, p<.01), socioeconomic status (OR, 1.20, p<.05), and ADL limitations (OR, 1.51, p<.01) predict volunteering. Social trust (OR, 0.94, p<.05) predicts voting behavior. Non-significant predictors included gender and social network size. Implications: Results suggest that providing adequate mental health treatment and social support is important for improving participation in community groups and resident council. Strategies for increasing civic engagement and related health and well-being outcomes that inform nursing home and community programming and policy efforts are discussed.

362. Comparative Effectiveness of the Safety and Cost of Veterans Affairs Medical Foster Home Program: A Nested, Matched, Case Control Study of Outcomes, *Cari Levy, University of Colorado and the Denver Veterans Affairs Medical Center; Farrokh Alemi, Washington DC VA Medical Center; Thomas Edes, VA Central Office*

Objectives: Learners will understand outcomes among participants in the VA Medical Foster Home (MFH) program, an alternative to nursing home placement, compared to those of Veterans who reside in Veterans Administration (VA) nursing homes known as Community Living Centers

Abstract Body: Objective: To compare outcomes in the VA Medical Foster Home (MFH) program, an alternative to nursing home placement, to those of Veterans in Veterans Administration (VA) nursing homes known as Community Living Centers (CLC). Methods: A nested, matched, case control design was used to analyze 817 MFH residents matched to 3 CLC residents on odds of mortality, 6-month interval before and after enrollment and history of the outcome. The MFH and 3 randomly matched CLC cases are contrasted based on odds of hospitalizations due to anxiety, delirium/other cognitive impairment, adverse effects of medical care, adverse medication events, falls, depression, pneumonia, other bacterial infections, septicemia, skin infection, or suicide/self-injury. Results: Compared to matched CLC cases, MFH residents were more likely to be hospitalized due to delirium/other cognitive impairment (OR=1.52, CI 1.08-2.15), and pneumonia (OR=1.80, CI 1.01-3.21). In contrast, MFH residents were less likely to be hospitalized for anxiety (OR=0.34, CI 0.23-0.52), depression (OR=0.31, CI 0.23-0.41), other bacterial infections (OR=0.59, CI 0.34-1.00), skin infection (OR=0.36, CI 0.16-0.80), suicide/self-injury (OR=0.10, CI 0.05-0.20), pressure ulcers (OR=0.34, CI 0.16-.72) and adverse effects of medical care (OR=0.20, CI of 0.05-0.82). Subjects did not differ in rates of adverse medication events, falls, other injuries, septicemia, and upper tract infections. Conclusions: MFH enrollment is associated with a lower likelihood of hospitalizations for psychiatric diagnoses, adverse effects of medical care and some infections. A higher rate of hospitalization for pneumonia and delirium may represent diagnoses that are more difficult to manage in a private home care setting.

363. Engaging Community Stakeholders in Fall Prevention for Older Adults: Moving from Research to Action, *Maureen Markle-Reid, McMaster University; Cathy Dykeman, Halton Regional Health Department; Holly Reimer, McMaster University; Carol Goodall, Hastings Prince Edward County Health Unit; Lorna Boratto, Oxford County Public Health Unit; Helene Gagne, Oxford County Public Health Unit; Susan Bonomo, York Region Community and Health Services; Chris Bowes, North Bay Parry Sound District Health Unit*

Objectives: Understand community service providers' knowledge of, attitude about, and use of fall preventing (FP) practices for older adults; Understand the extent to which diverse senior-serving community organizations are ready to implement FP practices.

Abstract Body: Purpose: Falls are a leading cause of injury and death among seniors. A community-wide approach to fall prevention holds the potential to reduce the economic and personal burden associated with fall-related injuries. The purpose of this study was to understand: (1) community service providers' knowledge of, attitude about, and use of FP practices for older adults, and (2) perceived barriers and facilitators to implementing FP practices within and across senior-serving community service organizations. Methods: A purposive sample of 84 community service providers, in varied roles within diverse senior-serving community organizations (both health and non-health), completed a structured questionnaire as part of a larger mixed-methods study. The purpose of the questionnaire was to assess knowledge, attitudes, and use of FP practices. Results: Almost all (90%) reported already implementing at least one evidence-based FP practice. Three-quarters (75 %) rated FP activities as beneficial to their clients, and 80% would provide FP if given the opportunity. However, only 37% felt very confident and only 34% felt knowledgeable about implementing FP practices. Less than one quarter (21%) felt that staff in their organization had the necessary knowledge and skills, and only 10% felt that their organization had the necessary resources to support implementation of FP practices. Participants perceived many benefits to collaboration. Conclusion: Community service providers supported FP practices, but knowledge and resources limited implementation. Engagement of community providers in FP can be optimized through translating FP evidence to better fit community settings, fostering collaboration among community organizations, and providing implementation expertise and supports.

356. Encore Careers, The Retiree – Human Services Connection: Preliminary Evaluation Findings of Older Adults Impact on Organizations., *Emily Smith Goering, The University of Maryland, Baltimore; Amy Cohen Callow, University of Maryland Baltimore School of Social Work; Andrea L. Jones, University of North Carolina Wilmington*

Objectives: Participants will become familiar with a model that supports civic engagement and meaningful work for retirees.; Participants will learn about themes related to the impact of encore career programs and retirees on human service agencies.

Abstract Body: Initiatives supporting work transitions for retirees, often referred to as 'encore careers' offers a model that support civic engagement and meaningful work for older adults (Civic Ventures, 2005; Cullinane, 2006). Few studies on encore career programs exist. This research explores the contributions that retirees bring to human service agencies when engaged in encore career work. This poster presents newly analyzed data from the perspective of staff at organizations employing one encore career model. The national ReServe program, ReServe Maryland implemented in 2012, connects skills and knowledge of experienced professionals 55 and older who are interested in giving back to their community through work with nonprofits in need of additional human resources. ReServists are paid a $10.00/hr stipend. Data from surveys was collected from 9 (50% response rate) organizations participating in the program and from interviews with 7 employees, at 6 organizations, who had the most experience with the ReServe Program . Preliminary themes identified based on a nascent thematic analysis process include: 1) Benefits received from ReServists; 2) Impact on capacity building through access to specialized skills and human capital to enhance organizational processes and programs, 3) Expectations regarding encore career programmatic design needs. Themes are further supported by survey data. Preliminary results may inform research on program design and policy development related to encore career program support and funding.

365. A faculty training and mentoring program in aging research: Special issue of Educational Gerontology., *Chandra Mehrotra, The College of St. Scholastica; Aloen Townsend, Case Western University; Barbara Berkman, Columbia University*

Objectives: To present examples of aging research funded by federal agencies.; To create widespread awareness of the training model and its outcomes.; To stimulate faculty training in aging research in a variety of disciplines.

Abstract Body: Given the untapped potential of social work faculty to conduct aging research, we designed, implemented, and evaluated a faculty training and mentoring program in aging research. To create widespread awareness of the program and its outcomes, we published a Special issue of Educational Gerontology: An International Journal in April 2014. This poster presents the journal's Table of Contents and abstracts of the papers to illustrate participants' experiences with the program and how it contributed to their ability to conduct aging research. In particular, the participants share the steps they took to secure grant support from agencies such as National Institutes of Health, Centers for Disease Control and Prevention, and Alzheimer's Association, and the research they conducted with this support. Program participants also describe how they involved students in their research projects, what activities the students undertook, and how the students benefited from these experiences. Since the visiting faculty played a key role in the program as instructors and mentors, we have also included a paper focusing on their reflections regarding why they agreed to serve as faculty, in what ways they contributed to the training activities, how their work in the program affected them, and what suggestions they would give to junior faculty. The proposed poster will augment our dissemination efforts regarding the training program and the Special Issue.

366. The Provision of Palliative Care Consultations In Nursing Homes and End of Life Hospitalizations, *Susan C. Miller, Center for Gerontology & Health Care Research School of Public Health Brown University; Roshani Dahal, Brown University; Orna Intrator, University of Rochester*
Objectives: Audience members will describe the mechanisms involved in providing palliative care consultations in nursing homes.; 2) Audience members will describe how the initiation of palliative care consultations is associated with end-of-life hospitalizations;
Abstract Body: While palliative care (PC) consultations provided in hospitals or outpatient settings are associated with lower acute care use, the impact of PC consults in NHs is largely unknown. This study examines whether the initiation of PC consults in NHs and their volume are associated with NH end-of-life hospitalization practices. For the years 2000 through 2010 we obtained annual NH PC consult data from 7 exclusive providers of NH PC consults within 25 counties (in 4 states). 335 NHs (and 2955 NH years) with and without PC consults are included. Independent variables include the start of PC consult provision (i.e., 1% or more of unduplicated residents received a consult) and the volume (number with consults per 100 residents). Using NH fixed-effects regression analyses (controlling for study year and facility-level casemix, staffing and occupany) we examined the longitudinal relationship between changes in consult use and the proportion of NH decedents with: any hospitalization and 2+ hospitalizations in the last 60 days of life. With initiation of PC consults there was a 2.5% decrease in the proportion of decedents with any hospitalization in the last 60 days of life (AOR -0.025; 95% CI -0.384,-0.012), and a 1.9% decrease in 2+ hospitalizations (AOR -0.019; 95% CI -0.030,-0.008). No statistically significant associations were observed between volume and study outcomes. These novel findings are important to NH researchers, educators and administrators since they form the basis for subsequent resident-level research and suggest the importance of introducing PC expertise in NHs to enable avoidance of end-of-life hospitalizations.

367. Cross-National Aging Research: An Example on Productive Activities in U.S., China, and Korea, *Nancy Morrow-Howell, Harvey A. Friedman Center for Aging, Washington University in St. Louis; Tim McBride, Harvey A. Friedman Center for Aging, Washington University; Ben Cooper, Institute for Public Health, Washington University in St. Louis; Yu-Chih Chen, Harvey A. Friedman Center for Aging, Washington University in St. Louis; Yi Wang, Harvey A. Friedman Center for Aging, Washington University in St. Louis; Huajuan Chen, Harvey A. Friedman Center for Aging, Washington University in St. Louis; Dongmin Wang, Harvey A. Friedman Center for Aging, Washington University in St. Louis; Ching-Ying Lai, Harvey A. Friedman Center for Aging, Washington University in St. Louis*
Objectives: Audience will have a deeper knowledge of methods for doing cross-national research.; Audience will have a deeper appreciation for the complexity.;
Abstract Body: Introduction. Cross-national aging research is needed to study issues across different socio-cultural contexts. The objective of this study is to develop methods for using country-specific data sets for cross-national comparison. We used productive activities (working, volunteering, and caregiving) across three countries (US, China, Korea) to understand more about the challenges and potential of this type of research. Methods. Using data from the Health and Retirement Study, the China Health and Retirement Longitudinal Study, and the Korea Longitudinal Study of Ageing, this study developed a sequence of methods for cross-national analysis. Specifically the methods included: defining the concepts of the three productive activities; creating a list of potential variables; rating the relevance of each variable; developing criteria for selecting variables for analyses; cleaning the data to produce rate/intensity measures for each productive activity. Detailed flowcharts and tables were produced that compare activity across the three countries. Findings. Three challenges were identified in conducting cross-national aging research: (1) differences of cultural context (e.g. in China, volunteering is an emerging concept with most volunteer activities occurring outside formal institutions); (2) variations in operationalization (e.g. definition differences across the data); and (3) variations in measurement (e.g. differences in response options). Implications. Given the difficulty of drawing conclusions without taking account of cultural interpretations in a global context, analysts should include team members who are familiar with the culture and language of the region of study. Researchers also need to determine whether data sets are valid for cross-national comparisons given some of the data limitations.

368. Assessing Alzheimer’s Disease Awareness Among Diverse Racial and Ethnic Population Groups in Salt Lake City (SLC), *Frederic Mugiraneza, The University of Utah; Kara Dassel, The University of Utah; Katherine Supiano, The University of Utah; Michael Caserta, The Universtiy of Utah*
Objectives: To show the need for research aiming at establishing national base-line data on public knowledge and awareness of Alzheimer's disease and its psychosocial and financial implications before the awareness campaigns suggested in national and state Alzheimer's disease plans.

Abstract Body: Assessing Alzheimer's Disease Awareness Among Diverse Racial and Ethnic Population Groups in Salt Lake City (SLC) Frederic Mugiraneza, MD, Kara B. Dassel, PHD, Kathie Supiano, PHD & Michael Caserta, PHD Alzheimer's disease (AD) is predicted to grow substantially over the next five decades. Based on these projections, it is imperative that individuals, families, and communities are aware of this disease in order to be able to successfully prepare for the associated psychosocial and financial challenges. The "Utah State Plan for Alzheimer's Disease and Dementia", states the need for Utah to be "dementia-aware". However, there is no baseline data available regarding AD knowledge in the state. In addition, minority old adults are 1.5 to 2 times as likely to develop AD as their white counterparts. Therefore, the goal of this pilot study is to assess AD knowledge in adults in five racial and ethnic groups in SLC. Through convenience sampling, participants received a demographic questionnaire and the Alzheimer's Disease Knowledge Scale (ADKS). The sample (N = 90) was 58 % female, 41years old and with 16 years education on average. The mean score on the ADKS was 20.9 (SD=4.0) (out of 30). One-way ANOVA revealed a significant difference, with white participants scoring higher, between the mean scores of the white subgroup and those of other racial and ethnic subgroups except the American Indians. There were no significant differences between the mean scores of the four other racial and ethnic groups. In conclusion, although white respondents scored higher on average than respondents from other racial and ethnic groups, the findings of this study reflect a relatively low knowledge-base of AD among a sample of SLC residents across all racial and ethnic groups.

369. Effects of Patient Centered Medical Home Plus Transitional Care for Complex Older Adults, *Mary Naylor, University of Pennsylvania School of Nursing; Karen Hirschman, University of Pennsylvania School of Nursing; Elizabeth Shaid, University of Pennsylvania School of Nursing; Ronald Barg, University Pennsylvania Health System - Clinical Care Associates; Kathryn Bowles, University of Pennsylvania School of Nursing; Mark Pauly, University of Pennsylvania School of Nursing*

Objectives: To provide researchers and clinical partners with details on rolling-out and scaling of evidence-based innovations targeting high risk older adults in the primary care setting

Abstract Body: With a goal of increasing the value of primary care among high-risk, community-dwelling, chronically ill older adults, an innovative delivery model combining two-evidence-based approaches–the Patient Centered Medical Home (PCMH) and the Transitional Care Model (TCM)–was designed and piloted. The combined model extended the PCMH beyond traditional office boundaries to include home care visits, telephone follow-up, and, when needed, hospital and post-acute care visits. The model is characterized by a partnership between patients and clinicians and emphasizes co-management by a primary care clinician and an advanced practice nurse in implementing a plan of care designed to meet each patient's goals and move patients from higher to lower risk. Patients received the combined intervention for an average of 60 days. Preliminary testing included 54 high-risk patients; mean age of 78 and 70% female. On average, patients had 10 documented chronic conditions and were prescribed 12 daily medications. Thirty five percent of the sample had depressive symptoms present at baseline. Among the 14 patients who had hospitalizations in the 30 days prior to enrollment, one patient was rehospitalized by 30 days following hospital discharge. Ninety days following implementation of the intervention, eight patients had been hospitalized nine times. Three of these nine hospitalizations were planned. After this ninety day period, hospitalization rates more closely approximated rates those reported for similar high-risk populations. This session will describe the complexity of care needs of this high-risk sample as well as the facilitators and barriers identified during the implementation of this combined delivery model.

370. Evaluating the Cost Effectiveness of the Elder Abuse Forensic Center Model, *Michael B. Nichol, University of Southern California; Joanne Wu, University of Southern California; Zachary D. Gassoumis, University of Southern California; Kathleen H. Wilber, University of Southern California*

Objectives: To define and discuss the outcome measurements of elder abuse cases;; To define and discuss the cost differences in processing elder abuse cases between the elder abuse forensic center model (EAFC) approach and Adult Protective Service (APS) usual care;; To define and discuss the estimation of an incremental cost-outcome ratio (ICOR) to determine the cost effectiveness of the elder abuse forensic center model.

Abstract Body: Elder abuse forensic centers (EAFCs) use a multidisciplinary team approach to address complex elder abuse cases. To date, no evaluation has assessed the cost for EAFCs to achieve their outcomes. This study evaluates the cost effectiveness of the Los Angeles County EAFC. We analyzed case files for 41 randomly selected cases seen at the Los Angeles County EAFC and 39 propensity-matched APS usual care cases from April 2007-December 2009 to obtain data on time spent processing cases and achieving outcomes. Salaries were obtained from publicly available sources and used to estimate case processing costs. Mean case processing costs are $1,101.80 for the EAFC model and $153.30 for usual care. The proportion of cases submitted to the public guardian is 39% for EAFC and 8% for usual care, which generates an ICOR of $3,059.68. The ICOR indicates that an additional EAFC case submitted to the public guardian costs an additional $3,059.68 over the cost of usual care. The proportion of cases that are granted conservatorship is 24% for EAFC and 3% for usual care, with an ICOR of $4,516.67. The proportion of cases successfully prosecuted is 17% for EAFC and 0.2% for usual care, with an ICOR of $5,645.83. There were no differences in recurrence rates within one year of case closure. These results indicate the EAFC model incurs greater case processing costs but yields large incremental differences in outcomes compared to usual care. This information can inform the sustainability of the model and the feasibility of replication across the U.S.

371. Is Polypharmacy Associated with Cognitive Impairment in Later Life? : A Community-based Cross-sectional Study

Study, *Hirotoshi Niikawa, Tokyo Metropolitan Institute of Gerontology / Researcher; Chiaki Ura, Tokyo Metropolitan Institute of Gerontology / Researcher; Fumiko Miyamae, Tokyo Metropolitan Institute of Gerontology / Researcher; Naoko Sakuma, Tokyo Metropolitan Institute of Gerontology / Researcher; Mutsuo Ijuin, Tokyo Metropolitan Institute of Gerontology / Researcher; Kae Ito, Tokyo Metropolitan Institute of Gerontology / Researcher; Shuichi Awata, Tokyo Metropolitan Institute of Gerontology*

Objectives: Participants in this poster presentation will be able to know how polypharmacy is associated with cognitive impairment in later life.; Participants will be able to discuss about the potential healthcare risk of polypharmacy in later life.; Participants will be able to gain insight into this unique study based on interviews. Most studies about polypharmacy have been using questionnaires or medication records. Those methods tend to exclude those who do not take a prescribed medication or are not registered with medical institutions. This interview method, on the other hand, can include them in the study, and is, therefore, able to show more representative demographic data on the elderly living at home in the community.

Abstract Body: Background: Polypharmacy is one of the major health care issues in later life. Objectives: To examine the association between polypharmacy and cognitive impairment in a community-dwelling elderly population. Methods: A postal questionnaire was sent to all residents (N=7,682), aged 65 years and older in an urban residential district in Tokyo, to examine socio-demographic and health-related variables. Then, 3,000 residents were randomly selected from this population. Trained nurses and researchers interviewed each participant at home to gain information on prescribed medications and cognitive functions, which were measured by the Japanese version of the Mini-Mental State Examination (MMSE-J). Multivariate logistic regression analyses were preformed to examine the association between the number of medications and cognitive impairment after potential confounding factors were controlled. Results: Out of 1,341 residents who agreed to the interview, 1,317 participants completed the whole process. The mean (standard deviation) MMSE-J score was 27.1(3.3) for all participants. 10.8% of participants was below the cut-off criterion of 23/24. The proportion of people who take more than six medications was 37.2% for all participants; 57.5% for those less than 24 on MMSE-J and 34.5% for those 24 and more ($\chi 2 = 21.3$, $p<0.001$). Multivariate logistic regression analyses showed that the number of medications was associated with cognitive impairment after controlling potential confounding factors (age; sex; education; history of neuropsychiatric diseases including dementia, depression, and other neurological diseases; using psychiatric medications; and number of illnesses) (OR: 1.95; 95%CI: 1.17-3.24). Conclusion: Polypharmacy might be associated with cognitive impairment in later life.

372. Perception Of Condom Use Among The Elderly People In Densely Populated high Risk Neighbourhood In Nigeria

Nigeria, *King Odor, Deakin University*

Objectives: This study therefore examined Perception of condom use among the elderly people in densely populated high risk neighbourhood in Nigeria

Abstract Body: HIV/AIDS is a growing public health challenge in Africa, the pandemic affects everybody including the elderly. To combat HIV/AIDS infection, condom-use is effective measure to interrupt its transmission. However, perception of the elderly about condom usefulness has been limited due to inadequate information. Moreover the sexual pattern this sub-group engages in is relatively unknown. The study was cross-sectional in design. A multi-stage-stratified-random-sampling technique were adopted to select 400 respondents aged 65years and above in Ibadan-Nigeria. A pre-tested questionnaire developed from results of 10 focus-group-discussions (FGD) was used to collect information. FGD and questionnaire data were analyzed thematically and descriptive/chi-square statistics respectively. Twenty-five percent of the participants who were sexually active, one year preceding the study had extramarital-sex. Among the subgroup that had extramarital-sex, few (6.8%) used condom in the episode. More males (5.3%) than females (1.5%) used condom in last extramarital-sex ($p<0.5$). Low condom-use was attributed to condom not-worthwhile (34.5%) and not meant (50.0%) for elderly. Non-condom use was due to confidence in traditional herbs perceived to prevent HIV/AIDS. Similarly, FGD participants were unanimous in their opinion that sex could not lead to pregnancy. While, majority (60.3%) posited patronizing traditional healers and believe (10.3%) herbs/concussion-use could prevent HIV/AIDS rather than condom-use. Risky sexual engagement among the elderly could be a distortion to HIV/AIDS reduction, because condom-use among this population is unimportant based on perception. In order to mitigate HIV/AIDS in Africa information on safe-sex practices for the elderly are needed to address this misconception.

306. The Association Between Physical Activity and Risk of Depression Among Older Adults Using MEPS 2009, *Fawaz Alotaibi, Virginia Commonwealth University, School of Pharmacy*

Objectives: Determine the association between regular physical activity and the risk of depression among older adults using MEPS 2009.; Quantify the prevalence of community dwelling older adults who are at high risk of depression in a nationally representative sample.

Abstract Body: Background: Depression is a major public health concern among older adults. Depression worsens many medical conditions including asthma, angina and arthritis. Objectives: To determine the association between regular physical activity and the risk of depression among older adults, and to quantify the prevalence of older adults who are at high risk of depression. Methods: The 2009 Medical Expenditure Panel Survey (MEPS) was used as data source. The dependent variable was risk of depression (a Kessler index score of 6 or higher), the primary independent variable was level of physical activity, and potential confounders included demographic and socio-demographic variables. Descriptive statistics were calculated and the association between physical activity and risk of depression was assessed using a logistic regression model with backward selection method at p-value 0.05, while the prevalence of older adults who are at high risk of depression was assessed using the weighted mean and t-test at p-value 0.05. SAS version 9.4 was used for the analyses. Results: Out of 4875 older adult survey participants, 1254 were at high risk of depression. . Females were more likely to be at high risk of depression than males. After adjusting for demographic and socio-demographic characteristics, those who do not engage in physical activity are twice more likely to be at high risk of depression than those who regularly exercised (OR: 2.16 and 95% CI 1.805- 2.612). Conclusion: The results suggest that weekly physical activity may play an important role in risk for depression among older adults.

307. The Association between Social Isolation and Chronic Disease Burden, *Sharon Qi, Department of Health Policy and Administration, The Pennsylvania State University; Elizabeth Munoz, Department of Human Development and Family Studies, The Pennsylvania State University; Jennifer E. Graham-Engeland, Department of Biobehavioral Health, The Pennsylvania State University; Christopher G. Engeland, Department of Biobehavioral Health, The Pennsylvania State University; Joshua M. Smyth, Departments of Biobehavioral Health and Medicine, The Pennsylvania State University; Mark Sciegaj, Departments of Biobehavioral Health and Medicine, The Pennsylvania State University; Martin J. Sliwinski, Department of Human Development and Family Studies and Center for Healthy Aging, The Pennsylvania State University*

Objectives: From attending this session, participants will be introduced to social isolation as a modifiable risk factor for chronic disease burden.; From attending this session, participants will understand the role that social isolation has in predicting an individual's outpatient cost, primary care visits, and total chronic conditions.

Abstract Body: Social isolation represents a potentially modifiable risk factor for chronic health conditions. Previous studies have only examined the association between social isolation and single chronic health conditions. Less is known about the link between social isolation and the burden of multiple comorbid health conditions. In this study, we examined the association between social isolation and summary measures of chronic disease burden based on self-reported medication use for chronic health conditions. Specifically, we implemented Clark and colleagues' (1995) chronic disease score to calculate three summary variables: total cost, total outpatient cost, and total primary care visits; we also calculated a total sum score of the number of chronic conditions reported by each participant and measured social isolation using the PROMIS social isolation scale. Our sample consisted of 285 diverse adults Mage=46.90, SD=10.96, range: 25-65; 36% male; 59% black; average chronic conditions=1.04, SD=1.43, range: 0-8. Bivariate correlations indicated that social isolation was positively associated with outpatient cost (r=.13), primary care visits (r=.15), and total chronic conditions (r=.16, ps <.05). Age was not associated with social isolation but was positively associated with all disease burden variables (rs= .17 to .34, ps <.05). Regression analyses that controlled for age, gender, race/ethnicity, and education revealed that social isolation was uniquely associated with more frequent primary care visits (B= .02, p<.05) and with chronic conditions (B= .04, p<.05); these effects were age invariant. Our results indicate that besides being associated with chronic conditions, social isolation also places a burden on individuals associated with primary care visits.

308. The Civic Engagement of Older Japanese Citizens as Long-term Care Support Volunteers: A Qualitative Study in Tokyo, *Yumika Shirase, National Institute of Population and Social Security Research*

Objectives: After attending this session participants will be able to understand the long-term care support volunteering program in Japan.; After attending this session participants will be able to understand why Japanese older citizens are engaged in volunteering activities.; After attending this session participants will be able to discuss effective programs to encourage older citizens to participate in volunteering.

Abstract Body: Background: As people 65 years and older account for approximately 25% of the Japanese population, they are not just regarded as individuals needing care themselves but also as a potential support system for the oldest members of society. X City, in suburban Tokyo, introduced the Kaigo Shien (long-term care support) Volunteer Program, which enables volunteers to earn evaluation points based on hours of engaging in long-term care support activities, and to exchange the accumulated points for cash (up to 5,000 yen per year). This qualitative study analyzes the organizational aspects of the volunteers' participation and what motivates them. Method: Participant observation and semi-structured interviews (N=15) were conducted from March to June 2014. The interviews explore what volunteers do and how they feel about their activities. Transcripts of the interviews were analyzed using the grounded theory approach. Findings: All the interviewees hoped to partially assist older people in the community after they retired from paid work or had finished raising children. Volunteers participated in the program by one of following three forms: joining a non-profit organization, joining a neighborhood group, or participating as individual volunteers. Discussion and Conclusion: This program met the needs of older volunteers and simultaneously provided them with an opportunity to decide how to spend the rest of their lives. They did not necessarily expect cash rewards, but they appreciated the evaluation points, viewing them as a form of gratitude for their contribution. After receiving points, the participants were encouraged to continue volunteering.

309. The Effect of Age on Executive Functioning in Geriatric Hoarding Disorder, *Mary Dozier, VA San Diego Healthcare System San Diego State University/University of California, San Diego Joint Doctoral Program in Clinical Psychology; Dawn Schiehser, VA San Diego Healthcare System; Catherine Ayers, VA San Diego Healthcare System*

Objectives: To investigate age-related differences in executive functioning in older adults with hoarding disorder

Abstract Body: Hoarding disorder (HD) is a chronic and progressive psychiatric condition. Previous studies of executive functioning in midlife and geriatric adults with HD have demonstrated impairment in both populations. This is the first investigation of age-related differences in impairment in adults with HD. The purpose of this study was to use the Wisconsin Card Sort Task (WCST-128) to examine age-related differences in executive functioning due to HD. Participants included 109 adults meeting DSM-5 criteria for HD. The mean age of the overall sample was 64.2 (SD=7.4;range=50-86;median=64). The sample was mostly female (72%) and Caucasian (81.5%). Age-based differences were investigated by comparing older and younger participants, using the median age to differentiate the two groups. There were no age-related differences in anxiety or depression (measured by the Hospital Anxiety and Depression Scale), or hoarding severity (measured by the Clutter Image Rating, the Saving Inventory-Revised, and the UCLA Hoarding Severity Scale). Using U.S. Census age-matched T scores, we found that the older HD group exhibited significantly more impairment in total errors, perseverative responses, perseverative errors, nonperseverative errors, and conceptual level responses (all p's<.01) than the younger HD group. Further, our older HD group demonstrated significantly higher percentages of impaired responses for total errors, perseverative responses, perseverative errors, and conceptual level responses (all p's<.05). Compared with our younger HD group, the older HD group demonstrated executive functioning problems, including attention, inhibition, and set shifting, suggesting that as adults age these constructs may form an increased barrier to psychotherapeutic interventions for HD.

310. The Effect of Sleep Medication Use and Poor Sleep Quality on Risk of Falls in Community-Dwelling Older Adults, *Yaena Min, Virginia Commonwealth University; Patricia Slattum, Virginia Commonwealth University*

Objectives: The objective was to evaluate the association between sleep medication use, sleep quality, and falls in adults 65 or older.

Abstract Body: Objective: Psychotropic medications are associated with risk of falls in older adults. However, very few studies have assessed the impact of poor sleep and sleep medication use on the risk of falls. The objective was to evaluate the association between sleep medication use, sleep quality, and falls in adults 65 or older. Methods: This was a 6 month prospective cohort study of older adults residing in independent living senior housing. Sleep quality was assessed with the Pittsburgh Sleep Quality Index (PSQI) and a medication review was conducted. Falls were collected over 6 months by calendar. Logistic regression modeling was used to examine the effect of sleep problems, sleep medications, and both on the risk of falls after controlling for covariates. Statistical analysis was performed using SAS 9.4 statistical software. Results: Among 113 community-dwelling older adults (female= 76.1%, mean age ±SD= 81.1 ±8.6), 46.9% fell at least once during 6 months. Sleep medication use (adjusted odds ratio, AOR=2.65; 95%CI=1.04-6.72) predicted prospective falls but not poor sleep quality. Compared to participants reporting good sleep quality and no sleep medication use, those who report poor sleep quality and sleep medication use had an increased risk of falls (AOR= 3.86 ; 95%CI =1.18-12.60). The other two groups had no significantly greater risk for falls. Conclusion: A combined effect of sleep quality and sleep medication use on the risk of falls suggests that medication effectiveness may be an important factor to consider in understanding the risk of falls associated with sedative medications.

311. The Effects of Daily Lifestyle Determinants on Well-Being in Younger and Older Adults, *Jonathan Rush, University of Victoria; Amanda Kelly, University of Victoria; Mai Stafford, Medical Research Council; Scott Hofer, University of Victoria; Angela Njenga, University of Utah*

Objectives: To better understand how daily behaviours and events account for day-to-day fluctuations in well-being in younger and older adults.; To determine if different behaviors play a different role in accounting for well-being at different stages of life (i.e., young adulthood versus older adulthood).

Abstract Body: There are many behaviours and activities that we engage in on a daily basis that play a role in our well-being. Much previous research has demonstrated that our lifestyle choices account for a portion of our general levels of well-being. However, the experience of well-being is a dynamic process that fluctuates regularly across time. It is still unclear how much our daily behaviours account for these fluctuations in well-being. Furthermore, different behaviours may play a different role in accounting for well-being across the life-course. The present study utilized a 14-day intensive repeated measurement design to examine the effects of daily lifestyle determinants on well-being in younger and older adult samples. Many daily behaviours and events significantly predicted well-being in both the younger and older samples (e.g., physical activity, time spent outdoors, helping others/volunteering). However, the younger and older adult sample differed in the amount that other behaviours accounted for well-being (e.g., healthy eating, time spent with friends). In combination, the daily lifestyle behaviours accounted for as much as 32% of the daily variation in well-being among older adults and 21% of the daily variation in well-being among younger adults. These results demonstrate that much of the variation in well-being within an individual can be accounted for by the behaviours and activities that they engage in on a daily basis. Gaining a better understanding of the behaviours that consistently coincide with an improved sense of well-being is critical to the promotion of lifestyle choices that foster well-being across the life-course.

312. The Effects of Social Support from Older Adults Toward Their Children or Partners on Role Identities: A Longitudinal Investigation, *Aya Toyoshima, Graduate School of Human Sciences, Osaka University,; Shinichi Sato, Graduate School of Human Sciences, Osaka University; Jun Nakahara, Tokyo Woman's Christian University,Japan Society for the Promotion of Science: Research Fellowship for Young Scientists*

Objectives: To examine the hypothesis that receiving and providing social support promotes role identities, which influence subjective well-being for older adults in the context of symbolic interaction the; To examine whether receiving social support from and providing it to a wife or husband enhances marital identities among older adults.; To examine whether social support provided by older parents to their children enhances parental identities more than receiving support does.

Abstract Body: Social support promotes older adults' subjective well-being by boosting positive identities, as indicated by symbolic interaction theory. The current study hypothesized that a relationship of receiving and providing social support between husband and wife enhances marital identities. Moreover, parental identities should be more enhanced among older adults when providing social support for their children than when receiving support. This is because providing support better fits their parental roles. We conducted a longitudinal survey of older adults (>60 years). Participants were assessed four times over two years (First: January–February, 2012. Second: September–November, 2013. Third: May–June, 2013. Fourth: February–March, 2014.). The total sample consisted of 355 older adults (240 men and 115 women). We examined the effect of social support at the first wave on the trajectory of role identities in a growth curve model. In the model of marital relationships, receiving and providing support were significantly associated with the intercept of marital identity ($\beta = .49$, $.50$), and there was no significant difference between the social support coefficients. In the model of parent-child relationship, both supports were significantly associated with the intercept of parental identity ($\beta = .26$, $.87$), and the "providing support" coefficient was higher than the "receiving support" coefficient ($p < .01$). These results suggest that social supports between family members promote role identities in family relationships. Especially, providing support for children is associated with enhanced subjective well-being because of its corresponding influence with parental roles.

313. The Impact of Mixed Stereotype Messages on Older Adults' Levels of Dementia Worry, *Joie Molden, University of Colorado Colorado Springs; Molly Maxfield, University of Colorado Colorado Springs*

Objectives: The objective of this research was to better understand how aging stereotype messages impact older adults' anxiety about developing dementia

Abstract Body: A common fear of growing older is the seeming inevitability of age-related memory loss. Recent research, however, suggests that psychosocial influences might be important contributors to poorer memory performance among older adults. Specifically, both positive and negative aging stereotypes are hypothesized to have significant impact on myriad areas of functioning, including memory performance (Levy, 2009). As concern with memory ability grows, so too does anxiety over the possible development of dementia—an experience termed dementia worry (DW; Kessler, Bowen, Baer, Froelich, & Wahl, 2012) or anticipatory dementia (Cutler & Hodgson, 1996). No known research exists examining the impact of aging stereotype messages on older adults' DW. In this study, older adults were randomly assigned to one of five conditions, each of which primed participants with different proportions of positive versus negative aging stereotype content. Participants were administered brief memory test batteries before and after priming, and were administered the Fear of Alzheimer's Disease Scale (FADS; French et al., 2012) post-priming to assess DW. Exposure to higher proportions of negative stereotype content elicited greater levels of DW. At the same time, actual memory performance was not significantly correlated with DW. Mean FADS scores did not differ by gender, but did correlate significantly with affect such that positive affect was associated with higher FADS scores; the inverse was true for negative affect. A positive correlation between age and DW approached significance. Results suggest that the content of age-related stereotypes is a powerful force with the potential to impact older adults' cognitive-related anxieties.

314. The Impact of Red Light Running Camera Flashes on Younger and Older Drivers' Attention and Oculomotor Control, *Timothy Wright, Florida State University; Walter Boot, Florida State University; Neil Charness, Florida State University; Thomas Vitale, Florida State University*

Objectives: To explore the distracting effects of RLRC flashes on drivers' attention and oculomotor control.; Examine age-related differences in the distracting effects of RLRC flashes.; Examine differences in the distracting effects of RLRC flashes as a function of RLRC flash salience, and potential interactions with age.
Abstract Body: Recent empirical evidence suggests that the flashes associated with red light running cameras (RLRC) distract younger drivers, pulling attention away from relevant roadway information and delaying visual processing (Sall, Wright, & Boot, 2014). Considering the perceptual and attentional declines that occur with age, older drivers may be especially susceptible to the distracting effects of RLRC flashes, particularly in situations in which the RLRC flash is highly salient (e.g., at night). The current study examined potential age and situational effects on RLRC flash capture. Two experiments utilized both covert (inhibition of return) and overt (eye movements) indices of attention in simulated driving scenes. Salience of the flash was manipulated by varying its luminance and contrast with respect to the background of the driving scene (either day or night scene). Results across both experiments suggest that simulated RLRC flashes capture observers' attention, but, surprisingly, no age differences in attention capture were found with either covert or overt markers of attention. An analysis examining early and late eye movements revealed that older adults may have been strategically delaying their eye movements in order to avoid capture by the flash. Findings have theoretical implications for understanding age differences in attention capture with more realistic and familiar stimuli and inform future work that will examine how the distracting effects of RLRC flashes influence driving behavior.

315. The Impacts of Service Experiences on the Trajectories of Self Rated Health, Functional Limitations, and Activities of Daily Living among Veterans, *Miles Taylor, Florida State University; Stephanie Urena, Florida State University; Benjamin Kail, Georgia State University*
Objectives: To understand the role of combat related experiences in later life health trajectories among veterans
Abstract Body: Using the 2013 Veteran's Mail Survey linked to the Health and Retirement Study, we use latent class analysis to examine multiple trajectories of self rated health, functional limitations, and activities of daily living over a decade. Among veterans, we find substantial variation in trajectories and explore the independent impacts of combat, exposure to the dead and wounded, and exposure to environmental hazards, net of sociodemographic controls. When combat is examined alone it is associated with universally poorer health across our three outcomes. The impact of combat is reduced once exposures are included, suggesting exposures during combat fuel this association and that not all combat experiences are equally detrimental for health. Further, the impact of exposures are independent, with environmental hazards predicting moderately poor health while exposure to death/wounded predicts only the worst health trajectories. Interestingly, historical period of wartime service (i.e. WWII, Korea, and Vietnam) was not significant, suggesting research using period of service among veterans was primarily capturing the effects of combat and other wartime exposures. These findings suggest that examining disaggregated levels of health over time is important in understanding the effects of service related experiences and for timing specific health interventions. We hope to expand analyses to 1) examine depressive symptoms as an additional outcome capturing mental health, 2) incorporate selection effects of early life factors into service experience in these models, and 3) examine current health behaviors as covariates to understand the pathways through which these service experiences impact health trajectories.

316. The Longitudinal Effects of Internet Use on the Depression of Korean Older Adults, *Myoung-Yong Kim, Human Life Research Center, Yonsei University; Hey Jung Jun, Yonsei University*
Objectives: This study was to examine the longitudinal effects of internet use on Korean older adults' depression.; This study was to examine whether the effects of late-life Internet use on depression was mediated by the social relationship satisfaction.; This study was to assess whether there were any gender differences in the effects of Internet use.
Abstract Body: The purpose of this study was to examine the longitudinal effects of internet use on Korean older adults' depression, with focus on the effects of social relationship satisfaction. Furthermore, we assessed whether there were any gender differences. A sample of Korean older adults aged 60 years and older, drawn from the Korea Welfare Panel Study (KOWEPS) across three waves of large scale longitudinal data starting from 2010 to 2012, were used for the analysis. The results from path analysis demonstrated that for men, not only did internet use in 2010 had a positive effect on depression levels in 2012, but the positive effects were partially mediated by the positive effects that internet use in 2010 had on social relationship satisfaction in 2011. The results were consistent even after controlling for various socio-economic factors and the base level of depression at time 5. However, interestingly, internet use did not have any significant positive effects on the depression levels of older Korean women. These results suggest that the benefits of internet use at late life vary depending on gender, which stem from differences that men and women have in terms of social relationships and social support. The findings imply that as older men tend to suffer more from decreases in social relationships and social support, internet use could be a useful method to prevent depression in late life for elderly men, suggesting that policies which encourage elderly internet use and that increases in internet education are essential.

317. The Neighbourhood Environment and Use of Neighbourhood Resources in Older People With and Without Osteoarthritis: Results from the Hertfordshire Cohort Study, *Erik Timmermans, Department of Epidemiology and Biostatistics, EMGO+ Institute for Health and Care Research, VU University Medical Center, Amsterdam, The*

Netherlands.; Suzan Van der Pas, Department of Epidemiology and Biostatistics, EMGO+ Institute for Health and Care Research, VU University Medical Center, Amsterdam, The Netherlands.; Cyrus Cooper, MRC Lifecourse Epidemiology Unit, University of Southampton, Southampton General Hospital, Southampton, United Kingdom; Laura Schaap, Department of Health Sciences, Faculty of Earth and Life Sciences, VU University Amsterdam, Amsterdam, the Netherlands; Mark Edwards, MRC Lifecourse Epidemiology Unit, University of Southampton, Southampton General Hospital, Southampton, United Kingdom; Dorly Deeg, MRC Lifecourse Epidemiology Unit, University of Southampton, Southampton General Hospital, Southampton, United Kingdom; Elaine Dennison, MRC Lifecourse Epidemiology Unit, University of Southampton, Southampton General Hospital, Southampton, United Kingdom

Objectives: The results provide some support for the environmental docility hypothesis, which suggests that the less competent the individual, the greater the impact of environmental factors on that individual.; Older people with osteoarthritis perceive more neighbourhood problems than older people without osteoarthritis.; Perception of more neighbourhood problems is associated with more use of public transport in older people without osteoarthritis, whereas perception of more neighbourhood problems is associated with less use of public transport in older people with osteoa

Abstract Body: This study aimed to examine whether the associations of perceived and objective neighbourhood characteristics with the use of neighbourhood resources are stronger in older people with osteoarthritis (OA) than in older people without OA. Data from the Hertfordshire Cohort Study were used. American College of Rheumatology classification criteria were used to diagnose OA in older people from Hertfordshire, United Kingdom. Use of neighbourhood resources was assessed using the Home and Community Environment instrument. Participants were asked about their perceptions of neighbourhood cohesion and neighbourhood problems. Objective neighbourhood deprivation was assessed using the Index of Multiple Deprivation score 2010 of census area of residence. Associations were examined using logistic regression analyses and were adjusted for several confounders. Of the 404 participants (71-80 years), 110 (27.2%) persons had OA in knee, hand and/or hip. Older people with OA perceived significantly more neighbourhood problems than older people without OA. A significant modification effect of OA showed that perception of more neighbourhood problems was associated with more use of public transport in older people without OA (OR=1.20, 95% CI=1.04-1.39), whereas more perceived neighbourhood problems were associated with less use of public transport in older people with OA (OR=0.60, 95% CI=0.40-0.91). Regardless of OA, objective neighbourhood deprivation was not significantly associated with use of neighbourhood resources in older people. The perception of neighbourhood problems has a greater influence on the use of neighbourhood resources by older people with and without OA than objective neighbourhood deprivation. These results could be used to guide environmental interventions.

318. The Prevalence of Elder Abuse in Western Part of Rajasthan State in India: A Random Sample Survey, *Dr. Alok Mohta, Dr. S.N. Medical College & M.D.M Hospital*

Objectives: To assess the prevalence of Elder abuse in community dwelling elderly in Western Part of Rajasthan State.; To educate elders about their rights and informing them of ways to access services.;

Abstract Body: 1.Introduction:- Elder abuse is a term referring to any knowing, intentional or negligent act by a Care giver or any other person that causes harm or severe risk of harm to vulnerable adult. The types of abuse are Physical, Psychological Financial & Sexual. It's a refusal or failure by those responsible to provide food, shelter, health care and protection for a vulnerable elder. 2.Objective:- To assess the prevalence of elder abuse in community dwelling elderly in western part of Rajasthan state of India. Our objective was also to educate elders about their rights and informing them of ways to access services and adequate places in case of need, ensuring that information is not denied to elders so that they can have the possibilities to make their own Personal choices. 3.Methods:- A total number of 2016 subjects were included in survey conducted over a span of one Year. The survey conducted among community dwelling elderly in western part of Rajasthan state. Both rural & urban area included randomly. A questionnaire was prepared based on living Conditions, family structure, financial support and types of neglect. The survey based on interview and observation based. 4.Results:- The observations obtained were analyzed statistically. A significant number of elderly show some or other form of elder abuse. The prevalence rate came as 42/1000 elderly facing abuse. The psychological & financial abuse were commonly encountered. In more than 50% cases, Close Family persons (son, daughter in law, spouse) were responsible. The survey is random, covered a limited area and sample size may not be large enough hence the study may not be very scientific & authentic in terms of results but certainly it signifies the emerging magnitude of problem in a community of growing aging population. 5.Conclusion: The Western part of Rajasthan state in India is mostly Desert & arid. Though the wave of development has changed the scenario but still the life in this part is hard task, particularly in rural area where younger people go to cities in search of employment & leave their elderly parents home alone, facing the harshness of day to day life & eventually neglect. The Govt. has launched various schemes and laws to safeguard the financial need, Medical aid & to prevent abuse & neglect but the elderly should be informed about these in order to know their rights.the key person in rural area villages particularly the "Gram sevaks" (servants to villages) responsible for informing and help in implementing various govt. schemes can play a major role by guiding & educating elderly about their rights & govt. plans & laws beneficial for them. This will be a cost effective approach too.

319. The relationships between cardiovascular events, risk factors, and sleep duration: Longitudinal study, *Daiki Kobayashi, St Luke's International Hospital*

Objectives: This study investigate the relationship sleep duration and cardiovascular events, its risk factors and related measurement by longitudinal analyses with large data

Abstract Body: Background: The goal of this study was to examine the relationship between cardiovascular events, risk factors, and sleep duration considering change of sleep duration over time with longitudinal data analyses. Methods: A retrospective longitudinal study was conducted involving individuals aged 20 years or older who underwent annual health check-ups at St. Luke's International Hospital, from 2005 to 2010. Data collected included self-reported demographic, clinical and health habits information (including sleep duration; <6, 6-7, 7-8, 8≤); baseline examination; and laboratory measures each year. We conducted mixed effects analyses to examine the associations between sleep duration and cardiovascular risk factors and event longitudinally. Results: A total of 31,830 participants were enrolled. 70.1% of them changed their sleep duration and 365 participants developed cardiovascular events during follow-up periods. Compared to those with less than 6 hours sleep, those who sleep longer were less likely to have cardiovascular events [odds ratio (OR) 0.62 (95%CI: 0.38-0.99) for 6-7 hours, OR 0.55 (95%CI: 0.32-0.94) for 7-8 hours and OR 0.68 (95%CI:0.34-1.34) for 8≤ hours group] and to report excessive alcohol consumption [OR 0.74 (95%CI: 0.67-0.82)]. Long sleep duration was associated with a lower likelihood of diabetes and related measures, a higher likelihood of hypertension and dislypidemia over time. Conclusion: Individuals with more than 8 hours sleep duration significantly were less likely to have cardiovascular events than other group. For risk factors, longer sleep duration was associated with development of hypertension and dyslipidemia , but protective against to diabetes.

320. The Role of Cognitive Control in Older Adults' Cognitive Reappraisal: Detached and Positive Reappraisal, *Meng Huo, Department of Human Development and Family Sciences, the University of Texas at Austin; Renlai Zhou, Department of Psychology, Nanjing University; Robert Kennison, Department of Psychology, California State University, Los Angeles*

Objectives: To understand how different aspects of cognitive control impact different subtypes of cognitive reappraisal in older age; To think about implications of this study for development of cognitive training interventions for the elderly.;

Abstract Body: Older adults compared to younger adults are more likely to regulate their emotions by engaging in cognitive reappraisal. However, depending on the type of cognitive reappraisal used, whether detached or positive, their efforts to regulate emotions are sometimes met with success and other times with failure. It has been suggested that the well-known age-related decline in cognitive control might be the culprit behind the poor use of detached reappraisal by the elderly. However, this possibility has not been thoroughly investigated. Also, studies have not examined which aspects of cognitive control (shifting, updating or inhibition) might be relevant to cognitive reappraisal. In the present study, 41 older participants (aged 55-72 years) were tested on cognitive control and their abilities to use detached and positive reappraisal. The study employed standardized emotional stimuli selected from the International Affective Picture System (IAPS) and a multi-method approach (subjective ratings and physiological measures) to assess effects of regulation. The results showed that detached compared to positive reappraisal relied more heavily on cognitive control, specifically mental set shifting. Results of this study have important implications for development of cognitive training interventions for the elderly.

321. The Unequal Burden of Oxidative Stress: An Intersectional Approach to Understanding Social Disparities in Telomere Length in Older Adults, *Lauren Brown, Leonard Davis School of Gerontology, University of Southern California; Belinda Needham, School of Public Health, Department of Epidemiology, University of Michigan; Jennifer Ailshire, Leonard Davis School of Gerontology, University of Southern California*

Objectives: After attending the session participants will be able to describe population variation in telomere length by the intersection of race and gender in the Health and Retirement Survey.; After attending the session participants will be able to identify Blacks as having significantly longer telomeres than both Whites and Hispanics in a population based sample.; After attending the session participants will be able to determine that group differences in telomere length vary with age.

Abstract Body: Background: Telomere length (TL) is a biomarker of aging and oxidative stress. Prior studies examined gender and race/ethnic differences in TL with mixed findings, but have not considered intersections of race and gender. This study takes an intersectional approach by examining the combination of race and gender, indicators of identity and social status, to determine the inter- and intra-group differences in TL. Methods: TL was assessed in a nationally representative sample of 5,861 Whites (82.9%), Blacks (9.2%), and Hispanics (8.0%) [53.6% female, mean(SD) age: 66.9(9.8) years] from the 2008 Health and Retirement Study. ANOVA was used to establish intergroup differences in TL. Pairwise linear regression models were used to estimate age adjusted intragroup differences. Finally, models were adjusted for demographic measures (marital status, occupational status, income, wealth) and health behaviors (BMI, smoking, physical activity) to determine if they accounted for group differences. Results: We observed differences in TL by gender (p=0.005) and race (p<0.001). After adjusting for age, Blacks had longer telomeres than both Whites and Hispanics, with Black women having the longest telomeres. White men had the shortest telomeres. Race/ethnic and gender differences in TL varied with age. Demographic characteristics and health behaviors did not account for group differences. Implications: Results reveal complex and unexpected interactive effects of gender and race in TL with age. These findings suggest the importance of investigating disparities in TL using multiple dimensions of identity and social status as an important distinction to understanding population variation in oxidative stress.

322. Tilting at Windmills: The Effects of Previous-Day Anticipatory Coping on Daily Cognitive Interference Across Older Adulthood, *Brent Nara, North Carolina State University; Shevaun Neupert, North Carolina State University*

Objectives: Past work has demonstrated that cognitive interference travels together with daily stressors (Stawski, Mogle, and Sliwinski, 2009), but no study to date has sought to explain the consequences of anticipatory coping for future stressors on daily cognitive; We examined whether endorsing adaptive strategies (problem analysis and planning) for managing upcoming stressors predicted an increase in self-reported cognitive interference (following performance on everyday cognitive tasks) the day after endorsing sai; We also examined age differences in these relationships across older adulthood.

Abstract Body: Methods: 43 older adults ages 60-96 completed two brief tasks of everyday cognition, a measure of cognitive interference, and a measure of anticipatory coping daily for eight days. Results: Multilevel modeling determined a main effect for anticipatory coping, a main effect of age, and an anticipatory coping X age interaction. Older-old adults were more likely to experience higher cognitive interference, as were those who elected to use anticipatory coping. Older-old (M + 1SD) participants experienced more cognitive interference than younger-old (M - 1SD) participants when they used problem analysis or planning to prepare for a future interpersonal stressor. Discussion: Our culture values planning and problem-solving, but our data suggest that this comes at a cost. As age increases, investing executive functional resources into coping for a future stressor may distract from cognitive performance in the present.

323. Trait Mindfulness in Older Adults Predicts Change in Loss Aversion in the Iowa Gambling Task, *Kateri Noble, The Catholic University of America; Katy O'Neil, The Catholic University of America; Kendra Seaman, The Catholic University of America; Chelsea Stillman, Georgetown University; Eileen Rasmussen, Georgetown University; Darlene Howard, Georgetown University; James Howard, The Catholic University of America and Georgetown University*

Objectives: Determine the relationship between mindfulness and real-world decision making

Abstract Body: As people live longer independently, they must increasingly make difficult decisions in the face of age-related cognitive changes. To date, many studies report beneficial effects of mindfulness on cognition in older adults, particularly regarding the amelioration of stress and subsequent benefits to executive function (Moynihan et al., 2013). However, not all studies report positive effects associated with greater mindfulness. Recent findings have shown that lower trait mindfulness is associated with better implicit sequence learning in both young and older adults (Stillman, Feldman, Wambach, Howard, Jr., & Howard, 2014). The present study examined the relationship between trait mindfulness as assessed by the Mindfulness Attention Awareness Scale (MAAS, Brown & Ryan, 2003) and decision making as assessed by the Iowa Gambling Task (IGT, Bechara, H. Damasio, Tranel, & A. R. Damasio, 1994) in 83 healthy older adults. In the IGT, participants choose between decks of cards on a series of trials with loss aversion defined as avoiding decks with frequent punishments. Results indicated a significant increase in loss aversion with practice, $F(4, 328) = 5.48$, $p < .001$ and this increase in loss aversion was related to mindfulness. Specifically, there was a significant negative correlation ($r = -.246$, $p = .025$) between trait mindfulness and the development of loss aversion, such that those lower in mindfulness showed a greater increase in loss aversion. Thus, low trait mindfulness in older adults is associated with increased learning of loss aversion in a task related to real-world decision making.

324. Translation of a BRI Care Consultation Intervention for Rural Individuals with Dementia and their Caregivers, *Michelle M. Hilgeman, Tuscaloosa VA Medical Center; T. Scott Martin, Tuscaloosa VA Medical Center; Mark E. Kunik, Houston VA Health Services Research and Development Center of Excellence; Branka Primetica, Benjamin Rose Institute; David M. Bass, Benjamin Rose Institute; Tiffany Sexton, Benjamin Rose Institute; A. Lynn Snow, Tuscaloosa VA Medical Center*

Objectives: Identify unmet care needs of individuals with dementia and their caregivers in a rural clinical setting.; Relate current findings of this clinical demonstration to the published research “Partners in Dementia Care,” a version of BRI Care Consultation.; Discuss modifications in the research and service protocols to enhance use of evidence-based programs for rural settings.

Abstract Body: The vast majority of efficacious, non-pharmacological evidence-based programs “remain on the shelf” after initial testing and go unused by clinicians in health and community organizations (Gitlin, 2013). This poster describes a large-scale community implementation of one evidence-based program in the VA, BRI Care Consultation, which is a telephone-based coaching intervention for individuals with dementia (IWD) and their caregivers. A unique feature of this implementation is its focus on families in 27 rural counties of Alabama, where there are limited health and community services. 115 IWD and 111 caregivers participated in the Telephone Assisted Dementia Outreach clinic where BRI Care Consultation was delivered over 16-months. Initial needs assessments revealed needed assistance with: arranging services (49%), memory problems and difficult behaviors (47%), and emotional/physical health strain (38%). Nearly one in three caregivers also (31%) expressed concerns about their capacity to provide care. Several key modifications were made to BRI Care Consultation to enhance its utility for rural settings: 1) reduced role of a partnering community agency due to a lack of service resources, 2) longer telephone coaching sessions with caregivers, and 3) incorporation of more psychotheraputic elements for those in acute distress. Other adaptations altering the Care Consultation Information System (CCIS) used to deliver the program are also described: reordering assessment domain presentation; considerations in when a care domain was triggered as a problem; and a simplified approach for integrating the CCIS and the VA electronic medical record. Systematic translation efforts like this one are critical for increasing access to evidence-based care.

325. Understanding Everyday Task Challenges for Older Adults with and without Disabilities, *Christina Harrington, Georgia Institute of Technology; Tracy Mitzner, Georgia Institute of Technology; Wendy Rogers, Georgia Institute of Technology*

Objectives: Synthesize and assess the data that exists on the everyday activity limitations for older adults aging with and without pre-existing disabilities (e.g., vision, hearing, and mobility).; Assess the current use of assistive technology by older adults for activity performance.; Demonstrate a critical unmet need for assistive support.

Abstract Body: The 65+ population is growing rapidly, with this age group expected to reach 21% of the population by 2050. With increased longevity of life spans, the number of older adults living with disabilities is projected to double from the year 2000 to 2040, becoming 4.2% of the population. Given these increases in the aging population, there is a need to know more about everyday activity challenges for older adults who have age-related limitations and those who have both a disability and age-related limitations. To develop solutions that facilitate successful aging, an understanding of the range, frequency, nature, and distribution of these limitations is required. This archival analysis integrated existing data on the functional limitations and challenges experienced by older adults with and without pre-existing disabilities. Longitudinal research study reports were reviewed for statistics pertaining to activity limitations including the Women's Health and Aging Study, the National Health and Aging Trends Study, the National Long-Term Care Survey, and the American Community Survey, as well as information from the National Institute on Aging, Federal Interagency on Age-Related Statistics, and the Census Bureau. Findings suggest that older adults both with and without disabilities reported significant task limitations in activities involving mobility (walking, getting in/out of bed/chairs, doing laundry, shopping, doing housework) and transportation (attending religious services/club meetings). Results also indicate that technological solutions to activity limitations exist; yet there is a rather low usage rate. These data provide guidance for the development of user-centered design solutions and education and training deployment.

326. Valuation of Life: Comparing Japanese and German Old and Very Old Individuals, *Takeshi Nakagawa, Osaka University, Graduate School of Human Sciences; Daniela Jopp, University of Lausanne, Institute of Psychology; Yasuyuki Gondo, Osaka University, Graduate School of Human Sciences; Jonathan Lehrfeld, Fordham University; Christoph Rott, Heidelberg University, Institute of Gerontology; Frank Oswald, Heidelberg University, Institute of Gerontology*

Objectives: To examine how old and very old individuals differ in their valuation of life.; To understand how cultural context affects the above relationship.; To examine age and cultural effects on predictors of valuation of life.

Abstract Body: Research on valuation of life (VOL) investigates how strongly individuals feel attachment to their lives. Studies still try to determine how VOL develops with advancing age and which factors contribute to VOL. Studies mostly focus on person factors (e.g., age, health), but it is also possible that societal/cultural aspects play a role. This study investigated mean levels and predictors of VOL in Japanese and German old and very old individuals. A total of 620 population-based participants (n = 310 per country) were matched by age, gender, education, and instrumental activities of daily living (IADL). Mean age of the total sample was 76.4 years (range: 65-92). VOL was assessed with 4 items from the Positive VOL Scale (Lawton et al., 2001). Findings revealed that there were no significant age differences between young-old, old-old, and oldest-old individuals, but Germans reported higher VOL levels compared to the Japanese. Regression analyses suggested significant roles of demographic, social, and health variables in the prediction of VOL. Among the young-olds, social contact, subjective health, and IADL were significant predictors in both cultures; education only mattered for VOL in the Japanese young-olds. Among the old-old, number of children was significant in both samples, but health predictors varied. No significant predictor was found for the oldest old, maybe due to small sample size. In sum, the extent to which older individuals value their lives seems to depend on global characteristics (e.g., health), but levels and the importance of specific aspects (e.g., education) may depend on age and culture.

327. Dissection of the Progenitor and Thymic Microenvironment in Aged Mice by Parabiosis, *Heather Thompson, Department of Immunobiology and the Arizona Center on Aging, College of Medicine, University of Arizona; John Davies, Department of Immunobiology and the Arizona Center on Aging, College of Medicine, University of Arizona; Vesna Pulko, Department of Immunobiology and the Arizona Center on Aging, College of Medicine, University of Arizona; Janko Nikolich-Zugich, Department of Immunobiology and the Arizona Center on Aging, College of Medicine, University of Arizona*

Objectives: Dissect defects in the hematopoietic progenitor population compared to the thymic microenvironment that occur with age; Understand immune dysfunction with age; Understand where interventions can improve immune function

Abstract Body: As the immune system ages, multiple defects occur as a result fewer naïve T cells are available to response to new infections. Consequently there is an increase in morbidity and mortality from infectious disease associated with aging. The defects that occur in aging are both cell intrinsic as well as cell extrinsic. Our goal is to identify areas of the aging immune system where we can intervene to improve immune function. To systematically understand the overlapping defects present in the aging immune system, including hematopoietic stem cell as well as lymphocyte progenitor function versus defects present in the thymic stromal microenvironment, we have begun to use parabiosis to join the circulation from different animals together. When wild type mice are parabiosed to RAG (recombination activation gene-1) knockout mice that lack mature B and T cells, we can test the contributions of the lymphocyte progenitors compared to the impact of the thymic microenvironment. When old mice were parabiosed to RAG knockouts we observed that old progenitors were able to effectively seed and reconstitute T cell development in the RAG knockout parabiont. Interestingly, the seeding of the RAG thymus was relatively consistent between the isochronic and heterochronic pairs despite the profound differences in cell numbers remaining between wild type adult and wild type old thymi through day 56 of parabiosis. This suggests that the old progenitor cells have the capacity to make T cells when given an empty adult thymic microenvironment in which to develop.

328. Metabolomics Analysis of the Effects of Rapamycin Treatment and Intermittent Feeding on Skeletal Muscles from Young and Old Rats Using Liquid Chromatography/Mass Spectrometry, *Yu-Hsuan Tsai, University of Florida Department of Chemistry; Timothy Garrett, University of Florida; Richard Yost, University of Florida; Christy Carter, University of Florida*

Objectives: Rapamycin-treated animals showed increased relative lean mass and decreased fat mass compared with IF suggesting that this compound may positively regulate lipid metabolism in muscle. Here, we present the first metabolomics analysis using high performance

Abstract Body: Rapamycin, an inhibitor of the target of rapamycin (TOR), increases mammalian lifespan but less is known regarding its direct effects on muscle lipid metabolism. We have demonstrated that male Fisher 344 × Brown Norway rats aged 6 and 25 months treated with rapamycin (1mg/kg 3X per week) or intermittent feeding (IF) showed reduced food consumption and body weight. Rapamycin-treated animals showed increased relative lean mass and decreased fat mass compared with IF suggesting that this compound may positively regulate lipid metabolism in muscle. Here, we present the first metabolomics analysis using high performance liquid chromatography/mass spectrometry (HPLC/MS). Thirty-one extensor digitorum longus (EDL) and soleus (SOL) lipid extracts were analyzed by a Thermo Scientific Q Exactive Obitrap in positive and negative ion modes. Results were processed by XCMS and principal component analysis (PCA) was performed. Separation by principal components (PC) between the treatment and age within each muscle type were observed from negative ion mode data. PCA on the SOL revealed separation between IF and rapamycin-treatment at both ages. For the 6 month group, another unique PC distinguished EDL controls from the IF and rapamycin-treatment groups. Separation between age groups within IF was also observed within EDL. Investigation on the loadings of the separating PCs and the identification of the significant metabolites and lipids are in progress and critical for generating hypotheses regarding the efficacy of rapamycin and IF on maintenance of muscle metabolism quality during the aging process.

329. TGF-□ impairs CD4 and Antibody Responses in Old Mice to Increase Chikungunya Virus Disease Severity and Viral Persistence, *Jennifer Uhrlaub, Department of Immunobiology and the Arizona Center on Aging, University of Arizona College of Medicine; Vesna Pulko, Department of Immunobiology and the Arizona Center on Aging, University of Arizona College of Medicine; Victor DeFilippis, Vaccine and Gene Therapy Institute, Oregon Health and Science University; Janko Nikolich-Zugich, Department of Immunobiology and the Arizona Center on Aging, University of Arizona College of Medicine*

Objectives: Are aged mice more susceptible to CHIKV infection?; Do aged mice mount effective immune responses to CHIKV?; Can disease severity in old mice be reduced through augmentation of the immune response?

Abstract Body: Chikungunya virus (CHIKV) is a mosquito-borne Alphavirus endemic to Africa, India, and Asia, which causes sudden onset of fever, rash, and debilitating poly-arthralgia in peripheral joints, which can persist for years, particularly in older individuals. The virus has been spreading around the world, including North America, with >100,000 confirmed cases of autochthonous CHIKV infection in the Caribbean by 2013, followed by the first confirmed transmissions of CHIKV in the U.S. in 2014. In response to the increased geographic distribution of CHIKV and the likelihood that elderly immune-naïve populations may experience severe and life-threatening disease, we have developed a mouse model of age-related vulnerability to CHIKV infection. We demonstrate reduced ability of old mice to mount effective immune responses to CHIKV and control viremia, leading to increased disease severity and viral persistence in the joints. Ineffective immune responses were due, in part, to uncoordinated cytokine production. Specifically, MIG and TGFβ, were identified as key contributors to impaired CD4 and antibody responses against viral epitopes in old mice. Moreover, neutralization of TGFβ restored both CD4 and Ab responses, improved viral clearance from the joints and reduced joint pathology. These results provide a valuable tool for further mechanistic dissection of age-related vulnerability to CHIKV and point to possible targets in CHIKV disease treatment.

330. Genotype-by-Age Interactions of Circulating miRNAs in Normal and Ames Dwarf Mice, *Berta Victoria Martinez, Burnett School of Biomedical Sciences, College of Medicine, University of Central Florida; Joseph M Dhahbi, Department of Biochemistry, University of California at Riverside; Yury O Nunez-Lopez, Translational Research Institute for Metabolism and Diabetes, Florida Hospital; Lina Spinel, Burnett School of Biomedical Sciences, College of Medicine,*

University of Central Florida; Michal M Masternak, Burnett School of Biomedical Sciences, College of Medicine, University of Central Florida

Objectives: We aim to characterize age-associated circulating miRNAs in serum of N and df/df mice

Abstract Body: There is evidence that miRNAs circulating in the bloodstream can be taken up by cells and alter expression of targeted genes. Aging involves changes in many cellular processes that are potentially regulated by miRNAs. To determine the role of circulating miRNAs in aging, we used deep sequencing to characterize circulating miRNAs in serum of normal (N) and Ames dwarf (df/df) mice at the age of approximately 4 and 20 months. Our analysis showed genotype specific changes in the levels of 43 circulating miRNAs during aging. A group of 38 miRNAs remains unchanged during aging in df/df mice, whereas 6 and 32 miRNAs increase or decrease, respectively, with age in N mice only. A second group of 5 miRNAs increase with age in df/df whereas 3 of them significantly decrease in old N mice and the other 2 miRNAs do not change. The predicted targets of the miRNAs, which decreased in N mice but did not change in df/df animals, are significantly enriched for signaling pathways (such as insulin, MAPK, Wnt, Notch, mTOR, and TGF-beta) and 11 types of cancer. In addition, previous studies reported several of these miRNAs being involved in cell signaling and tumor suppression in both mice and humans. Other miRNAs that we found increased in N mice but unchanged in df/df animals, have been associated with inflammation, proliferation, and cancer. Importantly, about 50% of circulating miRNA families that show genotype-by-age interaction in long-living df/df mice were similarly modulated by calorie restriction intervention known to extend rodents lifespan.

331. Sexual Dimorphism in Neuroinflammation from Inhaled Particulate Matter in Older Mice, *Nick Woodward, University of Southern California; mafalda cacciottolo, University of Southern California; David Davis, University of Southern California; Costas Sioutas, University of Southern California; Todd Morgan, University of Southern California; Caleb Finch, University of Southern California*

Objectives: After attending this session, participants will have an enriched understanding of the neuroinflammatory effects of particulate matter exposure from air pollution.; After attending this session, participants will have a greater understanding of how responses to air pollution are modulated by both sex and age.

Abstract Body: Air pollution, ubiquitous in urban environments, is responsible for large-scale morbidity and mortality in older populations. However, air pollution’s effects on physiology are still largely unknown. Particulate matter, a component of air pollution, is a primary factor in the detrimental health effects of air pollution. In this study, male and female C57BL/6NJ mice, ages 3 and 18 months, were exposed to reaersolized nanoscale particulate matter (nPM, diameter <200nm) three days a week, for ten weeks. Immunohistochemical analysis of the corpus callosum showed profound sex and age differences in the neuroinflammatory response, measured by the astrocytic marker, GFAP. Male corpus callosum GFAP levels increased 23% by nPM exposure in the 3 month group. The 18 month controls showed a 74% increase over young controls (ANOVA $p<0.039$). Interestingly, a plateau effect was observed with age, where nPM did not increase GFAP beyond the age-related increase. There was no change in 3 month treatment females, yet similar increases (70%) in the 18 month controls (ANOVA $p<0.0001$). Unlike the males, no age plateau effect was observed, with the female treatment group increasing 150% over controls. Western blot analysis of the cortex shows similar results, with 3 month, but not 18 month, males responding to nPM treatment, while the 3 month females remained insensitive to treatment. These pronounced differences in nPM responses based on age and sex, are of importance when considering efforts to minimize harm from air pollution in the population.

332. Views of Primary Care Physicians and Home Care Nurses on the Causes for Readmissions in Older Adults, *Allen Shih, Yale School of Medicine, Yale University; Kathy Tynan-McKiernan, Yale New Haven Hospital; Bianca Buurman, Section of Geriatric Medicine, Department of Internal Medicine, Academic Medical Center, University of Amsterdam, Amsterdam, The Netherlands; Mary Tinetti, Gladys Phillips Crofoot Professor of Medicine (Geriatrics) and Professor of Epidemiology (Chronic Diseases), of Faculty of Arts and Sciences and of Investigative Medicine; Section Chief, Geriatrics; Grace Jenq, Associate Professor of Medicine, Section of Geriatrics, Yale School of Medicine*

Objectives: To elicit qualitatively the views of primary care physicians and home care nurses concerning reasons why older adults are readmitted.; Describe how the views of primary care physicians and home care nurses are similar and different.;

Abstract Body: Interventions to reduce readmissions have largely focused on enhancing discharge communication between the hospital and patients and outpatient providers - primarily primary care physicians (PCPs), and ensuring early postdischarge patient visits to PCPs. Much of the posthospital care is provided by home care nurses (HCNs), requiring interaction between the HCNs and PCPs. Despite their key role in posthospital care, little is known concerning the views of PCPs and HCNs on reasons for hospital readmissions. To study qualitatively the perspectives of PCPs and HCNs, we conducted open-ended phone interviews with 10 PCPs and 10 home care nurses who cared for patients aged 65 and older who were readmitted to the hospital within 30 days of discharge. We categorized patient-, provider-, or system-related responses on reasons for readmissions. While PCPs and nurses both mentioned disease progression and multimorbidity as contributors, nurses further described other psychosocial factors like home environment, patient motivations, and family situation as reasons for readmission. For provider-level factors, PCPs often deflected responsibility for the readmissions to specialists, hospitalists, and emergency physicians. Nurses expressed frustration about the lack of communication and working relationships between them and PCPs. The poor relationship between HCNs and PCPS may play a bigger role in readmissions than currently appreciated. Additionally, medical providers other than PCPs may be responsible for ensuring appropriate postdischarge care and reducing avoidable readmissions. Study results suggest that current approaches of addressing readmission rates may not address all the core problems.

333. Creating a Palliative Community: Connecting Science to Culture Change, *Casey Shillam, Western Washington University; Hope Corbin, Assistant Professor, Western Washington University; Devyani Chandran, Western Washington University; Bree Johnston, PeaceHealth Medical Center; Rebecca VanGlubt, Western Washington University; Rebecca VanGlubt, Western Washington University; Heather Prieto, Western Washington University; Melissa Haun, Western Washington University*

Objectives: Describe the methodology employed to capture break-out discussions crafted to democratize the process of local health policy making by equalizing contributions and honoring all participants' perspectives equally.; Present the three key findings of the Summer Institute.; Provide best practices for engaging academic, healthcare, and community partners in establishing palliative care priorities for the community.

Abstract Body: Palliative care is specialized health care to improve quality of life for patients with serious illness and their families through prevention and relief of suffering by treating pain and other physical, psychosocial, and spiritual symptoms. The Palliative Care Initiative is an ongoing partnership with Western Washington University and community partners in educational and non-profit organizations in Northwest Washington to promote community palliative care. A 3-day Summer Institute was held to engage in a participatory process to capture participant voices about diverse needs, strengths and opportunities for improvement of palliative care in the community. Researchers employed qualitative data collection and analysis methodologies. Nearly 100 participants self-selected into 4 of 12 different breakout groups led by a session facilitator and recorded by a team of three faculty researchers and three student research assistants. Multivoting techniques were used to capture specific stakeholder interest in individual themes and to prioritize themes that captured larger group interests. This carefully crafted process intended to democratize local health policy making by and honoring all participants' perspectives. Real-time thematic analysis with member-checking revealed three key areas of focus: 1.Seeking financial support to ensure sustainability of the Palliative Care Initiative; 2.Establishing a workgroup to explore resources to support an outpatient palliative care service and resource center; 3. Creating a platform for programs to participate in the Palliative Care Initiative through research, teaching, service and practice. Findings from this study, as well as techniques employed, may provide useful insights for service providers, researchers and policy makers.

334. Life-Space Mobility and Cognitive Decline Among Older Mexican Americans Aged 75 Years and Older, *Seraina Silberschmidt, University of Geneva; Soham Al Snih, Division of Rehabilitation Sciences / Sealy Center on Aging / University of Texas Medical Branch; Amit Kumar, Department of Preventive Medicine & Community Health / Division of Rehabilitation Sciences.University of Texas Medical Branch; Mukaila Raji, Department of Internal Medicine / Division of Geriatrics / Sealy Center on Aging.University of Texas Medical Branch.; Kyriakos Markides, Department of Preventive Medicine & Community Health / Sealy Center on Aging.University of Texas Medical Branch; Kenneth Ottenbacher, Department of Preventive Medicine & Community Health / Sealy Center on Aging.University of Texas Medical Branch*

Objectives: Determine the trajectory of cognitive decline among older Mexican Americans.; Determine whether the relationship between life-space is modified or mediated by comorbid conditions.

Abstract Body: Objective: To examine the association between life-space mobility and cognitive decline among older Mexican Americans with normal or high cognition at baseline. Methods: We used data from the Hispanic Established Population for the Epidemiological Study of the Elderly to examine change in Mini Mental State Examination (MMSE) scores over the 5-year period as a function of life-space mobility. All participants (N=436) had MMSE scores $\geq$21 at baseline and complete data on socio-demographic, socio-economic, and environmental, medical conditions, depressive symptoms (CES-D), and activities of daily living (ADLs). Life-space assessment (LSA) was assessed by asking the participants: "during the past 4 weeks, have you been to other rooms in your home besides the room where you sleep (level 1); been to an area outside of your home (level 2); been to places in your neighborhood other than your own yard or apartment building (level 3); been to places outside your neighborhood but within your town (level 4); and been to places outside your town (level 5)." Results: The mean LSA score of participants was 43.1 (SD=14.0) and the mean MMSE score was 24.7 (SD=12.3). Mixed Model analyses showed that participants in the lowest life-space (level 1) experienced a greater cognitive decline over time (estimate = -1.32, standard error = 0.3, p=0.0001) compared to participants in the highest level (4-5), after adjusting for all covariates. Conclusion: Lower life-space mobility was independently associated with steeper decline in cognition over 5 years among older Mexican Americans with normal or high cognition at baseline.

335. LA Seniors Get "On the Move": A Pilot Evaluation of a Media-Based Intervention Aimed to Improve Physical Activity, *Kia Skrine Jeffers, UCLA School of Nursing; Scott Kaiser, Motion Picture & Television Fund; Ivy Lee, UCLA Division of Geriatrics; Phyllis Willis, Watts Labor Community Action Committee; Daniel Araiza, UCLA Division of Geriatrics; Laura Trejo, UCLA Division of Geriatrics; Catherine Sarkisian, UCLA Division of Geriatrics/VA Greater LA Healthcare System*

Objectives: To describe the associations between exposures to a theoretically-grounded television series entitled "On the Move", and changes in physical activity among racial/ethnic minority seniors

Abstract Body: Background: Regular physical activity is an important determinant of future health, quality of life (QOL), and maintenance of functional independence for older adults. Less than 25% of US adults ages 65 and older participate in regular physical activity, with racial minority seniors having the lowest rates. Objective: We partnered with the City of Los Angeles Dept. of Aging to develop a theoretically-grounded television series, "On the Move" (OTM), which documented the increased physical activity experiences of a group of previously sedentary seniors. This pilot evaluation aimed to identify associations between exposures to OTM and changes in physical activity among our sample. Methods: 12 participants met at a Senior Center for 6 consecutive weekly sessions. The participants viewed and discussed 1 episode per week with an RN study staff member, and shared experiences that impacted their physical activities during the previous week. We used accelerometers to collect objective data about the participants' number of steps per week, and conducted a 1-month follow-up to collect data from the participants' accelerometers. Results: Between baseline and 6 weeks, participants increased their steps a mean of 1,577 steps/day (st. dev. 1,391.82). 10 participants had 3 or more days per week with 3000 steps/day. Conclusions: Further research is needed to determine the psychological mediators that may be attributed to these outcomes, and the long-term impact on health, QOL, and functional independence among seniors.

336. Improving Oral Health of Long-Term Care Residents: A Virginia Dental Association Project Initiative, *Lyubov Slashcheva, Virginia Commonwealth University School of Dentistry; Patricia Bonwell, Lucy Corr Village Dental Clinic; Frank Iuorno, Virginia Dental Association*

Objectives: Demonstrate a process for identifying Long-Term Care residents in need of oral healthcare services.; Design a model for provision of needed oral healthcare services to Long-Term Care residents.; Discuss the importance of access to preventative oral healthcare services for decreasing morbidity and financial burden for Long-Term Care residents.

Abstract Body: Older adults are retaining their natural dentition and oral needs have shifted from denture care to brushing, flossing, oral-health therapy, and restorations. Despite the high prevalence of oral disease, the percentage of Long Term Care (LTC) residents with unmet oral needs ranges from 80%-96%. Oral-health funding for this population is a barrier. Medicare and, in Virginia, Medicaid do not cover routine oral healthcare for adults. Research supports links between oral-health and cardiovascular disease, diabetes, mental health, arthritis, and pneumonia. These chronic conditions are prevalent in the LTC population. Such links support the need and importance of providing oral care to maintain overall health of LTC residents. To improve access to oral care needed by LTC residents, the Virginia Dental Association created a LTC Access to Care Task Force to address oral health disparities of LTC residents across the state. A mini pilot project was conducted in one LTC facility utilizing a model developed for the provision of oral-healthcare in LTC facilities statewide. Dentists, dental hygienists, assistants, and dental students provided exams, extractions, denture relines, debridements and referrals. In half a day, 52 LTC residents were provided over $6,000.00 of oral-healthcare by 12 volunteer oral-health specialists. Residents in need of further oral-care treatment will be coordinated with VDA dentists. These findings support development and implementation of this pilot model to increase access to oral-health care and improve quality of life for LTC residents while decreasing oral-health related morbidity and financial burden.

337. Fall Prevention: Medications, Comorbidities, and Exercise, *Mandy Snyder, University of Utah College of Nursing; Ginette Pepper, University of Utah College of Nursing; Paul LaStayo, University of Utah Department of Physical Therapy; Lee Dibble, University of Utah Department of Physical Therapy; Robin Marcus, University of Utah Department of Physical Therapy*

Objectives: Distinguish the putative benefits of traditional and eccentric forms of resistance exercise for older adults.; Critique existing fall typologies.; Identify risk factors for serious injury falls in high risk older adults.

Abstract Body: Traditional resistance exercise has been shown to reduce falling in older adults, but requires effort that may limit adherence. Eccentric resistance exercise induces unprecedented muscle conditioning, and increases balance, mobility, and confidence, but it is unknown whether that translates to decreased falls. A central aim of this recently completed clinical trial was to determine of the contribution of fall risk, comorbidities, and medications on the incidence of fall events in older adults with positive fall history and multiple comorbidities in these two exercise groups. Secondary aim included evaluating existing typologies of falls. A sample of 134 older adults (mean 76.1years; 47 males, 87 females) participated in a 12 week multi-component exercise fall reduction program (MCEFRP) that included either traditional (TRAD) or eccentric (RENEW) resistance training programs. Data on medications, timed up-and-go, and Charlson index were determined at baseline and three follow-up assessments. Fall data were collected for one year using a modification of the monthly postcard method with follow-up phone calls to elicit detailed fall descriptions. Analysis involved multivariate logistic regression, content analysis, and data visualization. Fall events were common with 90 subjects experiencing one or more falls (N=63) and/or near falls (N=64), 39 injury falls, and 14 serious injury falls. TRAD and RENEW did not differ on prevalence of fall events. Baseline medications and fall risk scores were not associated with falling, but greater comorbidity index and medication changes increased risk of injury falls and serious injury falls. Potential modifications for existing fall typologies for older adults were identified.

338. Linking Fall Events and EMS Utilization of Older Adults In A U.S.-Mexico Border Community, *Guillermina Solis, The University of Texas at El Paso; Hector Olvera, The University of Texas at El Paso*

Objectives: Identify personal characteristics and fall events that may influence emergency service use for older adults

Abstract Body: Background. Falls rank 4th as the cause of death in older adults and common in injury-related hospitalizations causing physical and psychological disability. The devastation may be seen immediately requiring emergency medical service (EMS) initiating a downward spiral advent in the person challenging health services. Understanding EMS utilization related to falls will help design prevention program and prepare EMS to assist older adults. Purpose. Analyze characteristics of older adults who accessed EMS post fall and examine event. Methodology. 12 month retrospective study of persons 55 years and older who accessed EMS post fall. Results. Study included 1,116 older adults 55-102 years old (M 76.1, ±11.5), majority were female and Hispanic. Over half of falls occurred indoors and in the afternoon between 12:00-17:59. Trauma Level III was the most frequent level of care. The most commonly reported injuries were head, hip, and lower extremities. Nonparametric analysis identified a statistically significant association between the person's age, gender, place of fall, and transport level of care. Gender was associated with place of fall, type of injury, income, and transport level of care. Significance. Advanced age, low income, and indoor falls were common pointing to a group of older adults with potentially worse health and function. The time of fall alerts the possibility of chronic illness effect increasing fall risk. Gender differences were identified and warrant further studies to decipher. The EMS personnel needs to service for frail elderly and collaborate with community partners to initiate timely interventions to lessen the devastation of falls.

339. Examining the Role of Self-Care in Supporting Home Care Safety for Older Adults, *Winnie Sun, University of Toronto*

Objectives: Understand the importance of therapeutic self-care ability as the protective factor against the occurrence of adverse events in home care for the older adults.; Identify the need for health practitioners to shape change in their practice, and advance quality of care by mitigating older clients' safety risks and improving their health safety at home.; Strengthen evidence informed decision making by health care leaders and policy makers about the appropriate allocation of home care resources in supporting older adults' self-care functioning and chronic disease management in their homes.

Abstract Body: The purpose of this research study is to investigate the relationship between therapeutic self-care and adverse outcomes, and the role of self-care in supporting home care safety for older adults. This research study is a retrospective cohort design to examine the relationship between therapeutic self-care ability, and the frequency and types of adverse events experienced by home care clients using secondary data sources housed at the Institute of Clinical and Evaluative Sciences in Ontario, Canada. Using logistic regression analysis, geriatric home care clients' therapeutic self-care ability was examined in relation to two types of adverse events: (1) health care resource utilization, including emergency room visits and unplanned hospitalizations; (2) safety outcomes, including falls; unintended weight loss; urinary tract infection; decline in activities of daily living; pressure ulcer; medication non-compliance; and caregiver distress. Results indicated that the likelihood of unplanned hospitalizations was found to be higher among individuals with low therapeutic self-care scores. In particular, decline in activities of daily living, falls; unintended weight loss; and non-compliance with medication were associated with low therapeutic self-care scores when comparing with high self-care group. The study results provided a better understanding of the nature of relationships between therapeutic self-care ability, and the prevalence and incidence of safety outcomes for the older home care clients. This study provides implications to home care practitioners about the need to focus on improving client self-care functioning, as well as providing evidence for policy formulation related to the importance of home care services in supporting chronic disease management.

340. RISK FACTORS OF DELIRIUM IN ELDERLY PATIENTS WITH HIP FRACTURE, *Sunee Suwanpasu, King Chulalongkorn Memorial Hospital; Susan Grinslade, University at Buffalo, School of Nursing,; Wu Yow-Wu B., bUniversity at Buffalo, School of Nursing; Porock Davina, University at Buffalo, School of Nursing*

Objectives: To quantify the reported factors associated to delirium for patients with hip fracture

Abstract Body: Introduction: Delirium is a leading cause of death and disability in elderly with hip fracture. Identifying reliable risk factors for delirium is critical to support optimal outcomes for prevention and reducing delirium. Objective: To quantify the reported factors associated to delirium for patients with hip fracture. Methods: Electronic databases were searched (including Medline, Pub Med, CINAHL, EMBASE, Evidence Based Medicine Reviews, Cochrane Review, Web of Science, and PsycINFO) to identify all studies, published in English language, frome 1990-2012 that evaluated the risk factors of delirium hospitalized people with hip fracture. Two reviewers independently assessed methodology quality and extracted relevant data. The data from the included studies were summarized, and pooled estimates were calculated for 12 risk factors. Results: Thirty-seven studies were included in the review and 25 in the meta-analysis. The incidence of delirium was 32.4% (95% confidence interval [CI] = 25.9%–39.5%). Six predisposing and four precipitating factors predicted delirium among older patients with hip fracture confirmed. The predisposing factors included advanced age (ES=1.06, 95% CI=1.03–1.09), male sex (ES=1.34, 95% CI=1.08–1.68), impairment of cognitive (ES=2.91, 95%CI=1.91–4.42), and function (ES=1.75, 95% CI=1.39–2.2), comorbidity (ES=1.59, 95%CI=1.30–1.96), and health problems (ES=2.65, 95% CI=2.04-3.42). Precipitating factors were hypo- or hypernatremia (ES=1.73, 95% CI=1.14–2.64), depression (ES=4.07, 95% CI=1.95–8.49), more than three prescribed drugs (ES=1.28, 95% CI=1.10–1.49), and drugs including opioids (ES=2.13, 95% CI=1.42– 3.18) and anticholinergic agents (ES=2.10, 95% CI=1.60–2.75). Conclusion: This meta-analysis result provides evidence that these risk factors have a significant impact on delirium in elders with hip fracture during hospitalization. Developing formal screening, effective preventive and management strategies for delirium is important.

341. Gerontology Nursing Honors Program: An Innovative Teaching – Learning Model, *Ruth Tadesse, Oregon Health & Science University; Juliana Cartwright, Oregon Health & Science University*

Objectives: After viewing this poster the audience will identify advantages and challenges for students participating in a gerontology nursing honors program

Abstract Body: Older adults access the healthcare system more than any other age group. Yet, undergraduate (UG) nursing programs provide limited education about the care of older adults. The Gerontology Nursing Honors Program (GNHP) provides mentored experiences for students to develop competence in caring for older adults while exploring in depth a gerontology topic of their choice. Participant selection is based on the applicant's interest in and prior experiences with older adults, academic standing, leadership background, and faculty recommendation. Admitted students start the statewide program during their junior year when they independently complete case-based, online modules about pathophysiology, pharmacology, acute care and chronic illness in older adults. During their senior year, students meet by web conferencing in a 1-credit seminar. Seminars are used to discuss research related to best care practices for older adults, gaps in existing gerontology research, and how current research can be translated to practice to improve the quality and safety of care for older adults. Students submit individual theses on topics of interest at the end of their third year. Their upper division clinical experiences also focus on older adults. Seven students from four campuses were enrolled through distance technology in the first cohort that included three RNBS students and four traditional UG students. Students provided positive feedback on the experience although some found the thesis process challenging. All graduated from the GNHP with honors in June, 2014, obtained employment in settings where older adults receive care, and expressed interest in graduate gerontology nursing education.

342. Persistence of Pain using Pain Quality Descriptors in the Elder Population: The MOBILIZE Boston Study, *Manu Thakral, University of Massachusetts, Boston; Ling Shi, University of Massachusetts, Boston; Robert Shmerling, Beth Israel Deaconess Medical Center; Jonathan Bean, Spaulding Rehabilitation Hospital; Suzanne Leveille, University of Massachusetts Boston*

Objectives: 1.Identify factors associated with persistence of pain quality endorsed by community-living older adults; 2.Discuss the correlation of persistence of pain quality to other global pain characteristics and disability to better understand the elder pain experience;

Abstract Body: Despite its complexity, clinical assessment of geriatric pain is often very limited. Pain quality descriptors remain an untapped resource in geriatric pain assessment. The purpose of this study was to evaluate pain quality descriptors longitudinally in a population-based cohort of community-living adults aged≥70y. Baseline assessments included sociodemographics, health/function measures, and the McGill Pain Questionnaire, reassessed after 18mos. Pain qualities were classified into 3 categories: cognitive/affective, sensory and neuropathic. The persistence of pain qualities was defined as reporting descriptors within the same category(s) at both assessments. Pain severity and interference were measured using the Brief Pain Inventory. Disability was assessed as poor mobility performance (SPPB score<10) and self-reported mobility difficulty (difficulty walking ¼ mile or climbing stairs). Of participants with chronic pain (n=480 out of 681 with longitudinal data), 48.3% exhibited persistent pain qualities. Factors associated with persistent pain qualities included: female sex, lung disease, peripheral arterial disease, osteoarthritis, depression, daily analgesic use, and use of mobility aids. Pain severity was associated with persistence of pain qualities (69.0% of those with moderate to severe pain, 41.4% with mild pain and 30.1% with very mild pain). Similarly, self-reported mobility difficulty was associated with persistence of pain qualities (63.8% versus 36.2% among those with and without difficulty, respectively). Significant differences were also observed in persistence of pain qualities according to mobility performance (54.1% of those with poor performance and 45.9% of those without poor performance). Assessment of pain qualities may provide a potentially robust and clinically meaningful measure of pain, warranting further study.

343. Regional Differences in Incident Prefrailty and Frailty, *Sarah Tom, Pharmaceutical Health Services Research Department University of Maryland School of Pharmacy; Allison Wyman, Center for Outcomes Research, University of Massachusetts Medical School; Nancy Woods, Biobehavioral Nursing and Health Systems, University of Washington School of Nursing; Andrea LaCroix, Department of Family and Preventive Medicine, University of California, San Diego School of Medicine*

Objectives: Poster-viewers will understand individual social, demographic, and health-related characteristics that contribute to differences in incident prefrailty and frailty among women in North America, Europe, and Australia.; Poster-viewers will understand that differences in incident prefrailty and frailty among women in North America, Europe, and Australia may relate to the social and built environment.

Abstract Body: Background Frailty prevalence varies according to individual demographic, social, and health characteristics. The extent to which regional differences in frailty incidence reflect individual level characteristics versus environmental aspects has not been well-studied. Methods The Global Longitudinal Study of Osteoporosis in Women (GLOW) is an observational cohort study of women aged ≥ 55 years from Australia, Canada, Europe, and the United States. Participants reported on frailty risk factors, including age, education, Body Mass Index, history of falls and fracture, and chronic conditions such as cardiovascular disease, depression, and osteoporosis. A total of 22,470 participants were non-frail at baseline, provided information on relevant frailty risk factors used in analysis, and participated in at least 2 consecutive waves among baseline and follow-up years 2, 3, and 5. Frailty status was based on the Fried model. We used multivariable Cox proportional hazards models to examine the relationship between frailty and geographic region. Results Adjusting for social, demographic, and health-related characteristics, for age, chronic conditions, falls in the past year, and history of fracture, respondents from Europe had a decreased risk of developing pre-frailty (HR 0.81, 95% CI: 0.77 – 0.85) and frailty (HR 0.77, 95% CI: 0.70- 0.85), compared to respondents from the United States. Respondents from Australia/Canada had similar risks for these outcomes as respondents from the United States. Adjustment for education in available countries did not substantially alter results. Conclusions Differences in frailty onset between Europe and the United States persisted after considering individual social, demographic, and health-related characteristics. Environmental characteristics may play central roles in frailty prevention and management efforts.

344. Dietary Compliance and Influencing Factors among Patients after Coronary Stent Implantation, *Sumei Tong, Peking University Third Hospital/Cardiology Department; Hongjun Zhang, Peking University Third Hospital/Nursing Department; Meihua Hong, Peking University Third Hospital/Cardiology Department; Dongxiao Xu, Peking University Third Hospital*

Objectives: To understand the changing trend of dietary compliance in 9 months among CHD patients after they received the coronary stent implantation.; To describe the influencing factors of the dietary compliance among CHD patients after they received the coronary stent implantation.

Abstract Body: Purposes: Lack of adherence to diet contributes to ineffective dietary responsiveness and elevated cardiovascular risk factors in coronary heart disease (CHD) patients after coronary stent implantation. The purposes of this study were to describe the changing trend of dietary compliance in 9 months among CHD patients after they received the coronary stent implantation, and to analyze influencing factors of the dietary compliance. Methods: This was a longitudinal study. Telephone follow-up was conducted at 3, 6, and 9 months after CHD patients received the coronary stent implantation. Convenient sampling was used to recruit 108 participants with a mean age of 60 from a tertiary hospital in Beijing, China. Questionnaires were utilized to collect patients' demographic data, disease-related information, dietary compliance, and social support. Results: The rate of the dietary compliance at 3 time points were all under 70% (64%, 59%, and 56%). The mean score of dietary compliance significantly decreased over the 3 time points (F=17.15, p<.001). Regression analysis showed the shared significant influencing factors of dietary compliance at 3 time points were age, the level of education, social support, and the number of implanted stents. Conclusion: The level of dietary compliance is relatively low among CHD patients after coronary stent implantation and reduced along the time, especially among younger patients with lower education, few numbers of implanted stents, and limited social support. More Efforts should be made to improve the dietary adherence, such as strengthening the dietary education, providing more social support, and following up regularly.

345. Objective Frailty Assessment in Trauma Patients using a Novel Upper-extremity Approach, *Nima Toosizadeh, 1interdisciplinaryConsortium on Advanced Motion Performance (iCAMP), Department of Surgery, University of Arizona, USA. 2Arizona Center on Aging, University of Arizona, USA.; Michelle Heusser, 3Department of Biomedical Engineering, University of Arizona, USA.; Bardiya Zangbar, 4Division of Trauma, Critical Care, Burns, and Acute Care Surgery, Department of Surgery, University of Arizona, USA.; Bellal Joseph, Division of Trauma, Critical Care, Burns, and Acute Care Surgery, Department of Surgery, University of Arizona, USA.; Jane Mohler, 1interdisciplinaryConsortium on Advanced Motion Performance (iCAMP), Department of Surgery, University of Arizona, USA. 2Arizona Center on Aging, University of Arizona, USA.; Bijan Najafi, 1interdisciplinaryConsortium on Advanced Motion Performance (iCAMP), Department of Surgery, University of Arizona, USA. 2Arizona Center on Aging, University of Arizona, USA.*

Objectives: Strong evidence and guidelines exist for the benefit of assessing frailty in elders who are admitted after trauma, to provide cost effective and optimal hospital resource allocation. However, available tools are subjective and often require gait speed assessment, or time-consuming administrative data. The objective of the current study was to predict frailty status in bedbound trauma patients using a simple, quick, and objective body-worn sensor approach that only involves upper-extremity motion.

Abstract Body: Background: Older individuals account for over 23% of all trauma-related admissions in the US. Although age is strongly associated with adverse surgical outcomes, the overall response of older individuals to poor outcomes is highly variable and can be affected by level of fitness. Assessing frailty, as a syndrome that identifies homeostenotic older adults with low physiological reserves, is crucial for optimal hospital resource allocation. Methods: Thirty eight bedbound hospitalized adults (age≥65 years) who experienced ground-level falls were recruited, and frailty was measured using the validated Rockwood index. Participants wore wireless sensors on forearm and upper-arm, and performed repetitive elbow flexion and extension for 20 seconds. Frailty was characterized based on slowness (speed of flexion), weakness (muscle moments and power (speed × acceleration), exhaustion (speed reduction and variation), and flexibility (range of motion), which accounts for all but one Fried criteria (weight loss). Results: Based on Rockwood index, 20 (53%) were non-frail and 18 (47%) were frail (age=80±10 years; BMI=25.1±4.2 kg/m2). Results from ANOVA demonstrated significantly less speed of flexion (35%,P<0.01), muscle moment (45%,P=0.03), power (65%,P=0.03), and flexion number (29%,P=0.01) in frails. Using the parameters from upper-extremity motion in a regression model we were able to predict Rockwood frailty score (r=0.71) and frailty (100% sensitivity and specificity). Discussion: This innovative upper-extremity assessment method discriminates frail and non-frail individuals with high accuracy when compared to validated subjective approaches. This study serves as a proof of concept for an objective, simple, and quick method for identifying frailty in critically injured older non-ambulatory patients.

346. Accelerometry-based recognition of time of day, frequency and duration of walking in older adults, *Jacek Urbanek, Indiana University Richard M. Fairbanks School of Public Health; Vadim Zipunnikov, Johns Hopkins School of Public Health; Tamara Harris, National Institute of Aging; Nancy Glynn, University of Pittsburgh; Ciprian Crainiceanu, Johns Hopkins School of Public Health; Jaroslaw Harezlak, Johns Hopkins School of Public Health*

Objectives: Use of sub-second level accelerometry data to detect and quantify walking in elderly people; Use of walking quantification in prediction of health-related measures; Unbiased estimation of frequency and time of the day of walking in elderly people

Abstract Body: Accelerometers are widely used to measure minute level activity intensity in large epidemiologic observational studies of older adults. These devices enhance and complement self-report questionnaire measures of physical activity (PA) because they can capture short bouts and low level activities that are often difficult to recall. Among many types of PA, walking is extremely important because it is a common activity and it is associated with overall health and functional status. Thus, recognizing when and for how long a person walks during the day is essential. Although existing methods can identify walking in laboratory settings, recognizing it from accelerometry data acquired in the free-living environment remains a challenge. We propose an algorithm designed for automatic identification of walking and its characteristics based on the periodicity of walking. This method employs advanced spectral analysis using the sub-second level raw measurements to recognize walking periods and their properties (e.g., energy of produced acceleration and the number of steps/second). Using this method, we found that the total walking time and the number of walking bouts in a natural, free-living environment, collected over 7 days, is associated with age and sex in 51 older adults (median age: 79.1 years, IQR: 74.7-84.3; 25 Males/26 Females) from the Developmental Epidemiologic Cohort Study. We also present results which show that characterizing free-living walking and its properties provides better prediction of sex and age than the commonly used aggregated activity counts. In particular, more walking bouts and greater average daily walking time are associated with younger age.

347. The Effect of Tailored Antibiotic Stewardship Programs on the Appropriateness of Antibiotic Prescribing in Long-term Care Facilities, *Laura van Buul, EMGO Institute for Health and Care Research / Department of General Practice & Elderly Care Medicine, VU University Medical Center; Philip Sloane, Cecil G. Sheps Center for Health Services Research / Department of Family Medicine, School of Medicine, University of North Carolina at Chapel Hill; Sheryl Zimmerman, Cecil G. Sheps Center for Health Services Research / School of Social Work, University of North Carolina at Chapel Hill*

Objectives: Participants will understand how participatory action research (PAR) can be applied to the development of antibiotic stewardship programs in long-term care facilities.; Based on their own experiences and the study findings, participants will be able to discuss explanations for the absence of an intervention effect on the appropriateness of antibiotic prescribing.

Abstract Body: INTRODUCTION: The increase of antimicrobial resistance in long-term care facilities (LTCFs) highlights the importance of promoting appropriate antibiotic use. We evaluated the appropriateness of antibiotic prescribing following tailored interventions developed and implemented in a participatory action research (PAR) project. METHODS: A pre-post test controlled design involved 7 intervention and 7 control LTCFs. Baseline data regarding prescribing were provided to intervention LTCFs, and subsequently tailored interventions to improve prescribing were developed and implemented. A guideline-based treatment algorithm was used to evaluate appropriateness of decisions to initiate or withhold antibiotics. Effects of the interventions on appropriateness of treatment decisions were analyzed with a mixed logistic regression model. RESULTS: Appropriateness of 1,059 treatment decisions was assessed. Adjusting for pre-test differences in the proportion of appropriate decisions (intervention: 82%, control: 70%), post-test appropriateness did not differ between groups (crude: p=0.26; adjusted for covariates: p=0.35). There was no intervention effect on the amount of antibiotics prescribed, but there was a shift toward more guideline-recommended selection of antibiotic drug types. Conclusion: Tailored interventions developed with a PAR approach resulted in a trend toward more guideline-adherent selection of antibiotic drugs, but not in reduced prescribing or more appropriate decisions to prescribe/withhold antibiotics. A possible explanation for no effect is the little room for improvement a priori, given the high pre-test proportion of appropriate treatment decisions. Alternatively, staff failed to incorporate interventions directed at perceived uncertainty and the influence of others, which complicate appropriate prescribing. It is advisable to address these factors in future antibiotic stewardship efforts.

348. Community Based Rehabilitation Post Hospital Discharge Interventions For Older Adults With Cognitive Impairment Following A Hip Fracture: A Systematic Review, *Paula van Wyk, Department of Kinesiology, University of Windsor; Charlene H. Chu, Lawrence S. Bloomberg Faculty of Nursing, University of Toronto; Martine Puts, Lawrence S. Bloomberg Faculty of Nursing, University of Toronto; Jessica Babineau, Toronto Rehab Institution; Dina Brooks, Faculty of Physical Therapy, University of Toronto; Kate Paquin, Faculty of Physical Therapy, University of Toronto; Katherine McGilton, 2Toronto Rehabilitation Institute, Research, University Health Network*

Objectives: To determine the components of outpatient rehabilitation interventions for older adults with CI who have experienced a hip-fracture

Abstract Body: Background: Outpatient interventions maintaining the function and mobility of older adults with cognitive impairment (CI) after inpatient hip-fracture rehabilitation discharge are currently unknown. Objective: To determine the components of outpatient rehabilitation interventions for older adults with CI who have experienced a hip-fracture. Methods: The Cochrane Handbook for Systematic Reviews of Interventions and PRISMA guidelines were followed. Medline In-Process, Pubmed, PsycINFO, Embase, CINAHL, AMED, and 3 other databases were searched, resulting in 62 articles for full extraction. Two reviewers independently extracted and appraised articles. Results: After analysis, three RCTs with 563 participants were included. Significant improvements in activities of daily living and mobility were reported in two studies for those with CI. All three interventions began during inpatient hospitalization, followed by discharge planning, and physiotherapist visits at home. All three interventions varied in length and components (e.g. only one included nurse home visits). From the studies, no intervention was specifically designed for people with CI and none of the studies evaluated cost-effectiveness. Those with mild-CI were significantly more likely to stay at home in the first three months following discharge compared to those with moderate-CI, but these results were not sustained over time. Generally, participants with severe-CI had worse outcomes compared to those without CI or mild-CI. A meta-analysis was not conducted due to heterogeneity of measures and outcomes. Conclusion: Critical gaps were identified which will inform the development of a multifaceted outpatient rehabilitation program. Future rehabilitation interventions should be tailored to those with CI and include a cost analysis.

349. Predictors of Disability Among Middle-Aged and Older African American Women with Osteoarthritis, *Janiece Walker, The University of Texas at Austin, School of Nursing; Tracie Harrison, The University of Texas at Austin, School of Nursing*

Objectives: Name two significant predictors of function in middle aged and older African American women with osteoarthritis.; Name three significant predictors of disability in middle aged and older African American women with osteoarthritis.;

Abstract Body: Approximately one million African American women over the age of 55 live with osteoarthritis (OA), and it is well documented that these women experience high rates of functional limitations and disabilities. Little is known about factors that may influence these outcomes in African American women with OA. Hence, the purpose of this study was to examine if biological factor (BMI), intra-individual factors (pain and depressive symptoms), and/or extra-individual environmental factor (racial discrimination) influenced function and disability outcomes in African American women with OA. The sample included 120 African American women ages 50-80 (M=63, SD=8.57). Descriptive statistics, multiple regressions, and hierarchical regressions were completed. Results suggested that BMI ($b = .01$, $t(115) = 2.18$, $p < .05$) and pain severity ($b = .03$, $t(110) = 3.76$, $p < .01$) significantly predicted function. Pain severity ($b = –3.25$, $t(115) = –2.00$), $p<. 05$), depressive symptoms ($b = –89.19$, $t(118) = –2.07$, $p < .05$), and racial discrimination ($b=-119.31$, $t(118)=-2.02$, $p<.05$) significantly predicted disability. Further, depressive symptoms mediated the relationship between racial discrimination and disability (Sobel test $p<.05$). Results indicate that multiple factors influence disability outcomes in African American women. Of specific interest to this cultural group is our finding that the disabling effect of racial discrimination may be influenced by the treatment of depressive symptoms, which could also impact the effects of pain. These findings hold promise for future interventions. Support provided by National Hartford Center for Gerontological Nursing Excellence Patricia Archbold Scholarship and NIH/NINR (1F131NR014399-01)

350. Multimorbidity and Mortality in Two Prospective Cohorts of Older Adults: Simple Counts, Charlson, and a Novel Quality of Life-Weighted Index, *Melissa Wei, Beth Israel Deaconess Medical Center/Harvard Medical School; Kenneth Mukamal, Beth Israel Deaconess Medical Center/Harvard Medical School*

Objectives: Determine the association of a novel multimorbidity index with 10-year mortality.; Compare different multimorbidity metrics and their associations with mortality.; Appreciate the diverse impact of individual chronic diseases and conditions on physical health-related quality of life.

Abstract Body: Background: We derived a multimorbidity index that weights 88 diseases by their impact on physical health-related quality of life (HRQOL) in the Nurses’ Health Study (NHS), NHS II, and Health Professionals Follow-up Study (HPFS). Diseases varied several-fold in their impact on HRQOL. This study compares our index with other multimorbidity metrics.   Methods: We included NHS and HPFS participants who completed a questionnaire in 2000 on physician-diagnosed diseases and had complete follow-up through December 2010. The multimorbidity index, disease count, and Charlson index were examined continuously and categorically. Incident rate ratios for models with the best performance (lowest AIC) were estimated using Cox proportional-hazards and compared using Concordance statistics.   Results: In 2000, 124,828 participants had mean age 66 (SD 7) years, multimorbidity index 4.4, disease count 3.2, and Charlson index 0.54. After follow-up, 22,389 (18%) deaths occurred. Participants with the highest quintile multimorbidity index had >6-fold greater hazard rate of mortality than those in the lowest quintile (HR 6.47, 95%CI: 6.42-6.52, C-statistic 0.72-0.75, p<0.0001). The HR was 5.49 (95%CI: 5.42-5.56, p<0.0001) for disease count and 2.99 (95%CI: 2.96-3.02, p<0.0001) for Charlson for the highest versus lowest quintiles. The multimorbidity index was only moderately correlated with Charlson (Pearson r=0.57) and strongly but not perfectly correlated with disease count (r=0.88).   Conclusion: A HRQOL-weighted multimorbidity index was significantly associated with mortality and provided the best-fitting model compared with disease count and Charlson. Our index was sensitive to the accumulation and severity of diseases and increased mortality, which provides opportunities to intervene in multimorbidity progression.

351. Patient Outcomes Related to Education on Depression in Nursing Homes: The Practice Improvement in Education (PIE) Project., *Aida Wen, The Pacific Islands Geriatric Education Center, the John A. Hartford Foundation Center of Excellence in Geriatrics, Department of Geriatric Medicine, University of Hawaii John A. Burns School of Medicine; Christina Bell, The Pacific Islands Geriatric Education Center, the John A. Hartford Foundation Center of Excellence in Geriatrics, Department of Geriatric Medicine, University of Hawaii John A. Burns School of Medicine; Sung Jang, The University of Hawaii Geriatric Medicine Fellowship Program, Department of Geriatric Medicine, University of Hawaii John A. Burns School of Medicine; Sebrina Parkins, Kuakini Health System; Chris Stevens, PharMerica; Jan Shishido, PharMerica; Kamal Masaki, The Pacific Islands Geriatric Education Center, the John A. Hartford Foundation Center of Excellence in Geriatrics, Department of Geriatric Medicine, University of Hawaii John A. Burns School of Medicine*

Objectives: To examine the outcomes of interventions to improve depressive symptoms and behavior management of nursing home residents (through a behavior log and behavioral activation pilot quality improvement project) by comparing PHQ9 scores from before our QI pilo; 2.To examine the outcomes of interventions to improve depressive symptoms and behavior management of nursing home residents (through a behavior log and behavioral activation pilot quality improvement project) by comparing use of antipsychotic medications;

Abstract Body: Background: Depression is an important factor related to agitation and other behaviors in nursing home residents. As the next step in our Geriatric Education Center (GEC) Practice Improvement in Education (PIE) project on depression in nursing homes, we focused on non-pharmacologic behavioral management and psychoactive medication reduction.   Methods: This quality improvement (QI) pilot included training on effective interdisciplinary management approaches for depressive symptoms and challenging behaviors, and implementing an adapted ABC (antecedents, behaviors, consequences) log and behavioral activation. We targeted two nursing home floors and included data on residents present both before and after the QI, in June 2013 and July 2014. We examined changes in depressive symptom scores (Patient Health Questionnaire, or PHQ9, scale 0-15, higher=worse) and antipsychotic/antidepressant medication use with paired T-tests and Fisher's exact tests.   Results: Of the 66 nursing home residents in this QI pilot, 70% were female, 60.6% were >89 years old (range=48-108, mean=88.8), 83% were Asian and 51% had severe cognitive impairment. Mean PHQ9 scores decreased significantly from 3.74 to 2.38 (p=0.017). Of the 13/66 (19.7%) residents on antipsychotic medications, 10/13 (76.9%) had dose reductions and 4/13 (30.8%) had medications completely discontinued (p<0.0001 for change pre/post). Of the 34 (51.5%) residents on antidepressant medication, 15/34 (42.9%) had dose reductions and 3/34 (8.8%) had medications completely discontinued (p<0.0001 for change pre/post). Conclusion: Mean depression scores and antipsychotic and antidepressant medication use decreased significantly in this GEC PIE QI project to manage depression and behaviors non-pharmacologically in nursing home residents.

352. Cardiovascular Disease and Coping Behaviors among Centenarians, *Feng Zhao, Iowa State University; Peter Martin, Iowa State University; Leonard Poon, University of Georgia*

Objectives: The purpose of this study was to examine the association of ten specific coping behaviors with cardiovascular disease among centenarians with the method of multinomial logistic regression

Abstract Body: The purpose of this study was to examine the association of ten specific coping behaviors with cardiovascular disease among centenarians with the method of multinomial logistic regression. Centenarians (n = 239) from the Georgia Centenarian Study (GCS) were categorized into three groups (i.e., survivors, delayers, and escapers) based on the diagnosis of congestive heart failure, myocardial infarction, and hypertension. Survivors (24.2%) were those with at least one diagnosis of the three diseases before they turned into 80 years old, delayers (44.0%) those with at least one diagnosis of the three diseases in the age between 80-98 years old, and escapers (31.9%) those without any diagnosis of the three diseases at the age of 98 or older. The overall accuracy of the model's classification was 57.1%, with 50.0% survivors, 65.0% of delayers, and 48.3% of escapers correctly predicted. In addition, compared to escapers, the odds of using "Don't worry about it" coping was decreased by 66.5% and 69.5% for survivors and delayers respectively. Besides, the odds of using "Going over the situation" coping was 3.8 times as great for survivors as for escapers. The results indicated that specific coping behaviors could be important in differentiating centenarians with different disease trajectories.

353. Changes of Health Status and Institutionalization among Older Adults in China, *Rong Peng, National Economics Research Center and School of Economics, Guangdong University of Finance and Economics; Bei Wu, Duke University*
Objectives: To examine the admission rate of institutionalization. To examine the impact of changes of health status on the admission among Chinese community-dwelling older adults.
Abstract Body: Based on the 2002, 2005, 2008 and 2011 Chinese Longitudinal Healthy Longevity Survey data, weighted admission rate was calculated. Multiple logistic regression model was used to examine health status changes as associated risk factor of institutionalization. The results show that the rate of institutionalization increased from 0.5% at the first interval (2002-2005) to 0.8% at the third interval (2008-2011). Compared to their counterparts, the risk of institutionalization increased 70% for elders who had declined Activities of Daily Living, 53% for those with decline of cognitive function and 44% for those with increased number of chronic diseases. Decline of health status were main predictors of institutionalization. Developing policies and programs that help improve older adults' health status and family support system is essential to respond to the increased institutionalization.

354. Assessing Complete Streets Projects: An Exploratory Study on the Impact of Public Rights-of-Way Policy and Design on Aging and Disability Issues, *Molly Ranahan, SUNY University at Buffalo*
Objectives: Describe the benefits of municipal Complete Streets initiatives in promoting physical activity, functional independence, and social participation for older adults, particularly those with disabilities.; Identify the extent to which municipalities with Complete Streets policies have addressed the needs of older adults and people with disabilities in project implementation.; Discuss the implications of prioritizing aging and disability issues related to Complete Streets in policy, design and health education, professional practice, and future research.
Abstract Body: Older adults, and particularly those with disabilities, are vulnerable to poorly designed environments. Municipalities can uniquely promote regular walking, preserve functional independence, and enhance community participation for this targeted population through their planning and design processes. The Complete Streets (CS) movement affords a logical opportunity for communities to achieve societal inclusion goals for aging populations that also promote improved health due to increases in walking and bicycling, and improved access to daily services. The number of municipalities with CS policies has rapidly increased over due to growing public interest and municipal goals related to active living and walkability. The Center for Inclusive Design and Environmental Access (IDeA) recently completed research on Complete Streets initiatives in the United States. One goal of this research was to explore the extent to which CS projects addressed the needs of older adults and people with disabilities. Semi-structured phone interviews were conducted with officials from 13 municipalities to discuss their experiences implementing Complete Streets projects, and a web-based national survey was then launched to interface with staff in geographically dispersed municipalities that were implementing Complete Streets. Data analysis from interviews and surveys indicated that municipalities gave cursory consideration of older adults and people with disabilities during CS implementation. As municipalities continue to invest limited funds on CS, and the population continues to age with disabilities, these findings suggest the need for increased focus on aging and disability issues related to Complete Streets in policy, design and health education, professional practice, and future research.

355. PALETTE: Changing Students' Attitudes Toward Older Adults, *Sadie Rubin, PALETTE; Tracey Gendron, School of Allied Health Professionals, Virginia Commonwealth University; Cortney Wren, School of Pharmacy, Virginia Commonwealth University; Kelechi Ogbonna, School of Pharmacy, Virginia Commonwealth University; Ernest Gonzales, School of Social Work, Boston University; Emily Peron, School of Social Work, Boston University*
Objectives: Participants will understand the impact of students' participation in an intergenerational art program on their attitudes toward older adults.; Participants will understand the impact of students' participation in an intergenerational art program on their knowledge of aging processes.; Participants will understand program evaluation results and how they were translated into best practice.
Abstract Body: The PALETTE program partnered interdisciplinary undergraduate and graduate students with active older adults to engage in creative activities. 22 interdisciplinary undergraduate and graduate students were partnered with 21 active older adults to participate in PALETTE for a 14-week pilot program. Research data was gathered from the student participants through the use of pre- and post-test questionnaires, and qualitative data was collected through a reflection assignment and group discussion at the end of the program. After participating in PALETTE, students demonstrated a significant positive change in their knowledge and attitudes towards older adults. Having positively changed students' knowledge and attitudes towards older adults, PALETTE could enhance students' ability to work with older adults in any career path; further, improving students' capacity to see beyond stereotypes could lead to enhanced individualized care for older adults. PALETTE is an innovative and replicable model that can be implemented by partnerships between higher education programs and community organizations.

357. Resource and Future Care Planning for Chinese Baby Boomers, *YAJUN SONG, Department of Social Work & Social Administration, The University of Hong Kong; Elsie Chau Wai YAN, Department of Social Work & Social Administration, The University of Hong Kong*

Objectives: Grounded on Aspinwall's and Greenglass' proactive coping theories, this study investigated resource's functions as both a precondition and a planning behavior in the process of future care planning

Abstract Body: Objectives. Grounded on Aspinwall's and Greenglass' proactive coping theories, this study investigated resource's functions as both a precondition and a planning behavior in the process of future care planning. Methods. Path analysis was conducted on a sample of 516 Chinese baby boomers aged from 45 to 65 with equal gender ratio to examine the associations between goal-specific future care planning (Awareness Initiation, Information Gathering, and Preliminary Decision), available resource, and resource management in domains of finance, social support and health. Results. The results yielded good model fit ($\chi 2$ (14) = 13.541, p = 0.484; RMSEA = 0; CFI = 1.000; TLI = 1.004; and SRMR = 0.014). Except for Preliminary Decision, goal-specific future care planning was positively associated with finance and social support management. Among the three available resources, health emerged as the only significant factor for Awareness Initiation. Model fit improved when resource was treated as a precondition rather than a planning behavior. Discussion. The study integrated the two streams of proactive coping theories by confirming the necessity of differentiating resource management from available resource, and verifying resource's role of precondition in future care planning. We propose measuring both goal-specific behaviors and resource management to cover more planners especially among younger elders in developing countries, where planning duration is long and social service is limited. Practitioners may target females with lower SES for resource management skill development. Future studies may inspect how spouse, sibling, children and friends contribute in future care planning process.

358. Quality of Work Life: Research Shows Significant Characteristics Influencing Older Workers, *Diane Spokus, The Pennsylvania State University; Edgar Yoder, The Pennsylvania State University*

Objectives: Identify characteristics that affect the Quality of Work Life.; Discuss the changing nature of the workplace because of advanced technology.

Abstract Body: The study examined from a human resource perspective factors associated with quality of work life of older (55 years or older) health care workers (n = 153) in relatively small, rural health care organizations. The conceptual model developed by Korunka, Hoonakker, Pascale and Carayon (2005) provided the framework for the study. The framework identifies demographic factors, job characteristic factors and organizational factors that may influence quality of work life. Hierarchical linear regression was used to examine the respective influence of three blocks of variables on participants' quality of work life scores. The fully saturated regression model explained 48.2 % of the variance in quality of work life scores (R2 = .48; Adjusted R2 = .44; F= 10.75, p = < .01). The first block of demographic variables (R2 change = .03) included age and gender with gender being statistically significant (beta = .14, p = .05). The second block of job characteristic variables (R2 change = .30) included job demand, challenge of my job, role ambiguity and job rewards. Of the four job characteristic variables job demands (beta = -.15, p = .03) was statistically significant in the final fully saturated model. The third block of organizational characteristic variables (R2 change = .15)included satisfaction with career advancement opportunities, satisfaction with training opportunities and corporate fit. Corporate fit (beta = .36, p = <.01) and satisfaction with career advancement opportunities (beta = .19, p =.03) were statistically significant.

359. Health Care and Community-Based Organizations Integrated Care Partnerships For The Aging Population Since Health Reform, *Albert Terrillion, National Council on Aging; Xiao Wang, National Council on Aging; Xiao Wang, National Council on Aging*

Objectives: To study the trend of aging adults' self-rated health status and Health Reform-related experience from 2012 to 2014---including the synchronization of payment, the access to health care provider, and the access to community-based organizations.; To examine how aging adults' health status is associated with their Health Reform-related experiences from 2012 to 2014.

Abstract Body: The Patient Protection and Affordable Care Act and the Health Care and Education Reconciliation Act (Health Reform) provides new opportunities to benefit aging adults through expanding access to care and offering a more integrated health care system. However, timely information about the Health Reform's impact on aging adults (aged 60 and over) is hard to obtain. From 2012 to 2014, the United States of Aging Survey has been conducted annually and nationally to study aging adults' health and wellness, experiences within the community, and other health and wellness-related experiences. This study aims to examine how aging adults' health status is associated with their Health Reform-related experiences from 2012 to 2014. These Health Reform-related experiences include the experience of public health coverage, enrollment in private insurance, and health-related experience from health care system and community-based organizations. This study found increasing percentage of good or improved health report from 2012 to 2014 among adults aged 65 and over, but not for those in the 60-64 year old age bracket. In logistic regression models, we found that Health Reform-related experiences of health improvement have had positive influences on good health outcomes in all older adults since 2012. The significant models suggest the success of ongoing efforts to integrate conventional health care with community-based organization efforts to improve health. Limitations of the study were discussed.

360. Japan’s Long Term Care Insurance (LTCI) Reform Related to Lowest Eligibility Level: Examining the Evidence upon which the Reform is Based Before its Implementation, *Yasuko Torimoto-Sasai, the Dia Foundation for Research on Aging Societies; Tomoaki Ishibashi, the Dia Foundation for Research on Aging Societies*

Objectives: To examine whether the new reform of long term care insurance to be implemented in 2015 is evidence-based policy.; To explore the challenges to the implementation of the new policy of long term care insurance in 2015.;

Abstract Body: Background Japan’s reform of the long term care insurance (LTCI) for groups with the lowest level of care needs will be implemented in 2015. Since care recipients using home help services (HHS) and day care services (DCS) need only low levels of care in contrast to other services users, the providers of both types of services are to be shifted from “licensed staff” to “unqualified staff,” under this reform. Objectives This research tests the LTCI reform’s evidence that the users of HHS and DCS need only light care. Methods The study used a database of 229 people aged 65 years and over, who lived in a suburban city, who applied for LTCI from April 2013 to March 2014, and who were then certified as being eligible for the lowest level of LTCI care. It examined the difference of characteristics about care needs measured by loss of activities of daily living (ADL) among HHS, DCS, and other services users. Results More people using HHS and DCS have no loss of ADLs. However, examined in detail, some users of HHS and DCS have middle-, and late-loss ADLs requiring high level of care. Conclusion The care recipients using HHS and DCS include people with middle- and late-loss ADL. The reformed system will be required to address manage the care of those recipients with “unqualified staff.” The challenge to the reform of LTCI, therefore, is remaining that these recipients are left to unqualified staff, without any criteria for their ability to provide appropriate care.

361. Mental Health Services for Older Adults in Oregon: Gaps and Solutions, *Serena Worthington, Portland State University; Diana White, Portland State University*

Objectives: Participants will learn about the gaps in services for older adults with complex mental health needs.; Participants will be able to describe the role of Older Adult Mental Health Specialists in addressing gaps in services and building new systems to support older adults with complex mental health needs.;

Abstract Body: The State of Oregon and key stakeholders are creating systems to improve mental health services for older adults. Solutions are emerging from a needs assessment conducted with 35 key informants who responded to questions regarding gaps in services and how to address those gaps. Informants represented aging services, mental health, advocacy, and other sectors (e.g., long-term care, quality improvement, health care). They included those with a state level focus as well as representatives of local communities (including rural areas). Four themes emerged: fragmented systems, lack of priority for older adults in the mental health system, knowledge gaps about best practices in mental health with older adults, and limited resources. Lack of coordination at state and local levels was the most common gap mentioned. The organizations that could address the mental health needs of older adults work in silos with different funding priorities, eligibility requirements, and knowledge bases. Agencies are reluctant to take the lead in assessing, coordinating, and funding services for individuals with multiple diagnoses; therefore, these individuals typically do not receive adequate or appropriate services. A plan is emerging to address these gaps. Representatives from aging services, mental health, health care, long-term care, law enforcement and other emergency responders will work collaboratively. Efforts will be facilitated by a cadre of Older Adult Mental Health Specialists (OAMHS) based in local communities. Their role is to coordinate services, bridge service sectors, and facilitate training. This poster will describe the development and implementation of this role.

362. Childhood Adversities, Urbanization, and Depressive Symptoms among Middle-aged and Older Adults: Evidence from a National Survey in China, *Fan Yang, The University of Hong Kong; Vivian W. Q. Lou, The University of Hong Kong*

Objectives: To have a better understanding of how China's urbanization process and policy connect people's earlier life and lead to their psychological state in middle and old-age life.; To explore more possibilities of cross-sectional data in life-course research

Abstract Body: Abstract: The trajectory of modern China, i.e. from dire poverty and communist fever to economic boom and marketization under an authoritarian regime, makes the country a unique social laboratory for examining how social environment affects human development of individuals. This study investigated the correlation between childhood adversities and depressive symptoms of Chinese middle-aged and older adults, as well as how China’s urbanization moderates the correlation. A subsample (N = 14,681) of the baseline of China Health and Retirement Longitudinal Study (CHARLS) was analyzed. Seven variables were used in the latent class analysis to establish a childhood adversity typology. Three urbanization statuses were identified according to Hukou (household registration system) status and neighborhood type: non-urbanized, semi-urbanized, and fully-urbanized. Factorial analysis of covariance assessed how childhood adversity types were correlated with depressive symptoms and the moderating effect of urbanization on the correlation. Three latent classes for childhood adversities were identified: “normal childhood class”, “low childhood socioeconomic status and health class”, and “traumatic childhood class”. The three classes differed significantly in depressive symptoms ($p < .001$), and the urbanization status had significant moderating effect on the correlation ($p = .001$). Policy initiatives on enhancing children's health and education and shaping a socially and institutionally inclusive urbanization in China are suggested for improving psychological wellbeing in middle-aged and older stage of life.

363. Impacts of Individual Demographic Characteristics and Their Cognition of Nursing Profession on the Rural Residents Willingness to be Nursing Assistants- An empirical examination of Sichuan province

Yanan Zhu, Zhejiang University; Hong Mi, Zhejiang University

Objectives: The study is to examine the impacts of individual demographic characteristics and cognition of nursing profession on their willingness to be nursing assistants

Abstract Body: Background: The acceleration of aging, expansion of family size and a great number of nuclear families led by birth control policy in China calls for huge demand for formal caregivers, especially nursing assistants, to provide daily care for the first generation of singleton's parents. Objective: The study is to examine the impacts of individual demographic characteristics and cognition of nursing profession on their willingness to be nursing assistants. Method : using 2014 Social Pension Situation Investigation data, the study was conducted by the Population and Development Research Institute of Zhejiang University in Renshou and Zizhong of Sichuan province with the method of order logistic analysis. Results: 1, People under the age of 35 are prefer to be nursing assistants than those between 45 to 55ys ; people with high school or above education and with few sibling are less likely to be nursing assistants; Men rather than women prefer be nursing assistants .2 Whether to be nursing assistants is significantly decided by people's understanding of nursing occupation and the cognition of its social status, wage level and workload, of which the cognition of nurse' social status is the most significant factor. Conclusion and policy Suggestions: 1, The demand for nursing assistants is increasing.2, Improvement in nursing assistants social status is vital to the enhancement of people's willingness to be nursing assistants.3, Establishment of reasonable nursing career plan and professional qualification system is of paramount significance.

364. Episodic Memory and Alzheimer's Disease in Late-Life Depression: Does Age of Depression Onset Matter?

Nicole Rushing, Coastal Carolina University; Natalie Sachs-Ericsson, Florida State University; Jerad Moxley, Florida State University; David Steffens, University of Connecticut Health Center

Objectives: Define late-life depression, episodic memory, and Alzheimer's disease.; Describe leading theories explaining the relationship between depression and cognitive functioning.; Understand changes in cognitive functioning that occur differentially in older adults with early-onset depression versus late-onset depression.

Abstract Body: Late life depression is associated with subsequent cognitive impairment in older adults, but the mechanisms underlying the relationship are poorly understood and may vary with age of depression onset. The "glucocorticoid cascade hypothesis" posits depression over the lifespan damages the hippocampus, increasing risk for cognitive problems and Alzheimer's disease (AD). On the other hand, the "prodrome hypothesis" suggests underlying neurological insults give rise to both late-life, prodromal depressive symptoms and cognitive deficits. Thus, examining history of depressive illness among older adults is an important undertaking in determining risk for episodic memory impairment and conversion to AD. We followed clinically depressed patients age 60 and older with early-onset depression (EOD; <age 60) and late-onset depression (LOD; age 60+) for three or more years and measured episodic memory function, a domain affected in early AD. Using second-order latent-growth curve modeling, we found that, compared to those with EOD, those with LOD had poorer episodic memory function. Follow-up logistic regression analysis revealed greater rates of AD among the LOD group. Results are consistent with the prodrome hypothesis and suggest at least some subtypes of depression occurring for the first time in late life are associated with episodic memory impairment and increased risk for AD.

365. Estimation and Validation of the Auditory Short-Term Memory Store in both Older Adults and Younger Adults

Dustin Souders, Florida State University; Kristina Schiao, Florida State University; Ryan Best, Florida State University; Neil Charness, Florida State University

Objectives: Experimentally estimate the short-term auditory memory store for older and younger adults; Validate these estimated parameters using an adaptive staircase procedure; These Validated parameters can be used to fill in missing parameter values in the Older GOMS model

Abstract Body: Objective: Values for the auditory short-term memory half-life parameter of the Goals, Operators, Methods, Selection rules (GOMS) model was experimentally estimated for older adults (OAs) and validated. Background: GOMS modeling is a first approximation tool for designing hardware and software interfaces for routine performance. Originally, OA performance was estimated by using parameter values that predicted the worst performance. Jastrzembski & Charness (2007) updated this model by using a form of meta-analysis to provide an estimate of model parameters based on cognitive aging literature that takes age-related cognitive and perceptual changes into account. Method: For Study 1, we experimentally estimated auditory short-term memory duration for young adults (YAs) and OAs. For Study 2, we validated the results of Study 1 using an adaptive staircase procedure in an auditory phoneme recognition task that used a non-native language (Taiwanese Hokkein, Zhangzhou dialect). Results: Based on our experiment in Study 1, we estimated the auditory short-term store to be ~2 seconds in OAs and above 4 seconds for YAs using the same method. In Study 2, we validated the experimental result of Study 1, and found it to be 2.6 seconds for OAs and 3.5 seconds for YAs. Conclusion: Inclusion of this validated parameter supplements previous work done by Jastrzembski & Charness (2007). Application: This parameter permits the OA GOMS model to be applied to a broader range of tasks where retention of auditory stimuli influences performance and can guide design that accommodates older users.

366. Objective Assessment Of Dynamic Balance Control Under Single And Dual-task Conditions In People With Mild Cognitive Impairment, *Gurtej Singh Grewal, Department of Surgery, University of Arizona; Xi Zong, Arizona State University, Phoenix; Michael Schwenk, Department of Surgery, University of Arizona; Marwan Sabbagh, Banner Health; David Coon, Arizona State University; Jane Mohler, Arizona State University; Bijan Najafi, Department of Surgery, University of Arizona*

Objectives: To develop a dynamic balance test specifically developed for estimating dual task cost (time to complete single-task minus time to complete dual-task) in cognitively impaired

Abstract Body: Background: Controversial results have been reported for MCI related balance deficits using conventional static balance tests. Dynamic balance assessment may be more sensitive for identification of subtle MCI-related balance deficits, particularly when simultaneously performing a secondary task. This studies aim was to evaluate a novel dynamic balance testing integrating dual-task paradigm and wearable technology in people with confirmed MCI. Methods: Eight memory clinic MCI patients (80±6.4years) and 6 healthy control subjects were recruited. Subjects performed a dynamic balance test using wearable sensors combined with a virtual interface displaying cognitive tasks. Sensors were attached to lower extremities for real-time motion feedback on a screen. Two tasks were presented to participants during balance test; single-task: simple trail-making-task with predefined path; dual-task: complex trail-making-task with random path. The trail-making-task was accomplished through dynamic weight shifting and postural coordination during standing. Dual-task costs were calculated as difference in time to complete single-task and dual-task. Results: Dual-task cost were higher (34.3%) in MCI subjects compared to control (9.3%), although level of significance was not reached (p=0.07) in our small sample. The time to initiate the motor-cognitive task and reach to first number was also longer in MCI (25%) compared to healthy (13.1%). Conclusion: The results of this study may suggest that a sensor-based dynamic balance test incorporating a cognitive task can detect motor-cognitive deficits related to MCI. However, the test needs to be verified in a larger sample and use dual-tasks with different levels of severity, in order to quantify MCI-related motor-cognitive deficits.

367. Differences in Falls Among Older Asian Americans and Non-Hispanic Whites, *Benjamin Han, New York University School of Medicine, Division of Geriatric Medicine and Palliative Care; Rosie Ferris, New York University School of Medicine, Division of Geriatric Medicine and Palliative Care; Simona Kwon, Center for the Study of Asian American Health, New York University School of Medicine; Chau Trinh-Shevrin, Center for the Study of Asian American Health, New York University School of Medicine; Caroline Blaum, New York University School of Medicine, Division of Geriatric Medicine and Palliative Care*

Objectives: To examine ethnic differences in falls and fall correlates in older Asian Americans and Non-Hispanic Whites.; To understand the role of acculturation on fall risk.

Abstract Body: Unintentional falls are a common event for older adults and a significant cause of morbidity and mortality associated with a decline in functional status. Studies suggest that Asians may have a decreased fall rate compared to other racial groups; however, there is little understanding what may influence these differences and no studies specifically examining Asian American populations. Acculturation may play a role in particular health behaviors that may impact falls. Using data from the 2011-2012 California Health Interview Survey (CHIS) we analyzed falls and fall risks between non-Hispanic Whites (n=10,527) and Asian Americans (n=1,199) over the age of 65. Characteristics were compared between the two groups and bivariate analyses were performed using known and potential risk factors for falls. English language proficiency was used as an index of acculturation. Multivariable logistic regression was used to examine interactions in predicting falls by race. Analyses were adjusted for sociodemographic characteristics, body mass index, chronic diseases, and functional limitations and stratified by age and English language proficiency. Older Asian Americans were less likely to have >1 falls compared to non-Hispanic whites. However, this was significant only for limited English-proficient Asian Americans aged 65-74 with an adjusted odds ratio of 0.37 (0.15-0.96). The results highlight that less acculturation may decrease fall risk among Asian Americans, but only to a certain age when other factors such as chronic conditions and functional limitations play a greater role. More research is needed to explore fall risks, specifically the role of acculturation, among older Asian Americans.
